bustly. Finally, the decrease of the standard deviation of the processing times (variant 4) seems to have a negligible effect on the system's behavior as indicated by the experimental data presented in the last column of Table 7. Tables 8 and 9 contain data regarding the sensitivity of the system's behavior in respect to the parameters of the controlling policy. For example, in Table 8, the cells in the *i*-th row that belong to the columns labeled as "Base Stock" show the objective function value and service level that result when the *i*-th component (parameter S_i) of the corresponding decision variable vector is increased by the minimum possible value, i.e. by one. In general, the service level (objective function) is an increasing (decreasing) function of the control parameters. However, the rate with which the service level/objective function changes depends on the type of the control policy and the index (position) of the parameter in the parameter vector. For instance, in the five-station Kanban system, adding an additional kanban in the last stage will result in a larger decrease of the objective function value than adding an extra kanban in any of the upstream stages. It is interesting to observe the cases of the CONWIP and CONWIP/Kanban Hybrid systems where the unitary increase of a control parameter in any of the stages 2,3,4,5 seems to have the same effect. This can be explained by the fact that since the last workstation is authorized to produce whenever it has this ability all parts in upstream buffers are continuously "pushed" towards the finished goods buffer, and therefore WIP in intermediate stages is scarce. By increasing the initial stock in the first buffer the average WIP in intermediate stages increases and thus this change has greater impact to the objective value and service level. Generalized Kanban and Extended Kanban are characterized by two parameters per stage and therefore the sensitivity analysis must consider both of these parameters. The systems' performance for a unitary change in the base stock of the *i*-th stage is shown in the columns labeled as "base stocks" whereas the cells under the label "free kanbans" contain system performance information when the total number of kanbans of the *i*-th stage is increased by one but the base stock remains unaltered.

The effect of adding an extra base stock to a stage of a Generalized/Extended Kanban system is similar to that of adding a kanban to a stage of a Kanban system. The mean WIP is also an increasing function of the control parameters (K_i - S_i) but as one can see from Table 9 rather large changes in the number of free kanbans are needed for a significant change in the objective function value to occur.

CONCLUSION AND FUTURE RESEARCH

We implemented a hybrid optimization technique which combines a genetic algorithm with a local search procedure to find optimal decision variables for a family of JIT manufacturing systems. The goal was to maximize a weighted sum of the mean WorkInProcess inventories subject to the constraint of maintaining a target service level. Our numerical results indicate that the performance of a genetic algorithm can be easily enhanced by incorporating a local search component, however, the local search algorithm is more susceptible to falsely interpreting random noise as actual objective function improvements than the genetic algorithm. Moreover, our results support the intuitive perception that penalizing candidate solutions according to the level of constraint violation will yield better results than the "death penalty" approach most of the times. The performance of the JIT control policies with optimized parameters is presented analytically and commented upon. Finally, we conduct a sensitivity analysis in respect to the variation of the demand rate, the standard deviation of the service rates and the control parameter vector. The results of the analysis offer considerable insight to the underlying mechanics of the JIT control policies under consideration. Constraint handling and "noisy" or dynamic environments in the context of genetic optimization of manufacturing systems are currently active research fields. Indicatively, a relatively recent and interesting direction is to use evolutionary multi-objective techniques to handle constraints as additional objectives.

Chapter 38
Comparison of Connected vs. Disconnected Cellular Systems:
A Case Study

Gürsel A. Süer

ABSTRACT

In this chapter, two cellular manufacturing systems, namely connected cells and disconnected cells, have been studied, and their performance was compared with respect to average flowtime and work-in-process inventory under make-to-order demand strategy. The study was performed in a medical device manufacturing company considering their a) existing system b) variations from the existing system by considering different process routings. Simulation models for each of the systems and each of the options were developed in ARENA 7.0 simulation software. The data used to model each of these systems were obtained from the company based on a period of nineteen months. Considering the existing system, no dominance was established between connected cells vs. disconnected cells as mixed results were obtained for different families. On the other hand, when different process routings were used, connected system outperformed the disconnected system. It is suspected that one additional operation required in the disconnected system as well batching requirement at the end of packaging led to poor performance for the disconnected cells. Finally, increased routing flexibility improved the performance of the connected cells, whereas it had adverse effects in the disconnected cells configuration.

INTRODUCTION

Cellular Manufacturing is a well known application of Group Technology (GT). Cellular Design typically involves determining appropriate part families and corresponding manufacturing cells. This can be done either by grouping parts into families and then forming machine cells based on the part families or machine cells are determined first and based on these machine cells the part families may be formed or lastly both these formations can take place simultaneously. In a cellular manufacturing system, there may be a manufacturing cell for each part family or some of the manufacturing cells can process more than one part family based on the flexibility of the cells. The factors affecting the formation of cells can differ under various circumstances, some of them are volume of work to be performed by the machine cell, variations in routing sequences of the part families, processing times, etc.

A manufacturing system in which the goods or products are manufactured only after customer orders are received is called a make-to-order system. This type of system helps reduce inventory levels since no finished goods inventory is kept on hand.

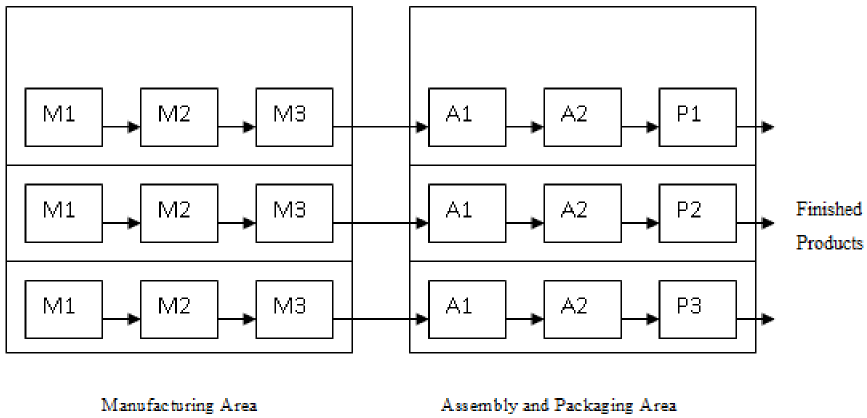
In this chapter, two types of cellular layouts are analyzed, namely connected cells (single-stage cellular system) and disconnected cells (multi-stage cellular system) and their performance is compared under various circumstances for a make-to-order company. This problem has been observed in a medical device manufacturing company. The management was interested in such a comparison to finalize the cellular design. It was also important to research the impact of flexibility within each system for different combinations of family routings. A similar situation of connected vs. disconnected cellular design was also observed in a shoe manufacturing company, and in a jewelry manufacturing company. Authors believe that this problem has not been addressed in the literature before even though it has been observed in more than one company and therefore worthy to study.

BACKGROUND

The connected cells represent a continuous flow where the products enter the cells in the manufacturing area, complete the machining operations and exit through the corresponding assembly and packaging area after completion of the assembly and packaging operations. In other words, the output of a cell in the manufacturing area becomes the input to the corresponding cell in the assembly and packaging area. The biggest advantage of connected cells is that material flow is smoother and hence flowtime is expected to be shorter. This is also expected to result in lower WIP inventory. This paper focuses on a cellular manufacturing system similar to the system shown in Figure 1. There are three cells in the manufacturing area and three cells in the assembly and packaging area. In these cells, M1 through M3 represent the machines in the manufacturing area, A1, A2 and P1 through P3 represent the machines in the assembly and packaging area. The products essentially follow a unidirectional flow. The three cells in manufacturing area are similar since they have similar machines and all the products can be manufactured in any of the cells. However, the situation gets complicated in the assembly and packaging area. The three cells have restrictions in terms of the products that they can process. Therefore, deciding which manufacturing cell a product should be assigned is dictated by the packaging cell(s) it can be processed later on. This constraint makes the manufacturing system less flexible.

In the disconnected cell layout, the products enter the manufacturing area, complete the machining operations and exit this area. On exiting the manufacturing area, the products can go to more than one of the assembly and packaging cells. In other words, the output from the cells in

Figure 1. Connected cells



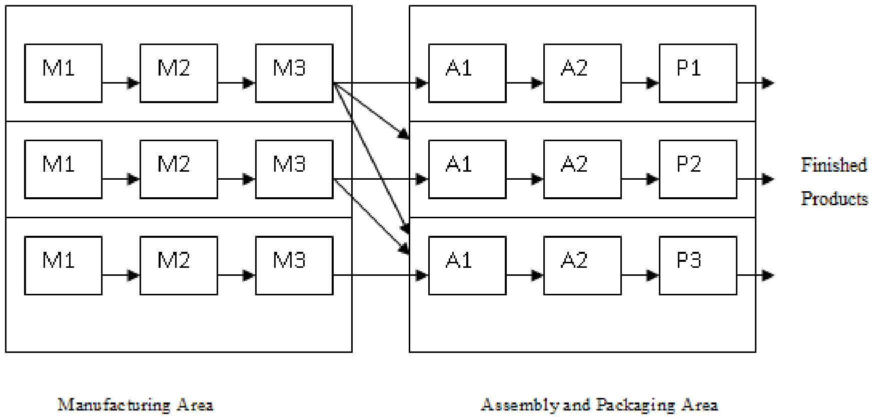
the manufacturing area can become an input for some of the cells in the assembly and packaging area (partially flexible disconnected cells) or all of them (completely flexible disconnected cells). Figure 2 shows a partially flexible disconnected cells case where the parts from cell 1 in the manufacturing area can go to any of the cells in the assembly and packaging area. Parts from cell 2 can only go to cell 2, and cell 3 of the assembly and packaging area. Parts from cell 3 of the manufacturing area can only go to cell 3 of the assembly and packaging area. The disconnected system design allows more flexibility. On the other hand, due to interruptions in the flow, some delays may occur which may eventually lead to higher flowtimes and WIP inventory levels.

LITERATURE REVIEW

A group of researchers compared the performance of cellular layout with process layout. Flynn and Jacobs (1987) developed a simulation model using SLAM for an actual shop to compare the performance of group technology layout against process layout. Morris and Tersine (1990) developed simulation models for a process layout and a cellular layout using SIMAN. The two performance measures used were throughput time and work-in-process inventory (WIP). Yazici (2005) developed a simulation model using Promodel based on data collected from a screen-printing company to ascertain the influence of volume, product mix, routing and labor flexibilities in the presence of fluctuating demand. A comparison between one-cell, two-cell configurations versus a job shop is made to determine the shortest delivery and highest utilization. Agarwal and Sarkis (1998) reviewed the conflicting results from the literature in regard to superiority of cellular layout vs. functional layout. They attempted to identify and compile the existing studies and understand conflicting findings. Johnson and Wemmerlov (1996) analyzed twenty-four model-based studies and concluded that the results of these work cannot assist practitioners in making choices between existing layouts and alternative cell systems. Shafer and Charnes (1993) studied cellular manufacturing under a variety of operating conditions. Queueing theoretic and simulation models of cellular and functional layouts are developed for various shop operating environments to investigate several factors believed to influence the benefits associated with a cellular manufacturing layout.

Another group of researchers focused on analyzing cellular systems. Selen and Ashayeri (2001) used a simulation approach to identify improvements in the average daily output through

Figure 2. Disconnected cells with partial flexibility



management of buffer sizes, reduced repair time, and cycle time in an automotive company. Albino and Garavelli (1998) simulated a cellular manufacturing system using Matlab to study the effects of resource dependability and routing flexibilities on the performance of the system. Based on the simulation results, the authors concluded that as resource dependability decreases, flexible routings for part families can increase productivity. On the contrary, from an economic standpoint they concluded that benefits will greatly reduce from an increase routing flexibility cost and resource dependability. Caprihan and Wadhwa (1997) studied the impact of fluctuating levels of routing flexibility on the performance of a Flexible Manufacturing System (FMS). Based on results obtained, the authors concluded that there is an optimal flexibility level beyond which the system performance tends to decline. Also, increase in routing flexibility when made available with an associated cost seldom tends to be beneficial. Suer, Huang, and Maddisetty (2009) discussed layered cellular design to deal with demand variability. They proposed a methodology to design a cellular system that consisted of dedicated cells, shared cells and remainder cell.

Other researchers studied make-to-order and make-to-stock production strategies. Among them, DeCroix and Arreola-Risa (1998) studied the optimality of a Make-to- Order (MTO) versus a Make-to-Stock (MTS) policy for a manufacturing set up producing various heterogeneous products facing random demands. Federgruen and Katalan (1999) investigated a hybrid system comprising of a MTO and a MTS systems and presented a host of alternatives to prioritize the production of the MTO and MTS items. Van Donk (2000) used the concept of decoupling point (DP) to develop a frame in order to help managers in the food processing industries to decide which of their products should be MTO and which ones should be MTS. Gupta and Benjaafar (2004) presented a hybrid strategy which is a combination of MTO and MTS modes of production. Nandi and Rogers (2003) simulated a manufacturing system to study its behavior in a make to order environment under a control policy involving an order release component and an order acceptance/rejection component.

Authors are not aware of any other study that focuses on comparing the performance of connected cells with disconnected cells and therefore we believe this is an important contribution to the literature.

DESCRIPTION OF THE SYSTEM STUDIED: THE CASE STUDY

This section describes the medical device manufacturing company where the experimentation was carried out. The products essentially follow a unidirectional flow. The manufacturing process is mainly divided into two areas, namely fabrication and packaging. Each area consists of three cells and cells are not identical. The one piece-flow strategy is adapted in all cells. The company has well defined families which are determined based on packaging requirements. Furthermore, the cells have been already formed. The average flowtime and the work-in-process inventory are the performance measures used to evaluate the performance of connected cells and disconnected cells.

Product Families

The products are grouped under three families: Family 1 (F1), Family 2 (F2), and Family 3 (F3). The finished products are vials consisting of blood sugar strips and each vial essentially contains 25 strips. The number of products in families 1, 2 and 3 are 11, 21 and 4, respectively.

The families that are described were already formed by the manufacturer based on the number of vials (subfamilies) included in the box. Family 1 requires only one subassembly (S), one box (B1), one label (L), and one Insert for instructions (I); family 2 (F2) requires 2 subassemblies, one box (B2), one label and one insert, and family 3 (F3) requires 4 subassemblies, one box (B3), one label and one insert to become finished product as shown in Table 1. Obviously, this family classification is strictly from manufacturing perspective and marketing department uses its own family definition based on product function related characteristics. The family definition has been made based on limitations of packaging machines. Not all packaging machines can insert 4 vials into a box. This seemingly simple issue becomes an obstacle in assigning products to packaging cells and furthermore becomes a restriction in assigning products to even manufacturing cells in connected cellular design.

Fabrication Cells

The fabrication area is where the subassemblies are manufactured. This area contains three cells which manufacture a single common subassembly and hence all three families can be manufactured in any of the three cells. The fabrication area has a conveyor system which transfers the products from one machine to another based on one-piece flow principle.

Operations in Fabrication Cells

There are three operations associated with the fabrication area:

- Lamination
- Slicing and Bottling
- Capping

The machines used for operation 1 in all three cells are similar and work under the same velocities (120 vials/min) but the number of machines within each cell varies. Operation 2 has machines that process 17 vials/min and 40 vials/min. Similarly, operation 3 has machines that process 78 vials/min and 123 vials/min. Table 2 shows the distribution of machines and velocities among the three cells.

Table 1. Product structures of families

	Components					
Family	S	L	I	B1	B2	B3
F1	1	1	1	1		
F2	2	1	1		1	
F3	4	1	1			1

Table 2. Number of machines and their production rates in fabrication cells

	Op. 1	Op.2		Op. 3		Output of Bottleneck (vials/min)
		Type I	Type II	Type I	Type II	
Production Rate (vials/min)	120	17	40	78	123	
Cell 1	1	2	2	0	1	114
Cell 2	1	4	0	1	0	68
Cell 3	2	3	2	0	2	131

Packaging Cells

The packaging area also has a conveyor system similar to the fabrication area which transfers products within packaging cells and also from the fabrication cells to the packaging cells. In the packaging area, the subassemblies produced in the fabrication area are used to produce the various finished products. The packaging cell 1 is semiautomatic while cells 2 and 3 are automatic. This difference in the types of machines results in constraints that do not allow the packaging of certain products in certain cells. There are a total of 36 finished products which differ in the quantity of vials they contain, the type of raw material the vials are made of, and the destination of the country to where they are shipped. The original cell feasibility matrix for the families is given in Table 3 and the restrictions are due to constraints in the packaging of the vials.

Table 3. Feasibility matrix of families and packaging cells

Family	Packaging Cell 1	Packaging Cell 2	Packaging Cell 3
F1	X	X	
F2	X	X	X
F3	X		X

Operations in Packaging Cells

There are five operations performed in packaging area and each operation requires one machine. The operations are described as follows:

- Feeding (This operation is only performed in the case of disconnected cells)
- Labeling
- Assembly (Automatic in cells 2 and 3, semi-automatic in cell 1)
- Sealing
- Bar Coding

Table 4 shows the production rates of the machines in all cells.

ALTERNATE DESIGNS CONSIDERED

In this section, the current product-cell feasibility restrictions are discussed for both connected and disconnected cellular systems.

Connected Cells

In this system, cells are set up such that the packaging cells form an extension or continuation of the respective fabrication cells. In other words, the output of a cell in fabrication area becomes the input for the corresponding packaging cell. Hence, it is referred to as a connected system. The connected system for the current product-

Table 4. Production rates for assembly-packaging machines in vials/minute

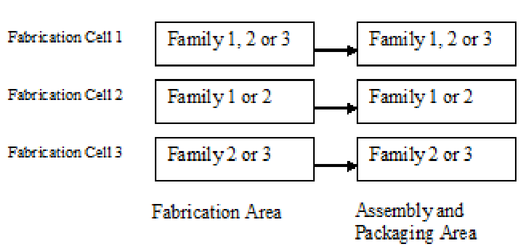
Cell	Family	Operation				
		4	5	6	7	8
Cell 1	Family 1	160	135	80	150	150
	Family 2	160	135	80	150	150
	Family 3	160	135	80	150	150
Cell 2	Family 1	160	135	100	150	150
	Family 2	160	135	180	150	150
	Family 3	NA	NA	NA	NA	NA
Cell 3	Family 1	NA	NA	NA	NA	NA
	Family 2	160	135	150	150	150
	Family 3	160	135	280	150	150

cell feasibility is shown in Figure 3. The output of family 1, family 2, and family 3 is essentially based on the bottleneck or the slowest machine in each cell of the fabrication or the packaging area and they are shown in Table 5.

Disconnected Cells

In this case, the output of a cell in the fabrication area can become an input for more than one cell in the packaging area depending upon the constraints in the packaging area. This can be considered to be a partially flexible disconnected cells type of system. The cell routing for each family is shown in Figure 4. In this figure, solid lines indicate that all the products processed in that particular fabrication cell can be processed in the assembly and packaging cell that they are connected to. On the other hand, the dashed lines show that only some of the products processed in the fabrication cell can be processed in the corresponding assembly and packaging cell. This provides a greater amount of flexibility with respect to the routing of the parts in the cellular system. The output rates of family 1, family 2, and family 3 depend on the fabrication-packaging cell combination and they are determined by the slowest machine as shown in Table 6.

Figure 3. Cell routing of families for the connected system



Cases Considered

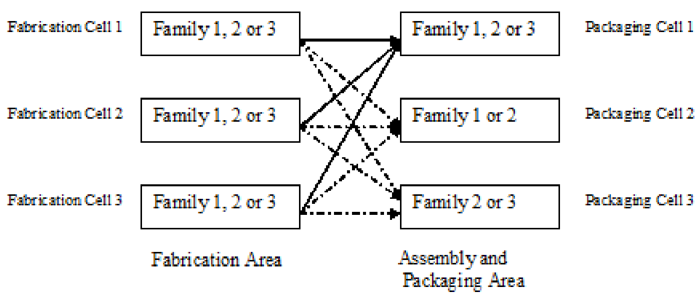
The experimentation discussed in this chapter can be grouped in the following sections:

- Original Family-Cell Feasibility Matrix
  Production orders are based on customer orders.
- Various Family-Cell Feasibility Options
  Seven different family-cell feasibility options have been considered as given in Table 7. In this case too, production orders are based on customer orders.

Table 5. Output rates for cells in the connected system

Cell #	Family #	Output Rate of the Bottleneck Machine in Fabrication Area (vials/min)	Output Rate of the Bottleneck Machine/Operator in Packaging Area (vials/min)	Output Rate (vials/min)
Cell 1	Family 1	114	80	80
	Family 2		80	80
	Family 3		80	80
Cell 2	Family 1	68	100	68
	Family 2		135	
Cell 3	Family 2	131	135	131
	Family 3		135	

Figure 4. Cell routing of families for disconnected system



METHODOLOGY USED

This section describes the methodology used to develop the different simulation models in Arena 7.0.

Input Data Analysis

Input data such as customer order distributions, their respective inter-arrival times, processing times, and routings were all obtained based on the data provided by the company. The data provided was basically the total sales volume in vials for each part belonging to one of the three families for a period of nineteen months. Table 8 shows the customer order sizes and the inter-arrival time distributions for each product.

Simulation Models

The models were run 24 hours a day which basically represented 3 shifts round the clock. Setup times and material handling times were negligible. Preemption was not allowed due to material control restrictions by FDA. Vials move based on one-piece flow between machines. The simulation models are discussed for different cases separately in the following paragraphs.

Case 1: Connected Cells: After the entities are created, they are routed to cells 1, 2 or 3 based on the type of family they belong to. The entities enter the fabrication area as a batch equivalent to the customer order size. Once a batch of entities enters the cell they are split and there is a one-piece flow in the cell. Entities belonging to a family go to one of its feasible cells based on the shorter queue length among 2nd operation. This is done

Table 6. Output rate of each routing combination for the disconnected system

Family #	Fabrication Area Cell (Output of the Bottleneck Machine in vials/min)	Packaging Area Cell (Output of the Bottleneck Machine in vials/min)	Output Rate of Routing Combination (vials/min)
Family 1	Cell 1 (114)	Cell 1 (80)	80
	Cell 1 (114)	Cell 2 (100)	100
	Cell 2 (68)	Cell 1 (80)	68
	Cell 2 (68)	Cell 2 (100)	68
	Cell 3 (131)	Cell 1 (80)	80
	Cell 3 (131)	Cell 2 (100)	100
Family 2	Cell 1 (114)	Cell 1 (80)	80
	Cell 1 (114)	Cell 2 (135)	114
	Cell 1 (114)	Cell 3 (135)	114
	Cell 2 (68)	Cell 1 (80)	68
	Cell 2 (68)	Cell 2 (135)	68
	Cell 2 (68)	Cell 3 (135)	68
	Cell 3 (131)	Cell 1 (80)	80
	Cell 3 (131)	Cell 2 (135)	131
Family 3	Cell 1 (114)	Cell 1 (80)	80
	Cell 1 (114)	Cell 3 (135)	114
	Cell 2 (68)	Cell 1 (80)	68
	Cell 2 (68)	Cell 3 (135)	68
	Cell 3 (131)	Cell 1 (80)	80
	Cell 3 (131)	Cell 3 (135)	131

Table 7. Different family-cell feasibility options

Cellular System	Cell Type	Cell	Options						
			O1	O2	O3	O4	O5	O6	O7
Connected Cells	Fab. Cells	C1	1	1,2,3	1,2	1,2,3	1	1,2	1,2
		C2	2	1,2,3	2,3	1,2	2	2,3	2,3
		C3	3	1,2,3	1,3	2,3	3	1,3	1,3

because the second operation in each cell has been identified as the bottleneck operation based on trial runs conducted. In cell 1 and cell 3, the entities undergo operation 1 and go to operation 2 where there are two types of machines namely the slow (Type I) and fast (Type II) machines available for processing. The entities are routed to either type of machine based on a percentage which was decided after a number of simulation runs in order to minimize the queue lengths and hence the waiting time. In cell 1, 30% of the entities were routed to the Type I machine and the rest were routed to the Type II machine. In cell 3, 40% of the entities were routed to the Type I machine and the rest were routed to the Type II machine.

Each of the entities leaving the fabrication cells enters the corresponding packaging cells. For example, entities from cell 1 in the fabrication area will enter cell 1 of the packaging area. The entities entering the packaging area undergo processing through operation 4. In the fifth operation, the vials are grouped based on the type of family they belong to. Family 1 consists of only 1 vial, family 2 consists of 2 vials and family 3 consists of 4 vials. Thus, the vials that are batched in Arena after operation 5 are processed in operations 6, 7 and 8 where they are boxed, sealed and coded. In the final batching, the vials are batched together in a box based on the final customer order sizes. The final batch sizes are the same as the input batch sizes. There is a waiting time associated since the entities might have to wait till the required batch size is reached and only then get disposed.

The warm up time for the model was determined to be 2000 hours based on steady state analysis. The simulation was run for 2500 hours after the end of the warm-up period.

Case 1: Disconnected Cells: The entities enter the fabrication area in batches as explained for the connected system. The batches of entities in disconnected system are routed differently as compared to the connected system. Here, the batches of entities are routed to cell 1, cell 2, or cell 3 of the fabrication area based on the shortest queue length of the bottleneck operation which is operation 2 as explained earlier. The flexibility of routing the families to any of the cells in this type of system is the only major difference between the connected and disconnected systems in the fabrication area. The processing times of the machines and the sequence of operations for the entities for both systems are the same. Since the flow is disconnected in this system, the entities are batched again to the same customer order sizes at the end of the fabrication area.

The batches of entities entering the packaging area are routed to specific packaging cells based on shortest queue length as shown earlier in Table 4. These batches are then split and the entities follow a one-piece flow. Also, there is an extra feeding operation at the start of the packaging cells in order to accommodate the transfer of entities from fabrication to packaging. The method in which the entities are transferred from fabrication to packaging and the extra feeding operation is the only major difference between the connected and disconnected systems in the packaging area. The processing times of the machines and the sequence of operations for the entities for both systems are the same.

Case 2: It is very similar to case 1 except that the routings for products are varied as given in Table 7. In this table, Option 5 (O5) is the least flexible arrangement where each cell can process only one product family for both connected and disconnected cells. Option 2 (O2) is the most flexible arrangement with three cells capable of running all three product families both in connected cells and disconnected cells. The remaining options vary in flexibility between O5 and O2. In Option 1, the system is highly inflexible in connected cells whereas it is very flexible in packaging cells of disconnected arrangement (three product families for each cell). In options 3, 4, 6 and 7, each product family can be run at least in two cells. In option 3, packaging cells of disconnected arrangement is more flexible (once again three product families for each cell). In option 4, a little bit more flexibility is added to both connected and disconnected cells (cell 1 can run three families). In option 6, more flexibility is now added to fabrication cells of disconnected system (three product families for each cell). In option 7, each family can be run in two cells. However, models for options 1 and 5 didn't stabilize and therefore they were not included in comparisons.

Production order quantities for products 33 and 36 were both reduced by 40% and 50%, respectively to fit into existing capacity for case 1. Validation and verification are an inherent part of any computer simulation analysis. Models were verified and validated before statistical analysis was performed for all scenarios.

RESULTS OBTAINED

The results obtained from simulation analysis for average flowtime and average work-in-process inventory are summarized in Tables 9 and 10, respectively. The results are based on 100 replications. The statistical analysis was conducted using the statistical functions available in Excel. A t-test assuming unequal variances for two samples was conducted for a 95% confidence interval for each family under each system. Table 11 displays the comparison for each family with respect to flowtimes and work-in-process between connected and disconnected systems. Table 12 displays comparisons for the families for the same performance measures but the comparisons are made between different connected systems from cases 1 and 2. Table 13 also displays comparisons for the families for the same performance measures but the comparisons are made between different disconnected systems from cases 1 and 2. Results are denoted as significant (S) or not significant (NS) based on the conclusions reached. Also whenever significant, better option was denoted in a parenthesis. The significance of the results was based on the p-value obtained from the T-test conducted for an alpha level of 0.05. As mentioned earlier, no results for options 1 and 5 were obtained as the system did not stabilize.

As observed in Table 11, for case 1, the flowtimes and work-in-process were observed to be different and the disconnected system had lower flowtimes and WIP for families F1 and F3 while the difference was significant for F1. On the other hand, WIP was significantly lower for F2 in the connected system. For case 2 with all the options considered, when there was a significant difference, this was always in favor of connected systems. For option 2, the flowtime for family 2 and the WIP for all three families for the connected system were significantly lower than those of in the disconnected system. For options 3, 6, and 7 which were the same for the connected system, the flowtimes and WIP for families 1 and 2 were significantly lower than the disconnected

Table 9. Average flowtime results for all cases

Cases and Options	Connected Cells Configuration			Disconnected Cells Configuration

system. For option 4, the WIP for family 2 in the connected system was the only significant result. From Table 12, it can be observed that option 2 (O2) provided the best results when compared to rest of the options within the connected system with lower flowtimes and WIP followed by option 3 (O3). From Table 13, it can be observed that the flowtimes and WIP for options 3 and 7 (O3, O7) were consistently and significantly better when compared to the rest of the options in the disconnected cells configuration. Also, when these two options were compared against each other there was no significant difference observed for any of the families and performance measures. A comparison between models C1 and O2 did not yield any significant results either and were definitely

less superior in performance when compared with the rest of the options.

CONCLUSION

In this chapter, the performance of connected and disconnected cellular systems was compared under make-to-order strategy in a real cellular setting. In the existing system (case 1), it was observed that no cellular manufacturing design dominated the other, i.e., mixed results were obtained as to which system did better for each family. The flowtime and work-in-process for family 1 for the disconnected system were lower. On the other hand, the WIP for family 2 in the connected system was lower. The other comparisons did not yield any significant results and hence dominance could not be established in terms of better cellular system.

In case 2, which is basically an extension of case 1, the impact of considering alternate cell routings for each part family was studied for both connected cells and disconnected cells. In most cases, connected cells outperformed disconnected cells with respect to both average flowtime and WIP, especially for family 1 and family 2. This leads to the conclusion that the connected system is the better system in this situation since family 1 and family 2 make up for 32 of the 36 products and comprise of about 85% by volume of the production orders in the system. The average flowtime and WIP conclusions are similar but not identical, i.e. there were incidents where flowtime was significantly better but not necessarily corresponding WIP and vice versa. If one wanted to choose the best connected cell configuration, that would be option 2. This is possibly due to option 2 having the highest flexibility among all options as each family could be routed to any of the fabrication and packaging cells. Options 3, 4 and case 1 followed in the order of performance leading to the conclusion that increase in routing flexibility of the families resulted in significantly lower flowtimes and WIP.

A similar comparison among all options developed for the disconnected system showed that options 3 and 7 performed better than the rest of the options. Option 3 had complete flexibility in the packaging area but limited flexibility in the fabrication area and option 7 had limited flexibilities in both the areas. Limited flexibility as applicable to these two options means that each family could go to at least two specified cells. On the other hand, option 2 was the worst performing system among the options for case 2 even though it had the highest flexibility. This can be attributed to the fact that routing decisions are made based on queue sizes only. Family 3 products have the highest processing times and it is possible that queues in all cells may contain products from family 3 thus leading to higher lead times for the parts that join that queue.

For case 1 and also option 2 from case 2, the disconnected system was modified to delete the extra feeding operation and the batching at the end of the fabrication area. This was done in order to determine the reason why the connected system performed better than the disconnected system in most of the comparisons made. The two modified simulation models were run and the results were statistically analyzed. In case 1, the flowtime for family 1 and the WIP for family 2 was significantly better for the disconnected system. In the original comparison, WIP and flowtime for family 1 in the disconnected system was better and the WIP for family 2 in the connected system was significantly better. The rest of the comparisons did not yield any significant results. For option 2, none of the comparisons yielded significant results as opposed to the original comparison when the connected system clearly performed better than the disconnected system. From these results it can be concluded that the extra operation and the extra batching increases the average WIP and flowtimes for each of the families and could be responsible for the disconnected system not performing as well as or better than the connected system.

Chapter 39
AutomatL@bs Consortium:
A Spanish Network of Web-based Labs for Control Engineering Education

Sebastián Dormido

José Sánchez
Universidad Nacional de Educación a Distancia, Spain

ABSTRACT

This chapter describes the effort of a group of Spanish universities to unify recent work on the use of Web-based technologies in teaching and learning engineering topics. The network was intended to be a space where students and educators could interact and collaborate with each other as well as a meeting space for different research groups working on these subjects. The solution adopted in this chapter goes one step beyond the typical scenario of Web-based labs in engineering education (where research-groups demonstrate their engineering designs in an isolated fashion) by sharing the experimentation resources provided by different research groups that participated in this network. Finally, this work highlights the key points of this project and provides some remarks about the future use of Web-based technologies in school environments.

INTRODUCTION

The evolution of the Internet has changed the education landscape drastically (Bourne et al. 2005, Rosen 2007). What was once considered distance education is now called online education. In other words, the method of teaching and learning is based on the use of the Internet to complete educational activities. A specific example of this new teaching model is the Spanish University for Distance Education (UNED). Compared to other Spanish universities, this institution has the largest number of students because distance education allows students to obtain a degree or improve

DOI: 10.4018/978-1-4666-1945-6.ch039

their professional skills without having to change their lifestyles. UNED is not a unique institution; there are many universities around the world with an online presence, such as the Open University in Colombia, Open Universities in Australia, the Open University in UK, the Open University in Catalonian, Fern Universität in Germany, and many more. The existence of these institutions confirms the viability and importance of computer-assisted teaching and learning through the Internet.

The implementation of a distance learning model is not an easy task in engineering and sciences studies (Williams 2007). In addition to textual/multimedia information and other resources required to demonstrate theoretical aspects in an online course, hands-on laboratories should also be included. This requirement is particularly necessary for control engineering, which is an inherently interdisciplinary field in which progress is achieved through a mix of mathematics, modeling, computation, and experimentation (Astrom 2006). In this context, students should be able to

- Understand the underlying scientific model of the phenomenon that was studied.
- Become acquainted with the limits of the model (i.e., how does the model accurately reflects real behavior and to what extent it remains a basic approximation).
- Learn how to manipulate the parameters of the model in order to fine-tune the behavior of the real system. (Dormido 2004)

To achieve these goals, the implementation of an effective Web-based educational environment for any engineering topic should cover three aspects of the technical education: concept, interpretation, and operation. The student should be provided with an opportunity to become an active player in the learning process (Dormido et al. 2005). In this context, the potential for Web-based experimental applications such as virtual laboratories (Valera et al. 2005), remote laboratories (Casini et al. 2004, Brito et al. 2009) and games (Eikaas et al. 2006) as pedagogical support tools in the learning/teaching of control engineering has been presented in many works. In fact, in the last decade, several academic institutions have explored the World Wide Web (WWW) to develop their courses and experimental activities in a distributed context. However, most of these developments have focused only on the technical issues related to building Web-enabled applications for performing practical activities through the Internet (e.g., how to start up remote monitoring of a real device or how to build sophisticated virtual interfaces). At most, these implementations may include a set of Web pages with a list of activities that need to be carried out by the users. Some examples of these implementations are provided in the additional reading section at the end of the chapter. In general, these developments do not take into account the social context of the interactions and the collaboration that is typically generated in traditional hands-on laboratories (Nguyen 2007). Indeed, direct contact with teachers and interactions with classmates are valuable resources that may be reduced or even disappear when hands-on experimental sessions are conducted via Web-based laboratories.

New trends in the use of Web-based resources for teaching and learning in the engineering disciplines include the use of Web 2.0 technologies such as social software in building virtual representations of face-to-face (f2f for short) laboratories in a networked, distributed environment (Gillet et al., 2009). This objective was grounded in the idea that educational institutions and many workplaces are equipped with a type of tool that connects people, contents and learning activities and can thus transfer information and knowledge. *Learning to learn* is the new challenge for the new generation of students. In other words, they have to learn to use Web resources to improve their teaching and learning.

Commonly, a mix of Web-based technologies and software agents (Salzmann & Gillet 2008) is used to develop remote experimentation systems for pedagogical purposes. For this reason, most of the remote experimentation systems are custom-made solutions. This means that the selection of software tools and global system architecture are not simple tasks due to the wide variety of software frameworks that are available. This chapter describes the structure of the remote experimentation system used in this study, which is based on the use of three software tools: Easy Java Simulations (Easy Java 2010), LabVIEW (LabVIEW 2010), and eMersion (eMersion 2010).

BACKGROUND

In a typical scenario for remote experimentation, universities provide the overall infrastructure required for the remote experimentation services offered to students, including a set of didactic setups that are specially designed for hands-on laboratories, a set of server computers used to interface these processes and a main server computer providing the complementary Web-based resources necessary to use the remote labs. The system users (clients) can access experimentation services from any Internet connection. However, developing a complete environment for experimentation services is not an easy task. For this reason, this section presents a systematic approach for developing such systems.

Although the development of an application with the previously described features can be structured in multiple ways, we have divided the problem into two levels or "layers." The first layer is the *experimentation layer*, which includes all the necessary software and hardware components needed to develop the experimental applications for the Web-based virtual or remote laboratories. Because Web-based labs do not supply all the elements needed to provide remote experimentation services, complementary Web-based resources are needed to manage students' learning. Thus, the *e-learning layer* incorporates the development of functionalities required to support teaching and learning through the Internet (Vargas et al., 2008).

Layer 1: The Experimentation Layer

The experimentation layer included the design methodology and construction of a graphical user interface for clients as well as the server application. This layer was developed with a client and server structure. The first step to start the development process was the analysis of the requirements and specifications for implementing the interface. The following subsections include some recommendations for developing this layer.

Requirements and Specifications for the Client

- The software should be multiplatform. For example, Java has the required characteristics for designing this kind of application; the user only needs a Web browser with Java support to access the Web-based lab.
- The protocol to communicate with the server should include low-level protocols to stream data through the Internet, such as TCP (Transfer Control Protocol) or UDP (User Datagram Protocol). These protocols allow for better control of data packet transmissions in networks.
- The graphical user interface must be simple and intuitive. It should be user-friendly and useful in different environments.
- Either virtual or remote access to the laboratory should be enabled with the same graphical interface. In simulation mode, the state of the system and its associated variables must be updated based on the evolution of a mathematical model of the process. Otherwise, in remote mode, these variables should be updated according to the real plant changes in the remote location. Video feedback should also be includ-

ed to provide distance users with a sense of presence in the laboratory.

- Events scheduling for program faults in the system should be included. The systems could be enabled to analyze systems in the presence of noise or disturbance measurements. The robustness of the system could also be evaluated under anomalous operating situations.
- Finally, it is recommended that the users define experiments in an easy manner. For example, a programmed change of a set-point value could be required to observe the process response at different operation points.

Requirements and Specifications for the Server

From a software design point of view, the server is composed of a set of modules (some of them optional) that are described below:

- A data exchange module: this software remains in a listening state while it is waiting for remote connections from users. It receives commands and queries from clients and makes these inputs effective over a physical system. The responses are retrieved from the real plant through the instrumentation hardware and are sent back to the client. The link between the server and clients would be established via a TCP/IP protocol suite.
- An access management module: this software module would manage all of the information related to the management of users and timeslot bookings for the use of real plants. A database manager would be used to handle the users' reservations and physical resources. Each register in this database would correspond to a booking scheduled for a specific time and date.
- An instrumentation module: this module would incorporate all of the hardware needed to connect the physical system with the server.
- A remote visualization module: this module would allow users to examine what is happening with the physical system during its remote manipulation by a client. Video cameras would be used to facilitate this feature. This system must be able to transmit a sense of realism to encourage its usage and increase the motivation of the users while completing tasks.
- Each module in the server has a counterpart on the client side. For example, to read the video streaming captured by the server, the client application must implement a software module that allows for the retrieval and decoding of video streaming from the remote camera and then renders it in the interface.

Layer 2: The E-Learning Layer

The previous section presented the main features that need to be taken into account when analyzing, designing, and building the experimentation layer. Additionally, a second key aspect that should be addressed is the development and/or use of a Web-based learning management system (LMS) to support a student's learning process. This platform should organize user access to the experimentation modules that are available and allow for students/teachers to interact and collaborate with one another. The implementation phase would require the following:

- Simplification of the organization of user groups.
- Notification services by email, instant messaging, news, and other methods.
- Documentation such as practical guides, task protocols, instruction manuals and any other information needed to per-

form a remote experimentation session autonomously.

- A sequence of activities that students must carry out during an experimental session. There can be two types of tasks: 1) tasks in *simulation mode* and 2) tasks in *remote mode*. Tasks in simulation mode are tasks that students must carry out prior to performing the experiments in the real plant. These tasks should be completed with a graphical user interface that allows students to work in a simulated environment. The objective should be to gain adequate insight about the procedures that are involved in the experiment. These tasks would reduce the time students spend on activities using the real plant. Remote access should not be allowed if the student has not satisfactorily completed the required tasks in simulation mode. If the student's work was evaluated positively by the teaching staff, then access to remote mode would be granted.
- A method for managing students and the assessment of their work as well as uploading reports.
- An automatic booking system to schedule access to the physical resources.
- At the end of the development process, the *experimentation* and *e-learning* layers have to be integrated to produce the final Web application for virtual and remote labs. This integration needs to establish certain links and channels between the Web modules from both layers. For example, in our particular framework, we made it possible to save data collected from an experimentation applet (experimentation layer) in a shared Web space that was part of the e-learning layer. The data stored in this space could be retrieved later for analysis.

IMPLEMENTATION

The implementation process of the remote experimentation system that is described in this chapter can be itemized into two independent processes that were combined to create the final environment. These developments can be summarized as follows:

- *Building hybrid laboratories for pedagogical purposes (the experimentation layer).*
- *Integrating the hybrid laboratories into a Learning Management System (LMS) to publish resources and provide mechanisms for accessing the real plants (the e-learning layer).*

Building Hybrid Laboratories for Pedagogical Purposes

A *hybrid laboratory* provides remote software simulations and real experiments in a single environment that can be accessed over the Internet. The client/server approach is commonly used for the technical implementation of both features (Callaghan et al. 2006, Zutin et al. 2008). Specifically, when a student is conducting an experiment in a virtual manner, he or she also works with a mathematical model of a process.

When developing the simulated portion of a *hybrid laboratory*, developers not only need to create a technology that covers all the aspects related to the use of simulations in a local mode. The applications must also work well in a distributed environment. The graphical user interface, for instance, could be a pure HTML/JavaScript application, or it could require a plug-in such as Flash, Java or ActiveX that runs in a Web browser.

Although one of the most relevant features of Java is the simplicity of the language, creating a graphical simulation in this programming language is not a straightforward task. Conceiving relatively complex Web-based applications requires advanced knowledge of object-oriented programming and other features of Java (Esquembre 2005). For this reason, the following subsection presents Easy Java Simulations (EJS), a software tool that was used to create the client interfaces for the hybrid laboratories in this chapter.

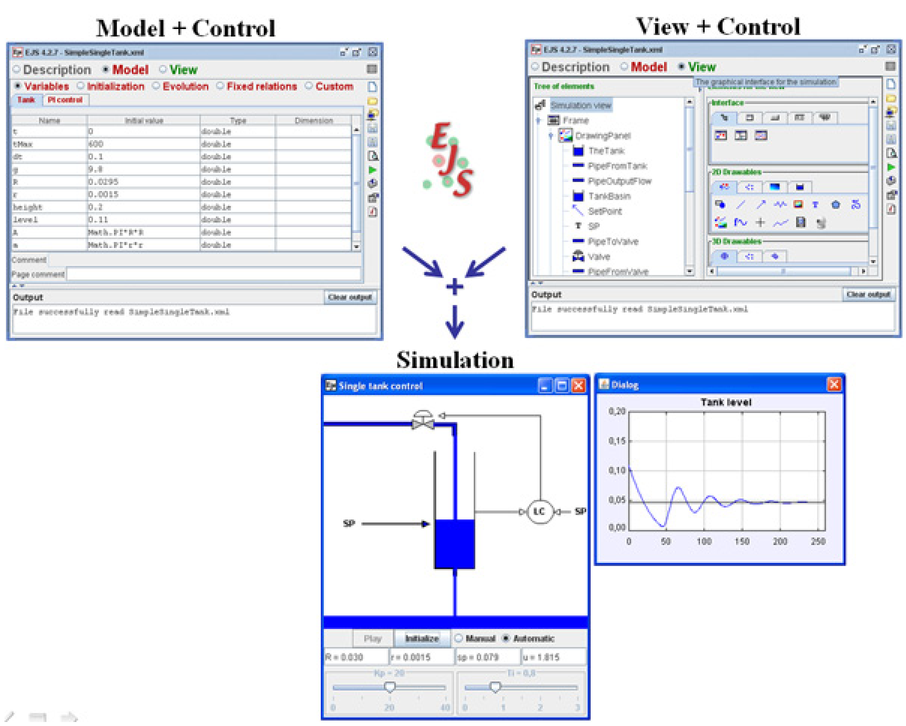
EJS as a Development Tool for Hybrid Laboratories

EJS is a freeware, open-source tool that was developed in Java and is specially designed for the creation of discrete computer simulations (Christian & Esquembre 2007). EJS was originally designed for users with little programming experience. However, users need to know the analytical model of the process and the design of the graphical interface in detail. The architecture of EJS was derived from the *model-view-control* (MVC) paradigm, a philosophy that is based on the fact that interactive simulations must include three parts:

- The *model*, which describes the process under study in terms of (1) variables, which define the different possible states of the process, and (2) the relationships between these variables, which are expressed by computer algorithms.
- The *control*, which defines certain actions a user can perform on the simulation.
- The *view*, which shows a graphical representation (either realistic or schematic) of the process states.

EJS makes programming simple by eliminating the control element of the MVC paradigm and fusing one part in the *view* and the other part in the *model*, as shown in Figure 1. Thus, applications can be created in two steps: (1) defining the *model* to simulate with the built-in simulation mechanism of EJS and (2) building the *view* by showing the model state and incorporating the changes made by users. Figure 1 shows a simple virtual-lab created

Figure 1. MVC paradigm abstraction of EJS



by EJS for teaching basic control concepts based on the well-known *single-tank process*.

Although EJS was initially conceived as a software tool to create interactive simulations for teaching physics, it has been successfully applied to many other research areas, including physical systems, mechanical systems, control systems (as in this essay), and medical systems. Thus, EJS could be classified as a general purpose tool intended to create interactive simulations of scientific phenomena based on models.

Finally, one of the most important features of EJS is that its applications can be easily distributed through the Internet in applet form. Applets are Java programs that can be executed in the context of a Web browser in a way similar to Flash or HTML/JavaScript applications. To find more information about the EJS mechanism, creating simulations, and additional features, please visit the EJS homepage (http://www.um.es/fem/EjsWiki/).

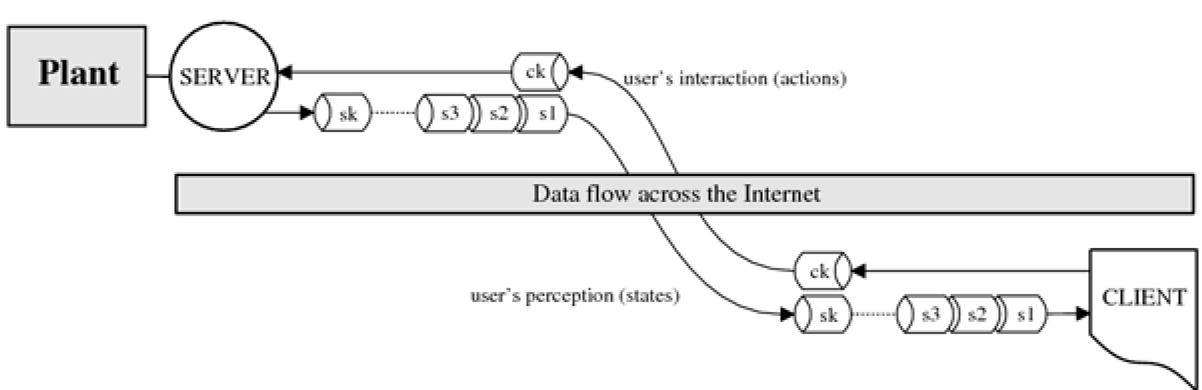
LabVIEW Server for Developing Hybrid Laboratories

Carrying out the remote operation of any physical device is challenging if we take into account the number of technical aspects that must be solved. In most cases, technical issues such as *performance*, *interaction level*, *visual feedback*, *real-time control*, *user perception*, *safety* and *fault tolerance* require extensive research (Salzmann & Gillet 2002).

In general, remote experimentation through the Internet requires an awareness of the current state of the distant real plant to change the value of any input parameter of the remote system and to perceive the effect of this change with a minimal transmission delay. Figure 2 shows the process in which a client application maintains a connection with a remote server to control a real plant remotely. The server-side sends a continuous flow of information, which is represented by the information blocks *s(k)* that reflect the current state of the plant, and the server receives information blocks *c(k)* containing changes in system input parameters that were carried out by a remote user. The client side of the system receives information on the state of the system that is sent by the server (contained in *s(k)* blocks) while simultaneously waiting for a user's interaction to report the changes to the server-side with new information blocks *c(k)*.

Regarding the software solutions for the server-side, there are many options for programming the *real-time control loop* (Matlab/Simulink, C++, Scicos, etc.). In this chapter, we propose a working scheme for LabVIEW developers. The set of tasks that should be executed in the Lab-

Figure 2. Stream of information between client and server



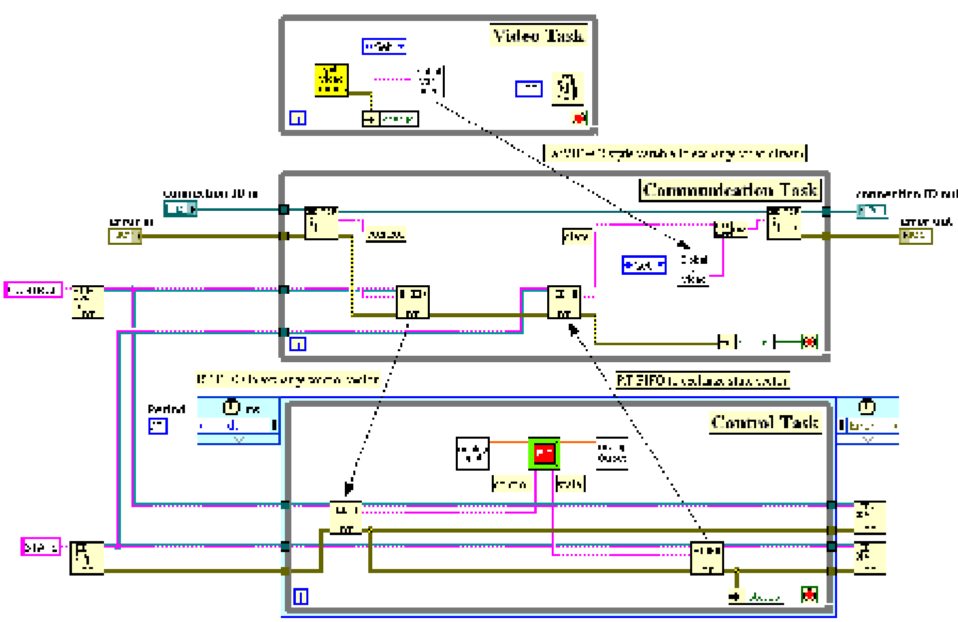
VIEW server to enable the remote experimentation are described below:

- **Control task:** This loop involves the execution of three sub-tasks: 1) recover control parameters from the communication task, 2) acquire data and closed-loop control, and 3) transmit the system state to the communication task.
- **Video task:** This loop involves the execution of two sub-tasks: 1) acquire images from the video camera and 2) transmit images to the communication task.
- **Communication task:** This loop involves the execution of three sub-tasks: 1) receive control data from clients and write the data to the control task, 2) read the system state from the control task and the images from the video task, and 3) link the state and images and then send them to the client.

Figure 3 shows a LabVIEW block diagram that corresponds to this communication architecture. The three loops in the diagram run concurrently to perform the main tasks: *control*, *communication*, and *video acquisition*.

The control task is a *time-critical* activity running at a sampling period of 20 ms with a priority greater than the other two threads. The *Analog Input Block* reads the analog input signal from the sensor, its output is compared to the setpoint input of the *PID Block,* and the result is fed into the *Analog Output Block*. Then the resulting value is sent to the actuator, which completes the control task. The data structure composed of the setpoint value, the PID control parameters, the command to the actuator, and other variables is known as the *control vector*. This vector is sent from the communication task to the control task through *RT FIFO* queue blocks (RT FIFO queues act as a fixed-size queue so that the writing of data to an RT FIFO does not overwrite previous elements). These variables are produced when users interact with the client interface. The data array formed by the values sent to the actuator, the measurement from the sensor, the current time, and other variables are known as the state vector, and these values are transferred from the control

Figure 3. Three loops running concurrently in the LabVIEW server



task to the communication task through RT FIFO queue blocks.

The video task is a *non-time-critical* activity because the loss of some video frames is generally acceptable for the user. For most applications, sending five images per second is enough to obtain adequate visual feedback of the remote system (Salzmann et al. 1999).

The communication task concatenates the current measurements (state vector) and the video frame in a new vector. This resulting vector is sent to the client using a *TCP Write Block*. In parallel, the control vector is received through the *TCP Read Block* from the clients and is passed to the control task through *RT FIFO* queues. The TCP protocol is used in both implementations because it guarantees packet delivery and bandwidth adaptation, although there is the cost of extra transmission delays (Lim 2006). A possible alternative would be the UDP protocol, which provides better control of the transmission delay. However, UDP does not have a guaranteed packet delivery mechanism or a bandwidth adaptation mechanism. Thus, the designer is responsible for implementing these features.

Once the server-side is completed, the EJS application on the client side must be modified to exchange information with the LabVIEW server. In other words, the virtual lab must be transformed into a remote lab by receiving data from the real system instead of the simulated one. The steps to allow a virtual lab connect to the server architecture will be explained in the next section.

First, a set of Java methods were programmed in EJS to control the connection with the LabVIEW server. Table 1 shows an example of the implementation of the methods connect(), disconnect(), sender(), and receiver().

Specifically, the upper part of Table 1 shows the excerpts of Java code that are used for establishing and releasing the connection with a server computer. TCP sockets are used to access the network layer. In Java, the socket programming creates an object and generates calls to the methods for the object. On the left part, the establishment of the connection is carried out in Line 4. To create a socket object, the *domain name* (or IP address) and the *service port* in the remote server are needed. Then, in Lines 5 and 6, the input/output stream buffers are created. These buffers act as FIFO storing queues whose filling and emptying depend on possible delays in network communication. The disconnection from the server is made by invoking the close() method in the socket and the input/output stream buffers (Lines 5, 6, 7 - right upper part of Table 1).

Conversely, the receiver() and sender() methods should be launched on independent Java threads when the connect() method is started. The sender() method is used to report changes in the user *view* that affect the operation of the remote equipment (for example, a change in a controller parameter). The receiver() method recovers the incoming data sent from the LabVIEW server. As shown in both pieces of code, the format of variables for the exchange must be defined. For the receiver() method, the *current time* (*t*), *liquid level* (*h*), and *input flow* in automatic mode (*qautomatic*) are received. These values constitute the states of the system (measurements). In the case of the sender() method, the *control mode* (*m/a*), the *input flow* in manual mode (*qman*), the *PID parameters* (*Kp*, *Ti* and *Td*), and the *setpoint* value (*ref*) are sent to the server-side when any user interaction is detected. These data are rendered to the client with an EJS *view*. The interface contains the same graphical elements of the virtual lab, but now the dynamic behavior of the elements is updated using the measurements obtained from the server.

Once the methods have been added to the EJS client, the programming logic that discriminates between working in a simulation or a remote mode has to be created. This logic depends on whether updating the variables in the hybrid lab is carried out based on the evolution of the mathematical model (virtual lab) or on real measurements that are obtained from the server when the remote working mode is active (remote lab).

Table 1. Excerpt of Java code to communicate with the LabVIEW server from the EJS client

Connect with the server

```
public boolean connect(){
connected = false;
try{
javaSocket = new Socket(“onetank.dia.uned.es”, 2055);
in = new DataInputStream(javaSocket.getInputStream());
out = new DataOutputStream(javaSocket.getOutputStream());
if (javaSocket != null) { // If connected ?
connected = true; // connection is ok...
_play(); // executing evolution
}
}catch (java.net.IOException io) {
System.out.println(“Problems connecting to host.”);
}
return connected;
}
```

Disconnect from the server

```
public void disconnect(){
if (connected) {
if (javaSocket != null){
try {
in.close();// close input stream
out.close();// close output stream
javaSocket.close();// close connection
javaSocket = null;
in = null;
out = null;
connected = false;
}catch (java.io.IOException e){
System.out.println(“Close socket error.”);
}
}
}
}
```

Receive data from the server

```
public void receiver(){
if (connected) {
try {
time = in.readFloat();//read time from server
level = in.readFloat();// read level from server
qautomatic = in.readFloat();// read input flow from server
}catch (java.io.IOException e) {
System.out.println(“Error receiving data.”);
}
}
}
```

Send data to the server

```
public void sender(){
if (connected) {
try {
out.writeBoolean(m/a);//write control mode
out.writeFloat(qman);//write input flow in manual
out.writeFloat(Kp);//write proportional gain
out.writeFloat(Ti);//write integral gain
out.writeFloat(Td);//write derivative gain
out.writeFloat(ref);//write setpoint
out.flush();// flush data to client
}catch (java.io.IOException e) {
System.out.println(“Error sending data.”);
}
}
}
```

Integrating Hybrid Laboratories into a Learning Management System

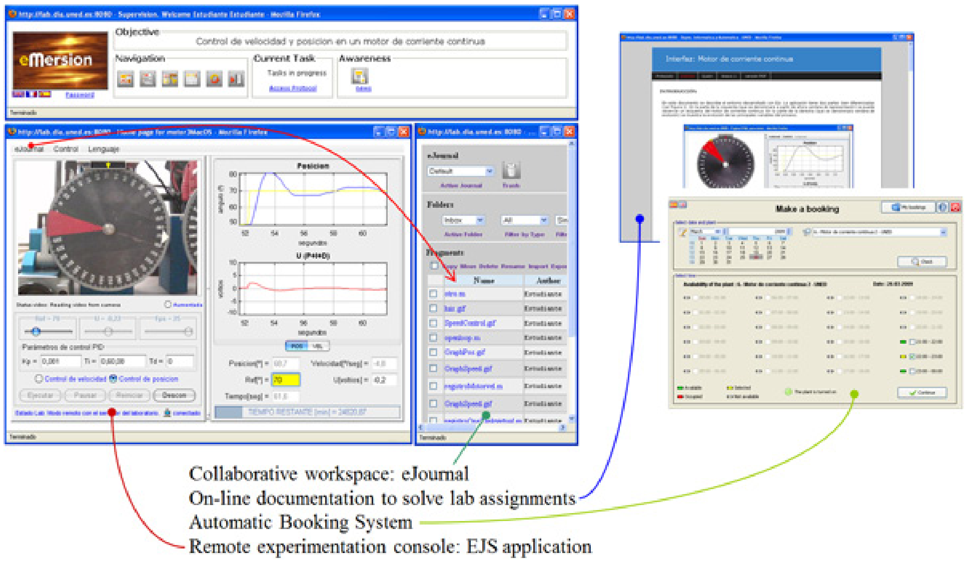
Remote and virtual control laboratories do not provide all the necessary resources to teach students in a distributed scenario. This section describes the Web infrastructure used to support the learning process of students in a distributed scenario. eMersion (Gillet et al. 2005) is the LMS tool we chose for publishing the virtual and remote laboratories on the Internet. This environment was implemented based on emulating the social behavior of the interactions and collaborations that exist in an f2f laboratory.

eMersion Description

Figure 4 shows a complete view of the experimentation environment for eMersion during a practical session with a DC motor system in remote mode. From a structural point of view, the environment is composed of five independent Web applications: *navigation bar*, *eJournal*, *experimentation console*, *online information*, and *external applications*.

The *navigation bar* provides access to the other Web resources for the environment. From the link labeled “Access Protocol,” users can obtain a complete user’s guide for the environment.

Figure 4. Learning Management System to publish web-based labs



The *eJournal* resource provides a shared workspace for users to communicate and collaborate during the learning process. The *eJournal* allows students to save, retrieve, and share their experimental results and documents. Furthermore, the presentation of results and discussions with teaching staff can be performed using the options that are provided. The users can also organize the information collected during the experimental sessions and through online repositories. Work tracking and awareness can be implemented based on this information.

The *experimentation console* corresponds to the EJS interfaces in which students carry out their experimental activities. These interfaces can interchange data with the *eJournal* space (see Figure 4). Thus, students can use the results they obtained (through images of the system's evolution or data registers) in the experimentation sessions to prepare their reports for the final assessment.

Online information is a collection of HTML pages and PDF files that allow students to visualize all the documentation necessary to solve the laboratory assignments.

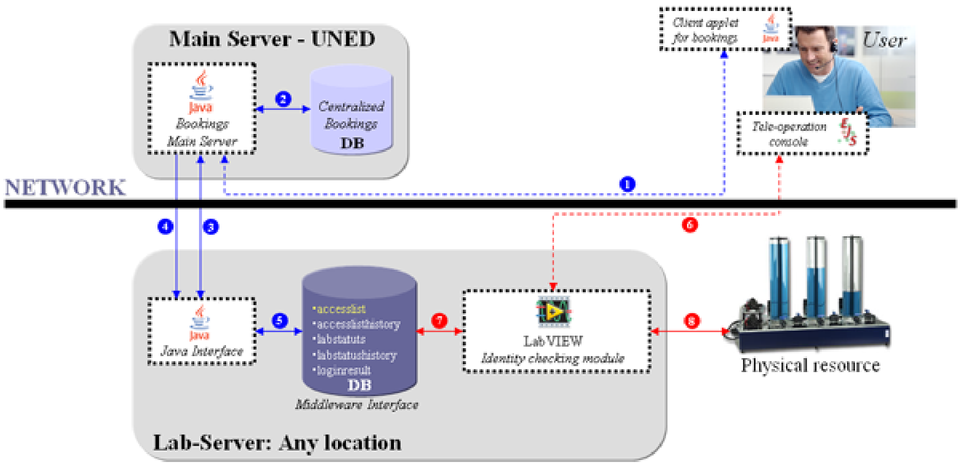
Finally, eMersion offers an ability to integrate external Web applications. In this context, the following subsection describes the *automatic bookings* and *authentication system* developed to organize students' access to the physical resources. This application was successfully integrated into eMersion.

A Flexible Scheme for Authentication and Booking of Physical Resources

A flexible scheme to let students book the use of a physical resource located in the laboratory was added to the LMS. Essentially, students can fill out a reservations database automatically from the client through a Web interface. The system includes three main modules.

For the first module, a Java applet was developed to perform new bookings on the client-side (see *Client applet for bookings* in Figure 5). For the second module, a centralized server application was also developed in Java to manage reservations, synchronism, and communications between the client applet for bookings and the Lab-Server (see *Bookings Main Server* in Figure 5). Finally, an

Figure 5. A flexible scheme for bookings and the authentication process



additional Java module located in the Lab-Server was developed (see *Java Interface* in Figure 5). This module informs the Bookings Main Server of the current state of the Lab-Server and other parameters that the central server requires.

The full process for booking a physical resource in the laboratory is divided into two stages, which are described below (see Figure 5):

Reservation Phase: A description of the states flow during a reservation occurs as follows:

- The Applet for bookings requests a new reservation (step 1)
- The Bookings Main Server takes the request and saves it in a local database (DB) (step 2)
- The Bookings Main Server asks the Java Interface for its time zone (step 3)
- The Java Interface provides its time zone to the Bookings Main Server (step 3)
- The Bookings Main Server calculates the time lag and amends the timeslot
- The Bookings Main Server reports the new register to the Java Interface (step 4)
- The Java Interface receives the register and inserts it in the Lab-Server DB (step 5)
- The Bookings Main Server tells the client that the new reservation has been made (step 1)

Authentication Phase: A description of the states flow during authentication occurs as follows:

- The Applet for experimentation starts the process by sending user credentials (step 6)
- The Identity Checking Module receives the keys and checks whether the user exists in the local DB. If the user exists, it then checks whether the connection attempt is between the start-time and the end-time of the timeslot reserved (step 7)
- The Identity Checking Module sends the result of the checking to the Applet for experimentation (step 6)
- If the checking result is acceptable, then the Applet for experimentation receives free access to the Target Plant (steps 6 and 8)

The *Applet for bookings* in which students schedule their reservations for any experiment is shown in Figure 4. The process to make a booking requires that when the student requests a reservation, the response of the bookings system must indicate the date and time assigned for the student to use the remote plant.

Other booking and authentication systems with similar features can be found in the literature. One of the most relevant is the booking and authentication mechanism for the iLabs Shared System (http://icampus.mit.edu/ilabs/), which was developed at the Massachusetts Institute of Technology (MIT). This program employs a middle tier Service Broker that manages the interaction between users and Lab-Servers. In this architecture, all of the reservations are hosted in the service broker and the users must pass through it each time they want to work with the real plants. Unlike the iLabs system, our system offers some additional features. When a user performs a new booking, the reservation is hosted and managed in a middle tier, which is similar to the iLabs Shared System, but the reservation is also stored in a simple database located in each Lab-Server. Thus, the post authentication process is carried out directly with the Lab-Server by passing this middle tier. Another advantage of this architecture is that in case a Lab-Server with valid bookings is damaged, these bookings could be retrieved later by the Lab-Server from the Central Server. Finally, the administrators of a Lab-Server could also manage the bookings locally. As such, if there were problems with the central servers, bookings could be made manually.

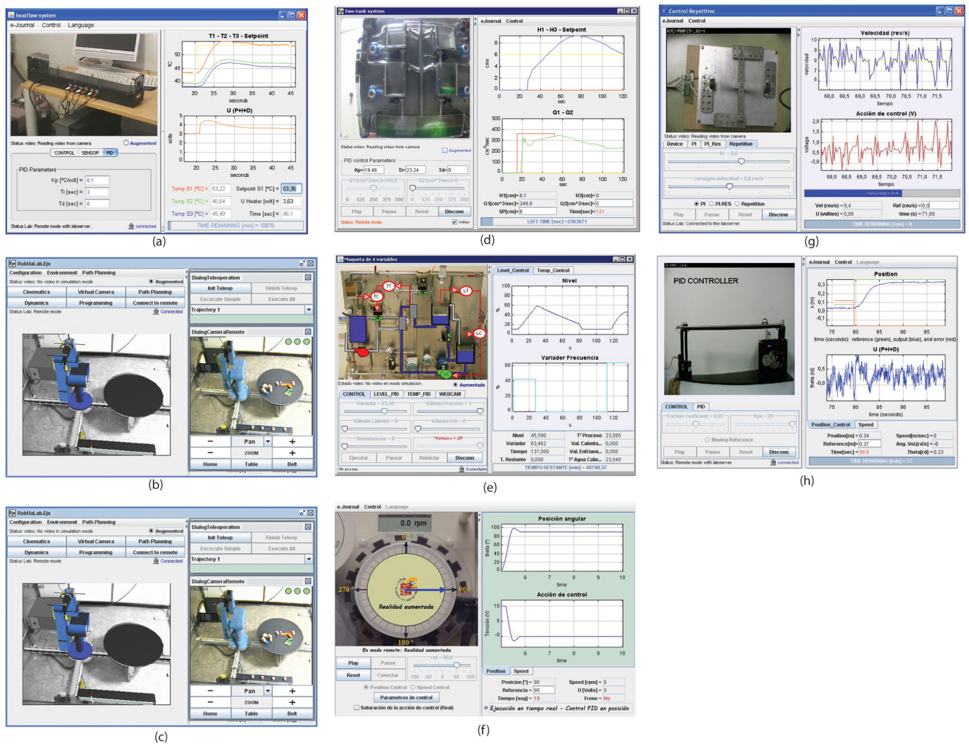
AUTOMATL@BS NETWORK

The AutomatL@bs network (http://lab.dia.uned.es/automatlab) is a consortium of seven Spanish universities that decided to expand their efforts in the use of virtual and remote laboratories for engineering education to a national level. The universities taking part in this project are UNED, the University of Almería (UAL), the University of Alicante (UA), Polytechnic University of Valencia (UPV), Polytechnic University of Catalonia (UPC), Miguel Hernández University (UMH), and the University of León (UNILEON). The main challenge of this work has been to manage and coordinate the integration of the *hardware*, *software*, and *human* resources in a Web-based experimentation environment hosted by the Department of Computer Science and Automatic Control of UNED in Madrid. The main aims of this project were

- Enabling students to access practical experiments that are not available at their universities.
- Increasing the quality and robustness of the network of virtual and remote laboratories for a higher number of students and teachers with different teaching concerns.

The Web-based laboratories were offered to a total of 112 master's degree candidates at engineering schools in the consortium. Figure 6 shows the GUIs of the virtual and remote laboratories for each participant university. Each GUI has the same arrangement of graphical elements, which provides a uniform structure. Also, the Web-based laboratories of the AutomatL@bs network were documented following the same guidelines and criteria. In general, the documentation defines a set of tasks or activities that students should carry out so they can be evaluated effectively by the teaching staff. This sequence of activities was divided into two phases: *PRE-Lab activities* and *Lab activities*. PRE-Labs are based on the use of the experimentation console in the simulation mode. Thus, the teaching team could be assured that each student had prior knowledge of the system before using it for an actual experiment. Lab tasks are based on the use of the experimentation console in the remote mode. Remote access to the system is allowed by the teaching staff once students finish their PRE-lab work in simulation mode, and the work is considered satisfactory.

Figure 6. The available remote systems in AutomatL@bs



Description of the Pedagogical Scenario

Students from each university worked on three of the nine available remote systems (three from UNED and six from other universities) offered by the AutomatL@bs project (one lab from their university and two labs from other locations). Then students were required to use the system to learn how to operate the interfaces. Finally, after several sessions, the students could complement their work with the Web-based AutomatL@bs experimentation system at their convenience through an outside Internet connection. UNED students were first offered the chance to access the systems that were available at UNED (a *servo-motor system*, a *heat-flow system*, and a *three-tank system*). Later on, they could complete their work remotely through the Internet. During these experimental sessions, students were able to save their data measurements and parameters for writing their final reports. The students placed their reports in the *eJournal* space for evaluation. Teaching assistants from each university were in charge of evaluation.

Outcomes

To obtain feedback regarding the use of the system, the students were required to complete evaluation questionnaires. We designed questions based on the guidelines of Ma and Nickerson (2006) to evaluate the infrastructure and the technical quality of the system as well as the educational value and the experiences of students. Some of the more relevant questions are described below:

Technical questions:

1. How would you describe the quality of the virtual laboratories?
2. How would you describe the quality of the remote laboratories?

3. Have you experienced hardware or software problems?
4. Did you appreciate the uniform structure of the client interfaces?
5. How was the navigation experience for the global system options?

Educational value questions:

1. How would you evaluate the quality of your learning with Web-based laboratories compared to traditional methods?
2. How would you describe your learning speed using remote and virtual labs compared to traditional methods?
3. In general terms, are you satisfied with the usability of the system?
4. What were the most important learning resources when you were learning to use the system?
5. How would you evaluate the level of difficulty of using the system?

Although this assessment was not an exhaustive evaluation, it provided initial information on what was necessary, or unnecessary, to include in this methodology for future engineering courses. The outcomes obtained from this survey are summarized in Table 2.

Sub-scale Number 1 provided the first general view concerning whether students felt satisfied with this new method for performing their practical experiments. The results showed that 19% and 69% of students strongly agreed and agreed, respectively, that they were satisfied with the system. Other questions about the advantages of using remote experiments in the educational process were also reported. The results showed that the use of new technologies, especially the Internet, encouraged students to conduct most of their practical exercises using this resource. *Sub-scale Numbers 2 and 3* show comparative information about learning with the new technological methods compared to traditional methods. In cases where students reported dissatisfaction (9%), the primary reason was that they were not able to work directly with the laboratory equipment. A way to solve this problem could be to apply an educational methodology based on *blended learning*. First, a face-to-face class where students could interact and experiment in situ with the real plant would be held. The students would then be allowed access to the experimental environment remotely to complete their practical exercises. Regarding the quality of the hybrid laboratories (*Sub-scale Numbers 4 and 5*), most students positively evaluated their development in terms of user functionality. Any negative results might

Table 2. Summary of the survey outcomes

Sub-scale	A%	B%	C%	D%	E%
1. Satisfaction degree	19	69	7	5	0
2. Learning compared to traditional methods	15	51	25	8	1
3. Facility of using the system	19	62	11	8	0
4. Quality of virtual labs	33	48	15	4	0
5. Quality of remote labs	25	38	25	10	2
6. Most important learning resource	18	44	27	11	0

1. A: Strongly Agree B: Agree C: Neutral D: Disagree E: Strongly Disagree
2. A: Much better B: Better C: Equal D: less E: Much less
3. A: Strongly Agree B: Agree C: Neutral D: Disagree E: Strongly Disagree
4. A: Very good B: Good C: Acceptable D: Bad E: Very Bad
5. A: Very good B: Good C: Acceptable D: Bad E: Very Bad
6. A: Documentation B: Questions to teacher C: Simulation D: Connection to plant E: Others

have been a consequence of the quality of the Internet connection speed because slow speeds lead to delays. Some of the students performed their experiments using old dialup connections (56 kbps), so the exchange of data with some processes was not fast enough and caused the user interfaces to update slowly. The experiments were also tested with low-speed ADSL lines (512/128 kbps), and the results were satisfactory. Finally, *Sub-scale Number 6* shows how queries of the teaching staff and the documentation of the practical exercises were essential resources for positive student performance.

CONCLUSION

Virtual and remote experimentation for engineering education can be considered a mature technology. However, the process of transforming a classic control experiment into an interactive Web-based laboratory is not an easy task. This essay provides a systematic approach for developing prototypes of remote laboratories from a pedagogical perspective using three tools: EJS, LabVIEW, and eMersion. This approach incorporates the development of online experimentation environments and provides an effective scheme to switch between the *simulation* and *teleoperation* of real systems.

The *AutomatL@bs project* has yielded benefits to the universities that have participated in the project over the last three academic years. The results from the previous evaluation allowed us to debug the system and identify necessary improvements in the framework. First, the number and variety of available experiments will be increased by enrolling new universities in the AutomatL@bs project (with special interest in universities from South America). To cope with this challenge, other LMS, such as Moodle or Sakai, are currently being evaluated. Second, the applets and all the materials are being adapted to the SCORM standards to simplify porting to another LMS. Additionally, the applets of the simulated physical processes are being integrated into the ComPADRE digital library (http://www.compadre.org) to gain visibility. These changes could help integrate and deploy our project in other institutions. We will also attempt to let students carry out their practical experiments using other devices (such as mobile phones and PDAs) and user interfaces (including e-mail, Web forms, and HTML/JavaScript thin interfaces).

KEY TERMS AND DEFINITIONS

Control Engineering: This form of engineering is an engineering discipline that applies control theory to design systems with predictable behaviors. The practice of control engineering uses sensors to measure the output performance of the device that is being controlled (e.g., a process or a vehicle), and those measurements can be used to provide feedback to the input actuators that can make corrections toward the desired performance.

Controller: This is a device that monitors and affects the operational conditions of a given dynamical system. The operational conditions are typically referred to as output variables in the system that can be affected by adjusting certain input variables.

Hybrid Laboratories: A Web-based laboratory where students can work with a simulation of a dynamic system (virtual lab) or on the real counterpart (remote lab).

LabVIEW (Laboratory Virtual Instrumentation Engineering Workbench): LabVIEW is a graphical programming environment from National Instruments used to develop sophisticated measurements, tests, and control systems with intuitive graphical icons and wires that resemble a flowchart.

Model–View–Controller (MVC): This is a software architecture that is currently an architectural pattern used in software engineering.

PID Controller: A proportional–integral–derivative controller is a generic control loop feedback mechanism (controller) widely used in industrial control systems.

Sharable Content Object Reference Model (SCORM): A collection of standards and specifications for Web-based e-learning. It defines communications between client-side content and a host system called the run-time environment, which is commonly supported by a learning management system.

Chapter 40
An Estimation of Distribution Algorithm for Part Cell Formation Problem

ABSTRACT

The aim of this chapter is to propose a new heuristic for Machine Part Cell Formation problem. The Machine Part Cell Formation problem is the important step in the design of a Cellular Manufacturing system. The objective is to identify part families and machine groups and consequently to form manufacturing cells with respect to minimizing the number of exceptional elements and maximizing the grouping efficacy. The proposed algorithm is based on a hybrid algorithm that combines a Variable Neighborhood Search heuristic with the Estimation of Distribution Algorithm. Computational results are presented and show that this approach is competitive and even outperforms existing solution procedures proposed in the literature.

INTRODUCTION

The principle objective of Group Technology is to reduce the intercellular flow of parts and to provide an efficient grouping of machines into cells. The main contribution in this chapter is to develop an efficient clustering heuristic based on evolutionary algorithms and to apply the proposed heuristic for Machine Part Cell Formation Problem which includes the configuration and capacity management of manufacturing cells. We propose to apply a novel population based evolutionary algorithm called Estimation of Distribution Algorithm in order to form part families and machine cells simultaneously.

DOI: 10.4018/978-1-4666-1945-6.ch040

The objective of the proposed heuristic is to minimize exceptional elements and to maximize the goodness of clustering and thus the minimization of intercellular movements. In order to guarantee the diversification of solutions, we added an efficient technique of local search called Variable Neighborhood Search at the improvement phase of the algorithm. Many researchers have combined local search with evolutionary algorithms to solve this problem. However, they did not apply yet the Estimation of Distribution Algorithm for the general Group Technology problem. Furthermore, we have used a modified structure of the probabilistic model within the proposed algorithm.

In order to quantify the goodness of the obtained solutions, we present two evaluation criteria namely the percentage of exceptional elements and the grouping efficacy. A comparative study was elaborated with the most known evolutionary algorithms as well as the well known clustering methods.

LITERATURE REVIEW

A wide body of publications has appeared on the subject of Group Technology (GT) and Cellular Manufacturing Systems (CMS). The history of approaches that tried to solve this problem began with the classification and coding schemes. Several authors have proposed various ways trying to classify the methods of Cell Formation Problem. It includes descriptive methods, cluster analysis procedures, graph partitioning approaches, mathematical programming approaches, artificial intelligence approaches and other analytical methods.

Burbidge (1963) was the first who developed a descriptive method for identifying part families and machine groups simultaneously. In his work "Production Flow Analysis" (PFA). Burbidge has proposed an evaluative technique inspired from an analysis of the information given in route cards to find a total division into groups, without any need to buy additional machine tools.

Then, researchers applied array based clustering techniques which used a binary matrix *A* called "Part Machine Incidence Matrix" (PMIM) as input data. Given *i* and *j* the indexes of parts and machines respectively, an entry of 1 (a_{ij}) means that the part *i* is executed by the machine *j* whereas an entry of 0 indicates that it does not. The objective of the array based techniques is to find a block diagonal structure of the initial PMIM by rearranging the order of both rows and columns. Thus, the allocation of machines to cells and the parts to the corresponding families is trivial. McCornick et al. (1972) were the first who applied this type of procedure to the CFP. They developed the Bond Energy Analysis (BEA) which seeks to identify and display natural variable groups and clusters that occur in complex data arrays. Besides, their algorithm seeks to uncover and display the associations and interrelations of these groups with one another. King (1980) developed the Rank Order Clustering (ROC). In ROC algorithm, binary weights are assigned to each row and column of the PMIM. Then, the process tries to gather machines and parts by organizing columns and rows according to a decreasing order of their weights. Chan and Milner (1981) developed the Direct Clustering Algorithm (DCA) in order to form component families and machine groups by restructuring the machine component matrix progressively. A systematic procedure is used instead of relying on intuition in determining what row and column rearrangements are required to achieve the desired result. King & Nakornchai (1982) improved the ROC algorithm by applying a quicker sorting procedure which locates rows or columns having an entry of 1 to the head of the matrix. Chandrasekharan & Rajagopalan (1986a) proposed a modified ROC called MODROC, which takes the formed cells by the ROC algorithm and applies a hierarchical clustering procedure to them. Later, other array based clustering techniques are proposed namely the Occupancy Value method of Khator & Irani (1987), the Cluster Identification Algorithm (CIA) of Kusiak & Chow (1987) and the Hamiltonian Path Heuristic of Askin et al. (1991).

McAuley (1972) was the first who suggested similarity coefficient to clustering problems. He applied the Single Linkage procedure to the CF problem and used the coefficient of Jaccard which is defined for any pair of machines as the ratio of the number of parts that visit both machines to the number of parts that visit at least one of these machines. Then, some other clustering techniques are developed namely Single Linkage Clustering (SLC), Complete Linkage Clustering (CLC), Average linkage Clustering (ALC) and Linear Cell Clustering (LCC). Kusiak (1987) proposed a linear integer programming model maximizing the sum of similarity coefficients defined between two parts

The category that is the most used in literature in recent years is heuristics and metaheuristics. Such heuristics are based essentially on Artificial Intelligence approaches including Genetic Algorithms (GA), Simulated Annealing (SA), Tabu Search (TS), Evolutionnary Algorithms (EA), neural network and fuzzy mathematics. In what follows we present some research papers that used this type of heuristics for designing CM systems.

Boctor (1991) developed the SA approach to deal with large-scale problems. Sofianopoulos (1997) proposed a linear integer formulation for CF problem and employed the SA procedure to improve the solution quality taking as objective the minimization of inter-cellular flow between cells. Caux et al. (2000) proposed an approach combining the SA method for the CF problem and a branch-and-bound method for the routing selection. Lozano et al. (1999) presented a Tabu Search algorithm that systematically explores feasible machine cells configurations determining the corresponding part families using a linear network flow model. They used a weighted sum of intra-cell voids and inter-cellular moves to evaluate the quality of the solutions. Solimanpur et al. (2003) developed an Ant colony optimization algorithm to solve the inter cell layout problem by modelling it as a quadratic assignment problem. Kaparthi et al. (1993) proposed an algorithm based on neural network for the part machine grouping problem. Xu & Wang (1989) developed two approaches of fuzzy cluster analysis namely fuzzy classification and fuzzy equivalence in order to incorporate the uncertainty in the measurement of similarities between parts. They presented also a dynamic part-family assignment procedure using the methodology of fuzzy pattern recognition to assign new parts to existing part families.

Recently many researchers have focused on the approaches based on AI for solving the part-machine grouping problem. Venugopal & Narendran (1992a) proposed a bi-criteria mathematical model with a solution procedure based on a genetic algorithm. Joines et al. (1996) presented an integer programming solved using a Genetic Algorithm to solve the CF problem. Zhao & Wu (2000) presented a genetic algorithm to solve the machine-component grouping problem with multiple objectives: minimizing costs due to inter-cell and intra-cell part movements; minimizing the total within cell load variation; and minimizing exceptional elements. Gonçalves & Resende (2002) developed a GA based method which incorporates a local search to obtain machine cells and part families. The GA is responsible for generating sets of machines cells and the mission of the local search heuristic is to construct sets of machine part families and to enhance their quality. Then, Gonçalves & Resende (2004) employed a similar algorithm to find first the initial machine cells and then to obtain final clusters by applying the local search. Mahdavi et al. (2009) presented a GA based procedure to deal with the CF problem with nonlinear terms and integer variables. Stawowy (2006) developed a non-specialized Evolutionary Strategy (ES) for CF problem. His algorithm uses a modified permutation with separators encoding scheme and unique concept of separators movements during mutation. Andrés

& Lozano (2006) applied for the first time the Particle Swarm Optimization (PSO) algorithm to solve the CF problem respecting the objective the minimization of inter-cell movements and imposing a maximum cell size.

ESTIMATION OF DISTRIBUTION ALGORITHM

It was first introduced by Mühlenbein & Paaß (1996). The Estimation of Distribution Algorithm belongs to Evolutionary Algorithms family. It adopts probabilistic models to reproduce individuals in the next generation, instead of crossover and mutation operations. This type of algorithms uses different techniques to estimate and sample the probability distribution.

The probabilistic model is represented by conditional probability distributions for each variable. This probabilistic model is estimated from the information of the selected individuals in the current generation and selects good individuals with respect to their fitness. This process is repeated until the stop criterion is met. Such a reproduction procedure allows the algorithm to search for optimal solutions efficiently. However, it considerably decreases the diversity of the genetic information in the generated population when the population size is not large enough. For this reason, the incorporation of a local search technique is encouraged in order to enhance the performance of the algorithm.

As a result, the Estimation of Distribution Algorithm can reach best solutions by predicting population movements in the search space without needing many parameters. The main steps in this procedure are shown in the following pseudo code:

Estimation of Distribution Algorithm

1. Initialize the population according to some initial distribution model.
2. Form P' individuals from the current population using a selection method.
3. Build a probability model p(x) from P' individuals using both the information extracted from the selected individuals in the current population and the previously built model.
4. Sample $p(x)$ by generating new individuals from the probability model and replace some or all individuals in the current population.
5. End the search if stop criteria are met, otherwise return to Step 2.

This method can be divided into two different classes. The first class assumes that there are no dependencies between variables of the current solution during the search. These are known as non-dependency Estimation of Distribution Algorithms: Population Based Incremental Learning (Baluja, 1994) and Univariate Marginal Distribution Algorithm (Mühlenbein & Paaß, 1996). The second class takes into account these variable dependencies: Mutual Information Maximization for Input Clustering (De Bonet et al., 1997), Bivariate Marginal Distributional Algorithm (Pelikan & Mühlenbein, 1999), Factorized Distribution Algorithm (Mühlenbein et al., 1999) and the Bayesian Optimization Algorithm (Pelikan et al., 1999a).

Generally, non-dependency algorithms are expected to have a worse modelling ability than the ones with variable dependencies (Zhang et al., 2004). But combining heuristic information or local search with non-dependency algorithms can compensate for this disadvantage.

Univariate EDAs

This category assume that each variable is independent; it means that the algorithm do not consider any interactions among variables in the solution. As a result, the probability model distribution,$p(x)$, becomes simply the product of Univariate marginal probabilities of all variables in the solution and expressed as follows:

$$p(x) = \prod_{i=1}^{1} p(x_i)$$

Due to the simplicity of the model of distribution used, the algorithms in this category are computationally inexpensive, and perform well on problems with no significant interaction among variables.

In what follows, we present the well-known works related to this category.

Population Based Incremental Learning

It was proposed by Baluja (1994). The algorithm starts with initialisation of a probability vector. In each iteration, it updates and samples the probability vector to generate new solutions. The main steps in this procedure are shown in the following pseudo code:

Population Based Incremental Learning

1. Initialise a probability vector $p=\{p_1,p_2,\ldots,p_n\}$ with 0.5 at each position. Here, each pi represents the probability of 1 for the i[th] position in the solution.
2. Generate a population P of M solutions by sampling probabilities in p.
3. Select set D from P consisting of N promising solutions.
4. Estimate univariate marginal probabilities p(xi) for each xi.
5. For each i, update pi using $p_i=p_i+\lambda(p(x_i-p_i)$
6. For each i, if mutation condition passed, mutate pi using

$p_i=p_i(1-\mu)$+randon (0 or 1)μ.

7. End the search if stop criteria are met, otherwise return to Step 2.

Univariate Marginal Distribution Algorithm

Univariate Marginal Distribution Algorithm was proposed by Muhlenbein & Paaß (1996). We note that this category can be seen as a variant of Population Based Incremental Learning when λ=1 and μ=0 Different variants of Univariate Marginal Distribution Algorithm have been proposed, and the mathematical analysis of their workflows has been carried out (Muhlenbein, 1998; Muhlenbein et al., 1999; Gonzalez et al., 2002). The main steps in this procedure are shown in the following pseudo code:

Univariate Marginal Distribution Algorithm

1. Generate a population *P* composed of *M* solutions.
2. Select a set *P'* from *P* consisting of *N* promising solutions.
3. Estimate univariate marginal probabilities *p*(*x*) from *P'* for each x_i.
4. Sample*p*(*x*)to generate *M* new individual and replace *P*.
5. End the search if stop criteria are met, otherwise return to Step 2.

Bivariate EDAs

In contrast with Univariate case, the probability model contains factors involving the conditional probability of pairs of interacting variables. This class of algorithms performs better in problems, where pair-wise interaction among variable exists.

In what follows, we present the well-known works related to this category.

Mutual Information Maximization for Input Clustering

The Mutual Information Maximization for input clustering uses a chain model of probability distribution (de Bonet et al., 1997) and it can be written as:

$$p(x) = \prod_{i=1}^{1} p(x_{\pi_1} \middle| x_{\pi_2}) p(x_{\pi_2} \middle| x_{\pi_3}) \ldots p(x_{\pi_{n-2}} \middle| x_{\pi_{n-1}}) p(x_{\pi_n})$$

where $\Pi=\{\pi_1,\pi_2,...,\pi_n\}$ is a permutation of the numbers $\{1,2,...,n\}$ used as an ordering for the pair wise conditional probabilities. At each iteration, the algorithm first tries to learn the linkage. Then, the algorithm uses a greedy algorithm to find a permutation Π that does not always give accurate model. Once the permutation Π is learnt, the algorithm estimates the pair wise conditional probabilities and samples them to get next set of solutions.

Combining Optimizers with Mutual Information Trees

The Combining Optimizers with Mutual Information Trees proposed by Baluja & Davies (1997, 1998) also uses pair-wise interaction among variables. The model of distribution used by this algorithm can be written as follows:

$$p(x) = \prod_{i=1}^{1} p(x_i \middle| x_j)$$

where, x_j is known as parent of x_i and x_i is known as a child of x_j. This model is more general than the chain model used by Mutual Information Maximization for input clustering as two or more variables can have a common parent.

Bivariate Marginal Distribution Algorithm

It was proposed by (Pelikan & Muhlenbein, 1999) as an extension to Univariate Marginal Distribution Algorithm. The model of distribution used by Bivariate Marginal Distribution Algorithm can be seen as an extension to the Combining Optimizers with Mutual Information Trees model and can be written as follows:

$$p(x) = \prod_{x_k \in Y} p(x_k) \prod_{x_i \in \{X|Y\}} p(x_i \middle| x_j)$$

where, $Y \subseteq X$ represents the set of root variables.

As a result, Bivariate Marginal Distribution Algorithm is a more generalised algorithm in this class and can cover both univariate interaction as well as bivariate interaction among variables.

Multivariate EDAs

The model of probability distribution becomes more complex than the one used by univariate and bivariate Estimation of Distribution Algorithms. Any algorithm considering interaction between variables of order more than two can be placed in this class. As a result, the complexity of constructing such model increases exponentially to the order of interaction making it infeasible to search through all possible models.

In what follows, we present the well-known works related to this category.

Extended Compact Genetic Algorithm

The Extended Compact Genetic Algorithm has been proposed by Harik (1999) as an extension to the Compact Genetic Algorithm. The model of distribution used in the Extended Compact Genetic Algorithm, is distinct from other previously described models as they only consider the marginal probabilities and do not include conditional probabilities. Also, it assumes that a variable appearing in a set of interacting variables cannot appear in another set. The model of distribution used by the Extended Compact Genetic Algorithm can be written as follows:

$$p(x) = \prod_{k \in m} p(x_k)$$

where, m is the set of disjoint subsets in n and $p(x_k)$ is the marginal probability of set of variables x_k in the subset k.

Factorised Distribution Algorithm

The Factorised Distribution Algorithm was proposed by Muhlenbein et al. (1999) as an extension to the Univariate Marginal Distribution Algorithm. The probability $p(x)$, for such linkage, can be expressed in terms of conditional probabilities between sets of interacting variables. In general, the Factorised Distribution Algorithm requires the linkage information in advance, which may not be available in a real world problem.

Bayesian Optimization algorithm

The Bayesian Optimization algorithm was proposed by Pelikan et al. (1999a). The probabilistic model $p(x)$ is expressed in terms of a set of conditional probabilities as follow:

$$p(x) = \prod_{i=1}^{n} p(x_i \,|\, \pi_i)$$

where, π_i is a set of variables having conditional interaction with x_i. Also no variable in π_i can have x_i or any children of x_i as their parent.

An extension to the Bayesian Optimization algorithm called hierarchical Bayesian Optimization algorithm has also been proposed by Pelikan & Goldberg (2000). The idea is to improve the efficiency of algorithm by using a Bayesian network with a local structure (Chickering et al., 1997) to model the distribution and a restricted tournament replacement strategy based on work of Harik (1994) to form the new population.

Estimation of Bayesian Network Algorithm

The Estimation of Bayesian Network Algorithm was proposed by Etxeberria & Larranaga (1999) and Larranaga et al., (2000) and also uses Bayesian networks as its model of probability distribution.

The algorithm has been applied for various optimisation problems, such as graph matching (Bengoetxea et al., 2000, 2001b,), partial abductive inference in Bayesian networks (de Campos et al., 2001), job scheduling problem (Lozano et al., 2001b), rule induction task (Sierra et al., 2001), travelling salesman problem (Robles et al., 2001), partitional clustering (Roure et al., 2001), Knapsack problems (Sagarna & Larranaga, 2001).

Learning Factorised Distribution Algorithm

The Learning Factorised Distribution Algorithm was proposed by Muhlenbein & Mahnig (1999b) as an extension to the Factorised Distribution Algorithm. The algorithm does not require linkage in advance. In each iteration, it computes a bayesian network and samples it to generate new solutions. The main steps in the Bayesian Optimization algorithm (BOA), the Estimation of Bayesian Network Algorithm (EBNA) and the Learning Factorised Distribution Algorithm (LFDA) procedures are shown in the following pseudo code:

BOA, EBNA and LFDA

1. Generate population *P* of *M* solutions
2. Select *N* promising solution from *P*.
3. Estimate a Bayesian network from selected solutions.
4. Sample Bayesian network to generate *M* new individual and replace *P*.
5. End the search if stop criteria are met, otherwise return to Step 2.

Markov Network Factorised Distribution Algorithm and Markov Network Estimation of Distribution Algorithm

The Markov Network Factorised Distribution Algorithm and the Markov Network Estimation of Distribution Algorithm were proposed by Santana (2003a, 2005). They used Markov network (Pearl, 1988; Li, 1995) as the model of distribution for $p(x)$. The first algorithm uses a technique called junction graph approach, while the second one uses a technique called Kikuchi approximation to estimate a Markov network.

PROBLEM STATEMENT

Manufacturing Cell Formation consists of grouping, or clustering, machines into cells and parts into families according to their similar processing requirements. The most known and efficient idea to achieve the objective of cell formation is to convert the initial Part Machine Incidence Matrix to a matrix that has a diagonal block structure. Among this process, entries with a '1' value are grouped to form mutually independent clusters, and those with a '0' value are arranged outside these clusters. Once a block diagonal matrix is obtained, machine cells and part families are clearly visible. However, the process engenders intercellular movements that require extra cost or time due to the presence of some parts that are processed by machines not belonging to its corresponding cluster. These parts are called Exceptional Elements. As a result, the objective of the block diagonalization is to change the original matrix into a matrix form minimizing Exceptional Elements and maximizing the goodness of clustering.

For cell formation problem, this matrix can be regarded as a binary matrix A which shows the relationship between any given m machines and p parts. Rows and columns represent respectively machines and parts. Each element in the matrix is usually represented by the binary entries a_{ij} where an entry of 1 indicates that a part i is processed by the corresponding machine j while an entry of 0 means a contrary situation. In Figure 1, we illustrate an (5×7) incidence matrix of King & Nakornchai (1982).

Figure 2 provides a block diagonal form for the initial matrix illustrated above. The obtained matrix has not any intercellular movement which means that it represents the optimal solution for the given matrix with 2 cells and 3 machines per cell.

In this chapter, we will deal with two efficient evaluation criteria namely the Grouping Efficacy (GE) and the Percentage of Exceptional Elements (PE). The Grouping Efficacy, proposed by Kumar & Chandrasekharan (1990), is considered one of

Figure 1. King & Nakornchai (1982) initial matrix

		Parts						
		1	2	3	4	5	6	7
Machines	1	0	1	0	1	1	1	0
	2	1	0	1	0	0	0	0
	3	1	0	1	0	0	0	1
	4	0	1	0	1	0	1	0
	5	1	0	0	0	0	0	1

Figure 2. A block diagonal matrix with no exceptional elements

		Parts						
		1	3	7	2	4	5	6
Machines	3	1	1	1	0	0	0	0
	2	1	1	0	0	0	0	0
	5	1	0	1	0	0	0	0
	4	0	0	0	1	1	0	1
	1	0	0	0	1	1	1	1

the best criteria which distinguish ill-structured matrices from well-structured ones when the matrix size increases and it is expressed as follows:

$$GE = \frac{e(X) - e_0(X)}{e(X) + e_v(X)}$$

Where:

$e_0(X)$: Number of Exceptional Elements in the solution X,
e: Number of 1's in the Part Machine Incidence Matrix,
$e_v(X)$: Number of voids in the solution X.

The second evaluation criterion is called the "Percentage of Exceptional Elements (*PE*)" is developed by Chan & Milner (1982) and expressed as follows:

$$PE = \frac{e_0(X)}{e} \times 100.$$

Some other performance measurements can be used to evaluate manufacturing cell design results. In what follows, we presents some of them.

The Grouping Efficiency which is developed by Chandrasekaran & Rajagopalan (1989). It expresses the goodness of the obtained solutions and depends on the utilization of machines within cells and inter-cell movements. This indicates that there are no voids and no exceptional elements in the diagonal blocks which imply a perfect clustering of parts and machines. Although grouping efficiency was widely used in the literature, it has an important limit which is the inability of discrimination of good quality grouping from bad one. Indeed, when the matrix size increases, the effect of 1's in the off-diagonal blocks becomes smaller, and in some cases, the effect of inter-cell moves is not reflected in grouping efficiency.

The Machine Utilization Index (MUI) which is defined as the percentage of the time that the machines within cells are being utilized most effectively and it is expressed as follows:

$$MUI = \frac{e}{\sum_i \left(m_i \times p_i\right)}$$

where m_i indicates the number of machines in cell i and p_i indicates the number of parts in cell i.

The Group technology efficiency which is defined as the ratio of difference between maximum number of inter-cell travels possible and number of inter-cell travels actually required by the system to the maximum number of inter-cell travels possible.

The Group efficiency which is defined as the ratio of difference between total number of maximum external cells that could be visited and total number of external cells actually visited by all parts to total number of maximum external cells that could be visited.

The Global efficiency is defined as the ratio of the total number of operations that are performed within the suggested cells to total number of operations in the systems.

PROPOSED EDA FOR MPCF PROBLEM (EDA-CF)

Solution Representation and Initial Population

Generally, for a Cell Formation Problem, a solution is represented by an m-dimensional vector $X=[x_1,x_2,\ldots,x_m]$ where x_i represents the corresponding assignment of the machine i to the specified cell. The problem consists in creating partitions of the set of the m machines assignments into a given number of cells. The created solutions must respect all the constraints defined in Section 3.3. We choose to generate the initial population randomly following a uniform distribution.

Selection

The goal is to allow individuals to be selected more often to reproduce. We adopt the truncated selection procedure to create new individuals: in each iteration, we select randomly P_1 individuals from the 50% of the best individuals in the current population. These P_1 individuals will be reproduced in the next generation using the probabilistic model to form new individuals.

Probabilistic Model and Creation of New Individuals

After the selection phase, a probabilistic model is applied to the P_1 selected individuals in order to generate new individuals.

The probabilistic model provides the assignment probability of the machine i to cell j and expressed in Box 1 where, $\varepsilon>0$ is a factor which guarantees that the model provides a probability $P_{ij}\neq 0$.

Replacement

The replacement represents the final step in our search procedure. It is based on the following idea: when a new individual is created, we compare it to the worst individual in the current population and we retain the best one.

Fitness Function

A fitness function is used for evaluating the aptitude of an individual to be kept or to be used for reproducing new individuals in the next generation. In the proposed algorithm, we used two fitness functions F_1 and F_2 to perform the objectives of minimizing the percentage of Exceptional Elements and maximizing the Grouping Efficacy respectively.

Let m_i be the number of machines assigned to the cell i. we define F_1 and F_2 as follows:

$F_1(X)=e_0(X)+Pen(X)$

Box 1.

$$P_{ij}=\frac{number\ of\ times\ where\ machine\ i\ appears\ in\ cell\ j\ +\ \varepsilon}{number\ of\ selected\ individuals\ +\ C\times\varepsilon}$$

and

$F_2(X)$=$GE(X)$-$Pen(X)$.

where:

$$Pen(X) = \alpha_1 \sum_{i=1}^{C} \max\left\{0, m_i - k_{\max}\right\} + \alpha_2 \sum_{i=1}^{C} \max\left\{0, 1 - m_i\right\}$$

expressed the distance between the solution X and the feasible space.

This penalty under-evaluate the fitness of solution X when X violate the constraint of the problem. i.e a penalty value is encountered either when the number of assigned machines exceeds the capacity of a cell or when machines are assigned to a number of cells that exceeds the fixed number of cells C.

Variable Neighborhood Search Algorithm

Variable Neighborhood Search is a recent meta-heuristic for combinatorial optimization developed by Mladenović & Hansen (1997). The basic idea is to explore different neighborhood structures and to change them within a local search algorithm to identify better local optima with shaking strategies. The main steps in this procedure are shown in the following pseudo code:

Variable Neighborhood Search

Select the set of neighborhood structures N_k,k={1,2,...,$n_{\max}$} that will be used in the search, find an initial solution X, choose a stopping condition.

Repeat the following steps until the stopping condition is met:

Set k=1

Repeat the following steps until all neighborhood structures are used:

1. Shaking: generate a point X' at random from k^{th} neighborhood of X $\left(X' \in N_k(X)\right)$
2. Local Search: apply some local search method with X' as initial solution; denote with X'' the obtained local optimum.
3. Move or not: if this local optimum X'' is better than the incumbent, or if some acceptance criterion is met, move there $(X \leftarrow X'')$, and set k=1 ; otherwise, set $k \leftarrow k+1$.

Local Search Procedure

Generally, obtaining a local minimum following a neighborhood structure does not imply that we obtain a local optimum following another one. For this reason, we choose to use two local search procedures which are based on two different neighborhood structures. The first neighborhood structure consists to select one machine and to insert it in a new cell. The second consists to select two machines from two different cells and to swap them.

Then, we apply these two local search procedures iteratively until there is no possible improvement to the current solution.

Shaking Phase

The main idea consists to define a set of neighbourhood structures that allow to obtain a distance equal to k between the solution X and the new neighbour solution X'. This distance can be defined by the number of differences between the two vectors X and X'. Then, we define N_k as the neighbourhood structure given by applying randomly k insertion moves.

COMPARATIVE STUDY

In order to show the competitiveness of the proposed EDA-CF algorithm, we provide in this section a comparative study with the well known approaches that treated Cell Formation problem. During all experiments, the proposed algorithm is coded using C++ and run on a computer Pentium IV with 3.2 GHz processor and 1GB memory.

Test Data Set

In order to evaluate the goodness of clusters obtained from the clustering heuristic for MPCF problem, 30 problems taken from the literature were tested. These data sets include a variety of sizes, a range from 5 machines and 7 parts to 40 machines and 100 parts, difficulties, and well structured and ill structured matrices.

For all instances, the initial matrix is solved by Estimation of Distribution Algorithm method and then improved by the Variable Neighborhood Search procedure. Then, the cells are formed and the machine layout in each cell is obtained optimally.

Table 1 shows the different problems and their characteristics. The columns illustrate respectively the sources of data sets, the problem size, the number of cells *C*, the maximum number per cell, k_{max} and the matrix density. All problems can be easily accessed from the references and they are transcribed directly from the original article they appeared. The appendix gives the block diagonal matrices for the improved solutions by the proposed algorithm. The maximum number of permissible cells *C* has been set equal to the best known number of cells as found in literature. The following equation expressed the density of the initial binary matrix and which informs about haw the one's elements are distributed inside the matrix.

$$\frac{\sum_{i}^{m}\sum_{j}^{n} a_{ij}}{m \times n}$$

Comparative Study

In this section, we evaluate the proposed algorithm by comparing it with the best results obtained by several well known algorithms respecting to the Grouping Efficacy and the Percentage of Exceptional Elements measures. In all tests, the proposed EDA-CF algorithm has proved its competitiveness against the best available solutions respecting to the same required number of cells.

As a stop condition to our algorithm, we fixed the maximal computational time to 5 seconds and the maximal number of iteration of Variable Neighborhood Search algorithm to 3.

The values of the following parameters are fixed as: ε=0,1; α_1=50; α_2=500; *P*=200 and P_1=3.

Comparison Respecting the Grouping Efficacy Measure

In this subsection we perform a comparative study with the best algorithm presented in the literature. These algorithms can be classified into two categories. The first category corresponds to the based population algorithm including Genetic Algorithm (GA) of Onwubolu & Mutingi (2001), Grouping Genetic Algorithm (GGA) of Brown & Sumichrast (2001), Evolutionary Algorithm (EA) of Gonçalves & Resende (2004) and Hybrid Grouping Genetic Algorithm (HGGA) of James et al. (2007). The second category represents the clustering based methods including ZODIAC of Chandrasekharan & Rajagopalan (1987), GRAFICS of Srinivasan & Narendran (1991), MST-Clustering Algorithm of Srinivasan (1994). Table 2 reports the results obtained by the proposed algorithm and these algorithms such that their results were taken from the original citations.

As seen in Table 2, in all the benchmark problems, the grouping efficacy of the solution obtained by the proposed method is either better than that of other methods or it is equal to the best one. We note that the solutions obtained by the GA method for problems 1, 7, 13, 24, 28 and 29 were not available. In five problems, namely 20, 21, 22, 23 and 24, the grouping efficacy of the solution obtained by the proposed method is better than that of all other methods. In other words, the proposed method outperforms all the other methods and the best solutions for these problems are reported in this paper for the first time. In eleven problems, namely 2, 3, 9, 15 and 17, the solution obtained by the proposed method is as good as the best solution available in the literature. In five problems, namely 4, 8, 10, 18 and 19, all the methods have obtained the same grouping efficacy.

Comparing with clustering methods, it is clear that the results obtained by the proposed algorithm are either equal or better than ZODIAC, GRAFICS and MST methods in all cases except for the problems 25 and 30. More specifically, the EDA-CF obtains for 6 (23%) problems values of the grouping efficacy that are equal to the best ones found in the literature by the three compared clustering methods and improves the values of the grouping efficacy for 19 (73%) problems.

Comparison Respecting the Percentage of Exceptional Elements Measure

Table 3 provides a comparison of the proposed algorithm against the best reached results available in literature. The comparison was done respecting to the Percentage of Exceptional Elements

criteria. PE^a represents the best-known Percentage of Exceptional Elements found in the literature.

We note that the compared solutions for problems 15, 16, 17, 24, 26, 27, 28 and 29 were not available. The results shows that in all the benchmark problems, the number of exceptional elements of the solution obtained by the proposed method is either better than the best reached values or it is equal to the best ones. In 11 problems, namely 3, 6, 7, 12, 13, 14, 19, 20, 21, 22 and 23 the *PE* of the solution obtained by the EDA-CF is better than that of all other methods. In other words, the proposed method outperforms all the other methods. In nine problems, namely 1, 4, 5, 8, 9, 10, 11, 18 and 25, all the methods have obtained the same Percentage of Exceptional elements.

CONCLUSION

Cellular manufacturing is a production technique that leads to increase productivity and efficiency in the production floor. In this chapter, we have presented the first Estimation of Distribution Algorithm (EDA) method to solve the Machine Part Cell Formation Problem. Detailed numerical experiments have been carried out to investigate the EDAs' performance. Although the EDA approach does not require any problem-specific information, the use of sensible heuristics can improve the optimisation and speed up convergence. For this reason, we used the Variable Neighborhood Search (VNS) procedure in the improvement phase of the algorithm. The results from test cases presented here have shown that the proposed EDA-CF algorithm is very a competitive algo-

Table 3. Comparison between the obtained results and the best-known results respecting to the PE criterion

rithm comparing with the previously published metaheuristics applied to the same problem. It has been shown that the EDAs provide efficient and accurate solutions for the test cases. The results are promising and encourage further studies on other versions of the Group Technology problems where we can introduce sequence data, machine utilization and routings.

Chapter 41
A LabVIEW-Based Remote Laboratory:
Architecture and Implementation

Yuqiu You
Morehead State University, USA

ABSTRACT

Current technology enables the remote access of equipment and instruments via the Internet. While more and more remote control solutions have been applied to industry via Local Area Networks (LANs), Wide Area Networks (WANs), and the Internet, there exist requirements for the applications of such technologies in the academic environment (Salzmann, Latchman, Gillet, and Crisalle, 2003). One typical application of remote control solutions is the development of a remote virtual laboratory. The development of a remote-laboratory facility will enable participation in laboratory experiences by distance students. The ability to offer remote students lab experiences is vital to effective learning in the areas of engineering and technology. This chapter introduces a LabVIEW-based remote wet process control laboratory developed for manufacturing automation courses. The system architecture, hardware integration, hardware and software interfacing, programming tools, lab development based on the system, and future enhancement are demonstrated and discussed in the chapter.

INTRODUCTION

As distance learning has progressed from basic television broadcasting into web-based Internet telecasting, it has become a very effective teaching tool (Kozono, Akiyama and Shimomura, 2002). Laboratory experiences are important for engineering and technology students to reinforce theories and concepts presented in class lectures. The development of a remote-laboratory facility will enable participation in laboratory experiences by distance students. The ability to offer remote students these lab experiences is vital to effective learning. The development of a remote

DOI: 10.4018/978-1-4666-1945-6.ch041

virtual laboratory is also motivated by the fact that presently, as never before, the demand for access to the laboratory facilities is growing rapidly in engineering and technology colleges. Being able to make the laboratory infrastructure accessible as virtual laboratories, available 24 hours a day and 7 days a week, goes far in addressing these challenges, and would also contribute to lowering the costs of operating laboratories. Additionally, remote virtual laboratories will provide the opportunity for students to explore the advanced technologies used in manufacturing remote control/monitor systems, and therefore, to prepare them for their future careers.

This chapter introduces a LabVIEW-based remote process control system, which is established to provide web based online virtual laboratory for an online computer-integrated manufacturing course. The physical setup of the system includes a wet process system, a FieldPoint control system with a NI cFP-2000 intelligent controller and eight I/O modules, a desktop computer, an Ethernet hub, and an Internet DLink camera. The wet process system is composed of three water tanks, pumps, discrete valves, continuous valves, temperature sensors, level sensors, and pressure transmitters. The software used for the system interfacing is LabVIEW 8.0 from National Instruments and the HyperText Markup Language (HTML). The desktop computer works as a control server as well as a web server for the system, providing a local interface for system control and maintenance and a remote interface for students to control and monitor the wet process through the Internet. The desktop computer, the intelligent controller, and the Internet camera communicate with each other through the Ethernet hub, and also connect to the Internet. All the sensors, valves, and pumps in the wet process system are wired to the I/O modules of the intelligent controller. Details of the system wiring will be examined later in this chapter. This system has been used in the lab of a computer-integrated manufacturing course for graduate students in the Manufacturing Technology option of the Technology Management program. Students are introduced to system integration, process control, LabVIEW FieldPoint programming, and the development of web-based manufacturing applications by involvement in the lab activities through the Internet.

This chapter explores the integration of the mechatronic equipment, computer software, and networking techniques to achieve a remotely controllable system. It demonstrates the development of a LabVIEW-based FieldPoint control system for a virtual laboratory. The implementation of the laboratory, future enhancement, and related researches are discussed in this chapter.

BACKGROUND

As in engineering and technology fields, the laboratory experiences associated with a technology curriculum are vital to understanding concepts (Saygin & Kahraman, 2004). They are also typically limited to a short group session each week due to time and space constraints. Increasingly practical and popular distance courses are hard-pressed to provide realistic lab experience at all. Simulation, which has seen increased use in education, is an especially valuable tool when it precedes instruction, but does not provide the problem-solving realism of actual hands-on experience (Deniz, Bulancak & Ozcan, 2003). Completing a project by remote operation of real equipment more nearly replicates problem solving as it would occur in the workplace and lends itself to teaching the processes and practice that are involved in true experimentation (Cooper, Donnelly & Ferreira, 2002).

With the rapid developments of computer networks and Internet technologies along with dramatic improvements in the processing power of personal computers, remote virtual laboratories are now a reality. In the early 1990's, the first remotely shared control system laboratory was proposed in the 1991 American Society of Engineering Education (ASEE) Frontiers in Education Conference. The system enabled sharing of laboratory data between universities using networked workstations. By its nature, automated manufacturing lends itself to remote access for education, and education that incorporates remote experimentation may better prepare students for the workplace of the future. With the development of standards for online lab sessions, the Accreditation Board for Engineering and Technology validated remote labs as educational tools (Carnevale, 2002). Saygin and Kahraman (2004) have successfully implemented lab exercises for manufacturing education and systems related courses using remote technology. Asumadu and Tanner (2006), who developed a remote wiring and measurement laboratory that utilizes a "virtual breadboard," acknowledge the flexibility and spontaneity of the tool which has potential for global access. Gurocak (2001) describes Programmable Logic Controller (PLC) and robot labs which are delivered via the remote lab concept by Internet connection to the PLCs and closed circuit TV of the labs. Thamma, Huang, Lou, and Diez (2004) integrated Computer-integrated Manufacturing equipment into a remote lab system via a Java based web site.

The virtual laboratory demonstrated in this chapter was developed by using LabVIEW FieldPoint control technology and a web-based application. The remote control panel provides real-time control and monitor function to remote clients and a live video of the real system operation. Remote clients can access the control panel from a web browser on their computers with the LabVIEW Runtime Engine installed as a plug-in. LabVIEW, developed by National Instruments, is a graphic programming language to build virtual instruments (VIs) for control systems. A VI developed in the LabVIEW environment provides an interface between a user and a control process. The main concept of such an interface is to provide a general view of the process and facilitate full control of the operations. LabVIEW is widely used in developing automatic control solutions in real world industries, research studies and academic laboratories. The locally controlled setup can be turned into a remotely controlled one by moving the user interface away from the physical setup with web-based functions. LabVIEW also provides advanced communication methods for the integration of LabVIEW VIs with other applications, such as ActiveX containers, File Input and Output, and.NET constructor nodes.

FieldPoint is a proprietary method for interfacing devices to computers developed by National Instruments, but it is very similar in principle to the concept of a fieldbus interfacing method used by many process control equipment suppliers. The idea of fieldbus grew out of the problem of interfacing hundreds or thousands of sensors and actuators to Programmable Logic Controllers (PLCs) and process control computers in large industrial plants. Instead of connecting each sensor or actuator to a central plant computer with hundreds or thousands of kilometers of wiring, the idea of fieldbus was to connect related groups of sensors and actuators to a local microcomputer that communicates with the central plant computer via an Ethernet local area network (LAN). The result was an enormous reduction in wiring and a corresponding increase in reliability. FieldPoint control in the LabVIEW environment is composed of four components, FieldPoint interface hardware, the FieldPoint Object Linking and Embedding for Process Control (OPC) server, the LabVIEW FieldPoint handler, and the Measurement and Automation Explorer (MAX). The FieldPoint interface hardware includes an intelligent controller, the I/O modules, and devices that connected to the modules. The FieldPoint OPC server is an invisible element of the software that can be invoked whenever the FieldPoint connection is setup with a LabVIEW application programmed for the control system. The communication with the FieldPoint unit does not necessarily occur at the precise instant when the application instructs it to happen. Instead, communication occurs both as a direct result of requests from the application and also as a result of the configuration for the intelligent controller. Any LabVIEW application that uses FieldPoint can be conveniently structured by incorporating all FieldPoint operations into a single module -- a FieldPoint handler. This module performs four different operations: initialization, close, read, and write. This handler directs all the communications between the FieldPoint unit and the LabVIEW application. The MAX provides an interface for the setup and configuration of the FieldPoint hardware. From the MAX interface, the LabVIEW application can locate and recognize the FieldPoint hardware, and the devices in the FieldPoint unit can be tested through data communication directly from the MAX.

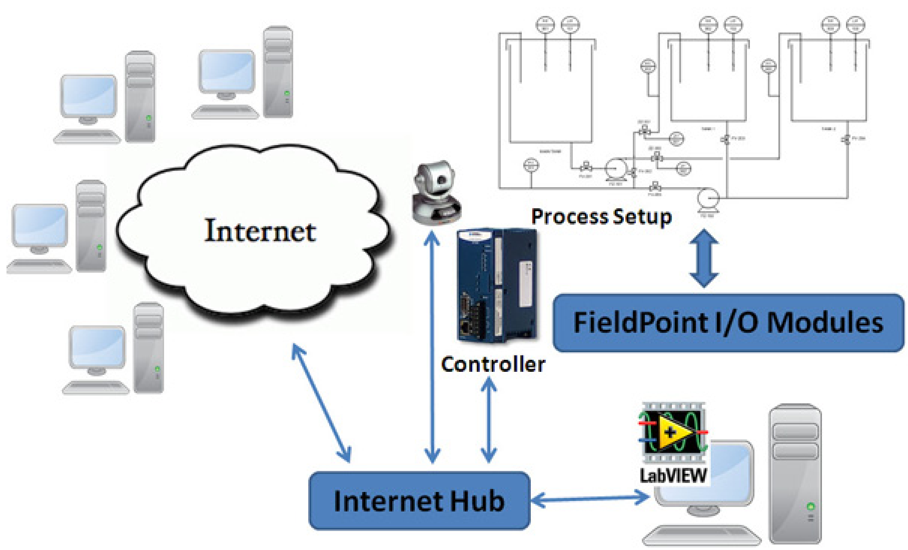
In the system introduced in this chapter, a virtual interface programmed in the LabVIEW graphical language provides a control panel for users to interact with the control process through FieldPoint Ethernet communication and the communication between the FP controller and I/O Modules. The remote laboratory introduced in this chapter provides an approach to implementing LabVIEW interfacing technology in manufacturing process control systems to provide remote virtual lab activities for students in a manufacturing engineering program. The development of this laboratory also has students explore the integration of computer and networking technologies into manufacturing control systems for higher flexibility and productivity. Researches and experiments related to web-based manufacturing control systems and remote virtual laboratories are being conducted based on this system.

SYSTEM OVERVIEW

Physical Setup of the System

The technology used for the development of the virtual laboratory system in the LabVIEW environment is FieldPoint. As mentioned earlier in this chapter, the physical setup of the system includes a wet process system, a FieldPoint control system with a NI cFP-2000 intelligent controller and eight I/O modules, a desktop computer, an Ethernet hub, and an Internet DLink camera. As shown in Figure 1, the intelligent controller, the Internet camera, and the desktop computer are connected to an

Figure 1. The system setup



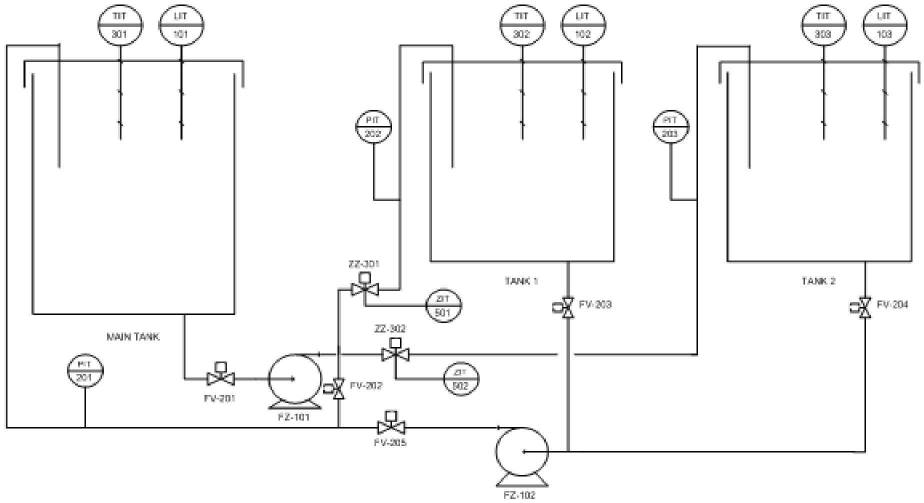
Internet hub, and then connected to the Internet. Clients (students) can access the remote control panel of the system over the Internet connection.

The wet process control system is comprised of three tanks, two pumps, five discrete valves, and two continuous valves, as shown in Figures 2 & 3. The sensors used in the system include three temperature sensors, three level sensors, one flow rate sensor, and two pressure sensors. Temperature sensors and level sensors were used to monitor each tank's water level and temperature. Two pressure sensors were installed to monitor the incoming flow pressure of tank 1 and tank 2. A flow sensor was installed to measure the incoming flow rate of the main tank. Figure 2 shows a picture of the real wet process system setup. In order to better demonstrate the level changes of the water in each tank, the water was dyed with green color. Also, a physical control panel with pushbuttons and a panel with light indicators was added to the system for local maintenance and control. The physical intelligent controller and its I/O modules can be seen on the picture as a blue panel mounted on the wall. Figure 3 demonstrates the components of the physical setup to give you a clearer idea of the system setup with pipeline connections running between tanks and the locations of all the system components.

All the values, pumps and sensors were wired to the Input/Output modules of the intelligent controller. There are four Input/Output modules used in this system, which include the analog input module cFP-AI-110, the analog output module cFP-AO-200, the digital output module cFP-DO-400, and the temperature module cFP-RTD-124. The National Instruments cFP-AI-110 is an 8-channel single-ended input module for direct measurement of milli-volt, low voltage, or milli-ampere current signals from a variety of sensors and transmitters. It delivers filtered low-noise analog inputs with 16-bit resolution, and features overranging, HotPnP (plug-and-play) operation, and onboard diagnostics. The National Instruments cFP-AO-200 is an 8-channel analog output module for 4 to 20 mA and 0 to 20 mA current loops. The module includes open-circuit detection for wiring and sensor trouble-shooting and short- circuit protection for wiring errors. It features HotPnP operation so it is automatically detected and identified by the configuration software. The National Instruments cFP-DO-400 module features eight sourcing digital

Figure 2. Picture of the wet process control system

Figure 3. Physical setup diagram of the wet process system



output channels. Each channel is compatible with voltages from 5 to 30 VDC and can source up to 2 A per channel with a maximum of 9 A squared per module (The sum of the squares of the output currents from all eight channels must be no greater than 9). Each channel has an LED to indicate the channel on/off state. The module features 2300 V transient isolation between the output channels and the backplane. It also features HotPnP operation and is automatically detected and identified by the configuration software. The National Instruments cFP-RTD-124 is an 8-channel input module for direct measurement of 2 and 4-wire RTD temperature sensor signals. With current excitation, signal conditioning, double-insulated isolation, input noise filtering, and a high-accuracy delta-sigma 16-bit analog-to-digital converter, it delivers reliable, accurate temperature or resistance measurements.

Table 1 provides a detailed list of the input and output devices in the physical setup of the system and the type of FieldPoint I/O module they were wired with. As shown in Table 1, the discrete valves and the pumps were wired to the digital output module; the continuous control valves were wired to the analog output module; the temperature sensors were wired to the RTD module for temperature readings; and the level sensors, the flow rate sensor, and the pressures sensors were wired to the analog input module.

LabVIEW Interfacing

As mentioned in the previous section, the devices on the wet process system including all the valves, pumps, and sensors, were wired to the four different Input/Output modules of the FieldPoint controller unit. All these devices were setup and configured through the Measurement & Automation software (MAX), and each of them was assigned a unique ID starting with an IP address, as shown in Table 1. The FieldPoint controller unit is recognized by the computer as a network node with its IP address. For the system demonstrated here, 139.102.29.56 was assigned to the controller. The four Input/Output modules then were recognized as different communication ports under this IP address. In this system, they are recognized as port 1, 2, 5, 7 respectively. Then, each device wired to the same Input/Output module was identified by a unique channel number. The unique ID for each device therefore is a combination of the IP

Table 1. I/O addressing of the control system

	\Channel 1	PIT-203	Pressure Sensor 2

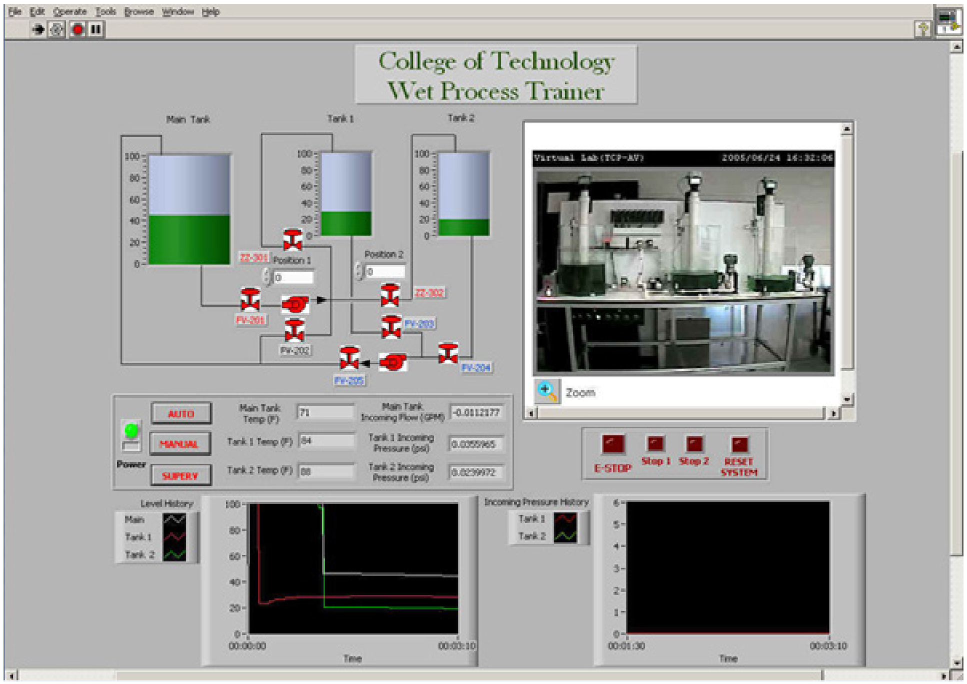
address (identifying the controller unit), the port number (identifying the specific module), and the channel number (identifying the device).

Once the physical system was connected and configured for the LabVIEW communication, a virtual interface programmed by using the LabVIEW graphical language can provide a control panel for users to interact with the control process on the local server as well as over the Internet from a client computer as shown in Figure 4. The virtual interface is called a virtual instrument (VI) in the LabVIEW environment.

As shown in Figure 4, this virtual interface has five major areas for users to interact with the real control process including a process simulator, a mode control panel with digital indicators, a stop button panel, a live video window, and waveform graphics for data tracking. The process simulator simulates the real wet control process by using control icons and indicator icons. In manual mode, users can control each individual device of the real process by clicking on the control icons, such as the valves and motors. Indicator icons will display the status of those devices by changing the color of icons to green or red. The mode control panel is used to change control mode, and can also provide real data readings from sensors. The stop button panel provides different buttons to stop major devices and the system itself. The current value of tank levels, temperatures, incoming flow rate for main tank, and incoming pressure for tank 1 and tank 2 are displayed by the graphic and digital indicators on the interface. A video window was integrated into the interface for users to monitor the real process through an Internet camera. Two waveform graphics windows provide history data tracking the temperature and incoming pressure of each tank.

Behind the Frontpanel of the virtual interface is the block diagram, programmed to provide the data flow, mathematic operations, and logic operations of the virtual instrument. The application

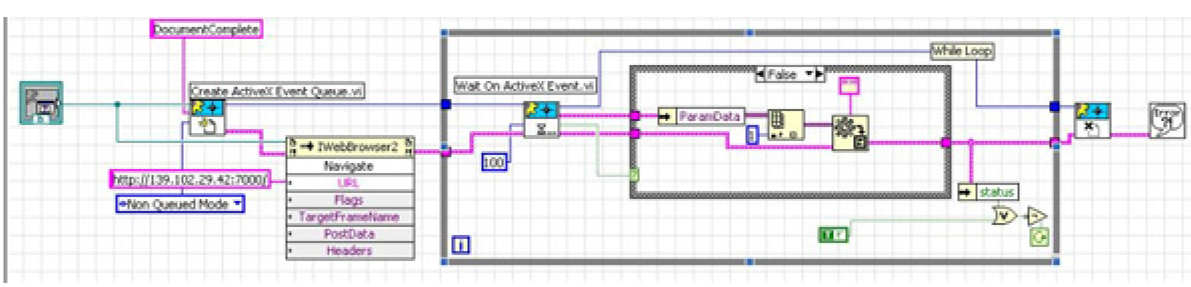
Figure 4. The virtual interface programmed in LabVIEW



programming utilized Case Structure functions to provide three different modes, auto mode, manual mode, and the supervision mode. A While Loop function was used to establish continuous data retrieving and command sending cycles from and to the physical wet process system. Part of the block diagram programmed for this interface is shown in Figure 5 which is a live video retrieving diagram from the Internet camera.

Real time control from the virtual interface on the real system is through the FieldPoint Ethernet communication and the communication between the FP controller and I/O Modules. FP controller, FB OPC Server, and FP manager are installed and configured through Measurement & Automation software (MAX). The communication between the FP controller and I/O Modules is similar among different types of network modules. The FP controller communicates with each module through the Ethernet module using the TCP/IP protocol. It uses the.iak file to determine which resource to communicate with. Each I/O module cycles through its internal routine of sampling all channels, digitizing the values and updating the values

Figure 5. Block diagram programmed in LabVIEW



on the module channel registers (buffer). This cycle time is set for each module and is specified as the all channel update rate. FieldPoint Ethernet communication uses an asynchronous communication architecture called event-driven communication. The network module automatically sends updates to a client when data changes. The server then caches the data from I/O modules and uses it to respond to read requests from the virtual interface. The network module scans all I/O channels with subscriptions to determine if a value has changed by comparing the current value to the cached value for each channel. If a change has occurred, the network module puts the difference between the two values in the transmit queue. The FP Server receives this information and sends an acknowledgement to the network module. The network module periodically sends and receives a time-synchronization signal so that it can adjust its clock and provide proper timestamping. When signals do not change over long periods of time, the client sends periodic re-subscribe messages to verify that the system is still online.

LabVIEW's architecture allows for easy integration of the laboratory environment for remote manipulation. The main concept of turning the locally controlled setup into a remotely controlled one is moving the user interface away from the physical setup. The local computer works as the web server as well as the control server. A number of clients can log onto the server, but only one user can be granted the control right. Other users can monitor the control process. They can monitor the process from their remote front panel (VI) while the one that has the control right can actually control the process from the panel. There is a waiting queue for users. When the control right is available, it will be granted to the next user in the queue. The remote client can be any computer with Internet access. The only tool that the client needs to use is a web browser with the LabVIEW Runtime Engine installed. The LabVIEW Runtime Engine is plug-in software provided by National Instruments to support the web application. Normally it is installed automatically on the client's machine the first time the user tries to view a front panel. The client can browse to the webpage integrated with the remote control panel by entering the Uniform Resource Locator (URL) address of the web server in the browser. The client only updates the screen and gets information from front panel interactions. The client cannot make changes to VIs. Execution happens only on the server machine.

The local server hosts a LabVIEW web server, which publishes the VI to the Internet. Through the LabVIEW Real Time Engine (RTE), the local server can communicate with the remote client. It controls the process according to the data from the remote control panel and sends the updated data back to the remote control panel. Remote clients are not required to have the whole LabVIEW software installed to view VIs for control and monitoring. They just require the LabVIEW RTE plug-in.

The security of the control system is ensured by management from the server side. On the server side, the user's permission to access the LabVIEW control panel is managed through editing the allowed list of IP addresses for clients. Also, access to the LabVIEW control panel can be limited to a specific domain or a group of domains. The virtual interface running on the server can be configured to be available to or be hidden from certain users. While in the process of remote control and monitoring, the IP address of the active client will be shown on the server. The lab instructor can always monitor the usage of the remote control panel, and make sure only authorized clients have access permissions. In the process of remote control, the lab instructor can take over the control right on the server side at any time in case of system malfunctions, user errors, or any unusual situations.

System Operation

Figure 6 shows the process simulator on the LabVIEW virtual interface. This process diagram simulates the real process of the system with controls/indicators corresponding to the components of the real system. Three tank indicators represent the main tank, tank 1 and tank 2 in the wet process trainer respectively. The green bar of each tank indicates the current water level which can vary from 0 percent to 100 percent. In this diagram, valves and pumps are controls for their corresponding parts in the real process. FV-201, FV-202, FV-203, FV-204, and FV-205 are controls for discrete valves. These five discrete valves and two pumps are controlled by ON/OFF Boolean signals; their status can be changed by a mouse-click on them. The color of each control represents the status of the control. Red represents OFF status while green represents ON status. ZZ-301 and ZZ-302 represent the two continuous control valves in the real process. The status of them is controlled by the digital control below the valve icons. The value of each digital control can be changed by clicking the arrows beside it from 0 to 100 with the increment of 10. The value of 0 represents closed status of the valve, and the value of 100 represents the totally open status of the valve. The color of ZZ-301 and ZZ-302 will be changed to green color when the value of their digital control is equal or greater than 10 to indicate an ON status. Otherwise, it will be changed to red indicating an OFF status. This process simulator provides a direct visual view of the whole wet process system for students to understand the process and identify the function of each component of the system. It can be used in the manual control mode for control testing and in the supervision mode for system maintenance and trouble-shooting.

Figure 7 displays the part of the virtual interface with power control, mode controls and digital indicators. The power control is used to turn on/off the system, which will be in green color when the system is running. The six indicators to the right of the mode buttons are digital

Figure 6. Process simulator

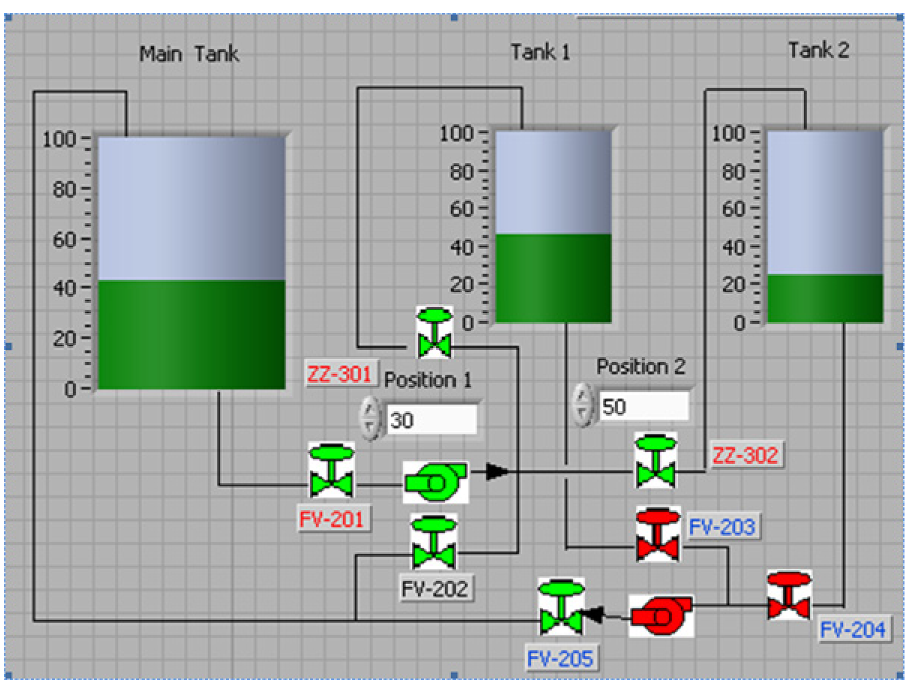


Figure 7. Mode controls and digital indicators

indicators displaying current values of tank levels, liquid temperatures, incoming flow rate, and incoming pressures.

The buttons with red labels are used to select a control mode for the system operation. This virtual interface provides three different modes for process control which include supervision mode, manual mode, and auto mode. Clients (students) are assigned different control capabilities when different modes are selected.

In supervision mode, all the valves and pumps in the wet process system can be turned on and off by users disregarding the readings from the sensors. This mode can be enabled only for maintenance and trouble-shooting purposes, and it is not available to remote clients for security reasons. In manual mode, the status change of valves and pumps will depend on both the current situation of the system and the commands from the user. For example, if the water level of the main tank is lower than 20 percent or valve FV-201 is closed, pump 1 cannot be activated even if the user intends to do so by clicking on the pump icon on the process simulator of the virtual interface. When certain conditions are met from the sensor readings (which means it is a safe situation), the user can manually control any device of the wet process system. This mode is available for both local and remote users. It helps users to test device status, get familiar with the control interface, and adjust control parameters when necessary. In auto mode, the system demonstrates a fully automated control process to users, depending on the water levels of each tank. The user can only control continuous control valves by changing the percentage values without changing the on/off status of the valves. The user can adjust the percentage of the continuous valves by clicking the toggle switch beside the digital control or typing values in the digital controls directly. These three modes provide flexibility for students to explore the wet control process, and also ensure the security to protect the system physical setup.

The LabVIEW interface panel provides three emergency stop buttons and one reset button in the stop button panel. E-Stop button will stop the whole system when pressed. Stop 1 and Stop 2 buttons will disable pump 1 and pump 2 respectively when pressed. The Reset button is used only in auto mode to reset the system when the main tank level reaches its limits. This stop button panel is available for both local and remote users. Lab instructor can also disable the system by clicking the stop button on the LabVIEW window from the server side, or press the emergency stop button located on the physical system in any emergency situations.

The live video window integrated in the LabVIEW virtual interface displays the live video from the Internet camera to remote users. Remote users can view the liquid levels and the light indicators clearly from a remote interface. There are seven green light indicators on the indicator panel mounted on the physical system. The seven green lights were wired to the five discrete valves and two pumps to indicate the On/Off status. This will help remote users to compare the status of devices on the virtual interface and the ones on the physical system when necessary for their operation. This is a great tool to help remote users observe the operations of the real system.

LABORATORY IMPLEMENTATION

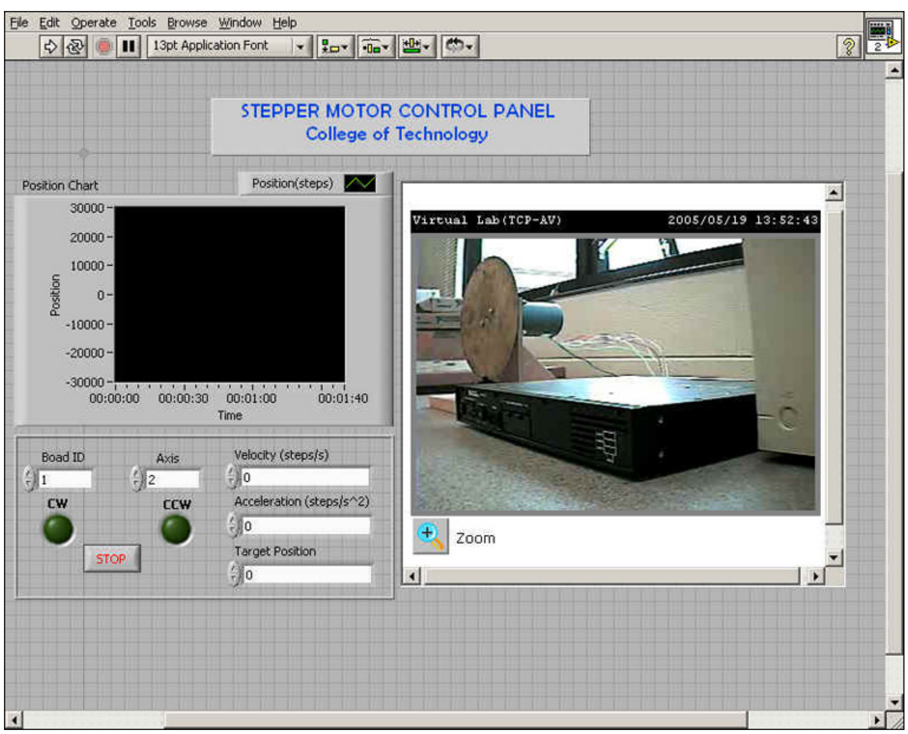
There are six labs that have been developed and implemented in the computer-integrated manufacturing course as part of the required lab activities.

Lab 1: Introduction to the LabVIEW Environment

The purpose of this lab is to introduce the LabVIEW graphic programming environment to students. A simple single-axis motor control system is used to help students get familiar with the LabVIEW front panel and block diagram. First, students will remotely access the single-axis motor control system developed in LabVIEW to control and monitor a stepper motor over the Internet. The LabVIEW interface for this motor control system is shown below in Figure 8.

A LabVIEW program consists of two parts, the front panel and the block diagram. The front panel is used to design graphic interfaces; a control palette provides various controls and indicators to be used for a control interface. The program which runs behind the graphic interface is called the block diagram. A function palette associated with this block diagram provides all kinds of functions and operations. In the second part of this lab, students are required to install a LabVIEW student version on their computers. Students will open the LabVIEW front panel window and block diagram window to explore each control and indicator used in this simple program, so that they can get familiar with the LabVIEW programming environment.

Figure 8. Single-axis stepper motor control interface



Lab 2: Programming the Motion Control

The purpose of this lab is to help students understand the major components in a motion control system and functions of basic motion control VIs, and gain skills in programming motion control systems. Students are required to develop a simple single-axis motor control program by following instructions provided by the instructor, send the program to the lab instructor, and run their own program for remote motor control. The board ID and the axis number will be assigned to each student for their programming process. The lab instructor configures the motor and monitors students' remote operations on the control server.

Lab 3: Introduction to Remote Process Control Using FieldPoint

The purpose of this lab is to help students understand the integration of input and output devices in FieldPoint, examine the available devices and technologies used for remote process control applications, and explore the implementation of remote process control applications. Students are required to operate the virtual process control system through the Internet (as shown in Figure 2), examine each mode available on the virtual interface, and understand the mechanism for the system integration. The lab instructor will monitor the control process while students are using the virtual control interface to access the wet process setup in the lab.

Lab 4: Programming a Simple Process Control Program in FieldPoint

The purpose of this lab is to gain skills in design and to program a process control system with digital input/output signals and Boolean operations. Students are required to design a process control system with part of the components available in the physical system setup including valves and pumps, send their program to the lab instructor, and test their program through the Internet after the program is loaded into the control server.

Lab 5: Programming for Remote Measurements

The purpose of this lab is to help students understand the mechanism for retrieving analog data remotely, examine the available devices and technologies for remote data acquisitions, and gain skills in developing a remote data retrieving system. Students are required to design a LabVIEW VI for remote analog data retrieving from temperature sensors, level sensors, and pressure sensors. These sensors are already installed as part of the wet process control system, as shown in Figure 3 and Table 1. The lab instructor will send the data sheets of the sensors to students. Students will then design the interface, and program the block diagram by using the technical data provided by the lab instructor to retrieve signals from sensors and display correct data on their program interfaces. Students will send their programs to the lab instructor and test their programs after the program is loaded into the system.

Lab 6: Design a Virtual Manufacturing Work Cell

This lab is to encourage students to apply their knowledge, skills and experiences gained from the lectures and lab activities to design a virtual manufacturing cell for remote control and monitoring. Students are required to use sensors for measurements and use motors to simulate machine status. The machines in the manufacturing cell include three Computer Numeric Controlled (CNC) machines, three industrial robots, and one conveyor system. Based on what they have learnt, students need to integrate machines and devices into a connected network by using a FieldPoint system, assign an Input/Output address to each device and machine, design the control interface, and program the block diagram. Then students will send their programs to the lab instructor, test their programs by operator and monitor the sensors, valves, and motors of the process control system through the Internet.

The educational value of these online lab activities has been assessed through students' feedback. It is shown that most students find these labs are very interesting, convenient to access and easy to follow. They consider the lab necessary for them to understand the concepts of mechatronic system integration, remote control, and Human-Machine Interface (HMI). Students gain experience by exploring, operating, and programming the system. In addition to helping students understand the concepts and principles of remote control applications in manufacturing, these lab activities provide the following major benefits collected from students' feedback.

- Hands-on experience with LabVIEW programming.
- Great hands-on experience with online control and monitoring.
- Broader view on the future of industrial networking in implementing computer-integrated manufacturing.
- A convenient way to access lab facilities.
- Flexible schedule to work on lab activities.

However, some of the students did mention that the time delays in the control process have caused problems for their remote operation, and the programming difficulties with remote measurements have made them frustrated when testing is not available until the program has been completed. These problems could be solved in the future with system enhancement by implementing more web-based applications. Also, the online laboratory is not available 24/7 for online students now due to the safety and security concerns. But it does provide convenient access to labs for online students. They can schedule their lab activities in evenings and weekends with the lab instructor when either the lab instructor or a lab assistant can sit by the server or monitor the process through the Internet.

ISSUES OF RELEVANCE TO THE LABORATORY

There are several issues related to this virtual laboratory that will affect the future development of the laboratory according to feedback from students, lab instructors, and faculty. The issues include the influence of network bandwidth on information transmission for remote control, the user management system, and the limited functions of the LabVIEW web server to support online programming.

In this virtual process control system, time delays exist in data transmission especially when the client accesses through a dial-in network connection. Obviously it is caused by the different bandwidth of networks. In the development of the remote laboratory, not only parameter and administrative data but also audio and video data need to be transmitted via network connections. Web cameras will bring live images of the physical setups to remote clients. Undoubtedly, it is critical to use the available bandwidth efficiently in data transmission in the project; otherwise, time delays will mar the whole remote experimentation execution. Several networking techniques can be used in solving this problem. For example, setting respective data priorities for the transmission rate of different data can ensure critical data is transmitted without delay. Another technique that can be used is data compression, but it involves a trade-off because of the additional delay resulted from the compression and decompression processes. This delay should be kept much smaller than the transmission delay. Data compression is especially useful for audio/video transmission which involves a huge amount of data. At the same time, the server needs to adapt to different bandwidth requirements of remote clients. For example, some might be on the same local LAN with the server on the same campus while others may be connected from home using a dial-up line.

When implemented in the lab of the graduate course, there were only 12 students in the class. There was not any complaint from students about the access method. If implemented in classes with more students, user management becomes an issue. Not all students would like to wait in the queue for their online lab activities. A user management system will be developed using Visual Studio 2005 to integrate an interface and an ACCESS 2007 database, and communicate with the LabVIEW web server to realize a user reservation system. This will increase the flexibility for students allowing them to login and schedule their lab activity online. It will also provide a more secure way to manage users with permission assignments.

The function of the LabVIEW web server is the second issue in the remote virtual laboratory. In this remote control process, the LabVIEW web server publishes the VIs to the Internet, but clients can only update and get information from front panel interactions. Clients cannot make changes to VIs directly from the remote interface. In order to let students to learn and practice programming in the LabVIEW environment, clients must have the capability to re-program the process and re-download their programs to the controller for testing purpose. This takes time for students to complete one program-test cycle, and requires more work for the lab instructor to load students' programs to the server manually. To achieve a remote programming function, the LabVIEW web server must be separated from the control server. Some programming languages with powerful web-based function are recommended to extend the LabVIEW web server, such as JavaScript and VB. NET.

To better address the requirements from students on virtual laboratories and improve the performance of the system, a form will be developed for students and lab instructors to evaluate the performance of the system. As laboratories are implemented in more classes with more students, the evaluation and feedback will provide more ideas about system improvement and better implementation.

CONCLUSION

Remote virtual laboratories accessed through the Internet are feasible for long-distance applications. Experiences from developing this virtual laboratory and implementing it in a Computer-integrated manufacturing course show that multiple aspects must be taken into consideration to obtain adequate performance of the online laboratory. These include the connection and communication between a web server and the physical setup (machines and processes) and the connection and communication of the web server and the Internet. In the next step in adding more systems into this laboratory, data acquisition, motion control, FieldPoint controllers, Programmable Logic Controllers (PLCs), and industrial robots will be integrated together to achieve a virtual flexible manufacturing cell that can be operated and monitored through the Internet. Technologies for system integration and web-based human-machine interfaces (HMI) need to be applied for future development. The future system will also provide an ideal research platform for studying the performance of those advanced web-based technologies in manufacturing environments, and the efficiency of system integration for improving flexible manufacturing systems.

KEY TERMS AND DEFINITIONS

FieldPoint: FieldPoint is a proprietary method for interfacing devices to computers developed by National Instruments but it is very similar in principle to the concept of a fieldbus interfacing method used by many process control equipment suppliers.

LabVIEW: NI LabVIEW is the graphical development environment for creating flexible and scalable test, measurement, and control applications rapidly. It is the major programming tool in developing virtual control interfaces.

Process Control: Process control is a statistics and engineering discipline that deals with architectures, mechanisms, and algorithms for controlling the output of a specific process.

VIs: VIs are virtual instruments. In this chapter, VIs represent the graphical user interfaces programmed in LabVIEW environment for the purpose of motion control and process control.

This work was previously published in Internet Accessible Remote Laboratories: Scalable E-Learning Tools for Engineering and Science Disciplines, edited by Abul K.M. Azad, Michael E. Auer and V. Judson Harward, pp. 1-17, copyright 2012 by Engineering Science Reference (an imprint of IGI Global).

Section 4
Utilization and Application

This section discusses a variety of applications and opportunities available that can be considered by practitioners in developing viable and effective Industrial Engineering programs and processes. This section includes 14 chapters that review topics from case studies in Cyprus to best practices in Africa and ongoing research in the United States. Further chapters discuss Industrial Engineering in a variety of settings (air travel, education, gaming, etc.). Contributions included in this section provide excellent coverage of today's IT community and how research into Industrial Engineering is impacting the social fabric of our present-day global village.

Chapter 42
Using Serious Games for Collecting and Modeling Human Procurement Decisions in a Supply Chain Context

Souleiman Naciri
Laboratory for Production Management and Processes, Ecole Polytechnique Fédérale de Lausanne, Switzerland

ABSTRACT

Computer simulation is often used for studying specific issues in supply chains or for evaluating the impact of eligible design and calibration solutions on the performance of a company and its supply chain. In computer simulations, production facilities and planning processes are modeled in order to correctly characterize the supply chain behavior. However, very little attention has been given so far in these models to human decisions. Because human decisions are very complex and may vary across individuals or with time, they are largely neglected in traditional simulation models. This restricts the models' reliability and utility. The first thing that must be done in order to include human decisions in simulation models is to capture how people actually make decisions. This chapter presents a serious game called DecisionTack, which was specifically developed to capture the human decision-making process in operations management (the procurement process). It captures both the information the human agent consults and the decisions he or she makes.

DOI: 10.4018/978-1-4666-1945-6.ch042

INTRODUCTION

In fast-paced markets, companies try to improve product service level and quality while decreasing costs in order to get high market shares. Whereas some companies implement solutions to improve performance without prior verification, a wiser approach is to use computer simulation to evaluate the impact of potential solutions on the performance of the company and its supply chain. In these simulations, production facilities and planning processes are modeled in order to capture company behavior. However, the main drawback of this approach is that little attention is given to the human decisions that take place in this context. Human decisions are very complex, varying across individuals and even across time for a single individual. Traditional simulation models thus neglect this component. But this in turn limits the models' reliability; in fact, modeled companies often exhibit different behavior than their real-world counterparts.

The challenge is to be able to capture how human decisions are made, use this knowledge to develop reliable human decision-making models, and then implement these models in computer simulations. For this purpose, the first task is to capture human decisions as they *are* made rather than how they *should be* made. Capturing actual human decisions is not straightforward, however, because people are not very good at verbalizing what they know (Vermersch, 2006).

The utility of the conventional simulation approach in studying system behavior in general has been proved (Robinson, 2005) even though it does not involve active user participation during simulation runs. However, for the purpose of knowledge elicitation (Edwards et al., 2004) as well as user training or education, using more advanced simulation technique that integrates visual simulation and user interaction (Van der Zee & Slomp, 2009) should be a promising approach.

This chapter presents a serious game called *DecisionTack* that was specifically designed to capture the human decision-making process in a procurement context. The main motivation for developing the game is to be able to take full advantage of simulations that include active user interaction for the purpose of quantitatively analyzing decision-making behavior.

This serious game captures both the information consulted by the player and the decision he or she makes. This is done repetitively during the game, because an operational decision (procurement) is required from the player on a daily basis. This leads to the capture of a series of *decision versus consulted information pairs* that can later be used to develop human decision-making models. Subsequently, the outputs of the game are analyzed using four metrics that characterize each player's behavior in terms of data consultation and decisions.

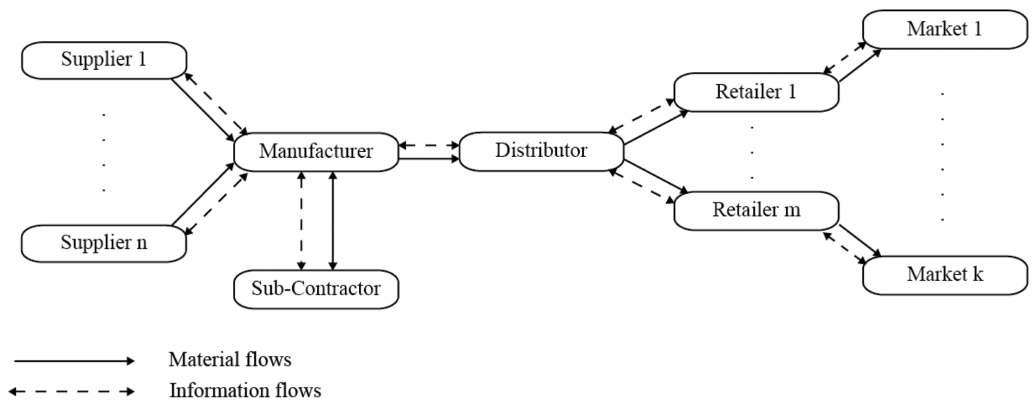
In the rest of this chapter, we lay out the basic concepts of Supply Chains, decision-making in a supply chain context, and describe previously developed serious games (*Background*); describe current weaknesses and define the goal of the research (*Motivation & Goals*); describe the details of our serious game (*DecisionTrack Game);* outline our analysis and interpretation approach (*Analysis and Interpretation*); illustrate a case study (*Application case*); discuss strengths, weaknesses and further challenges of our serious game (*Issues & Controversies*); outline potential further development (*Research Directions*) and draw final conclusions (*Conclusions*).

BACKGROUND

1. Supply Chain

In the current global economy, enterprises do not act as isolated companies, but are integrated in complex networks involving many entities (manufacturing, transportation, warehousing, etc…) that are linked by complex material flows (such as products and components) and informa-

Figure 1. Schematic representation of an enterprise network (supply chain)

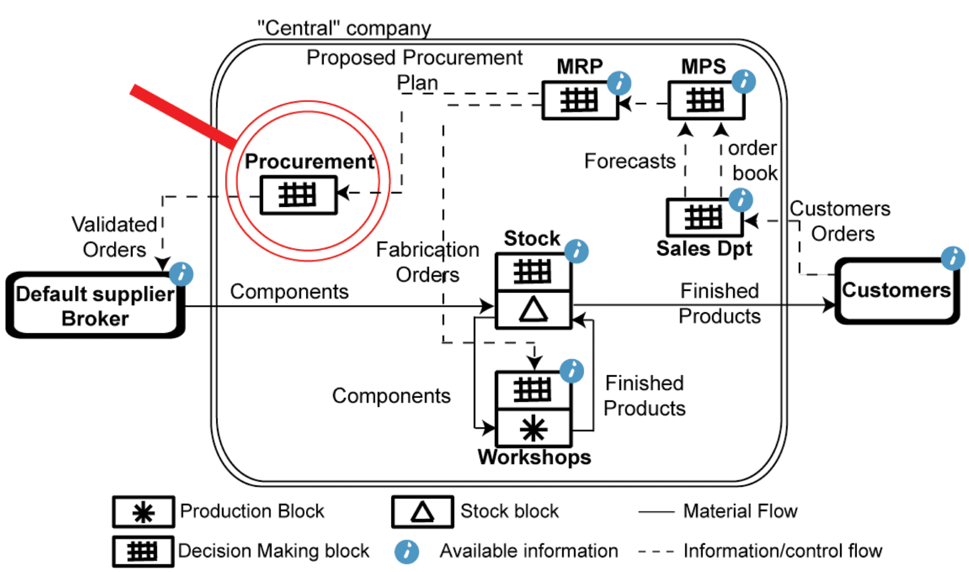


tion flows (such as customer orders or production orders). This is schematically illustrated in *Figure 1*. Terms such as 'Supply Chain' or 'Value Adding Network' are used to describe these complex networks. For simplicity, we will just use the term 'supply chain'.

Within a manufacturing company (one constitutive entity of a supply chain, see "Manufacturer" on Figure 1), the main material and information flows can be schematically described as illustrated in Figure 2.

Customer orders are received. They are entered into the order book of the company. The order book serves as the basis, together with market demand forecasts, to create a plan called Master Production Schedule (MPS). The MPS contains confirmed and expected customer orders, listed according to their desired delivery dates. Based on the MPS, a procedure is run to anticipate the need for product assembly, part production and component procurement. This procedure, called Manufacturing Resources Planning (MRP), is widely used in repetitive manufacturing.

Figure 2. Schematic representation of the material and information flows within a manufacturing company



2. Decision Making in a Supply Chain Context

In each entity of a supply chain, people are constantly making decisions; these decisions are the cornerstone of the company management and have very important and direct consequences on company performance. Human decisions can be classified according to the time horizon affected by the decision as strategic (long-term), tactical (medium-term) or operational (short-term). In supply chain management, strategic decisions are tied to the network's configuration (for example, the selection of a manufacturing location). Tactical decisions involve the calibration of the network's main management parameters (for example the level of safety stocks). Finally, operational decisions are related to the execution of repetitive tasks (for example launching production orders).

Simulations are often used in tools that support strategic and tactical decisions. If these simulation models are to help humans to make strategic and tactical decisions, they must be able to reliably reproduce the behavior of the actual Supply Chain. But the supply chain is strongly affected by operational decisions that are continuously being made by humans. Paradoxically, operational human decision-making has hardly been taken into account in Supply chain simulation models, thus limiting the reliability of these tactical and strategic decision-making tools.

Operational decisions in a supply chain context are characterized by their repetitive nature; i.e. the same decision type (for example launching a production order) must be frequently made (for example daily). The decision situation may change for each decision occurrence, however. The decision made is thus dependent on both the decision context and on the human decision-making behavior, as schematically represented in Figure 3.

Many operational decisions are made in a supply chain context, from shipping to planning and procurement. In particular, one output of the MRP procedure described above is a set of lists of time-paced propositions for launching assembly, production and procurement orders. A human decision is then required to execute the MRP-proposed orders. This decision involves confirming the MRP propositions, modifying them (date and/or quantity) or grouping some of them. In the specific case of the procurement process considered here, the operational decision can be illustrated as shown in Figure 4.

The decision elicitation problem can therefore be formalized and formulated as follows:

Each planner j makes decisions D_{ij} at time i, according to the decision context he/she perceives at the time i (DC_{ij}). This decision context

Figure 3. Schematic representation of an operational human decision making process in a supply chain context

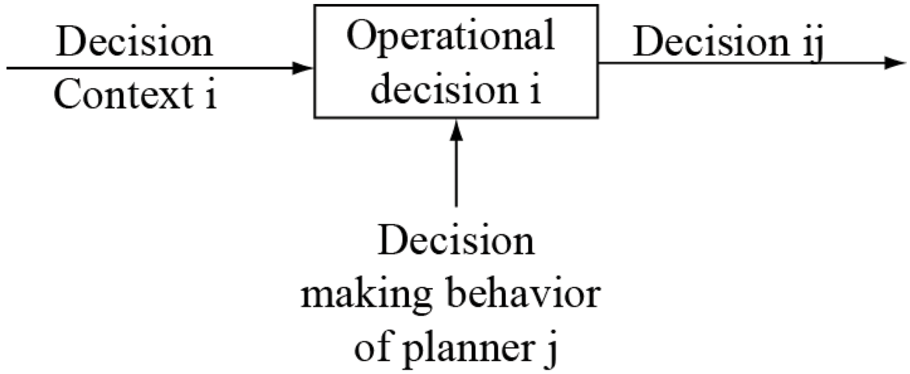


Figure 4. Illustration of the procurement decision-making process

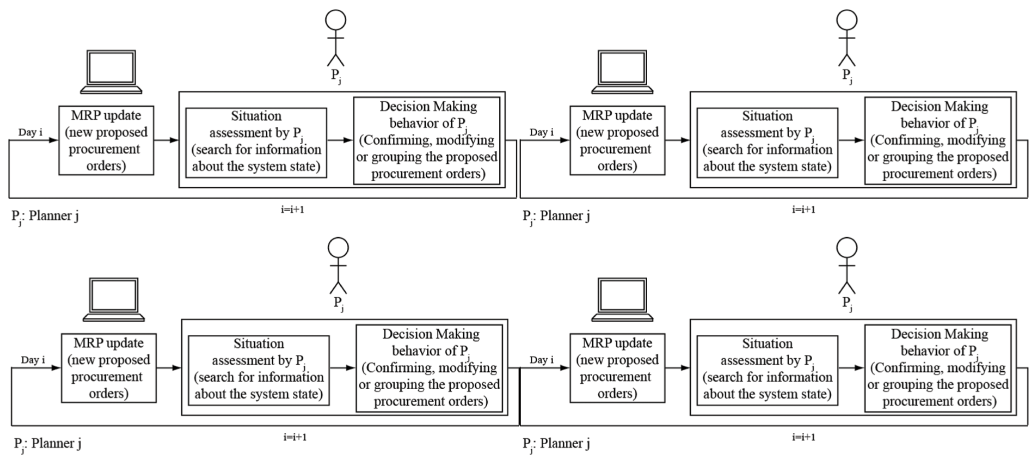


encompasses the updated proposed procurement plan (MRP_i), as well as the collected information (CI_{ij}) gathered by the planner j at time i. Thus, the decisions D_{ij} made by the planner j at time i can be expressed as:

$$D_{ij} = f_j\ (DC_{ij}) \tag{1}$$

$$D_{ij} = f_j\ (MRP_i, CI_{ij}) \tag{2}$$

Consequently, the elicitation process consists of identifying the decision-making behavior f_j of planner j in order to predict planner j's decisions according to the information at hand. The first task in identifying f_j is to capture the decision inputs and outputs:

- Decision inputs:
  - MRP proposed orders (MRP_i), which create the decision alternatives;
  - The information collected by the planner j (CI_{ij}).
- Decision outputs:
- MRP proposals modified and validated by the planner's orders (D_{ij}).

3. Serious Games and Dynamic Decision Making

Serious games have been used for several decades for studying dynamic decision-making (DDM). DDM encompasses the decision-making processes that take place within an environment characterized by *dynamics*, *complexity*, *opaqueness* and *dynamic complexity* (Gonzalez et al., 2005). In this paper, the authors review the ten most significant serious games that have been developed since the 1980s. One of these is of particular interest here, as it involves operations and supply chain management. *Beer Game* was initially developed in the 1960s as a board game before being converted into a serious game in the late 1980s by Sterman (Sterman, 1989). The *Beer Game* has 4 entities (factory, distributor, wholesaler and retailer) that provide the market with beer. The goal is to achieve the highest service level with the lowest costs. Players are separated in four groups, each group being in charge of the replenishment decisions of a single supply chain entity. This game was popular with users (master's students and managers) because it illustrates supply chain dynamics and the virtues of collaboration across supply chain partners very well. However, one disadvantage of this game is that it is difficult to use it to understand player decision-making behavior. Indeed, the *Beer Game* does not track the information consulted by players, and thus the causal relations between the system state and the decisions made by the players cannot be explicitly rendered. This drawback is also observable in a simulation game developed to study maintenance decisions in Ford assembly lines (Robinson et al., 2005). In this game, a production process is simulated until a breakdown occurs, at which point the simulation stops and players (maintenance operators) are presented with the breakdown characteristics. Then they are asked to make a decision among a discrete set of alternatives (repair now, repair later, ask somebody else to do it, etc.). Each breakdown instance is recorded including both the breakdown characteristics and the corresponding decision. The authors then used this set of instances to model and reproduce maintenance operator decision-making behavior. However, by presenting the entire set of breakdown characteristics to maintenance operators at each breakdown, the assumption is made that all of the breakdown characteristics are equally important in the decision making process, while some of them would probably not have been consulted if the operator had had to look for relevant information by himself.

Serious games are a very efficient way of representing complex and dynamic decision making contexts (time dependency, feedback loops, endogenous and exogenous variations), but often fail to handle a very important phase of dynamic decision making - the *situation assessment* -- that can vary greatly from person to person.

MOTIVATION AND GOALS

Conventional data collection techniques such as observation, questionnaires and interviews are not well suited for the elicitation process described above (Naciri, 2010). Several hurdles (the time required, difficulty in designing suitable questionnaires, difficulty that interviewees have in explicitly describing their actions and decisions) make it difficult to rely on such techniques to collect relevant data for analyzing and modeling human decision-making behavior.

On the contrary, serious games seem to be better suited for the elicitation of human decisions in an operational context. They have several demonstrated benefits:

- First, serious games require players to "act" and not to "explain," therefore, "action satellites" can be avoided. According to Vermersch (Vermersch, 2006), "action satellites" refer to the four dimensions of the action (context, judgments, theoretical knowledge, goals) that interviewees often cite instead of discussing the action (or decision) itself;
- Second, in serious games several player actions can be recorded, giving results at a faster pace than using conventional techniques;
- Third, it is possible to analyze how decisions made at time t influence the environment at time t+1, making it possible to capture the dynamic aspects of decisions and, in particular, the notion of feedback;
- Finally, serious games create an environment in which player actions can be recorded, as well as the context in which decisions occur. Thus, once the simulation is finished, it is possible to pair the simulation context with the decisions that were made.

Participatory simulation via serious games thus appears to be a well-adapted tool for capturing the various dimensions of human decision-making, and thus for obtaining a quantitative understanding of human decision making behaviors.

The goal of this work is to develop a serious game that will elicit operational human decisions in a supply chain context, more specifically, in procurement.

Because the objective is to reliably generate human decision-making situations that are representative of what happens in the industry, the game must fulfill the following criteria:

- Interfaces similar to typical industrial tools: this ensures that players (procurement agents) act (make decisions) as they would in their working environments. It thus ensures that the information collected in the virtual environment is representative of procurement agent behavior in the "real world."
- Available information similar to that in actual ERP systems: this ensures that players are familiar with the information at hand in the simulator and that no specific training is required to explain how the information is displayed.
- Decision pace to avoid player stress: one of the main drawbacks of real-time serious games is that the pace is often accelerated, giving the player little time to make decisions. Consequently, players must control the simulation pace in order to get enough time for making relevant decisions.

The main function of the developed serious game, *DecisionTrack,* is to collect data to identify:

1. What information procurement agents are interested in, and
2. What kinds of decisions procurement agents make.

According to Van der Zee & Slomp (2009), a framework for game design has four phases:

- Initialization: definition of the scope and objectives of the game.
- Design: Detailed development of the basic ideas formulated in the initialization phase. The outcome of this phase is a simulation game concept.
- Construction: construction of the game using software or other physical elements.
- Operation or game running: actual use of the game, which may include a test of the game for its intended purpose.

We have covered the "Initialization" phase of the game design framework in this section. The next section explains development methodology of the *DecisionTrack* serious game.

DECISIONTRACK GAME: FROM DESIGN TO IMPLEMENTATION

1. Definition of Game Concept

The *DecisionTrack* game was designed according to the following objectives:

1. To provide the player with a realistic decision making context (similar to the one he/she is usually involved with),
2. To allow the player to consult the information he/she feels relevant,
3. To allow the player to make the decisions he/she feels relevant,
4. To capture player actions (consulted information and decisions) and to save this information as readable data (log file).

The underlying motivation behind these four objectives is to build a decision making context that is similar to the one players are used to working with, in order to capture decision making situations that are as close as possible to those they encounter in reality. This can be done not only by creating realistic decision-making situations, but also by not constraining players to limited sets of data or decisions.

Finally, keeping track of player's actions makes it possible to subsequently identify the relationship between the decision-making context and the decision made.

2. Virtual Decision Making Environment

The virtual decision making environment chosen for this game is a two-tier supply chain, in which the player is in charge of the procurement process. His/her task is to modify (if needed) and validate the procurement orders based on MRP propositions, as described in the previous section. In order to provide players with a familiar decision making environment, a virtual supply chain with a commonly used production management policy (make to stock) is used. It is illustrated in Figure 2.

Several entities representing departments of the company such as *production*, *warehousing*, *planning* (i.e., *MPS*, *MRP* and the *procurement* process under study) are included in this virtual environment. It also includes some external entities such as *customers* and *suppliers*.

The circles (containing the letter "i") on the top of entity icons in Figure 2 indicate that information concerning the corresponding entity is available for player consultation.

Table 1 summarizes the game elements that are included in *DecisionTrack*.

The following subsections describe in detail how the game elements are constructed.

3. DecisionTrack interfaces

The game is developed in Java 1.6 (Java SE 6) fully benefiting from the built-in Java Swing libraries in order to implement complex user interactions. The main goal of *DecisionTrack* interfaces is to provide information about the company and its supply chain. This information, which is modified daily, enables players to update their knowledge of the system.

Displayed Information

The relevant information to be displayed was identified by conducting an analysis of the procurement process with experts in the procurement field. This analysis provided valuable insight into the kinds of information procurement agents consult, and the kinds of decisions they make.

Two ERPs (Enterprise Resource Planning) widely used in Switzerland, SAP (SAP, 2011)

Table 1. Summary of DecisionTrack main game elements

Game elements	Definition
Model and Scenarios	- A 2-tier supply chain - Context: a manufacturing company, MRP information to consult - Decision making options: accept the MRP propositions, postpone, anticipate, group orders by modifying the order launching date
Game process	1. Presentation of the game to each player 2. Each player plays the game 3. Data collection and analysis 4. Player decision making modeling
Events	New customer orders, new forecasts, component deliveries from suppliers (on time and late deliveries)
Periods	One period per simulation day A complete run with a single player lasts at least 30 periods
Roles	Procurement agent
Results	Performance indicators such as inventory levels and service level
Indicators	MRP data, supplier-related data, customer-related data Above-mentioned performance indicators (see "Results")
Symbols, Materials	Various user interfaces (windows) that mimic real ERP systems in companies

and Proconcept ERP (Proconcept, 2011) were investigated, in order to design *DecisionTrack*'s interfaces to mimic the interfaces procurement agents are accustomed to working with.

Tracking Methods

As stated before, players can navigate through *DecisionTrack* interfaces in order to update their knowledge of the decision context. Because different people search for information in different ways, it is essential to track which specific information is consulted. This is accomplished by isolating the information related to each supply chain entity in a separate tab of the game window. Each tab is associated with a mouse-listener that is activated once the tab is selected. The record of the activated tab is stored in a "log file".

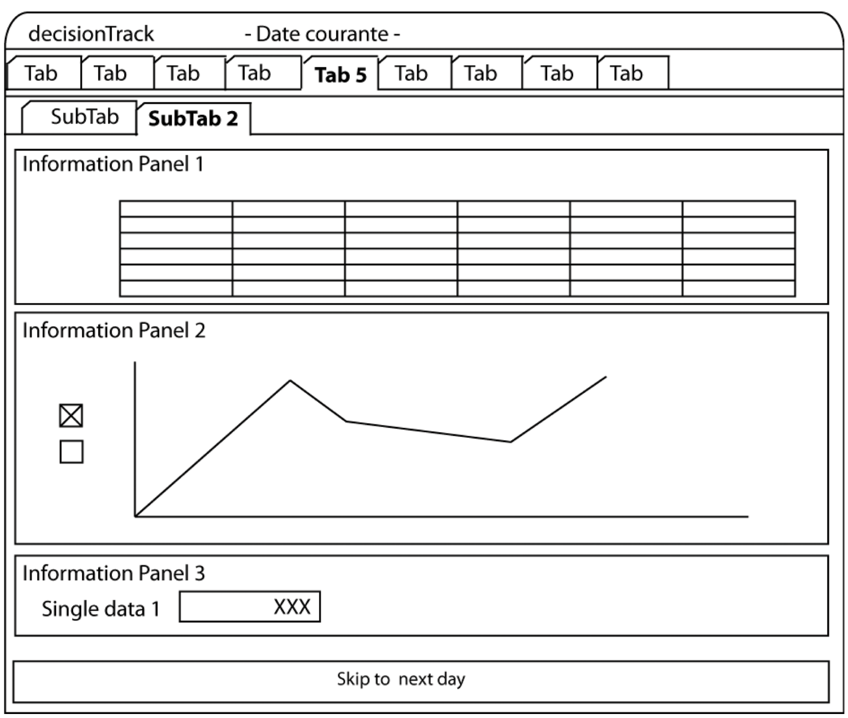
In this way it is possible to track which supply chain entity a players is interested in. Because several pieces of information may be needed to describe a supply chain entity, a single interface may not have enough space to correctly display the whole set of information. In these cases, tabs may contain two or more sub-tabs between which the entity-related information is split.

In the case where a single sub-tab contains heterogeneous information, checkboxes are added to help track the consulted information. These checkboxes are by default unchecked, which makes the corresponding information unavailable. When a player is interested in a piece of information, he/she checks it, releasing the corresponding information.

In sub-tabs and their checkboxes, the technique of tracking consultations is similar to the one described for the tabs. Using mouse-listeners which are attached to each graphic element, the name and the value (when relevant) of the consulted information is recorded in the log file.

Tabs, sub-tabs, information panels and checkboxes are organized in a hierarchical way as illustrated in Figure 5.

Figure 5. Illustration of the hierarchical structure of the information within a DecisionTrack window



Interfaces for Collecting Data

The central part of Figure 6 illustrates the window corresponding to the *Customers* tab. This interface provides various pieces of information. The first information panel (1) is the evolution of the service level (ratio of the orders delivered on time) since the beginning of the simulation. The second information panel (2) contains only the current service level, and the third panel (3) contains the list of pending orders, (orders that have not yet been delivered).

To get to this specific interface, the player must go through the following steps:

1. Select the *Customers* tab
2. Select the *Service level* sub-tab
3. Activate the *Service level* checkbox in the upper information panel
4. Activate the *Service level* checkbox in the second information panel

The right hand side of Figure 6 shows the corresponding data recorded in the log file.

Interfaces for Making Decisions

All the interfaces except *Purchaser* contain information for consultation that cannot be directly modified by the player. The information contained in the *Purchaser* tab (proposed procurement orders generated by the MRP algorithm) can be updated by the player with or without modifications.

The *Purchaser* interface is illustrated in Figure 7. As shown in the bottom panel, several procurement orders with a proposed launching date and quantity are displayed. According to his/her knowledge of the system state, the player can modify the propositions by clicking on an order, and then on the line corresponding to the new launching date. Four kinds of modifications can be made:

- *Anticipation* (the new order date is closer to the current simulation date than the former one),
- *Postponement*,
- *Grouping* (when the new launching date of the order corresponds with the launching date of existing orders),
- *Do Nothing* (no modification is made to the proposed order).

Once the player has chosen one of these alternatives, he/she can click on the padlock to validate the order and send it to the supplier.

All the decisions made by the player are recorded in the log file, so that the correspondence

Figure 6. Illustration of a specific interface (left) and the corresponding log file records (right)

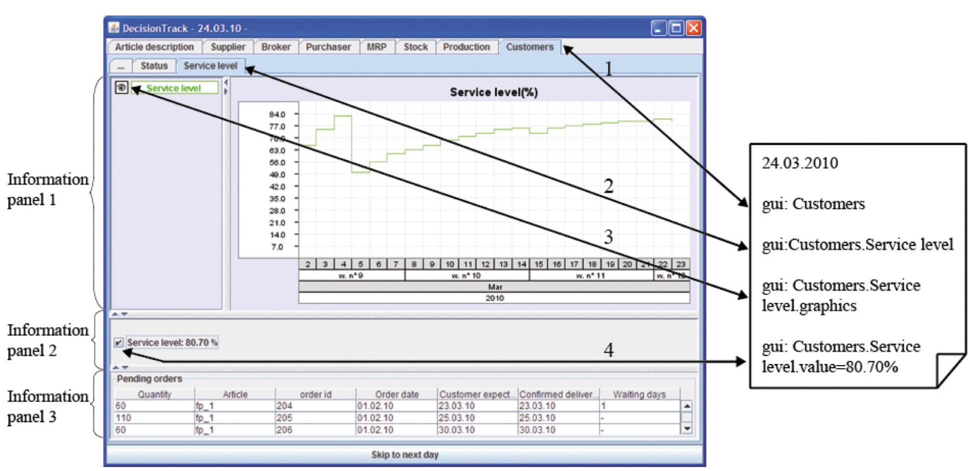


Figure 7. Snapshot of the "purchaser" tab

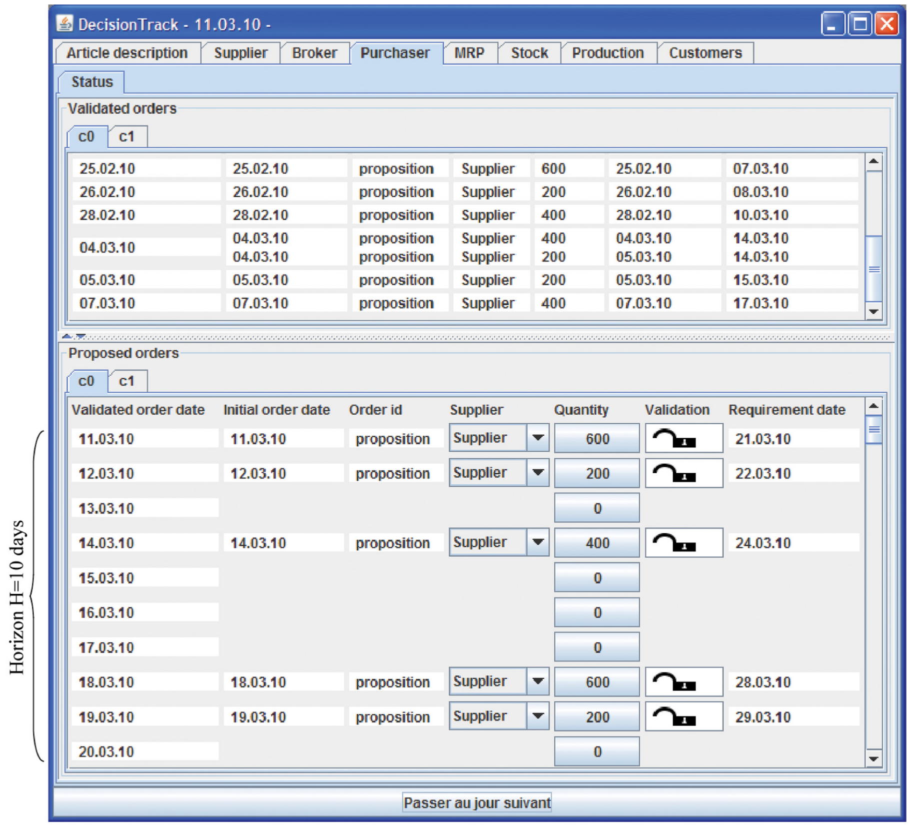


between player knowledge of the system state and the decisions he/she has made can be identified.

4. DecisionTrack Scenario

Game scenarios refer to the evolution of game variables across time. When designing a new game, two categories of variables must be differentiated. The first category encompasses variables that cannot be modified by the player -- *exogenous* variables. The second category relates to variables that can be modified by the player through his/her decisions -- *monitoring* variables. The latter help the player monitor the impact of his/her decisions on company performance.

The *exogenous* variables are identified through a literature review and discussions with domain experts. These variables must vary across time to create decision-making situations that require specific attention.

In this research, the goal is to identify how procurement agents make decisions according to the evolution of the environment (suppliers and customers). Table 2 provides the list of all *exogenous* and *monitoring* variables used in this study. Among the *monitoring* variables, it is worth noting that the service level value depends on the way the player updates the proposed procurement plan.

The selected *exogenous* variables that should vary across the simulation are those that are related to the supply chain environment, such as component delivery times, market behavior (customer orders), and forecasts (see Table 2).

By making the above-mentioned *exogenous* variables change across time in the game scenario, a difference appears between planning algorithm

Table 2. Exogenous and monitoring variables

Displayed information	Location	Exogenous variable	Monitoring variable
Customer orders and forecasts	- *Customers* tab - *Status* sub-tab	YES	NO
Actual and predicted component delivery time	- *Supplier* tab - *Graphics* sub-tab	YES	NO
MRP tables	- *MRP tab* - *Status* sub-tab	NO	YES
Inventory levels	- *Stock* tab - *Status* sub-tab - *Graphics* sub-tab	NO	YES
Work in process	- *Production* tab - *Status* sub-tab	NO	YES
Service level	- *Customers tab* - *Service Level* sub-tab	NO	YES

propositions (that are based on MRP theoretical parameters), and the current simulated situation. Such gaps create critical decision-making situations that require the player to make decisions that impact the company performance. The gaps between the planning algorithm's recommendations and the evolution of company's environment correspond to realistic and very common situations that routinely appear in companies in which the MRP parameters are not updated according to variations in the environment.

Supplier Delivery Time Variations

Supplier delivery times are set in the scenario to differ from the theoretical delivery time introduced in the MRP algorithm. In this way, actual delivery time may be either 1) longer than the theoretical one (which leads to delivery delays), or 2) shorter than the theoretical one (which leads to deliveries that enter the stock earlier than expected). The scenario is set so that situation 1) occurs most often, encouraging the player to make decisions instead of choosing the status-quo alternative.

Supplier-predicted delivery time data are provided in the form of a table in the *Supplier* tab.

In addition to the predicted delivery time, the actual delivery time is reported after each order delivery. All three delivery times (theoretical, predicted and actual) are reported as shown in Figure 8.

Forecast Patterns

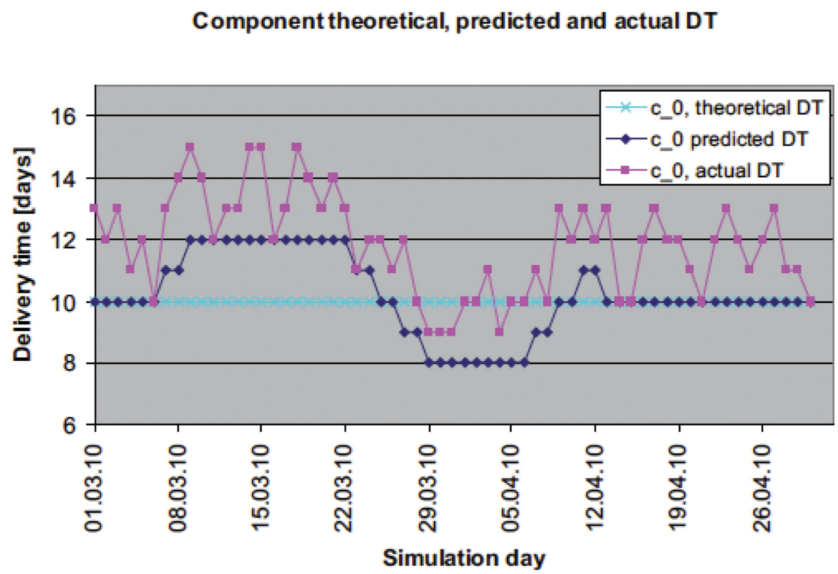
In addition to customer orders that represent the actual impact of the market on the "central" company, forecasts are designed to anticipate market requirements. The remainder of this section discusses forecast patterns (evolution of the forecasted demand over the planning periods) and whether they adequately predict customer order patterns.

Forecasted demand and customer order patterns are designed so as to lead to either overestimation (Delta>0) or underestimation (Delta<0) of the future demand. These two situations correspond to the Case 1, Delta>0, and to the Case 2, Delta<0, in Figure 9.

In addition, both patterns vary across time. Figure 9 shows an increase in both forecasts and customer orders during the end of April, followed by a decrease and stabilization by the end of May.

There are two arguments for introducing relative and absolute variations of customer orders and forecasts across time. First, it attempts to capture the real market characteristics of *seasonality* (for example, the increase of customer orders during the month of May) and *volatility* (modeled by the inability of forecasters to correctly predict market behavior). Second, it creates different decision-making situations (under- and over-estimation of actual demand), making it possible to record player reactions in several decision contexts and capture

Figure 8. Evolution of forecasts and customer orders for product fp_0 (DT stands for Supplier Delivery Time)



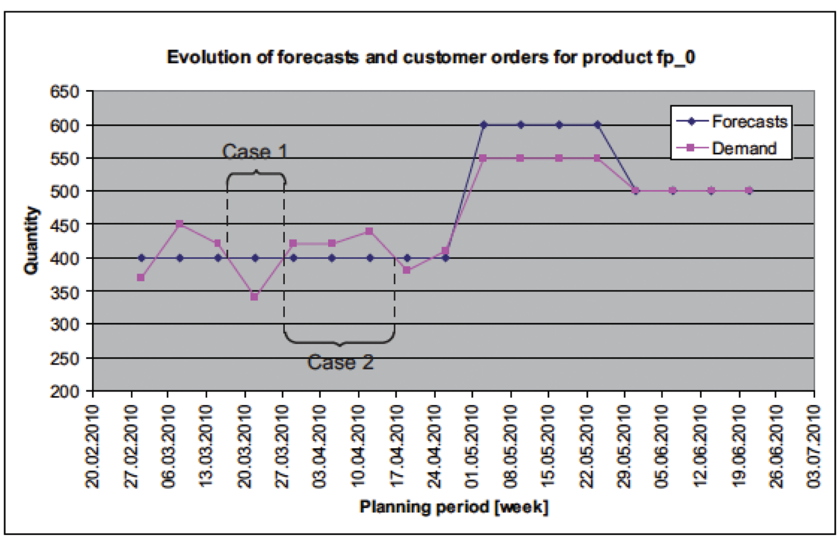
the variability that may exist among players in terms of decision-making behavior.

Because the production process is downstream of the procurement process, there is no need to make changes in the production lead-time. It is thus fixed to 8 days throughout the simulation.

Assigned Goals

Players are asked to validate the procurement plan proposed by MRP on a daily basis and to achieve the following two objectives:

Figure 9. Variations between forecasts and demand as set in the game scenario



- Minimize inventory (inventory levels are available in the "Stock" tab),
- Maximize service level (service level is available in the "Customer" tab).

These two objectives are justified by the fact that the two most common assignments for procurement agents are to control inventory and service levels:

- **Inventory levels:** high inventory levels usually correspond to high amounts of immobilized capital and may represent a risk in case of item obsolescence. Moreover, high inventory levels require large storage areas and may induce high costs in terms of temperature and hygrometry control. Procurement agents are thus often encouraged to minimize their stock, unless this leads to shortages.
- **Service level:** this performance indicator represents the ratio of the orders delivered on time by procurement to production (production lead-time fixed to 8 days). It thus provides relevant information about the extent to which the procurement agents fulfill their mission of assuring a reliable supply to the production department.

5. Simulation Sequence

Experimental Setup

In order to collect data in a consistent way across participants, an experimental procedure is designed that provides all players with the same knowledge of the game. It consists of the following four steps:

1. The *DecisionTrack* game and goal assignment is presented, and a slide show explains the displayed information in the game graphical user interface. Duration: 10-15 min.
2. Each players browses the *DecisionTrack* interfaces and the displayed data in each tab and sub-tab is described to the player. Duration 10-15 min.
3. Each player plays the *DecisionTrack* game for a minimum duration of 30 simulation days. Duration: around 1 hour.
4. Each player is interviewed to verifying his/her understanding of the game, as well as the strategies he/she engaged during the game. Duration: 20 minutes.

Simulation Day Description

To provide players with enough time to consult data and make decisions, the length of the simulation day is not constrained by the game, but dictated by the player. The player decides when to skip to the next day by clicking the *Skip to next day* button in the bottom of the window. This updates all the game variables, in particular, the procurement plan proposed by the MRP, which is updated by taking into account former decisions, current inventory levels, and variations in demand.

As described in step 3) of the experimental procedure, the average duration of a game is around one hour. It may vary around this value depending on the amount of time players spend on each simulation day, which in turn depends on the time each player needs for assessing the system state and for making his/her decisions.

ANALYSIS AND INTERPRETATION

The analysis of *DecisionTrack* outputs is based on the definition of appropriate metrics, which allows each player's behavior to be characterized in a quantitative fashion. This section discusses how to characterize a player's decision-making behavior after his/her game play. (Notation: Each experiment is labeled as Xi, where X refers to the company id and i indicates the number of the participant. For example, A2, refers to the game played by player number 2 of company “A”.)

1. Result Characterization Using Metrics

This section presents four metrics that were specifically developed to characterize player behavior in a procurement context. Two of them (M1 and M2) concern the search for information within the game interfaces, while the other two (M3 and M4) characterize the decisions made by the players. Each of these metrics is associated to a graphical illustration that helps to visually understand how the player’s behavior varies across participants.

1. Metric M1

Metric M1 is the average number of tabs consulted on a daily basis by the player over the game. The objective is to measure the player’s willingness to update his/her knowledge of the system.

2. Metric M2

Metric M2 is the number of tabs representing at least 80% of the total number of consulted tabs over the game. M2 provides cues about the extent of the information the player bases his/her decisions on.

3. Metric M3

Metric M3 is the maximum number of days between an initial order launching date and its new launching date after the player’s decision. Thus, it measures the amplitude by which the player modifies the initial procurement plan.

4. Metric M4

Metric M4 is the most distant day, from the current game day, for which a decision is made. This metric captures how early a player modifies the proposed orders, either by validating, anticipating, grouping or postponing them. Thus, this metric indicates to what extent the player focuses his/her attention on a short or a long-term horizon.

2. Clustering of Decision Making Patterns

Each metric is accompanied by a corresponding graphic that offers a visual feedback about a player’s behavior. In addition to this visual feedback, the metrics quantify an intangible process (tabs and number of times they are consulted, decisions that vary in terms of nature and amplitude).

This quantification lets us pursue the analysis further, by identifying clusters of players who behave in the same way according to the four metrics.

The clustering process is run using a k-means algorithm. Because the number of clusters is considered as a parameter (Ray & Turi, 1999), several clustering iterations are carried out with various numbers of clusters. The number of clusters is then set by selecting the iteration with the lowest error, based on the Square Mean Error and the Davies-Bouldin index (Davies & Bouldin, 1979).

APPLICATION CASE

In this section, a procurement decision application of the *DecisionTrack* game is described. For this experimentation, 14 games were played by procurement agents. Then the simulations results were analyzed according to the previously described metrics and clustering algorithm.

1. Player Characteristics

Players were purposely chosen among professionals and not students. Because of the focus on the procurement task, procurement agents were selected for participating in the game, based on these three constraints:

- **Company management policy**: We restricted participants to those whose companies use a Make to Stock policy using MRP planning. This ensures that players know how the MRP procedure works, which in turn facilitates their understanding of the game.
- **Company size**: We limited participants to those working in medium-sized and multinational companies. This ensures that people in charge of procurement are dedicated to this function, which may not be the case in small companies.
- **Geographical location**: for practical reasons, players were selected among companies located within a two hour driving distance.

2. Analysis of the Experimental Results

After experimental game runs with several players were concluded, the simulation outputs were analyzed to characterize each player's decision-making behavior. The analysis is based on the four above-mentioned metrics, which allow a quantitative characterization of the player's decision-making behavior. This is complemented by graphical representations that provide visual explanations of how a player behaves during the game.

Metric M1: Average Number of Tabs

The two graphs in Figure 10 show a high variability in data consultation patterns; player F1 regularly updates his knowledge of the decision context (M1=3.34) by consulting the available tabs, while player C3 does it on a less regular basis (M1=1.85).

Metric M2: Most Often Consulted Tabs

The illustration in Figure 11 provides the consultation intensity per tab (see number of tab-consultations close to the name of each tab) and allows the identification of the most consulted tabs. For instance, player H1 in Figure 11a shows a particular interest for the *MRP*, the *Stock*, the *Production* and the *Supplier* tab (M2=4). In Figure 11b, player H3 shows interest in a limited set of tabs (M2=2), i.e. the *MRP* and the *Stock* tabs.

This data reinforces the hypothesis that different players do not necessarily base their decisions on the same set of information, and they do not update their knowledge of the decision context at the same pace.

Figure 10. Graphical illustration of the metric M1 for players F1 and C3

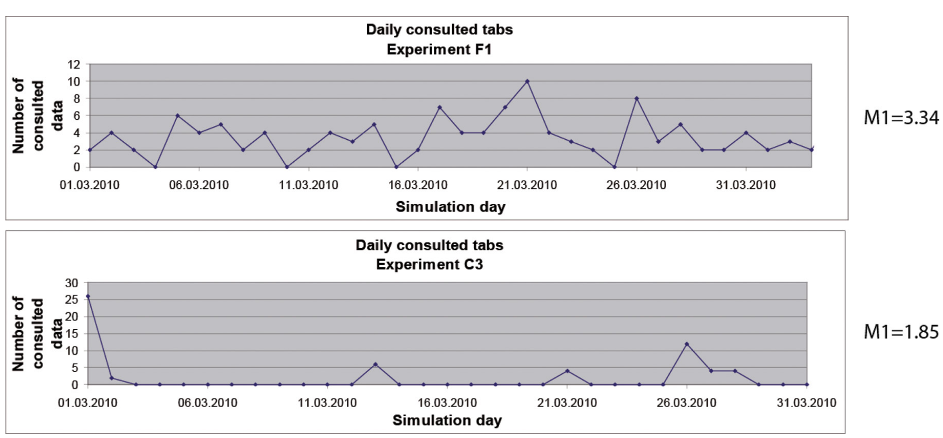


Figure 11. Graphical illustration of the metric M1 for players F1 and C3

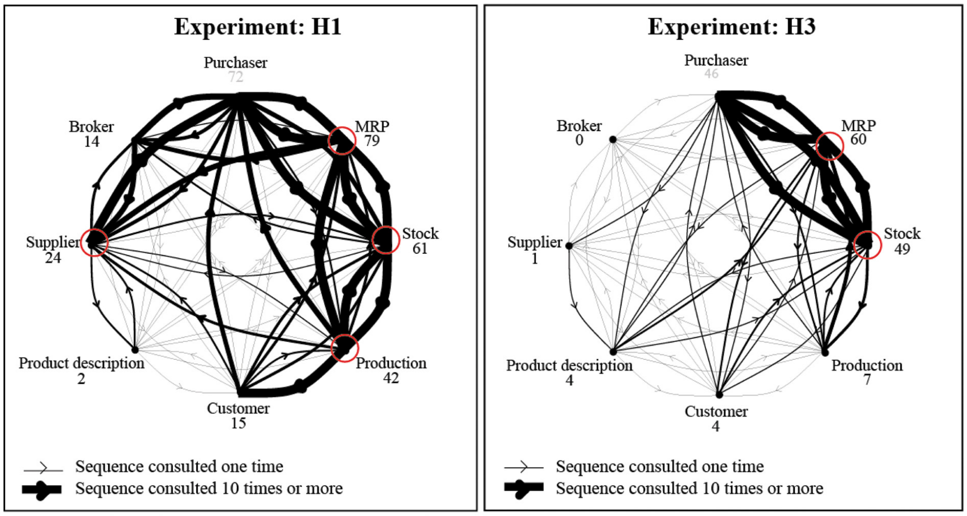


M2=4 M2=2

Metric M3: The Difference between the Initial Setting and the Modified Date

Figure 12 shows two different player behaviors. Player D2 (M3=1) seems to be very confident in MRP propositions as he/she always (with two exceptions) validates the MRP propositions. Player D1 (M3=9), however, often anticipates the orders, which may mean that his/her knowledge of the company and the supply chain (M1=3.375 and M2=4) encourages him/her not to blindly follow MRP recommendations.

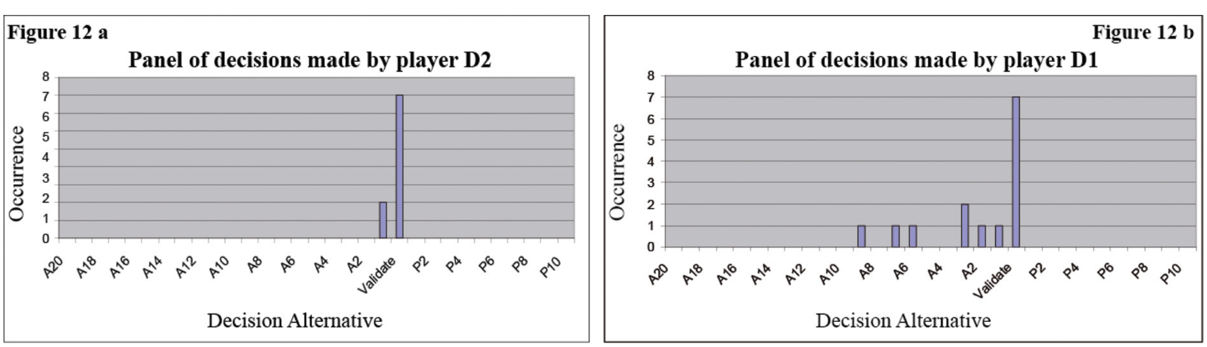
Metric M4: How Early Was the Decision Made?

In Figure 13a, we see that player A2 takes a long horizon into account as his/her decisions are contained in a 19-day span. Player C2 (Figure 13b) makes decisions on a short-term horizon -- M4=4.

Clustering

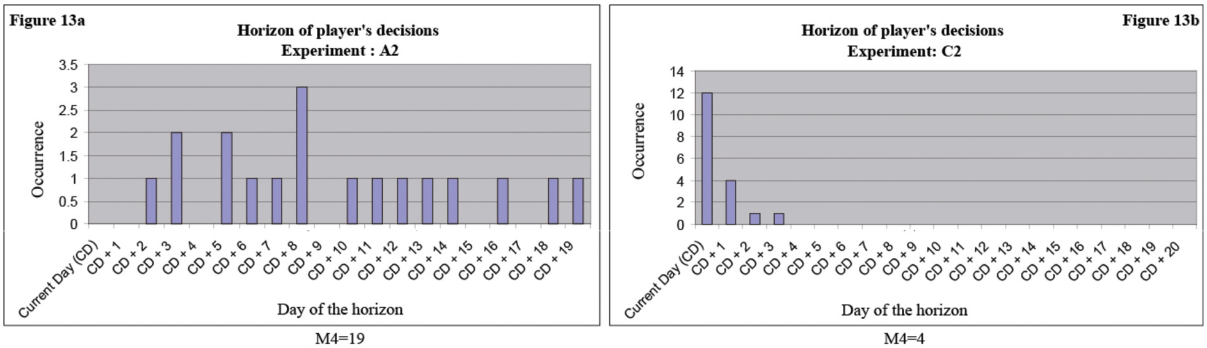
Once the fourteen experiments (players A2, B1, C2, C3, D1, D2, E1, F1, F2, F4, G2, H1, H2 and H3) are completed, the four metrics are com-

Figure 12. Graphical representation of the metric M3 for players D2 and D1



M3=1 M3=9

Figure 13. Graphical illustration of the metric M42 for players A2 and C2



puted for each experiment using the information recorded in the log file. Then, each experiment's metrics are ordered in a four-element vector, and the goal of the clustering process is to identify whether similarities exist among the 14 vectors, indicating similarities in player behavior.

The clustering results obtained using the k-means algorithm are outlined in Table 3.

Table 3 shows that the constituted clusters do not contain players who are hired by the same company.

This is evidence that the variations across players are not only related to the players' specific working contexts, but also to individual personality characteristics (such as risk-seeking and risk-averse behavior).

This is confirmed by Figure 11 and Figure 12, which show that players from the same company exhibit completely different behavior.

3. Discussion of the Application Case

There are two main observations to be drawn from the experiments. First, players vary widely in terms of the data they consult. Some focus on a limited range of information, while others deeply investigate the decision context. This corresponds to individual differences in data consultation approaches; either a systematic consultation of the same limited set of tabs, or a problem solving approach in which the search for information is adapted to previously consulted tabs. Second, players vary widely in terms of the decisions they make. Some trust the planning algorithm and modify the MRP propositions very little, while others significantly modify the initial procurement plans.

The clustering approach allows us to identify categories of players who behave the same way. This classification can be very useful as it may permit the identification of a specific category of players that deserve further attention. For instance, cluster 4 (M1=3.65, M2=2.67, M3= 2.33 and M4=4.67) deserves less attention than cluster 1 (M1=1.69, M2=3.5, M3=18.5 and M4=19.5), because in cluster 1, the modification of the proposed procurement plan is limited, decreasing the impact of the human decisions on the company and its supply chain performance.

Table 3. Player behavior clustering analysis

Cluster number	1	2	3	4	5
Cluster components	C3, G2	D1, E1, F1, F3, H1	B1, H3	C2, D2, F2	A2, H2

ISSUES AND CONTROVERSIES

The several experimental tests carried out before the final data collection tests allowed us to identify several hurdles related to the use of serious games. They are detailed below, along with measures we adopted to overcome them, as far as was possible.

1. Player Behavior Distortion

When using laboratory experiments in general and serious games in particular, there is a risk that the observed player behavior is distorted in comparison with his/her actual behavior in the "real world." This gap can be explained by three factors: *stakes, social norms* and *scrutiny* (Levitt et al. 2007).

- *Stakes* within games often differ from the stakes in real world. For example, the consequences of badly managing the procurement orders in *DecisionTrack* are less critical than those engendered by badly managing the procurement orders in a real company (overstocking, shortage, customer dissatisfaction, etc.). Because this, players may show a lack of commitment in a virtual game scenario. In our experiments, *stakes* have a limited impact on player commitment, as all the players are professional procurement agents who participate in the name of their company, thus who have implicit motivation to behave in the best way to uphold the good image of their company.
- *Social norms* refer to the fact that laboratory experiments lack the "rich real-life" context that exists outside the laboratory. Because this aspect typically characterizes "social experiments", it does not affect the consistency of the data collected with *DecisionTrack*. It is thus not discussed further.
- Finally, *scrutiny* refers to the fact that within laboratory experiments, player may act such a way to please the experimenter. This is also called the experimenter *demand effect* (Orne, 1962). To avoid this, the instructions provided before the data collection phase reiterate the researchers' interest in collecting and reproducing their decision-making behavior as it is, regardless of the quality of their decisions or the corresponding performance. Thus, players do not have any preconceived idea about particular behavior the experimenter is seeking to observe. Thus, players cannot please the experimenter by adopting a particular behavior.

2. Platform Understanding

The main drawback of providing players with a realistic, though virtual, environment is the multiplication of the data at their disposal in the *DecisionTrack* interfaces. As a consequence, players may find it difficult to handle the serious game, and to understand the interface contents in an exhaustive way.

In order to help players to correctly handle the tool, a two-phase protocol – learning phase and verification phase -- has been designed to ensure player understanding of the game. The learning phase is divided into two sub-phases that occur before the game is played; in the first, the experimenter presents a slide show describing the research approach, the assigned goals, and shows interfaces screen shots. In the second sub-phase, the experimenter browses *DecisionTrack* interfaces with the player and explicitly describes the information they contain. During the learning phase, the experimenter also answers player questions.

The verification phase takes place after the data collection phase is carried out, using an interview. The goal of this interview is to ask the player about his or her strategy and the kind of decisions he/

she has made. This verification interview is later used to compare what the player has said about his/her decision-making behavior with what has been recorded in the log file.

This verification allows us to withdraw experiments in which players did not understand the meaning of the displayed information, or in which players did not manage to log their decisions in the game because they misunderstood the game commands.

3. Identification of the Consulted Information

Although measures are put in place to track each player's search for information (tabs, sub-tabs, checkbox, mouse listeners), situations come up in which accurate identification of the consulted information remains tricky -- particularly in the case of graphs and tables. Indeed, even if the tracking tool identifies that a table is consulted, it is difficult to identify which rows or columns are actually read by players. In a similar way, it is difficult to identify exactly how a player consults a graph (trend, horizon, scales, etc.). This issue could be addressed using gaze-tracking technology, and will be discussed in the next section.

Several things may hinder the relevance of the collected data. Some are related to human characteristics and behavior while others are due to the game complexity resulting from the game realism.

However, the effort taken to run the experiments according to a validated protocol, the attention given to introduce the game and to train players, the care in the choice of words in order not to influence players, the attention given to isolate the information within the interfaces make it possible to overcome the hurdles that commonly stand in behavioral researcher's way give us a very high level of confidence in the relevance of the collected data.

FUTURE RESEARCH DIRECTIONS

To address the consulted information identification issue mentioned in the previous section, gaze-tracking devices could be used.

Gaze tracking technology does exactly what it advertises – it tracks the direction in which a user's eyes are looking. Several gaze tracking technologies exist; they vary according to the positioning of their sensors or cameras, and how they are calibrated. Conventional gaze tracking devices rely on sensors that are placed on the computer display and must be calibrated prior to the gaze direction collection phase. A more innovative approach (Noris et al., 2010) is portable devices that can capture gaze directions in non-laboratory settings (outdoor environments, workplaces). The main obstacle in making these devices applicable for the identification of consulted information within serious games is the synchronization between the eye tracking device and the information contained in the game interfaces. If this could be overcome, it would be possible to know how many rows a player is looking at in a table at a given time and the data displayed in these rows, for example.

CONCLUSION

This study shows that when consistent efforts are made to create realistic virtual environments, serious games provide a relevant approach for capturing consistent human operational decisions, while avoiding the drawbacks (e.g. verbalization, theorization) that are met using conventional data collection tools (e.g. interviews, questionnaires).

A large panel of information was gathered from experts in the field under study in order to identify the set of information players may consult and the set of decision alternatives players may make. Interfaces were organized in a way that was familiar to players, to make them comfortable with the game. In addition, scenarios were designed to introduce perturbations and to create decision situations that required players to make decisions. And before games were played, a protocol was designed to provide all players with exhaustive information about the game interfaces, the assigned goals and the commands for interacting with the game.

The present work focuses on procurement decisions, but this serious game approach could be applied to almost all other operational decisions found in Supply Chain management.

The analysis of the collected data using four metrics reveals a large variability among player behavior, which supports our initial observation that people make decisions in highly individual ways, and that this variability should be taken into account in computer simulations. This is also confirmed by the clustering analysis that shows that even people working within the same company vary in their decision-making behavior.

Future challenges for serious games include incorporating new tracking technology capabilities (synchronized gaze tracking) that will enable more accurate data collection, improving our understanding of how people make decisions according to the information they have at hand and their perception of their working environment.

ACKNOWLEDGMENT

Our heartfelt thanks go to Olivier Gobet for his outstanding participation in the development of the DecisionTrack game, as well as Mary Parlange who reviewed the English phrasing of this paper.

KEY TERMS AND DEFINITIONS

Elicitation: Is a process used to help experts to share their knowledge. It consists of using several methods that make expert's tacit knowledge more explicit, and thus easier to analyze, model and reuse.

Mouse-Listener: A mouse-listener is a JAVA listener interface that records the mouse events (press, release, click, etc.) on a component (button, checkbox, etc.). Thus, mouse-listeners are either used to record user actions (for example, enters the consulted information and the decisions in the log file) or to react to user actions (for example, when the user checks the "skip to the next day" button in DecisionTrack's window, the simulation day is incremented and all the game variables are updated).

ABSTRACT

Becoming a sustainable global manufacturing enterprise is a challenge for almost every manufacturing organization in the world because of its multidimensional nature. Sustainability combines environmental, economic, and social dimensions and is considered to be a complex and hard to learn subject needing a lot of experience and competences. Traditional ways to create such experience and develop competences like role playing and simulations tend to take a lot of time and are expensive. On the other hand, serious gaming has proven to support learners in acquiring new and complex knowledge and is ideally suited to support problem based learning by creating engaging experiences around a contextual problem where users must apply competences to solve these presented challenges. This chapter introduces a new learning environment which is build around a gaming engine supporting the development of competences in specific subject areas. Selected competences in sustainable global manufacturing lead to the definition of scenarios, which then can be executed by a game engine, thus creating experience within the user. A knowledge ecology space allows the user to interact and reflect on learning outcomes with other participants. The subject of sustainable global manufacturing is the application case presented in this chapter showing how specific competences in this area have been identified and how a game scenario has been developed. Finally, its implementation and evaluation is discussed.

DOI: 10.4018/978-1-4666-1945-6.ch043

INTRODUCTION

An early and broad definition for sustainable development has been provided by Gro Harlem Brundtland, former prime minister of Norway, during her presentation of the Report of the World Commission on Environment and Development to the UNEP's 14th Governing Council Session in 1987: *"Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs".* Overall sustainability includes the balancing of three dimensions: Environmental, economical and social sustainability.

In order to handle such a complex subject the main competence of involved managers is most probably the ability of multi-dimensional thinking, which is a competence hard to teach. Gaining such a competence relies strongly on experience. Traditional teaching (and learning) methods would focus on a one-to-one case study (or role play simulations) which is time consuming and, therefore, quite expensive in the end. The question is how such competences can be build in a learner with less time and less efforts concerning teaching staff.

There is a growing interest in games for purposes beyond entertainment. There is a common agreement that Serious Games are potential facilitators of improved learning whilst at the same time entertaining and engaging users. Examples have been developed in a wide range of fields including management science, economics, intercultural communication, psychology, military strategy, sociology, political science, and interpersonal skill development (Raybourn & Bos 2005). The hypothesized benefits of digital game-based learning include increased motivation of learners, and improved transfer of learning to the context in which the learning is applied. There is growing recognition of game based learning as a useful tool to support learning within schools and universities (Eck 2006).

However, a key challenge of building a Serious Game as an effective learning tool is the need to tailor the game design to address the competence domain. Although important, a serious game alone does not suffice to ensure learning and it is necessary to have a set of methodologies and tools to provide a learning environment that enable the tailoring of personalized learning plans tailored to the needs of the learner and supporting the individual (and the teacher) in assessing the progress made. Finally, understanding of a subject is often gained through reflection and exchange with other learners.

This chapter follows several objectives. First, the complex subject of Sustainable Global Manufacturing (SGM) is introduced and motivated. A detailed literature research provides insights in the competences one need to have to handle issues related to SGM. Based on those competences a game scenario which is part of a larger learning platform is introduced supporting learners to create such competences. Finally, the implementation and evaluation of that game scenario in the context of the learning environment is discussed.

WHY THERE IS A NEED FOR SERIOUS GAMING IN SGM

Manufacturing industries account for a significant part of the world's consumption of resources and generation of waste. Worldwide, the energy consumption of manufacturing industries grew by 61% from 1971 to 2004 and accounts for nearly a third of today's global energy use. Likewise, they are responsible for 36% of global carbon dioxide emissions (IEA 2007).

Manufacturing industries nevertheless have the potential to become a driving force for the creation of a sustainable society. They can design and implement integrated sustainable practices and develop products and services that contribute to better environmental performance. This requires a shift in the perception and understanding of industrial production and the adoption of a more holistic approach to conducting business (Maxwell, Sheate et al. 2006).

Sustainable Manufacturing is part of a larger concept of sustainable development, which emerged in the early 1980's in response to increased awareness and concern over the environmental and social impact of economic growth and global expansion of business and trade.

The concept of sustainable development implies firstly the integration of environmental issues with the imperatives of economic development in order to meet the immediate needs of populations today without undermining the aspirations of future generations. However, the definition of the term "sustainable development" has been expanded to include the ideas of fairness and interdependence, not only between generations, but between the countries and peoples of the Earth. Social, cultural, economic and natural environments, whose harmonious development is essential to the welfare of humanity and of nature, are also included in the concept (WCSD 2010).

The three main ingredients of the sustainability are environment, economy and society.

- The **Environmental Sustainability** is the ability to sustain quality of the physical environment. It concerns issues as exploitation of renewable and non-renewable natural resources, preservation of quality of water, air and soil, energy efficiency, waste management, balance of eco-systems and preservation of biodiversity.
- The **Economic Sustainability** concerns sustainable human development and growth, leading to improved quality of life, employment, social and economic equity. Moreover, it requires improvements and better exploitation of technologies, knowledge and innovations as source of cost optimization and resource efficiency.
- The **Social Sustainability** is the relationship between development and current social norms. It implies distribution of wealth and services within and between generations. An activity is socially sustainable if it conforms to social norms or does not stretch them beyond the community's tolerance for change. Social norms are based on religion, tradition, and custom; they are rooted in values attached to human health and well-being.

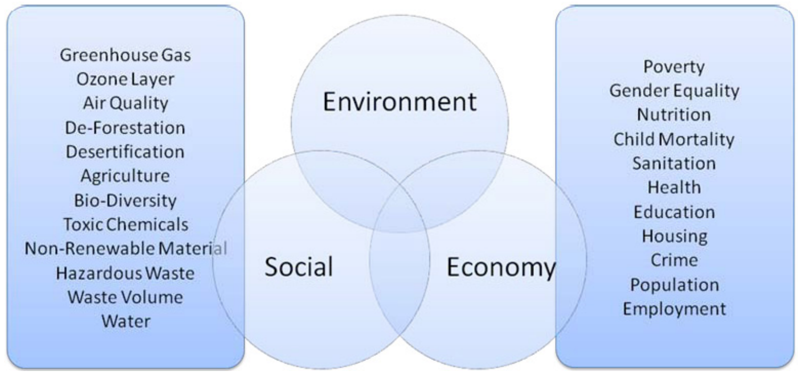
Sustainable development is used more often as an umbrella term, including many multidisciplinary areas of human activity. Some of them are: Urban regeneration, Community development, Energy, Transport, Ecology, Pollution, Climate change, Peak oil, Resource efficiency, Carbon foot printing, Workforce development, Organizational learning, Corporate responsibility, Human rights, Social justice. Sustainable development is emerging as basic principle for development in several industries as: sustainable building, sustainable transportation, sustainable manufacturing, sustainable utilities and services (WCSD 2010).

Sustainable Manufacturing is a business practice of the industrial sector, which expands all the company's processes and decisions into the broader social and natural environments in which the company operates in and affects with its actions. This is executed with the explicit objective of reducing or eliminating any negative impact, while pursuing the desired level of technological and economic performance (Leahu-Aluas 2010).

The US Department of Commerce defines Sustainable Manufacturing as the creation of manufactured products that use processes that minimize negative environmental impacts, conserve energy and natural resources, are safe for employees, communities, and consumers and are economically sound (Leahu-Aluas 2010).

Sustainable manufacturing is more comprehensive and systemic than e.g. green, eco-manufacturing, eco-machining, clean production by dealing with all three components of sustainability: environment, economy and society. While it

Figure 1. The three dimensions of sustainability and United Nations indicators



includes all the environmental concerns, such as pollution, material toxicity, GHG emissions, it is not limited to those concerns, nor is it a component of an environmental management system. Sustainable manufacturing uses both technological and non-technological solutions, from selection of materials and production processes to organizational mission, structure and performance reporting. It shifts the focus from "end-of-pipeline" solutions, disposal of waste, clean-up, recovery, a liability approach, to the very beginning, at product or process design stage, an opportunity approach (Leahu-Aluas 2010).

It resolves some of the limitations and controversies of an exclusively green/environmental view by aiming for a balance in satisfying all three components of sustainability, by aiming for a "triple bottom line" and a "triple top line". Unlike some green/environmental models and concepts, sustainable manufacturing builds upon and improves an advanced and technologically sophisticated industrial base. It recognizes the weakness of economic growth which disregards the limits of natural resources and the demands of the society for sharing the benefits of successful enterprise. Another important distinction is the inclusion of time, as a component of sustainable manufacturing, from extending the viability and longevity of the business to assessing and owning the entire life-cycle of a product or service (Leahu-Aluas 2010).

Sustainable manufacturing uses a more holistic approach that considers all life-cycle stages, from pre-manufacturing, manufacturing and use through post-use. This holistic view of sustainable manufacturing takes the aim of adopting sustainable principles across the whole manufacturing life-cycle, and identifying all inputs and outputs for continuous improvement action. These stages are spread across the entire supply chain with different partners managing activities at each of these stages. Thus, many players in the manufacturing process must adopt sustainable principles to ensure that higher production standards are met (WCSD 2010).

From historical perspective, different objectives for education that address environmental and sustainability challenges have been documented for the first time at the Intergovernmental Conference on Environmental Education organized by UNESCO in Tbilisi in 1977, also known as the "Tbilisi declaration" (ICEE 1977). Furthermore, Education and competence development for Sustainable Manufacturing and Sustainable Development is perceived as a matter of global importance and has been one of the top priorities in national policy documents and on the global agenda since the UN's Earth Summit in Rio in 1992 (UN 1992) and again brought to the forefront of the international attention at the UN World Summit on Sustainable Development in Johannesburg in 2002 (UN 2002). Both reports argue that education is critical for promoting sustainable development issues which should be integrated in all disciplines, should employ formal and informal methods and effective means of communication (UN 1992; 2002).

According to several national strategies and reports (e.g. Forum for the future 2004; NCS 2007; ASCE 2009; NAE 2004; Higher Education Academy 2008) the engineering profession can and should play an important role in securing a sustainable future. Engineering educators around the world are witnessing a significant shift in societal expectations of the engineering profession, to help address immediate and longer-term sustainable manufacturing challenges. Fokkema et al. (2005]) stated that "*each engineer has a responsibility to society and should have an awareness of possible ethical, social, environmental, aesthetic, and economic implications of their work and to act accordingly.*" As there is still a common global concern about the lack of sustainability content in engineering curriculum (e.g. Desha et al., 2009; Holmberg et al., Azapagic et al., 2005) trends of introducing competence-based sustainability-oriented education and training are becoming more and more apparent (e.g. NCS, 2007; Lourdel et al., 2005; Fenner, et al., 2005; Fokkema et al., 2005; Barth et al., 2007; Desha et al., 2009; Anderberg et al., 2009).

There is a broad range of research described in the literature dealing with competences in the field of sustainable manufacturing and sustainable development. De Haan (2010) proposed a model of "Gestaltungskompetenz" that centers on defining key competencies and related sub-competencies in the field of sustainable development in the education sector. Gestaltungskompetenz can be split into 12 sub-competencies, namely the ability to

1. gather knowledge in a spirit of openness to the world, integrating new perspectives;
2. think and act in a forward-looking manner;
3. acquire knowledge and acting in an interdisciplinary manner;
4. deal with incomplete and overly complex information;
5. co-operate in decision-making process;
6. cope with individual dilemmatic situation of decision-making;
7. participate in collective decision-making process;
8. motivate oneself as well as others to become active;
9. reflect upon one's own principles and those of others;
10. refer to the idea of equity in decision-making and planning actions;
11. plan and act autonomously; and
12. show empathy for and solidarity with the disadvantaged.

The Australian Manufacturing Skills Council imported the Guideline Competency Standards for Sustainability and they are designed to guide teaching and learning of respected competences in the field of sustainable manufacturing in formal vocational training and education settings as well as on the job (NCS 2007). The required knowledge, skills and relevant performance criteria required for the upper management level are structured under the competitive manufacturing unit "Develop workplace policy and procedures for sustainability". This unit is furthermore divided into four main competence elements:

1. Develop workplace sustainability policy;
2. Communicate the policy;
3. Implement the policy;
4. Review the policy implementation.

The Institution of Civil Engineers (ICE) established a Task Group to drive the implementation of sustainability principles into education, training and professional development (Fenner et al., 2005). It proposed the following broad skill requirements in the domain of sustainable development:

1. The ability to work with complex/ill-defined problems;
2. The development of team work and communication skills, and
3. The ability to evaluate the merits and demerits of options.

The Royal Academy of Engineering (RAE) identified a set of principles of Engineering for Sustainable Development (Fisk and McQuaid, 2004). Engineers are required to have the ability to:

1. operate and act responsibly, taking account of the need to progress environmental, social and economic issues simultaneously;
2. use imagination, creativity and innovation to produce products and services which maintain and enhance the quality of the environment and community and meet financial obligations, and,
3. understand and encourage stakeholder involvement.

Engineering Department at Cambridge University proposed essential competence ingredients for well informed engineers to tackle the sustainability issues (Fenner et al., 2005). They can be summarized as:

1. the need to engage in problem definition through careful dialogue with all stakeholder groups and a proper recognition of context;
2. an understanding of mechanisms for initiating and managing change in organizations so future engineers are equipped to play a leadership role;
3. an acknowledgment that technical innovation and business skills also must be understood, nurtured and combined as precursors to the successful implementation of sustainable solutions.

Forum for the future (2004) established a Higher Education Partnership for Sustainability that identified a sustainability literate person, who would be expected to:

1. Understand the need for change to a sustainable way of doing things, individually and collectively;
2. Have sufficient knowledge and skills to decide and act in a way that favors sustainable development;
3. Be able to recognize and reward other people's decisions and actions that favor sustainable development.

These explications show that Sustainable Global Manufacturing is a complex and hard to learn subject needing different competences and a lot of experience, while at the same time it is important for the industry to continue into this direction. There is a strong need that students practice and learn about sustainable manufacturing areas which may be currently underspecified in conventional courses (e.g. holistic and systems thinking, decision making for sustainability, interdisciplinary cooperation, communication skills etc.); new to the manufacturing industry (e.g. life cycle analysis, Eco-Management and audit scheme etc.) or ones that pose new challenges that have not been foreseen earlier. Consumers furthermore expect to be offered products which have low impact on environment and being socially acceptable (e.g. exclusion of child work).

CHALLENGES IN SUSTAINABLE MANUFACTURING

Challenges for Globally Acting Manufacturing Enterprises

Manufacturing enterprises which want to introduce Sustainable Global Manufacturing do face several challenges. First of all, the demand of customers for green products is still growing. There are several forces driving this trend: energy process are volatile, governments are interested in and try to regulate environmental issues, in public concerns about product and food safety do exist, and finally the environment isn't getting cleaner just by its own. A recent study shows that 34% of European adults are systematically looking for and often purchase green products and 24% of European adults would accept a higher price for green products in 2008 (Manget et al, 2009).

As outlined above, Sustainable Global Manufacturing could only be reached by balancing the three dimensions of environmental, economic and social sustainability. Therefore, the main challenge when implementing sustainability is to deal with this multi-dimensional issue in a holistic way. Optimization of specific factors may result in negative impacts in other areas (e.g. to make a product more green may result in higher energy consumption of manufacturing processes).

Complex products are assembled form many parts delivered by lots of different suppliers. To assure the green quality of a product there is a need to manage all the delivery parts to be green as well. In some sectors, suppliers are organized in tiers, where the first tier suppliers are cooperating quite closely with the manufacture while second and third tier suppliers are handled by the first tier. The challenge is to manage all suppliers down this hierarchy to support sustainability in order to ensure sustainability on the top level.

Each product is following a life cycle running through three phases starting with BOL (Beginning of Life) via MOL (Middle of Life) to the EOL (End of Life). The BOL phase deals with product development and manufacturing, MOL is about product usage and maintenance, and finally the EOL phase is for disassembly, refurbishing, and recycling. Note, that a sustainable view on manufacturing includes the absence of waste, there is nothing which needs to be disposed or dumped throughout the whole life cycle because everything acts as input for other manufacturing processes (McDonough and Braungart, 2002). Here, the challenge is to make a product sustainable throughout its whole life cycle.

If an enterprise decides to offer green products and to be sustainable it is necessary to act sustainable in all matters. It wouldn't be a good idea to offer green products while the management staff is flying round the world using cheap airlines and thus contributing to unnecessarily to air pollution. Sustainability is a behavior which should be reflected by each single employee of that company otherwise the image of the enterprise concerning sustainability is beyond belief.

Finally, connected with sustainable manufacturing one can observe the emergence of many different standards. Examples for these include ISO 14001, GRI (Global Reporting Initiative), EMAS (Eco Management and Audit Scheme), LEED (Leadership in Energy and Environmental Design), PEFC (Program for Endorsement of Forest Certification Schemes), OHSAS (Occupational Health and Safety Assessment Series) and ENERGY STAR which is a product label for energy-saving equipment and buildings.

Summarizing this discussion, the main challenges for globally acting manufacturing enterprises are:

- Responding to the growing demand for green products
- Holistic or systemic view on sustainability, i.e. balancing the three dimensions
- Covering the whole supply chain by including suppliers, but not just first tier suppliers, also second and third tier suppliers
- Managing the process of selecting and introducing sustainability standards

Challenges for Developing Competences in SGM

Among the main identified disadvantages of the traditional engineering and manufacturing education is firstly the predominant orientation towards factual knowledge (Dolinsek et al, 2004;

O'Sullivan et al, 2009; Westera, 2001); and secondly the issue that curriculum is not reflecting the real needs of the business, manufacturing industry and society as a whole (O'Sullivan, 2009; IMS Zurich, 2007). It has been argued that traditional engineering and manufacturing education is still mainly focused on developing the production skills of engineering students (Lehmann et al. 2008). With the acknowledgement that the sustainable development of today's societies relies on more than this potential, it inherently becomes necessary for future employees and knowledge workers to contribute with other potentials and skills as well.

The research from Azapagic et al. (2005) demonstrate that students generally believe that knowledge on sustainable development is important for them, although they often have difficulties in making a direct link between the theory of sustainable development and practice. As employers demand for competent individuals that can effectively tackle with real-world complex problems it appears that the results from the accomplishment of learning tasks which support a traditional knowledge-based curriculum are no longer sufficient for these dynamic social and work conditions (Sampson and Fytros 2008; Westera, 2001). The concept of competence is highly associated with the ability to master such complex and ill-defined situations. As a result, the term has become attractive for both educators and employers because it is easily identified with valued capabilities, qualifications and expertise. It appears that the general understanding is that competences are the crucial explanatory factor in situations where the employee is theoretically equipped to handle a work situation but in practice fails. Therefore, competence-based education and training can be seen as a way forward in addressing this kind of "missing piece" required in successful work performance.

In order to remain competitive manufacturing enterprises need to recruit and train competent employees who will be able to operate in future sustainability-oriented environments and who will provide the knowledge and expertise to master real-life complex situations. As sustainable manufacturing is and will become a major player in the landscape of developed economies, these skills and methods of their acquisition and development will need to change. Problem based technology enhanced learning can add to those skills by providing and promoting the linkages to and the understanding of other items and dimensions of the sustainability potential through context-based, interdisciplinary learning. This can enable students to solve complex and situated problems. Therefore universities and other education and training institutions need to offer their students innovative learning environments that will facilitate their learning and competence acquisition (Wert 2004; IMS Zurich 2007; Sampson and Fytros 2008; Petersen and Heikura 2010). The Technology-enhanced competence-based learning (Sampson and Fytros 2008) is recently gaining much interest in educational settings as it can enable the delivery of successful courses that take full advantage of the benefits made possible by the technology.

The research conducted within the European FP7 Integrated project TARGET on competence identification and development, that was based on the classic full-scale 6 step version of a competence study (Spencer and Spencer 1993), critical incident technique (Flanagan 1954; McClelland 1973; Cerinsek et al. 2007; Cerinsek and Dolinsek 2009) and job analysis (Pearn and Kandola 1990),identified, that employees at upper management levels are involved in the development and implementation of strategic sustainability initiatives. Many sustainability problems require solutions/concepts that take a system and holistic view of the world, accounting for complexity and coupling inter-disciplinary understanding with a much broader concept of system performance. The attempt to understand complexity and relationships should be the starting point for the employees. They are furthermore required to demonstrate personal responsibility and autonomy in performing complex technical operations and to take full responsibility for personal and group outcomes. They are required to consult widely with different stakeholders in order to develop workplace sustainability strategy and procedures that are in alignment with the strategy. The generic competences with related sub-competences that have been identified in the field of sustainable manufacturing for employees at upper management levels are presented in a form of the following competence set:

1. Personal commitment to the sustainability
   - Corporate social responsibility awareness
   - Environmental care and green future orientation
   - Broader view and open mind; integrating new perspectives
   - Decision making for sustainability (every decision takes into account sustainability issues)
   - Understanding the nature, principles, drivers, barriers and impacts of sustainability
   - Taking initiative and actions that reflect commitment to sustainability
   - Ability to understand, cope with and manage change
   - Ability to raise general sustainability awareness
   - Communication skills
2. Systems / holistic thinking
   - The ability to take a multi-scale perspective,
   - Life-cycle thinking,
   - Ability to perceive environmental challenges and policies (regulations and standards) not as a barrier to growth but as a new opportunity
   - Ability to differentiate between short and long term options and strategies and their consequences,
   - Ability to critically value situations from sustainability perspective,
   - Analytic thinking and the ability to identify and consider particular smaller parts of the system (zoom in and breaking things apart)
   - Synthetic thinking and the ability to consider system as a whole, perceiving the big picture (zoom out and putting things together)
   - The ability to understand the interrelationships, cause-effect chains and trade-offs between different parts of a system
   - Conceptual thinking as seeking connections/patterns or inconsistencies/discrepancies that are not obvious to others
   - Ability to deal with complexity
   - Ability to make sense of a large amounts of complex and incomplete information and identifying key issues in complexity
   - A strong macro-ethic,
   - Ability to acquire knowledge and act in an interdisciplinary manner,
   - Ability to act in heterogeneous and multidisciplinary groups and utilize the diversity
   - Openness, creativity and flexibility in thought,
   - A strong business sense,
   - The ability to empathise with other people,
   - Communication skills (formal and informal),
   - An aptitude for lifelong learning
3. Development of a sustainability strategy and related policies
   - The ability to think and act in a forward-looking manner
   - Ability to define future requirements and interpret them into strategy

- Analytic and research skills (to research, identify and evaluate different sustainability policies, standards, legislation, regulations)
- Ability to understand and deal with different tools and methods that are addressing sustainability from various points of view
- Ability to manage cost implications of sustainability
- Communication and negotiation skills (to consult relevant stakeholders)
- Social networking skills
- Ability to introduce new business model
- Ability to plan cross discipline work
- Ability to search for relevant feedback
- Decision making
- Creativity and resourcefulness
- Ability to cope with change
- Readiness to compromise
- Ability to understand emerging market trends

4. Communication of a sustainability strategy in the organization and fostering sustainability culture
   - Ability to embed sustainability into company processes and organization structures
   - Communication and negotiation skills (communicate and effectively present the strategy and other relevant messages to critical stakeholders)
   - Consultation, delegation and empowerment (people who will be implementing the strategy; employee involvement)
   - Ability to motivate, lead awareness and drive sustainability idea forward
   - Capability to generate enthusiasm and encourage cooperation
   - Ability to develop common understanding
   - Social networking skills
   - Ability to co-operate in decision-making process
   - Readiness to compromise
5. Implementation of a sustainability strategy
   - Goal orientation
   - Ability to work through obstacles to complete assignments
   - Communication skills (effectively communicate procedures to help implement the strategy)
   - Delegation and assigning responsibilities
   - Decision making
   - Ability to effectively manage possible trade-offs (triple bottom line)
   - Ability to identify needs and take appropriate actions
   - Ability to manage cost implications of sustainability
   - Demonstrating managerial courage
   - Time management
   - Ability to engage in complex processes
   - Ability to manage multiple complex projects
   - Ability to implement cross discipline work
   - Ability to work under pressure
   - Ability to deal with differences and contradictions (not rushing to a single solution but handles tensions)
6. Formation and leadership of multi-disciplinary teams (multidisciplinary cooperation)
   - Social networking skills (building multi-sectoral and multi-stakeholder networks)
   - Communication, verbal and negotiation skills (ability to listen to others)
   - Flexibility
   - Ability to build positive relationships with others
   - Ability to motivate

    - Ability to drive sustainability idea forward
    - Capability to generate enthusiasm and encourage cooperation
    - Ability to express complex issues when dealing with people coming from different backgrounds (in multidisciplinary teams)
    - Ability to utilize diversity in teams
    - Ability to take over different perspectives
    - Tolerance and acceptance with regard to other disciplines
    - Demonstrating managerial courage, leadership
    - Problem solving and conflict resolution
    - Ability to supervise the work of the team
    - Readiness to compromise
7. Review, evaluation and reporting of strategy implementation
    - Analytic skills
    - Ability to interpret the relevant data
    - Ability to provide feed back to key stakeholders
    - Ability to investigate success
    - Deliver rewards and recognition (e.g. other people's decisions and actions that favour sustainability)
    - Ability to drive results across multiple simultaneous projects

The main target groups addressed by the serious game described in the following section are young management professionals and engineering students involved in manufacturing relevant courses (e.g. MBA students with an experience level of two years). The serious game is applied in a blended learning concept: First, students get a series of lectures on sustainability followed with gaming sessions to deepen acquainted knowledge.

Serious Gaming seems to be the most promising approach to generate competences as mentioned above due to the complex and inter-linked competences. In the mid 90s of the 20th century, unaware of the term Serious Gaming, several research institutes started to develop games to be applied in the domain of manufacturing (Hauge et al. 2010). Most of these games have been developed either at one single institution or as a part of multi-national research projects. Furthermore, Hunecker (2008) presents a game that aims to help the player understand complex production systems. The game uses a resource-based process model in which a process transforms resources from one form to another. The payer's goal is to use the resources in a way that maximizes profit. Another serious game within the area of production systems is presented in by Duin et al. (2007). In this game the player manages a production system and competes on a global market. The game aims to teach young management staff strategic decision making in global production.

Serious games can be very effective for teaching sustainability to students as they not only convey hard/technical skills but also mediate soft skills like collaboration, creativity and communication (Scholz-Reiter et al. 2002; Hauge et al. 2010), thus tackling wicked problems that are characterized by a high degree of complexity, uncertainty and conflict and are not usually addressed by other learning methods. According to Digiesi et al. (2010) experiential and problem-based learning performed through a competitive serious game helps practitioners, engineers and master students in being aware of the overall problem complexity of sustainability (e.g. addressing the triple bottom line of sustainability).

A SERIOUS GAME MEDIATING COMPETENCES IN SGM

Requirements for the Serious Game

The methodology for collecting and defining user requirements for the Sustainable Manufacturing Scenario is based on two premises:

1. The requirements engineering is incremental and iterative. Therefore, each report just provides a snapshot on the results of requirements engineering for a specific point in time.
2. The methodology to elicit, document and manage user requirements which has been used in earlier phases of the TARGET project is also applied in the Sustainable Manufacturing area. Small modifications concerning the templates have been done. The methodology is based on the Volere template (Robertson & Robertson, 1999).

The requirements presented in the following chapter arise from two main sources:

1. Interviews with subject matter experts have been performed. Besides the collecting of information about necessary competences to implement SGM those experts were also asked to provide potential requirements for a system supporting the learning of such competences. These interviews were performed by various consortium members of the TARGET project.
2. The SGM game scenario is continuously developed and refined. A critical reflection and analysis of that scenario also provided valuable input for the requirements analysis.

The template shown in Table 1 has been used for elicitation and documentation of user requirements within the interviews. The same table has also been applied while analysing the GSM game scenario.

In total 45 requirements have been identified from which are 15 functional requirements, 22 usability requirements, three security requirements and three organizational requirements. Two requirements are related to costs. As for the date this chapter is provided not all of the scheduled interviews have been completed it is expected that further requirements will emerge in future. Table 2 provides some examples of identifies user requirements.

Methodology

Unlike entertainment games, serious game development relies on a close collaboration between game designers and developers and domain experts, as game designers and developers are usually not familiar with the pedagogical content, whilst domain experts rarely have the skills to design and build games (Eck 2006). Anecdotal

SGM-FU-04	Sustainability Dimensions in Simulation	None
SGM-FU-05	Environmental Indicators in Simulation	None
SGM-FU-08	Resembling a Real Office	None
SGM-FU-09	Permanent Access to Data	Concerning simulated data.
SGM-FU-10	Staff Meetings (Virtual)	None
SGM-US-01	Positive User Experience; Responsive Environment; providing hints when player get stuck	None
SGM-US-02	Accurate Virtual Reality	This raises security issues when the environment of the customer is accurately modeled.
SGM-US-04	Real Life Examples (which happened already at the customer)	None.
SGM-US-05	Provision of SGM Knowledge	Provision of learning materials.
SGM-SE-01	Anonymity	Could be conflicting with SGM-OR-01, SGM-OR-03
SGM-SE-02	Secure Access to the TARGET System	None
SGM-OR-01	Integration of Colleagues / Partners (Multiplayer)	None

evidence suggests that gathering and using information via traditional mechanisms such as focus groups and interviews for serious game design can be problematic. For example, in the case of the Virtual Leader serious game, plans for close collaboration with domain experts were eventually dropped when it became clear that the insights yielded would be difficult to integrate into the game. In the end, the game design relied on a crafted approach confined to the ideas of the developers (Aldrich 2009).

The adopted methodology (Seager et al 2010) to devise the serious game in the domain of sustainable manufacturing is based on a structured approach to game design for serious games by extending the Applied Cognitive Task Analysis (ACTA) method, resulting in Table 3.

The Game Scenario

The game scenario reflects the phases an enterprise has to run through when dealing with sustainability issues. The first phase – the initialization phase – is about identification of problems and issues concerning sustainability. The enterprise checks whether it is already compliant with sustainability standards or whether there is potential for improvements. An outline of new sustainable processes within the enterprise is developed. During the second phase different options concerning process standards, product standards, and other company wide standards are evaluated. Examples for standards are: ISO (International Standardization Organization), EMAS (Eco-Management and Audit Scheme), or GRI (Global Reporting Initiative). During the third phase a decision has to be taken about what standards to apply or introduce in the organization. The fourth phase is the realization or implementation of the decision follow by the last phase which concerns reiteration, i.e. continuous improvement on the selected standard and restarting the process with other standards.

Enterprises dealing with sustainability issues often apply a standard called Life Cycle Analy-

Table 3. Steps of the methodology

Step	Description
1	Determine who the target learner is
2	Determine the overarching competence to be captured by the game
3	Breakdown the chosen competence into critical incidents
4	For each critical incident: Identify main task and the main decisions that a learner must do Explore various alternatives Identify what is difficult and challenging in those decisions Identify typical mistakes made by a novice, along with cues/strategies to deal with mistakes If critical incident involves more than one character, identify how they can be used to shape the situated context towards achieving the desired learning outcomes
5	Define the task model
6	Identify the belief, desire and intentions for the agents representing the different characters

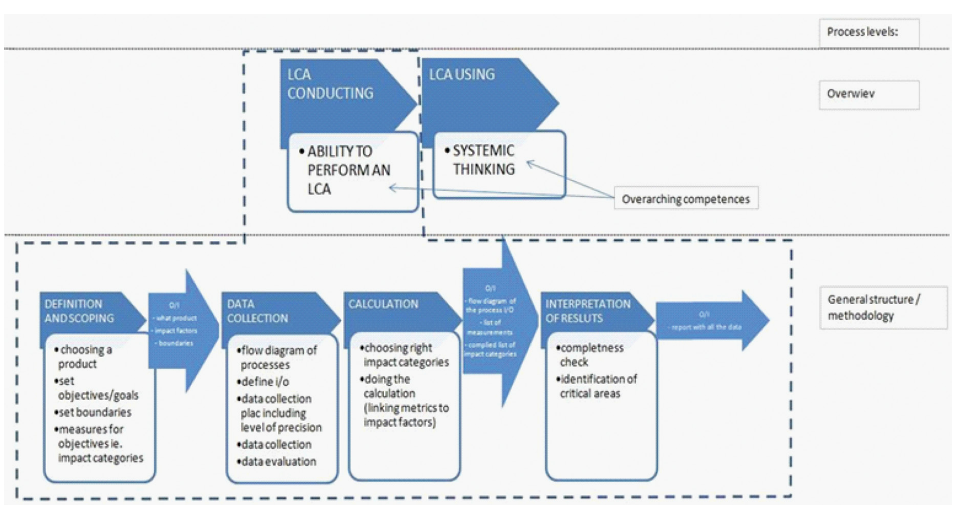
sis (LCA) to identify environmental impacts of their organization, products or processes (Curran, 2006). Generally, the application of LCA includes two major phases (see Figure 2):

1. Conduction the LCA, i.e. defining the scope of the analysis, collecting necessary data, to calculate the environmental impacts and to evaluate and interpret the results.
2. Using the results of the LCA to decide on enhancement measures to reduce the environmental impact.

This LCA process serves as our first case in the context of the SGM game scenario. The overarching competences addressed by this case are the ability to perform an LCA and systems thinking.

Within the game scenario the player takes over the role of a Sustainability Manager who was recently hired by the CEO (Chief Executive Manager) of a production company. When starting the game scenario the player finds himself in a meeting with the CEO and other important managers (production manager, logistics manager, human resources director, etc.). The CEO introduces the

Figure 2. The life cycle assessment (LCA) case



plan that a LCA should be conducted concerning a specific product and advises the player to do so. He also urges the other managers to support him. The CEO and the other managers are non-player characters who are driven by a sort of artificial intelligence of the game engine. After the meeting finishes the player – who is already familiar with the process of conducting a LCA – starts to execute the four phases.

In the first phase (scoping of the LCA) the player has to define the objectives and goals of that LCA. He can do so by just deciding on the information he got from the CEO or by interviewing other managers. On whatever he decides it will have some impact on costs, time and the final quality of the LCA. The next step for the player is to decide on the boundary, i.e. focusing on a specific department, or focusing on the production, or focusing on the whole supply chain or analyzing the whole life cycle of the selected product. The player is supported by a virtual LCA Tool where he enters the decisions he has made.

During the second phase (data collection) the player needs to draw up the process(es) necessary to produce the selected product. A process step is considered as a black box which has some inputs (materials, parts, energy, etc.) and outputs (parts, products, waste water, pollution, etc.). All process steps are put together to a flow diagram which determines what data needs to be collected. Again, the player has virtually any freedom to do this job. He can e.g. ask the production manager about the processes, he can talk to the shift managers or he is visiting the shop floor by himself to see how production is working. After identifying what data is needed he is going to collect that data by asking colleagues to provide it. The results are entered in the virtual LCA tool.

The third phase is about the calculation of environmental impacts. To do so, the right impact categories need to be selected. The final calculation is done by the virtual LCA tool which also reports whether all necessary data has been entered or not.

Finally, the fourth phase is checking the completeness and consistency of all collected data and the evaluating the results in terms of impacts per category. The final result is a report to be created with the virtual LCA tool and delivered to the CEO. Connected with this report is the costs and time which was needed to generate that report and its quality (meaning the right focus, correctness of processes and collected data).

For inexperienced users of the LCA method there are several opportunities to make mistakes while executing the conduction of a LCA. The following Table 4 provides an overview on the challenges a player is confronted with when conducting a LCA.

Typical mistakes a novice in LCA can make include:

- Setting wrong goals and objectives, selecting too little or too many parameters
- Ending with an unbalance between overall quality, time and costs in conducting the LCA project
- Choosing planned vs. real process execution facts
- Too broad or too focused boundaries for the LCA
- Selection of wrong or not relevant impact categories for the LCA
- Lack of holistic view of interviewed persons: usually people's knowledge does not cover overall end-to-end processes
- Lack of holistic and systematic view of player
- Incomplete or wrong definition of the product production processes
- Incorrect definition of the unit of measurements
- Incorrect use of measurement units
- Biased measurements
- The player does not understand each of impact category
- The player has focused too much or too less in details of each impact category

Table 4. Challenges for the player while conducting a LCA

Phases	Challenges and Opportunities for Mistakes
Phase 1 Definition and Scoping	The selection of objectives and goals (parameters) has direct impact on the result of LCA. A wrong choice of parameters can have negative impacts on the overall quality, time and costs of the LCA project. The player has the challenge of getting information from the right source of information. The player should choose from whom he wants to get the information. The player needs to define the scope of LCA in order to outline how to proceed, make efficient use of time and resources, the final results obtainment and better identification of boundaries. The system boundary determines which unit/department and which processes are included in the LCA and must reflect the goals of the project.
Phase 2 Data Collection	The determination of inputs and outputs in each process will help the player to better understand what data is required to collect. The player needs to define the measurement units correctly. Any incorrect or biased data will lead to wrong results and at the end it would negatively impact on quality, time and cost indicators of project. The determination and selection of the right impact categories for conducting the LCA could influence the overall time, quality and cost of LCA project.
Phase 3 Calculation	The whole LCA process is based on data and the player's ability to capture complete and accurate data. The players need to have the ability to dynamically re-scope the project in case of finding any insufficiency in the captured data. In the real world there are many possibilities to conduct the LCA process. Finding the most efficient order is a challenge for player.
Phase 4 Interpretation of Results	The interpretation of results is difficult in regard to the appropriateness and correctness of data in relation to the parameters and the impact categories of the LCA.

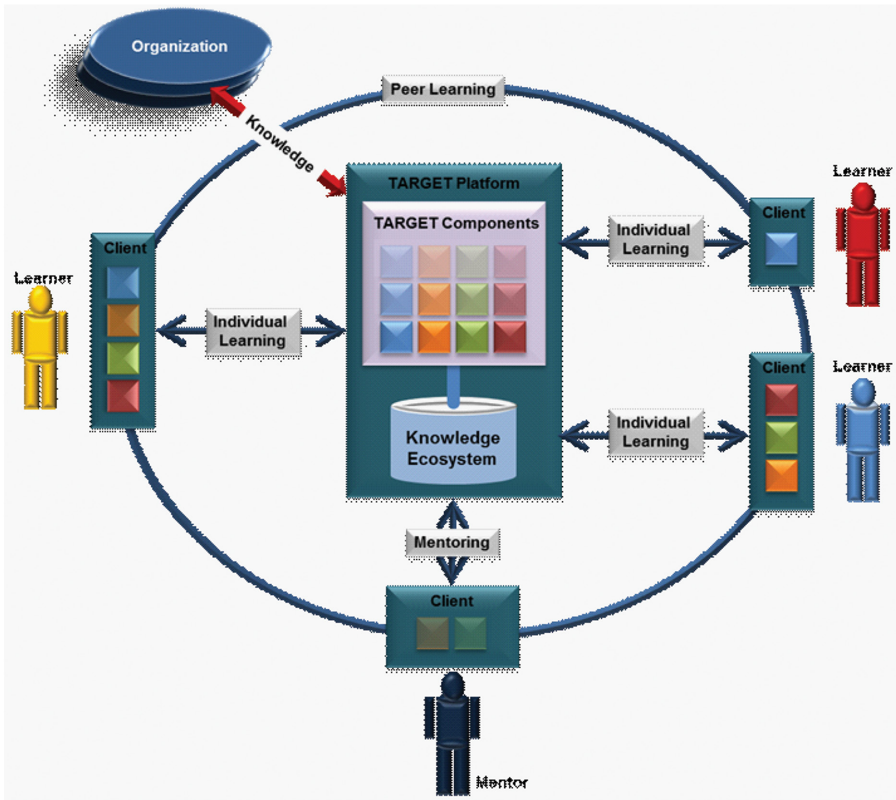
- The player has no idea of availability of data
- The player has problems with interacting with involved people and getting information from them
- The player just conducts desk work instead of going and visiting the shop floor level
- The number of conducted interviews is not adequate
- The player changes his mind too frequently and too often re-scopes the project
- The player does not re-scope the project when needed
- The player cannot decide on the quality of captured data
- The player couldn't find the most efficient order in executing the necessary steps of a LCA
- The player has a too narrow view and cannot see the different possibilities in conducting each phase

Implementation and Discussion of the Game Scenario

The Transformative, Adaptive, Responsive and enGaging EnvironmenT (TARGET) project aims to develop a novel Technology Enhanced Learning (TEL) platform that provides learners with a responsive environment that addresses personalized rapid competence development and sharing of experiences. The approach taken reflects upon James Baldwin's paradox (Baldwin, 1911) "*in order to be social you have to be individual and in order to be individual you have to be social*", thereby treating learning as a non-linear process moving away from a dichotomy of individual and social aspects of learning, whilst emphasizing dialogue and transformation (e.g. Threshold Concepts Framework (Flanagan et al, 2010)). An overview of the TARGET platform and its main stakeholders is captured in the diagram of Figure 3.

The resulting platform is based on an open architecture that supports different learning domains, with the project delivering support for the

Figure 3. Overview of the TARGET platform and its main stakeholders



domains of global sustainable manufacturing with strong focus on soft skills. In TARGET, the learning process draws heavily from Problem Based Learning (PBL) (Barrows and Tamblyn, 1990) and Action Learning (AL) (Gabrielsson and Politis, 2010), resulting in the use of digital interactive stories that provide situated rich contexts where a learner is required to apply and develop competences to achieve successful outcomes.

The approach taken in TARGET was to avoid developing another complete TEL platform, which would require the resulting platform to compete with an already established competitive market of existing solutions catering the needs of the enterprises concerning the human resource management landscape of services and tools. Consequently, the TARGET approach was to leverage the Service Oriented Architecture (SoA) alongside the "mash-up" paradigm to define an open framework of components can be put together in different destination platforms. As an example, one may consider the ROLE1 platform or even a well-established solution like iGoogle as feasible destination platforms for deployment of the TARGET platform.

The instantiation of the TARGET Learning Process is illustrated in the diagram of Figure 4, which can be characterized in the following stages:

- **Competences**. The TARGET Learning Process begins with the learner deciding on what competences to develop. This is done in one of two ways, either goal-oriented or self-directed learning. In the case of goal-oriented learning, the learner defines their current competence profile and their desired learning outcome in the form of outlining their target competence pro-

Figure 4. Overview of the TARGET learning process

file. The result of profiling leads to the creation of a learning plan based on custom stories tailored to the particular needs of the learner. Each story captures a business context, which may also involve defined characters with particular roles. The process of creating the learning plan is governed and shaped by a learning strategy that is chosen by the learner. In the case of self-directed learning, the learner builds their learning plan from the experiences of others within the community and these are stored in the knowledge ecosystem.

- **Story**. The learner is provided a background to the Story, which gives insight into the context, including the various characters available and their role in the Story. Some of the characters are available to the learner to be played by them, but in many cases the characters are only manipulated by non-learner character.
- **Experience**. Whilst engaged with the Story, the system provides an environment where the learner engages with other characters (either controlled by another learner or a Non-Player Character) and the environment, enacting their decisions. These decisions will have an impact which will affect and change the situated context of the Story. By monitoring the actions of the learner and taking into account the desired learning outcomes, the TARGET platform makes changes to the Story if necessary. As examples, these changes may be modifying the personality of a Non-Player Character to be more confrontational or delaying tasks within a project.
- **Reflection**. The learner is presented with the assessment of their competence during the experience in the form of a timeline manner. The ability of looking back on their decisions by reviewing how the story unfolded whilst cross-referencing the assessment of their competence at each point in time, allows the learner to evaluate their performance leading to reflection.
- **Peer Learning**. The TARGET learning process supports the learner in externalizing the tacit knowledge acquired after their experience of a Story, thereby contributing

to the creation of knowledge assets that are uploaded to the Knowledge Ecosystem. Once uploaded, the learning community plays an important role in the process with the support of recognized mentors as facilitators and in discussion with other learners. The social aspects address the need of an ability to deal with flux and instability, and to thrive in situations of flux (Kelly 1994).

Each of the four phases of the TARGET learning process is supported by a set of well-defined services embodied into components that are event driven, thus loosely decoupled from one another with some sharing functional dependencies. This means that the TARGET platform need not be entirely deployed as an integrated solution, but only subsets of the supported functionality. However, one needs to ensure that those components sharing functional dependencies are deployed together otherwise they may be operational at run-time but not work as required.

The adopted architectural design enables the platform functionality to be extended from the baseline features developed within the scope of the TARGET project and to replace existing components with alternate ones, provided there is compliance to the interfaces and the communication mechanisms.

The TARGET platform is geared towards a relatively thin client, which manages the flow supporting the TARGET learning process and provides interfaces for the different components. So within the context of the project, the learner engages with the TARGET platform through a web-based client, which interacts with the different TARGET components residing on the backend server. The decision to adopt a web based solution minimises adoption barriers associated to the deployment of technological solutions in corporate environments. However, it is possible for an organization to consider the deployment that is not necessarily web-based.

FUTURE RESEARCH DIRECTIONS

Future research in the context of the competence development will involve further modeling of competences in a way that reflects their complexity by incorporating more of the contextual factors to competences and illustrate how these contextual factors and the competences themselves are related to each other. This will furthermore facilitate the design of appropriate personalized learning plan and to associate specific competences to appropriate game scenarios. Additional application of the competence model in the field of sustainable global manufacturing will allow the identification of operationalized and measurable performance indicators taking identified contextual factors into account. The identified performance indicators and observing their occurrence within the context of the serious game will allow provide the evidence about the presence of the specific competences and sub-competences and therefore allow effective assessment.

While the implementation of the game scenario of performing a Life Cycle Assessment within the TARGET platform continues, first insights and experiences are quite promising. Therefore, besides simple testing an evaluation on a larger scale needs to be performed to collect user feedback. The objective of the evaluation is twofold: First, the believability of the game scenario has to be proven by involving subject matter experts (i.e. managers who have already substantial experience in performing an LCA in a corporate context). Second, expectations on competence enhancement in learner target groups need to be evaluated in comparison with other methods. User feedback will be interesting especially for the evaluation of the personal progress in that field (i.e. how engaging is the game and does the cognitive load balancing really works).

The development process in the TARGET project is based on agile principles. It is expected that new requirements will emerge while the implementation of the system matures. Also, the development of other game scenarios, e.g. based on another standard like the GRI, will lead to new requirements coming from the stories to be developed.

CONCLUSION

This chapter introduced the topic of Sustainable Global Manufacturing and related competences as an application area for Serious Gaming. While traditional manufacturing problems have already been addressed by serious games, the application area of Sustainable Manufacturing is new in this field.

The intended platform for game execution is called TARGET and combines functionality for mentoring and individual as well as peer learning. The TARGET platform allows the management and development of competences through story generation, experience acquisition and peer learning through reflection. As this platform is still under development only early reflections from pilot users are available but not yet formally recorded. The tenor of feedback received so far was positive. However, a large scale evaluation of the TARGET Platform and the SGM Scenario still has to be performed.

ACKNOWLEDGMENT

This work has been partly funded by the European Commission through the Project TARGET under contract No IST-FP7-231717. The authors wish to acknowledge the Commission and all project partners for their support.

KEY TERMS AND DEFINITIONS

Competence: Within the TARGET project, a competence is defined as a specific, definable and measurable knowledge, skill, ability and/or other deployment-related characteristic (e.g. attitude, behavior, physical ability) which a human resource may possess and which is necessary for the performance of an activity within a work context. An overview of definitions of competences is available in Sampson and Fytros (2008).

Life Cycle Analysis: Is a "cradle-to-grave" approach for assessing industrial systems. "Cradle-to-grave" begins with the gathering of raw materials from the earth to create the product and ends at the point when all materials are returned to the earth. LCA evaluates all stages of a product's life from the perspective that they are interdependent, meaning that one operation leads to the next. LCA enables the estimation of the cumulative environmental impacts resulting from all stages in the product life cycle, often including impacts not considered in more traditional analyses (e.g., raw material extraction, material transportation, ultimate product disposal, etc.) (Curran, 2006).

Serious Gaming: Serious games are computer and/or video games used beside entertaining goals for educational technology. Serious games can be of any genre and many of them can be considered a kind of edutainment. Computer based serious games are an e-Learning methodology (Thoben et al, 2005)

Sustainable Development: Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own need (Brundtland, 1987).

Sustainable Manufacturing: Sustainable manufacturing deals with the application of sustainable development in the manufacturing sector. Commonly agreed measures in sustainable manufacturing include e.g. reduction of energy and raw material use, substitution of toxic and non-renewable materials, reduction of unwanted outputs (pollution, waste), reuse (recycling) of outputs, change structures of ownership in global manufacturing.

Chapter 44
Reengineering for Enterprise Resource Planning (ERP) Systems Implementation:
An Empirical Analysis of Assessing Critical Success Factors (CSFs) of Manufacturing Organizations

C. Annamalai
Universiti Sains Malaysia, Malaysia

T. Ramayah
Universiti Sains Malaysia, Malaysia

ABSTRACT

Reengineering is a concept that is applicable to all industries, particularly information and communication technology (ICT) projects regardless of organizational type, size, culture, or location. The enterprise resource planning (ERP) system frequently requires organizations to change their existing business processes to harmonize them its functional activities. 72% of the ERP implementation failures reported worldwide (Eric, 2010) because of the various critical success factors (CSFs). A Critical Success Factor (CSF) is defined as a factor needed to implement ERP system successfully. Assessing the importance of CSFs of Enterprise Resource Planning systems has always remained an important concern for academicians and researchers. This study explores and assesses the CSFs affecting the ERP implementation success. Long term Top management Support (LTS), Perceived ERP benefits (PEB), ERP in-house Training (EIT), Project Tracking (PTG), Visible Project Phases (VPP), Project Phase Update (PPU), Interdepartmental Cooperation (IDP), Strategic IT planning (STP), ERP vendor Support (EVS), and Data Analysis and Conversion (DAC) were found dominant critical factors for the success of the ERP implementation in the manufacturing sector. This study investigates how many CSFs are strongly correlated with each other for the success of ERP projects in the manufacturing sector. Furthermore, this study also tests empirically using the Statistical Package for Social Science Analysis of Moment on Structures (SPSS AMOS 18.0) to justify the level of CSFs among the local and joint-venture companies using a t-test analysis.

DOI: 10.4018/978-1-4666-1945-6.ch044

1 INTRODUCTION

An organization must proactively reengineer and plan for changes to business process before implementing a particular ERP module. The following are the important modules of ERP: sales and distribution, production planning, financials and controls, material management, and human resource management. Critical success factors (CSF) help implementing ERP system successfully. Alaranta (2006) pointed out the growth of information systems in the organizations resulted in the production of significant amounts of information for analysis and decision making which leads to the success of the information system projects, in particular enterprise resource planning (ERP) systems. Many research studies discussed numerous CSF factors that are needed to minimize the ERP failure rates (Eric, 2010; Cotran et al. 2005; Deloitte, 2005; Esteves, 2005; Al-Mashari, 2003; Nah & Lau, 2001).

A legacy system is an operational system that has been designed, implemented and installed in a radically different environment than that imposed by the current ICT strategy (Tromp & Hoffiman, 2008). The only reason a new system is developed is to replace an aging system (i.e. legacy system) that is failing to meet current enterprise needs. Ransom et al. (1998) pointed out that legacy systems are usually critical to the business in which they operate, but the costs of running them are often not justifiable. Furthermore, the legacy system contains the existing information technology (hardware and software), business processes, organization structure, and culture.

Appropriate business and legacy systems are important in the initiation stage of the project life cycle. Because of integrated nature of the ERP package, there is a choice to be made on the level of functionality and approach to link the system to legacy systems. In addition, to best meet business needs, companies may integrate other specialized software products (i.e. third party software packages or interfaces) with the ERP suite (Nah & Lau, 2001).

Many researchers highlighted that ERP implementation involves a complex transition from legacy information systems and business processes to an integrated IT infrastructure and common business process throughout the organisation (Al-Mudimigh et al. 2010; Jarrar et al. 2000; Gibson et al. 1999).

Al-Mashari (2003) and Seethamraju (1999) suggest that future ERP systems will be developed based on components rather than modules and will be designed for incremental migration rather than massive reengineering. Furthermore, Sato *et al*. (1999) identified several areas for future research, including integrating ERP and other business intelligence systems such as customer relationship management (CRM), supplier relationship management (SRM) and business data warehousing (BDS).

Most authors preferred an incremental approach to implementing either the business process reengineering (BPR) or ERP systems (Tromp & Hoffiman, 2008; Calvert, 2006; Robey et al. 2002). Hill (1994) pointed out rapid IT innovation and increasingly intensive global competition as two main reasons why organizations have had to consider the introduction of radical change. Reengineered processes drive the shape of an organization. These radical changes are not limited to inside the organization but can go beyond to other organizations, which generate innovative views for an organization (La Rock, 2003).

Most researchers lately found the actual acceptance of incremental or cyclical Enterprise Systems (ES) implementation approaches are slowly beginning to become authentic. In the last century the incremental implementation of ES was mentioned (Nagaraj et al. 2010; Mezeszaros & Aston, 2007; Karimi et al. 2007; Katsma & Spil, 2003). But the massive technology behind the ERP systems at first forbidden actual incremental implementation approaches. This technological hurdle is only slowly disappearing via the implementation of for example service oriented architecture (SOA) or software as a service (SAAS) based technologies.

The chapter is presented in ten main sections as follows: Section 2 describes research framework; Section 3 provides a detailed review of the CSFs, Section 4 discuss implementation success (IS), Section 5 illustrates data collection, Section 6 analyzing the results, Section 7 deals with the implications of the CSFs on IS, Section 8 discuss research limitations of this study, Section 9 describes future direction of this research and Section 10 concludes.

2 RESEARCH FRAMEWORK

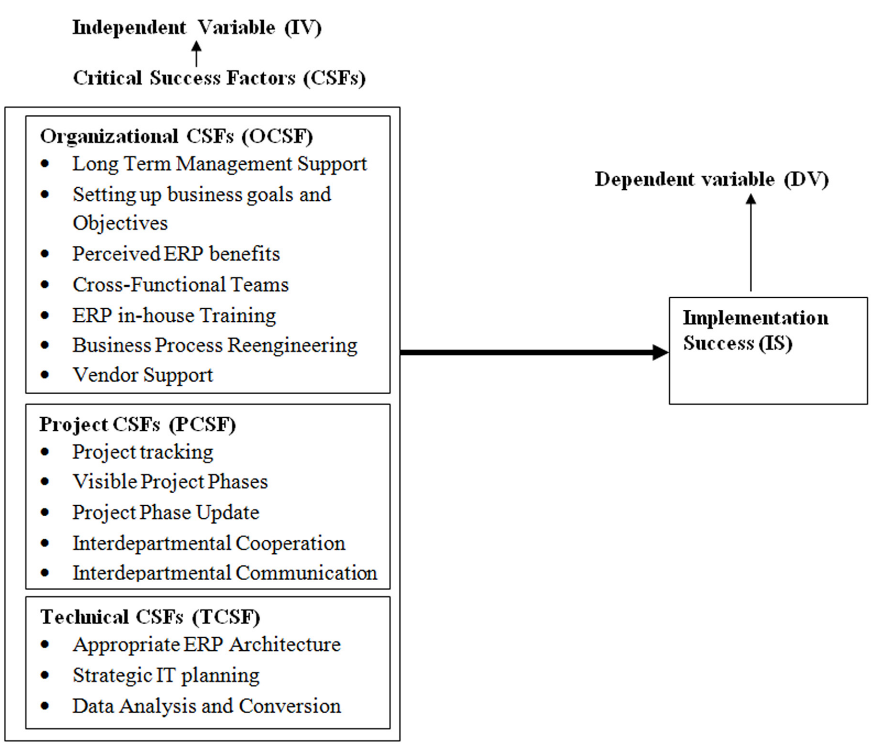
The research framework for the CSFs (the independent variable) on the ERP implementation success (IS as the dependent variable) is as shown in Figure 1. The above framework is proposed and used to assess the success of a migration effort from a legacy system to the new system that has to be measurable. Therefore, a number of critical success factors (CSF's) must be defined against the implementation success to measure the direct relationship between them. These success factors are used to check the correlations among each other which are very important to make a decision in the strategic plan and in line with the organization's business objectives (Tromp & Hoffiman, 2008). In this particular case, the following CSF's were identified based on the organizational, project and technological aspects which are described below in the next section.

3 LITERATURE REVIEW ON CSFs AND IMPLEMENTATION SUCCESS (IS)

3.1 Organizational Critical Success Factors (OCSF)

The Organizational Critical Success Factors consist of the following seven factors: long term

Figure 1. Proposed research framework



management support, setting up ERP business goals and objectives, perceived ERP benefits, cross-functional teams, ERP in-house training, business process reengineering and ERP vendor support.

3.1.1 Long Term Management Support (LTS)

Liang et al. (2007) explored that the top management support is the topmost CSF's among all critical success factors identified in the survey of information systems implementation success (IS). Furthermore, they argue that the entire team constitutes the senior and middle level management starting from the project initiation stage until the deployment stage in the entire ERP project life cycle (Carroll & Fitz-Gerald, 2005).

3.1.2 Setting up ERP Business Goals (SEB)

Remus (2006) and Geib et al. (2005) identified that a clear vision of business goals will help the ERP project better to achieve its expected business results. Furthermore, the value of information technology (IT) investments helps align between the business processes and strategies.

3.1.3 Perceived ERP Benefits (PEB)

Most researchers (Esteves, 2005; Freeman & Seddon, 2004; Gable et al. 2002) suggest that the employees need to encourage each other and work as a team in order to achieve the full potential benefits of ERP systems. O'Leary (2004) investigated the key benefits of ERP implementation and argues that the ERP tangible benefits are consistent across various industries such as manufacturing, hardware and software where as the ERP intangible benefits differ across the industry.

3.1.4 Cross-Functional Teams (CFT)

The communication must be shared across the cross-functional teams among the ERP with other systems; for instance Supplier Relationship Management (SRM) systems, Customer Relationship management (CRM) systems which will play a dominant role in the success of technology project. El Amrani et al. (2003) highlighted that this cross-functional systems help to reengineer and improve the business processes across the enterprise and further stated how challenging it was particularly in small medium enterprise (SME) sectors.

3.1.5 ERP In-House Training (EIT)

Mabert et al. (2003) and Sumner (2000) pointed out that when the ERP system is up and running it is very important that the users be capable of using, hence they should be aware of the ERP logic as well as concepts and should be familiar with the system's features.

3.1.6 Business Process Reengineering (BPR)

Markus and Tannis (2000) observed that the business process is based on best practices and reengineering the vision of business process through new methodology in information technology is crucial for information system success (Huq et al., 2006; Cao & Rahmati, 2005).

3.1.7 ERP Vendor Support (EVS)

Xue et al. (2005) and El Amrani et al. (2003) recognized that the ERP vendors need to provide support to the interfaces with cross-functional systems. In addition, they also have to realize the impact of implementation failures in cross-cultural issues.

3.2 Project Critical Success Factors (PCSF)

The Project Critical Success Factors consist of the following five factors: project tracking, visible project phases, project phase update, interdepartmental cooperation and interdepartmental communication.

3.2.1 Project Tracking (PTG)

Sumner (2006) pointed out that the project manager needs to track the projects from the initiation to the infusion stage with the respective team members in order to achieve better results.

3.2.2 Visible Project Phases (VPP)

Bajwa et al. (2004) and Esteves et al. (2003) studied the ERP project phases. They argue that it must be visible from the initiation to the infusion stage to the entire team members so that they can understand better and manage the whole project until deployment.

3.2.3 Project Phase Update (PPU)

According to Brazel (2005), the ERP project life cycle phases from the initiation to infusion stage need to be updated on a regular basis and to inform the team members as well as the top management in order to succeed the implementation of ERP systems. This is in consistent with Chang (2004) research study also.

3.2.4 Interdepartmental Cooperation (IDP)

Most projects have a collaborative requirement across other departments and conflicting schedules and constraints to generate the cooperation of the resources from other departments. The paradox being that the goal in introducing technology is to introduce business functions across several departments in a seamless fashion (Sternad & Bobek, 2006).

3.2.5 Interdepartmental Communication (IDC)

The importance of communication across different business functions and departments is well known in the IT implementation literature (Nah et al., 2001), because communication has a high impact from the initiation phase until the system acceptance, as it helps to minimize the user resistance. Communication has to cover the scope, objectives and tasks of an ERP implementation project. ERP systems need to have effective communication in project team and within the organization (Sternad & Bobek, 2006; Somers & Nelson, 2004).

3.3 Technical Critical Success Factors (TCSF)

The Technical Critical Success Factors consists of the following three factors: appropriate ERP architecture, Strategic IT planning and Data Analysis and Conversion. An appropriate ERP architecture should be in place before developing the ERP system (Molla & Loukis, 2005).

3.3.1 Appropriate ERP Architecture (AEA)

Holland and Light (2001) and Hung et al. (2004) argue that a good ERP architecture is well in place and should be discussed with the top management as well as other team members so that they can understand the entire model and its functions

3.3.2 Strategic IT Planning (STP)

Forcht et al. (2007) described that the strategic IT planning is an organization's process of defining its IT strategy, or direction, and making decisions on allocating its resources to pursue the strategy. Strategic IT planning also leads the ERP to achieve organization's competitive advantage. The process of strategic planning provides a means for ensuring that the entire organization is focused on a shared purpose and vision.

3.3.3 Data Analysis and Conversion (DAC)

The data analysis and conversion factor plays a vital role towards an implementation successful of an ERP system. If one may ignore problems with data that are not fixed in legacy systems, they will be apparent in the new system as well. ERP is an integrated package and all the modules in ERP are interlinked to one another; inaccurate data input into one module will adversely affect the functioning of other modules. (Jayaraman & Bhatti, 2007; Jafari et al., 2006; Akkermans & van Helden, 2002).

4 ERP IMPLEMENTATION SUCCESS (IS) AS A DEPENDENT VARIABLE

ERP implementation success, the dependent variable in this study, is different from the traditional information system success measure; which it is not evaluated by the general users but by the project team members. The term success means that the ERP project should be completed on time and within the budget (Chen et al. 2009; Magnusson et al. 2004; Hong & Kim 2002). ERP implementation success is measured in terms of the perceived deviation from the expected project goals such as cost overrun, schedule overrun, system performance deficit, and failure to achieve the following benefits: inventory reduction, personal reduction, productivity improvement, order management improvement, technology cost reduction, procurement cost reduction, cash management improvement, revenue/profit improvement, transportation/logistics cost reduction, maintenance reduction, and on time delivery improvement (Singla, 2008).

To sum up the literature review, the weakness of the above studies were just focusing only on organizational CSFs (OCSFs) and technical CSFs (TCSFs) but very few on the other hand about the importance of ERP systems' topmost project critical success factors (PCSFs) such as the visible project phase, the project tracking, and the project phase update. This gap needs to be considered especially when it comes to ERP implementation system because of its huge investments and its long-term benefits which would further lead to guidelines for practitioners and academicians.

5 DATA COLLECTION

The main goal of this study is to explore and identify the important Critical Success Factors (CSFs) for the successful ERP implementation in the manufacturing organization. In order to test the questionnaire of this study, it was first sent by email to the senior managers of ERP systems. After the feedback was processed and analysed, some minor changes were made to the wording and layout of the questionnaire.

The final copy of the research questionnaire was posted on the web page (i.e. Blog) at http://erpphd.blogspot.com/. A link to this URL was then sent to 1269 manufacturing organization. After several follow-up emails and phone calls, only 223 responses were received and all of them were used in the data analysis. Therefore, the response rate in this study is 20.82% when compared with other studies for ERP systems is higher than those represented by Nah et al. (2007) (5.4%), and Somers and Nelson (2001) (13.5%). The response to the survey indicates that there are sufficient observations to analyze the dataset with Structural Equation Model (SEM). Hair et al. (2006) consider that samples in the range of 150 to 400 are sufficient for SEM analysis.

6 RESULTS AND DATA ANALYSIS

Test of Significance on Difference of Means

Having analyzed the first section of the survey, it was found that some statistical tests would be helpful to further justify the level of CSFs among the local and joint-venture companies. Some tests are carried out to discover whether there was any significant difference between some aspects of CSFs factors on implementation success. These tests were analyzed using an ordinary comparison t-test. In order to conduct the tests, the following hypotheses were set up to test for a significant difference between the local and joint-venture companies' means on each of the CSFs factors:

H_0: There is no significant difference between the two means
H_1: There is significant difference between the two means

Significant Difference between the Local and Joint-Venture Companies

T-test analysis has been used in many research studies to compare different means of different groups (i.e. local and joint-venture companies). The t-test was carried out to investigate if there are any significance difference between the local and joint venture companies' means on each of CSFs. The result of the t-test is presented in Table 1.

Table 1 illustrated that the CSFs on IS were differed significantly ($p<.05$) with regards to their perceptions on the following CSFs: *Long term Top management Support (LTS), Perceived ERP benefits (PEB), ERP in-house Training (EIT), Project Tracking (PTG), Visible Project Phases (VPP), Project Phase Update (PPU), Interdepartmental Cooperation (IDP), Strategic IT planning (STP), ERP vendor Support (EVS), and Data Analysis and Conversion (DAC)*. These are the dominant CSFs which played a success role in ERP implementation in the manufacturing sector. Furthermore, it shows that there is a difference between the local and joint venture companies' CSFs towards an ERP implementation success in the manufacturing sector. When implementing the ERP projects, the implementers need to consider all the above CSFs and ultimately will discover that many more business processes would need reengineering after the ERP system went live.

The instrument measure of correlation analysis from the Table 2 shows that the *Long term Top management Support (LTS), Setting Business Goals and Objectives (SEB), Perceived ERP benefits (PEB), Business Process Reengineering (BPR), Visible Project Phase (VPP), Interdepartmental Cooperation (IDP), and Interdepartmental Communication (IDC*) are *strongly* correlated towards an ERP implementation success in the manufacturing sector. The CSFs such as *Cross-Functional Teams (CFT), Project Tracking (PTG), Project Phase Update (PPU), ERP vendor Support (EVS), and Data Analysis and Conversion (DAC)* have *medium level* correlation and the CSFs such as *ERP in-house Training (EIT), Appropriate ERP Architecture (AEA), and Strategic IT Planning (STP)* are *weakly* correlated toward an ERP implementation success in the manufacturing sector. The empirical result of the correlation analysis is given in Appendix 1.

7 IMPLICATIONS

The implications of this chapter include: literature review with altogether different viewpoint and synthesizing the CSFs for ERP implementation in the manufacturing sector. Such an implication provides the further scope of applying results from this review to successful ERP implementation. It is expected from the top management that CSFs would help them to better decision making in the ERP implementation from initiation to infusion of the ERP life cycle stages. While implementing

ERP projects, the reengineering experience have been difficult but rewarding to reap the tangible and intangible benefits.

8 LIMITATIONS

This chapter has some limitations. First, the study is limited to only Indian manufacturing organizations and cannot be generalized. Second, the study

Table 2. Results of CSFs correlation analysis

OCSF	Instrument Measure	Correlation
LTS	OCSF1.There have been top management support including commitment and leadership of management throughout ERP life cycle stages OCSF2.There have been enough knowledge on change management involving commitment to change and degree of process adaptation OCSF3.There have been role of top management communication about ERP benefits among all staffs OCSF4.There have been role of top management communications about ERP operations OCSF5. There have been top management support to allocate enough budget and resources	*Stronger*
SEB	OCSF6.There have been a clear goal and objectives of ERP business plan OCSF7. There have been set the goals of the ERP project before seeking top management support	*Stronger*
EIT	OCSF8. There have been training on how the new system will help improve business functions OCSF9. There have been training on how the ERP architecture works OCSF10. There have been training which should start early, preferably well before the implementation begins	*Weak*
BPR	OCSF11. There have been need to have a considerable knowledge in enterprises' Business Process Reengineering (BPR) methodology OCSF12. There have been alignment of BPR to ERP implementation OCSF13. There have been BPR which helps to contemporary measures such as cost, quality, service and speed	*Stronger*
EVS	OCSF14. There have been a good interpersonal skills between the organization and vendor OCSF15. There have been good vendor relationship with at least one firm for long term support after the implementation of the ERP project OCSF16. There have been vendors who are knowledgeable in enterprises' BPR methodology OCSF17. There have been Service Response Time which is almost immediate and lifelong commitment	*Medium*
CFT	OCSF18.There have been a policy to allow organizational team members to interface with inter-disciplinary team OCSF19. There have been mix of external consultants and internal staff involved in the ERP project OCSF20. There have been a policy that allows services and ERP functions without passing through hierarchical channels	*Medium*
PEB	OCSF21. ERP would improve in customer interaction and relationship OCSF22. ERP would improve supplier interaction and relationship OCSF23. ERP would considerably reduce raw material cost OCSF24. ERP would help to improve organization's strategic move OCSF25. ERP would facilitate better day-to-day management OCSF26. ERP would reduce lead time for customers OCSF27. ERP would considerably reduce production time OCSF28.ERP would improve organization's Return-On-Investments (ROI) OCSF29. ERP would help better resource management OCSF30. ERP would decrease Total Cost of Ownership (TCS)	*Stronger*
PCSF		
PTG	PCSF1. There have been empowered project manager and decision makers to track the ERP projects PCSF2. There have been a mechanism which would avoid budget overrun and ensuring implementation within schedule PCSF3. There have been a mechanism which would track the ERP project throughout the life cycle stages (i.e. Initiation Stage to Infusion Stage)	*Medium*
VPP	PCSF4.There have been visible project phases from the initiation to infusion stage of the project life cycle PCSF5. There have been a project champion who should provide strategic input for each project stage PCSF6. There have been a project champion market the ERP benefits back to the business process	*Stronger*

There have been CSFs approach which has been used by managers as a framework for strategic planning to direct them and achieving the goals and objectives TCSF10. Strategic IT planning provides a means for ensuring that the entire organization is focused on a shared purpose and vision.	*Weak*

is based on the opinion of respondents (questionnaire) only. The questionnaire might have excluded some important factors. Third, the results will be different if one employs moderating variables such as organizational culture or implementation stage using ERP project life cycle stages. Fourth, the entire set of data analysis is based on three ERP packages namely SAP, ORACLE and RAMCO and cannot be generalized. Finally, the results were limited to Commercial-off-the-shelf (COTS) and customized ERP packages only.

9 FUTURE RESEARCH DIRECTIONS

This research was conducted among manufacturing sector, thus further research can be done with different sectors of the organizations and to make comparison between different types of organization. For example, it would be prudent to make comparison between government and private companies, as it will give rich information pertaining CSFs in both types of companies and whether there is a difference or not, in order to make a better strategic planning to implement ERP projects in the manufacturing sector.

10 CONCLUSION

This chapter was focused on the ERP critical success factors. Despite some limitations, this study is among the first to assess the CSFs of ERP implementation success, particularly in the manufacturing sector. The aim of this study was to investigate CSFs affecting the implementation success of the ERP projects in the manufacturing sector. Further, the proposed model explains that there is difference about the CSFs on the implementation success of the ERP projects by the local and joint-venture companies. There was a strong correlation among the *seven* out of the *fifteen critical success factors* identified towards an implementation success of ERP projects in the manufacturing sector. The ERP project is not a matter of changing software systems; rather it is a matter of repositioning the company and transforming business reengineering practices. If one choose customization of the software it results in higher implementation cost and longer duration of implementation.

KEY TERMS AND DEFINITIONS

Business Process Reengineering (BPR): The project process and activities have to be aligned with the new system.

Critical Success Factors (CSF): Critical Success Factor (CSF) is defined as the factors that are needed to implement the ERP system successfully.

Enterprise Resource Planning (ERP): Enterprise Resource Planning is an integrated package with a central database supported business intelligence application such as sales and distribution, service applications, financial management, manufacturing and inventory applications.

ERP In-House Training (EIT): Train potential users on how the architecture works and how new functionality relates to the business process of a new system.

Long-Term Top Management Support (LTS): The support from the top management is important throughout the project life cycle in order to conduct a successful ERP implementation.

Perceived ERP Benefits (PEB): The primary benefits that are expected to result from the ERP implementation are closely related to the level of integration that is promoted across functions in an enterprise.

Project Phase Update (PPU): Project phases are spread out thought ERP project life cycle and are critical from the initiation phase to infusion stage and keep updated at regular intervals.

Project Tracking (PTG): Tracking the ERP projects from all phases of ERP life cycle (i.e. initiation to infusion stage).

Setting up ERP Business Goals (SEB): It is the objectives that are specific to the scope of the corporate project, the user community that is affected, and the timeline that needs to be met.

SPSS AMOS: Statistical Package for Social Science Analysis of Moments on Structures.

T-Test: The t-test assesses whether the means of two groups are statistically different from each other.

Visible Project Phases (VPP): It is the individual project stage from the initiation to infusion in an ERP project life cycle which must be visible to all team members.

Chapter 45
Optimal Pricing and Inventory Decisions for Fashion Retailers under Value-At-Risk Objective:
Applications and Review

Chun-Hung Chiu

ABSTRACT

Motivated by the popularity of Value-at-Risk (VaR) objective in finance, this chapter reviews and studies its application in fashion retail operations management. First, a formal optimization model is reviewed in which the fashion retailer aims at optimizing a VaR objective with both pricing and inventory decisions. Second, the detailed solution schemes are explored. Third, numerical examples are included to illustrate applications of the proposed models. Fourth, the performance of pure buyback contract and pure wholesale pricing contract in enhancing supply chain efficiency is examined. Insights are generated and future research directions are outlined.

INTRODUCTION

The fashion retailing problem and the newsvendor problem share many common features. The fashion retailer faces uncertain demands in selling fashion products. The purchase cost of a specific fashion product is fixed, the selling season is short, the end-of-season markdown will clear the unsold leftover, and the fashion retailer needs to determine the order quantity of the fashion product from his supplier before the selling season starts. If we check the classical newsvendor problem (see, e.g., Lau, 1980), we can see that the problem faced by

DOI: 10.4018/978-1-4666-1945-6.ch045

a fashion retailer is very close to the newsvendor problem. As a result, there are quite a number of studies which employ the newsvendor model to investigate supply chain management problems in fashion retailing. Examples include an investigation of trade promotion scan-back rebate scheme in fashion supply chains (Kurata & Yue, 2008), a mean-variance analysis of quick response fashion supply chains (Choi & Chow, 2008), and a study on risk hedging problem in multi-product fashion supply chains (Vaagen & Wallace, 2008).

Over the past few years, there are extensive studies of inventory models with the consideration of risk in the literature (see, e.g., Wu et al., 2009; Tapiero, 2005; Choi and Ruszczyriski, 2008). However, most of these studies do not consider pricing and only explore the corresponding optimal inventory policies. In addition, for those which include both inventory and pricing decisions, they only illustrate the technical details but do not show the applications of the algorithms (e.g. Chiu & Choi 2010). Since retail pricing is undoubtedly a crucial decision for fashion retailers and applications are important, we explore in this chapter the joint optimal pricing and stocking algorithms with an optimization objective based on the Value-at-Risk (VaR) function for a single-period product with price-dependent demand. We propose detailed algorithms to illustrate how the optimal pricing and stocking policies can be determined for different forms of price-dependent demand functions. This chapter can be taken as a review plus extended works supplementing the related literature (such as Gotoh & Takano, 2007; Chiu & Choi, 2010) with detailed algorithms, numerical analysis and discussions on channel coordination challenge.

The rest of the chapter is organized as follows. A literature review is first provided. The basic model is then discussed. Afterwards, the solution schemes are proposed and numerical examples are provided to further illustrate the findings. The performance of pure buyback contract and pure wholesale pricing contract in enhancing supply chain efficiency is examined. We finally conclude with a discussion on probable future research directions.

LITERATURE REVIEW

As we mentioned earlier, the newsvendor problem, despite being simple, has been employed widely to study stochastic supply chain inventory problems for fashion products. One of the major differences between the fashion retailing problem and the classical newsvendor problem is that the fashion retailer can (and actually will) decide the retail price by his own while the selling price of newspapers is fixed for the newsvendor in the classical newsvendor problem. In the literature, there are several extensions investigating pricing issue for newsvendor problem. For example, Petruzzi and Dada (1999) review and extend the newsvendor model with price-dependent demands. Under the respective analytical models, they study the newsvendor problem in which the optimal stocking quantity and selling price are jointly determined. Important theoretical insights and structural properties of the "price-setting" newsvendors are hence developed. Later on, Dana and Petruzzi (2001) extend the price-dependent demand newsvendor problem by considering the expected utility maximizing consumers who would choose between the firm's product and the competitor's product. Other related works which make use of price-dependent newsvendor models include a study of the supply chain coordination problem between a newsvendor and its supplier with price-dependent demand (Chiu et al., 2010), and a study of newsvendor model which captures the joint pricing and procurement of fashion products in the existence of clearance markets (Karakul, 2008). All these works include the joint optimal decisions in both inventory and price, and they are known to be more challenging than the works that focus solely on the inventory (i.e., quantity) decision. In fact, notice that even for the expected profit maximizing newsvendor problem, the existence of a unique joint solution (of quantity and price) is not universally true for any distributions (see Petruzzi & Dada, 1999). Moreover, between the newsvendor problem and the fashion retailer's inventory and pricing problem, there exists another major difference in which the classical newsvendor model considers a fixed and known salvage value for the unsold products while this "salvage value" can vary or even be unknown for a fashion retailer (Ferdows et al., 2004). Even though we do not consider the salvage value issues in current chapter, some prior studies which extend the inventory decision model with investigation of this issue can be found (Cachon & Kok, 2007; Karakul, 2008).

In addition to the extensions with the price-dependent demand models, there are a lot of studies that extend the newsvendor problem in other directions. These extensions include the study of a newsvendor pricing game (Chen et al., 2004), the study of a capital constrained newsvendor problem (Dada & Hu, 2008), and the newsvendor problem research with resalable returns (Mostard & Teunter, 2006), etc. In particular, more and more studies related to the newsvendor problems explore risk related issues. For instance, pioneered by Lau (1980), the use of a mean-variance (MV) objective in the newsvendor setting has become popular in exploring risk averse newsvendors. Choi et al. (2008a) apply the MV analysis to study the newsvendor problems in which decision makers with different risk-attitudes are examined. Wu et al. (2009) perform MV analysis in the newsvendor setting with a stock-out cost and they demonstrate an interesting result that the optimal newsvendor quantity under the MV setting for a risk averse decision maker can be larger than that of the risk neutral case for a demand following a power distribution. Choi et al. (2008a) apply the MV analysis to the buyback contract in a two-stage supply chain. Besides the use of MV model, the VaR and conditional value-at-risk (CVaR) approaches have also been applied in the newsvendor problem and several inventory control models.

Some related works include: the incorporation of the CVaR and mean-CVaR in the newsvendor setting (Gotoh & Takano, 2007), the VaR approach in the multi-period inventory problem (Luciano et al., 2003), the multi-product newsvendor problem with VaR objective (Özler et al., 2008), optimal inventory control with VaR measures (Tapiero, 2005). Most recently, Chiu and Choi (2010) explore the structural properties and optimization problems of the newsvendor problem with VaR considerations. Although VaR (or CVaR) has been explored in the inventory related literature, the existing works seldom demonstrate the applications of the VaR approach in a relatively realistic setting. Plus, the issue of supply chain coordination with a supply chain agent which employs a VaR objective has not been explored. As a consequence, this chapter aims at reviewing some important results related to VaR objective in joint pricing and inventory problem, exploring the details of the respective applications, and examining the channel coordination issues. Numerical examples are included and future research directions are also discussed.

THE MODEL: A REVIEW

In this section we review an analytical model which basically follows the standard newsvendor problem with price-dependent demands. First, we consider a fashion retailer which sells a short-life fashionable product with the unit purchasing cost (i.e., product's wholesale price) c, and the unit retail selling price r. Any unsold product will be cleared with a big discount at "markdown price" and we denote the net unit value of the leftover product as v. Notice that in the classical newsvendor problem, v is usually assumed to be positive. However, for the fashion retailer, v can be negative especially for some fast fashion retailers of which product turnover rate is very high and usually leftover has negative effects on their brand images and promotion of new products (Ferdows et al., 2004).

The fashion retailer makes two important decisions before the season starts: the optimal retail price and the optimal order quantity. For the demand functions, two common forms of price-dependent demand functions, namely the linear demand and the multiplicative demand, are considered (Petruzzi & Dada, 1999; Chiu & Choi, 2010): (a) The linear (L) demand: $D_L(r)=k-ar+x$, *for* $0<r\leq k/a$, where $k>0$, $a>0$; and (b) The multiplicative (M) demand: $D_M(r)=gr^{-b}x$, where $g>0$ and $b>1$. For both linear demand and multiplicative demand, we consider x as a non-negative random variable with mean μ and standard deviation σ, with a density function $f(\cdot)$ and a cumulative distribution function $F(\cdot)$. We define the inverse function of $F(\cdot)$ by $F^{-1}(\cdot)$, and $\bar{F}(\cdot)=1-F(\cdot)$.

Noting that the above fashion retailing model is similar to the newsvendor model with price-dependent demand. Therefore, we can apply the price-dependent demand newsvendor problem to capture the fashion retailing problem. Now, we consider the case that the fashion retailer is risk-sensitive and it follows the VaR approach to determine the joint optimal retail price and order quantity. We first define $\Pi_i(q,r)$ as the fashion retailer's profit under demand function $i=L,M$. For a given confidence level α, where $0<\alpha<1$, suppose that a fashion retailer wants to determine the optimal quantity and selling price so that the following is achieved,

$$\Pr(\Pi_i(q,r)\leq V)=1-\alpha,$$

where V is the profit threshold, and the probability of having $\Pi_i(q,r)\leq V$ is $1-\alpha$. Notice that V is called the VaR, with a confidence level of α.

Now, in our optimization problem, the fashion retailer would like to maximize V by selecting the optimal price and quantity subject to a constraint that the probability of having $\Pi_i(q,r)\leq V$ is no larger than $1-\alpha$:

$$\max_{(q,r)} V$$

$$\text{s.t. } \Pr(\Pi_i(q,r)\leq V)\leq 1-\alpha.$$

Notice that the above optimization problem has been defined and employed in the literature (Chiu and Choi, 2010). For a notational purpose, we define $C(\alpha)=F^{-1}(1-\alpha)$.

A SOLUTION SCHEME

With the model reviewed and defined, we present the solution schemes in this section for both the linear and multiplicative price dependent demand functions. Based on the structural properties of the optimization problem defined above and the analytical results revealed in the literature (Chiu and Choi, 2010), we have the following two algorithms for any given confidence level $0<\alpha<1$,

For the Linear Price Dependent Demand - Algorithm L:

Step 1: Define and compute: $K_{L-}=k-ac$, $K_{L+}=k+ac$.
Step 2: Compute $C(\alpha)$.
Step 3: If $K_{L-}>C(\alpha)$: The optimal retail price = $0.5(C(\alpha)+K_{L+})a^{-1}$, the optimal quantity = $0.5(C(\alpha)+K_{L-})$, the corresponding optimal VaR = $0.25(C(\alpha)+K_{L-})a^{-1}$, and the corresponding service level = $1-\alpha$; otherwise, the optimal retail price = ka^{-1}, the optimal quantity = $C(\alpha)$, the corresponding optimal VaR = $C(\alpha)+K_{L-})a^{-1}$, and the corresponding service level = $1-\alpha$.

For the Multiplicative Price Dependent Demand - Algorithm M:

Step 1: Define and compute: $B=(b-1)$, $Z=bc$, and $\beta=B/Z$.
Step 2: Compute $C(\alpha)$.

Step 3: The optimal retail price = Z/B, the optimal quantity = $gC(\alpha)(B/Z)^b$, the corresponding optimal VaR = $gC(\alpha)b^{-1}$ $(B/Z)^{b-1}$, and the corresponding service level = $1-\alpha$.

NUMERICAL EXAMPLE

In this section, we present two numerical examples.

Example 1. In this numerical example, x follows a normal distribution with mean μ and standard deviation σ, and the market parameters are given in Table 1(a).

The optimal joint solution of retail pricing and stocking quantity (inventory) under the linear demand and the multiplicative demand, and the corresponding optimal VaR values for different α are shown in Table 1(b). Moreover, the service level and the stock out probability for different values are also shown in Table 1(b). Note that for the sake of simplicity, the salvage value v is set as zero in Table 1(b).

Table 1(a). Parameter setting of Example 1

c	μ	σ	a	k	B	g
100	100	10	0.5	200	1.5	10000

Notice that α and $VaR_{i,\alpha}$ have some managerial meanings for the fashion retailer. The fashion retailer with a VaR objective can make optimal decisions based on its own managerial requirements; for example, a VaR fashion retailer who wants to provide a 95% inventory service level to the customer should follow the row with α=0.05 in Table 1(b) in setting the respective parameters (i.e., set the optimal price = 300 and optimal quantity =224 under the multiplicative demand case). Another fashion retailer (with VaR objective and under the linear demand case) who wants to sell the fashion product at a price 340, should follow the row with α=0.85 in Table 1(b), i.e., set the optimal quantity=120, and bear a high sold out probability of 0.85 but only a small maximum attainable profit of 28713.

Example 2. In this numerical example, the focus is on the profits of the VaR fashion retailers with α = 0.05 (high service level), α = 0.55 (middle between high service level and high stock out probability) and α = 0.95 (high stock out probability), when x varies. Here, x follows a normal distribution, and the market parameters are given in Table 2(a).

The optimal joint solution of retail price and stocking quantity under the linear demand and multiplicative demand, and the corresponding

Table 2(a). Values of market parameters of Example 5.2

c	μ	σ	a	k	b	g	v
100	100	30	0.5	200	1.5	10000	0

optimal VaRs with $\alpha = 0.05$, $\alpha = 0.55$ and $\alpha = 0.95$ are as shown in Table 2(b). The profit of the VaR fashion retailers having $\alpha = 0.05$, $\alpha = 0.55$ and $\alpha = 0.95$, under different market situation, i.e., different values of x, are summarized in Table 2(c).

Table 2(c) shows that the maximum attainable profit of the VaR fashion retailer is decreasing in α, while the probability of achieving the maximum profit is increasing in α. Moreover, when the market situation is bad, i.e., x is small, the profit of the VaR fashion retailer is increasing in α. For some cases, e.g., when both x and α are small, the VaR fashion retailer suffers a loss. Furthermore, the variation of profit under both the linear demand and the multiplicative demand cases for α =0.05 is the biggest among the three listed cases. Therefore, a small α of the VaR fashion retailer implies that the VaR fashion retailer shares (1) a high maximum attainable profit, (2) a low probability that achieves the maximum profit, and (3) a high variation of profit.

COORDINATION

We now consider a supply chain in which there are two echelons with one upstream manufacturer and a downstream retailer. The retailer takes the VaR objective (we call it "VaR retailer") and makes the optimal pricing and ordering quantity decisions accordingly. In the literature, under the expected profit maximizing model, owing to the double marginalization effect, a decentralized supply chain would not be optimal by itself. In particular, for the case when the retailer only makes the ordering quantity decision, a supply contract in the form of a pure wholesale pricing

contract (PWPC) cannot lead to an optimal supply chain (i.e., cannot coordinate the supply chain) whereas a pure buyback contract (PBC) can. For the case when the retailer makes both the retail pricing and ordering quantity decisions, both pure PWPC and PBC will fail to coordinate the supply chain even though PBC can enhance the supply chain's efficiency. In the following, we compare the performance of PBC and PWPC in enhancing the supply chain's efficiency with a VaR fashion retailer (as we modelled in the earlier sections).

First, we represent the unit production cost of the product by p, and the optimal supply chain price and product quantity are denoted by q_{SC*} and r_{SC*}, respectively. Under PBC, the manufacturer promises to buyback any unsold quantity by the retailer and the respective unit buyback price is denoted by E. Second, in order to guarantee the existence and uniqueness of q_{SC*} and r_{SC*}, we need some mild conditions on the demand distribution. To be specific, we assume that $\forall x \geq 0$: (a) $F(x)$ has a unique inverse function, and (b)$(1-F(x))^2/f(x)$ is decreasing in x (Petruzzi and Dada, 1999). For the multiplicative case, the logic is similar and hence we omit the details here.

We proceed to explore the performance of PWPC. First, we have Observation 1.

Observation 1: *Under PWPC: (a) For the multiplicative demand function: The supply chain can be coordinated if and only if* $q_{SC*}=gC(\alpha)[(b-1)/bc]^b$ and $r_{SC*}=bc/(b-1)$. (b) For the linear demand function: (i) When $c<(k-C(\alpha))/a$: The supply chain can be coordinated if and only if $q_{SC*}=0.5(C(\alpha)+k-ac)$ and $r_{SC*}=0.5(C(\alpha)+k+ac)a^{-1}$. (ii) When $c\geq(k-C(\alpha))/a$: The supply chain can be coordinated if and only if $q_{SC*}=C(\alpha)$ and $r_{SC*}=ka^{-1}$.

Proof of Observation 1: First, notice that by definition, coordination means providing incentive to make the retailer's optimal decisions under VaR objective to be the same as the supply chain's best decisions. Second, following Algorithms L and M, we can find the closed form expressions for the optimal decisions of the retailer under different demand functions. Combining the above two points yield the necessary and sufficient conditions and complete the proof. (Q.E.D.)

Obviously, *the required necessary and sufficient conditions as summarized by Observation 1 are unlikely to be satisfied in a general supply chain*. In other words, PWPC probably fails to coordinate the supply chain with price-dependent demands but in most cases (the multiplicative demand case, and case (b-i) of the linear demand), the retailer's optimal decisions do depend on the wholesale price c and hence adjusting c can enhance the supply chain's efficiency by making the retailer's optimal decisions closer to q_{SC*} and r_{SC*}. We summarize the key findings in Proposition 1:

Proposition 1: *In general, PWPC cannot coordinate the supply chain with a VaR retailer but it can enhance the supply chain's efficiency by making the optimal pricing and ordering decisions of the VaR fashion retailer closer to the optimal decisions of the supply chain.*

Suppose that we consider a scenario in which there is a fixed retail selling price policy in the supply chain, i.e., the retailer sells the product at a fixed retail price (which is exogenously given). This case arises in several situations, e.g., when there is a recommended standard price as requested by the fashion brand owner (for branding positioning reason), etc. In this case, the retailer only makes a decision on the optimal ordering quantity and coordination becomes achievable by the PWPC. Proposition 2 summarizes the result and the proof is similar to the proof of Observation 1.

Proposition 2: *Under PWPC and the retail selling price is exogenous: (a) For the multiplicative demand function: The supply chain can be coordinated if and only if* $c=(b-1)[gC(\alpha)/q_{SC*}]^{1/b}$. (b) For the linear demand function: The supply chain can be coordinated by settling the wholesale c such that $c=(C(\alpha)+k-2q_{SC*})/a$ and $c<(k-C(\alpha))/a$.

Following the same logic, we proceed to explore PBC. From Algorithms L and M, it is easy to prove Proposition 3:

Proposition 3: *PBC has zero impact on the optimal pricing and ordering decisions of the fashion retailer under the VaR objective. As a result, it is an ineffective incentive alignment scheme for enhancing supply chain's efficiency.*

Proposition 3 shows an interesting result that counter-intuitively, PBC can neither coordinate the supply chain with a VaR fashion retailer, nor enhance the supply chain's efficiency. This result shows a big challenge to the existing literature on the effectiveness of PBC and calls for more research to investigate the performance of different supply contracts in coordinating the supply chain when individual agents take different optimization objectives (Choi et al., 2008b).

CONCLUSION AND FUTURE RESEARCH DIRECTIONS

VaR is a popular performance measure/objective and a hot topic in risk management. Based on the existing literature, this chapter reviews and studies VaR's application in deriving the optimal pricing and inventory decisions in fashion retailing. We first review the standard analytical model and discuss the VaR related optimization model for the fashion retailer. We then propose two detailed solution schemes, one for the linear price dependent demand and one for the multiplicative price dependent demand. Numerical examples are included to illustrate applications of the proposed models and to reveal some properties of the solutions. For future research directions, one can extend the work by further considering the effect of advertising with "advertising-effort and price" dependent consumer demands and examine the respective optimal decisions with a VaR objective. Following our analysis on channel coordination, one can investigate whether some hybrid policies can successfully achieve channel coordination when the fashion retailer takes a VaR objective. It is interesting to explore the joint pricing and stocking inventory decisions for the fashion retailer with a VaR objective in both the multi-period and multi-product cases. This extension is challenging while deserves deep investigation.

ACKNOWLEDGMENT

We sincerely thank the three anonymous reviewers for their comments which help enhance the quality of this chapter. This work was supported in part by the Hong Kong Research Grants Council Competitive Earmarked Research Grant under a grant number of PolyU 5143/07E.

KEY TERMS AND DEFINITIONS

Linear Demand: Is a widely used price-dependent demand model which is a linear function of the retail price.

Multiplicative Demand: Is a widely used price-dependent demand model under which demand is the product of market parameters and the retail price.

Newsvendor Problem: Is a classical single-period inventory model with stochastic demand.

Price-Dependent Demand Newsvendor Problem: Is an extension of the newsvendor problem with price-dependent demand model.

Value-at-Risk (VaR): It is a useful and popular objective in risk analysis.

Chapter 46
Implementation of Rapid Manufacturing Systems in the Jewellery Industry in Brazil:
Some Experiences in Small and Medium-Sized Companies

Juan Carlos Campos Rúbio
Universidade Federal de Minas Gerais, Brasil

Eduardo Romeiro Filho
Universidade Federal de Minas Gerais, Brasil

ABSTRACT

This chapter presents the rapid prototyping and manufacturing concepts applied as means to reducing time between jewellery designs and manufacturing process. Different processes on jewellery modelling production are presented. Nowadays, the use of technologies as CAD/CAM - Computer Aided Design and Manufacturing in high production companies are very disseminated. However, the implementation of these resources at the design and manufacturing processes of jewels and fashion accessories, in small and medium size businesses, is still insipient. As reference, is presented the situation observed in small and medium companies located in Minas Gerais, Brazil.

INTRODUCTION

This chapter presents an analysis of the use of CAD/CAM systems (Computer Aided Design and Computer Aided Manufacturing) aiming to improve the connection between design and production in small and medium size jewellery companies located in the state of Minas Gerais, Brazil. In addition to that, the changes caused by this technology in the professional relationships are also discussed. The principal point is related to the influence of the use of CAD/CAM system on the designers' skill (competence) and design methods in an interactive design process and a Rapid Manufacturing (RM) system implementation.

DOI: 10.4018/978-1-4666-1945-6.ch046

In a global and highly competitive market, it is critical for the companies to develop distinctive products, joining aesthetic features with the effective control of the production processes, in order to ensure improved results. Within this scenario, the designer's activities are becoming more important for the jewellery industry; nevertheless, the design process is frequently regarded as an artistic activity dissociated to the industrial process. Improvements in jewel manufacturing process are extremely important, because the jewels and fashion accessories presents a high aggregate value. It is most important when raw material is abounding too. Brazil is a precious metal and stones products country, namely gold, silver, diamonds, emeralds, etc. Thus, better products imply in leadership of the market and consolidate designer's names in global market.

The intensive use of rapid manufacturing and CAD/CAM systems brings new opportunities to the integration between design and manufacturing process. Through a better assessment of the products during the preliminary phases of the project it is possible to predict mistakes that could result in additional labor, as well as increased production time and cost. In spite of technological advances and the use of machines at several stages of the industrial production of jewels (conception and execution of the first model), the process still maintains essential handcraft features. The intrinsic limitation of the manufacturing processes used in this phase for designer and goldsmith, results in mistakes which are transferred to the next phases, impairing process control and manufacturing phase. This is an important aspect to be considered in the product development, especially in small and medium size companies, which are typical of the jewellery industry in Brazil.

Changes in the communication methods and technical tools, such as CAD/CAM systems, must be carried out simultaneously with changes in the designers work method, aiming to adjust their projects to the needs of other production sections (including the goldsmith), with the purpose of obtained a finished product with the required quality. The RM concept can be used when the development of moulds or tools for moderate volume parts or products is required. Among the various RM processes, computer numerically controlled (CNC) machining is recognized as the technology most widely used in industry for the application of CAD/CAM systems. The production of jewels is based on the investment-casting process, in which the moulds and casting pattern can be produced in plastic or wax using an RM technology, thus reducing time and cost as well as ensuring the production of goods with high quality.

Different researches (as Rocha, 2007, Fernandes et al., 2005 and Han Boon et al., 1992) indicates that the use of Computer Integrated Manufacturing (CIM) systems can offer a substantial assistance to the solution of issues related to the interface between design and manufacture of jewels. However, some drawbacks associated mainly with the lack of qualified professionals (especially designers) were identified (Siu & Dilnot, 2001). The use of these technologies is only possible by employing three-dimensional CAD systems and trained professionals able to handle this task are currently not available in the jewellery industry. Moreover, the application of these tools alone is not enough to ensure the satisfactory integration of all phases of the project.

In jewels international market the Brazilian designer and manufacturer are traditionally competitive at producing small stones fashion jewellery and their skills in gem setting. These products attend the needs of its customers in terms of originality, creativity and fashion. However, the Brazilian Jewelers needing to search for ways to increase the efficiency and improves the productivity. Thus, this Chapter is concentrated on study of the rapid manufacturing innovative technique and their use in jewellery production for Brazilian small-size companies.

DESIGN AND MODELING PROCESS IN THE JEWELLERY COMPANIES

The first step of jewellery industry production process is the concept and design of a new jewel, normally by a specialized industrial designer. After design process conclusion, another professional, the goldsmith, creates a prototype that will be the base for all subsequent industrial process. The interaction difficulties observed between designers and goldsmiths in the design and production stages are various and bring many problems to production results.

The deficiencies observed in the information transference at initial stages of jewel design and production results in important consequences for next phases, including serious imperfections in the final product, re-work in the production process, increasing of operational costs and delays in delivery product. In the same way, the improvement in the initial phases of jewel production represents a global development of all process quality results. Special attention is necessary on the design product process, for the reason that in this phase are elaborated most important specifications to an adequate and balanced production process. The design decisions are fundamental to a better quality in the final product and the success in a highly competitive market.

The Design Process

The designer activity begins with the creation of a piece or collection jewel. Ordinarily, the project includes specifications about costs, market share, piece weight, materials etc. From this information, the first ideas and freehand sketching drawings are doing on paper. After that, an adequate solution selection between different proposals is selected and refined in another development phase, a detailed and formal design plan. This result is sent to production phase (Figure 1). Conventionally the jewel design includes a perspective view (in colour, with an "artistic presentation", when is possible to anticipate the formal result, close to the real appearance of jewel to manufacturing) and a technical drawing (with the essential view to execution, in most times, superior and lateral views) that includes measure and materials used, finishing, enlarged details etc.

However, this formal representation, including perspective and artistic representation, technical drawings and others technical information, sometimes is not completed. In majority, the designs are presented to goldsmith using partial or alternative draws (Figure 2), unstudied techniques in different forms:

- Colour draw with one side of the piece, accomplished with measure-simplified representation;
- Technical drawing, using ISO norms;
- Technical detail with material and dimension description;
- Sketches and drafts;
- Prototypes using alternative materials (clay, paper etc.)

About representation ways, Noguchi (2003) presents a designer interview: "Some pieces are illustrated using technical draw, surfaces, cuts etc. A clay model is used when the goldsmith is not a high skilled professional. Sometimes, when I am tired of drawing, I do only a mock-up, the "direct form". Other times I do only a "sketch" on paper. When the goldsmith is highly skilled, he almost knows the future result, if it will be satisfactory".

Figure 1. A final jewel design (including details)

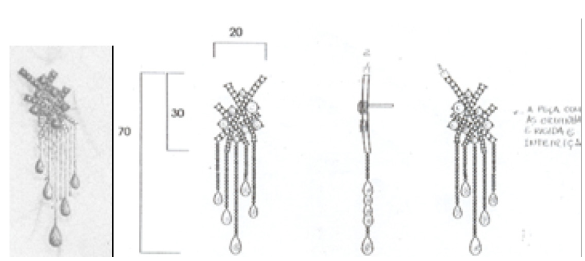

Figure 2. Jewel Design Examples. (Left: Design including only a colour draw, with material indication. Right: Design with only a 3 views draw, including fittings solutions. Source: Rocha, 2007.)

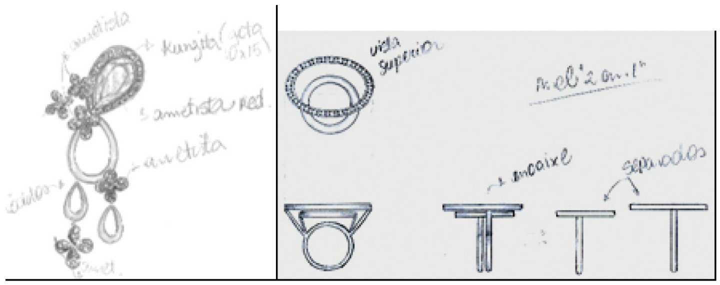


The Figure 2 presents some examples of "unconventional" designs, released by jewel designers.

The most important communication element between the conception and production steps is the jewel design. The quality and rules used in design process are important, however sometimes the information included in design documentation are not sufficient to goldsmith comprehension and don't trust the consistence in the process, requiring others representations (and communications) resources. Eventually, some design characteristics are "deduced" by goldsmith, because cannot be presented on paper as like as in a three-dimensional model. Movements, fitting systems, volume and weight of pieces are items not always adequately represented in the conventional draw. Moreover the characteristic limits on the representation process, there is the problem of the ignorance by designers about the jewel production process, its possibilities and restrictions. This fact can cause a series of incompatibilities between design and production, bringing delays and changing necessities in the pieces.

For this reason, it is usual that modelling goldsmith modify some design characteristics, adapting it to product process limits and avoiding problems in the final model. These modifications can respect and maintain the original design aspects, when are about specific adaptation as plate thickness, measurement or fitting adjust etc. However, in some cases the goldsmith change important aspects of design pieces, owing to impracticability in the production process or about difficulties in the design interpretation.

The Wax Model

After conclusion of design work, the draws are sending to goldsmith, which start the construction of a "model" (or prototype) of jewel piece, in plastic or special wax. This model can be made by metal (gold, silver etc.), plastic or a special wax (used in jewel industry). The choice depends fundamentally of the techniques used in the piece confection. In this process are used specific tools like files, saws, drills etc. in a handcraft process, until the final form of the piece.

In the traditional process, the model construction is a fundamental step at industrial process. In cases of exclusive pieces, made to order, the goldsmith finalizes his work producing the first piece directly in metal. But in the industrial process, thousands pieces can be produced from the wax model. This step (model construction) is a handcraft work and depends on highly of the goldsmith skill. For this reason, problems can be caused by limitations in the work conditions and tools. Some design pieces propose details and symmetries impossible to handcraft techniques. In the same way, complex geometric parameters turn impossible an adequate control by goldsmith about some aspects like exact weight and thickness in all points of piece, in order that the final product will be different that described in the design.

REVIEW ON JEWELL RAPID PROTOTYPING

In recent years, the use of computers throughout all engineering disciplines has obtained an increase importance. This is particularly true in activities that span the life cycle of discrete products development, namely in products design and in manufacturing. Computer-aided manufacturing design (CAD) and computer-aided manufacturing (CAM) software programs, computer numerical control (CNC) machining and Rapid Prototyping (RP) process has certainly gained momentum in the marketplace.

Several works have been published aiming to evaluate the RP process and computer technologies on the manufacturing mechanical and medical complex pieces. However, a few studies have been making of the RP techniques and CAD/CAM/CNC tools in jewellery industry. Leong et al (1998) showed the effect of abrasive jet deburring processes on the surface finishing of jewellery models built by stereolithography apparatus (SLA). The investigation aims to determine the significant parameters of the deburring process, to determine a practicable range of settings of these parameters for effective deburring, and to establish the optimum settings to the jewellery models built by stereolithography.

Traditionally, a human process planner performs the manufacturing process planning, with acquired expertise in machining practices that determines from a parts engineering drawing what the machining requirements are. Wong et al (1999) developed a decision support system to assist in the operations of typical jewellery manufacturer. The paper describes the development of a management information system with a specially designed decision support system to meet the specific requirements of Hong Kong's jewellery industry. It aims at assisting a jewellery manufacturer to make decisions in various areas of operation, including price quotation, sales analysis, materials requirement planning, vendor selection and job assignment.

Using the conventional design and production system in the Hong Kong jewellery industry as a case, Siu and Dilnot (2001) investigated the reason for the high degree of failure of design representations in the jewellery context, through illustrating the difficulties and problems (in maintaining quality of craftsmanship) when introducing CAD/CAM/RP technologies in production of craft-based object as jewellery in modern factory production. In this study, the authors affirm that the tacit-format attributes, which were separately contributed by the jewellery designers and goldsmith, can be extracted, recaptured, recorded, integrated and finally coded into CAD database.

Many commercial CAD systems have been developed for the purpose of designing jewellery (e.g., JewelCAD, JewelSpace, Rhinoceros, Matrix, ArtCAM Jewelsmith, etc). They provide graphical interfaces with excellent rendering capabilities. The majority of these systems provide built-in libraries of settings and cut gems and stones and advanced feature-based design tools. Also, the majority of these systems have the capability of exporting models to RP Machines. However, none of these systems is appropriate for designing and creating pierced Byzantine jewellery or other jewellery of this kind of detailed engraving. Stamati and Fudos (2005) shows a parametric CAD system for the design of pierced medieval jewellery, which is jewellery created by piercing, a traditional Byzantine technique. For other hand, Soo et al. (2006) applied fractal geometry for artistic product design in a CAD platform. Based on the proposed data structure, the geometrical information of the fractal can be extracted in a more effective way and the fabrication of a fractal shape for an artistic product design can be realized. The CAD platform has been employed to fabricate a physical prototype in RP technology.

Recently, in the paper titled "I want and now", Langer (2008) affirm that consumers demand for individualized products. This individualized series production, or call it mass customizations, is driving a paradigm shift for manufacturing and electronic manufacturing (e-manufacturing) with its flexible and fast response times is a major factor in the drive for change. The e-manufacturing allow delivers end products, functional parts and tools directly from computer aided design (CAD) data. A laser heats and melts powdered metals or plastics layer by layer, until the build is complete. Among the novel products with highly complex and sometimes filigreed structures and forms that are unthinkable geometries for conventional series production is jewellery, clothes, lamps, chairs or others functional parts for industry.

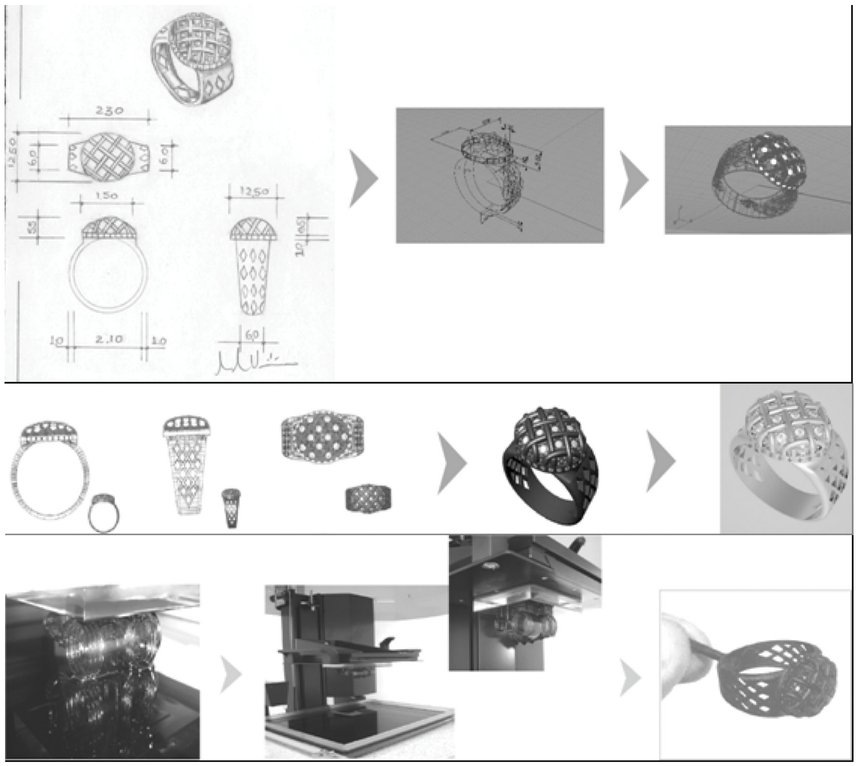
NEW TRENDS ON CAD/ CAM IMPLEMENTATION IN JEWERLY INDUSTRY

As far as concerned on computer technologies, the resources are today very popular and used in different industrial sectors since 1960 decade. At first in the aerospace and automotive industries, the CAD/CAM (Computer Aided Design and Manufacturing) has been expanded the application on jewellery. CAD Software, CNC (Computer Numeric Control) machines and Rapid Prototyping equipments are improving the jewellery sector results, bringing new competitive advantages. On the other hand, some questions obstruct an accelerated diffusion of new technologies between the users, especially in the medium and small companies. These questions are highly related to the difficult in the learning process by designers and the conflict between using the new CAD/ CAM technologies and the traditional work process, including the relationship between designers and goldsmiths.

The improvements on results of new technologies application are only possible, in practice, with an intensive use of Three-dimensional CAD Systems (CAD3D). However, the professionals with a high knowledge about CAD are almost rare, and can be observed a resistance by traditional designers in front of new tools, in general more complex and (initially) slower than the traditional sketch process. The sub-utilization and unfamiliarity with the real potential of CAD are, as a rule, the main reason of the problems observed. In fact, many designers put questions about use of CAD technologies instead of traditional sketches and manual draws. The CAD application needs a high detailed solution, which can need more time in the initial steps of design process. However, the reduction of mistakes in the next steps and the improvement of a global result, owing to a better evaluation of design alternatives, can result in a time and resource economy in a long time. These aspects justify an effort in learning and application of these systems in the product development and production process. Notwithstanding the apparent complexity, after the software learned, the total time necessary to design process can be significantly reduced with facilities to generation of new alternatives, for example.

In the midst of new exigencies of consumers, quality improvement, reduction of products life cycle (time in market) and technical innovations, the jewellery industry has slowly introducing resources as CAD/CAM. By means of its characteristics, these systems present potential benefits in a crucial problem in jewel design: the communication interface between design and production sectors. The use of CAD system associated to CAM tools and rapid prototyping technologies turn possible a total integration in the initial steps in jewel production. A CAD3D system using solid modelling is able to simulate a virtual (and three-dimensional) model, showing forms and dimensions exactly as a real piece, including elements as colour, stones and construction details. These characteristics can be anticipated and visualized in the conception stage, avoiding problems like inaccuracy interpretation, improving quality in final design and reducing fails in the production process (Figure 3).

Figure 3. An example about a jewel development process: (a) handmade sketches; (b) first studies using a CAD system; (c) wire frame perspective; (d) different views in CAD; (e) jewel perspective; (f) jewel materials simulation in CAD3D; (g) and (h) model production;(i) final model in special resin.



Using a CAD3D virtual model, the designer can visualize the final appearance of jewel, with a “rendering” resource. It is possible to simulate a change of the material (for example, testing the results in same piece applying gold or silver as material basis). The modern CAD technologies present simulations very close to the real product. Different evaluation versions can be generated quickly, without wax models or different draws. The CAD systems bring great benefits in highly detailed pieces, when the exact dimensions and mechanisms descriptions are essential. Fitting and fixation mechanisms in these models are, in practice, impossible to a goldsmith. Also in the repetition of components in different pieces (as a collection), is possible by achievement in computer memory. At long last, CAD system can automatically generate all technical information essential to production and directly send to CAM machines, evicting mistakes interpretation.

After design process conclusion by CAD, nevertheless is possible a traditional production process, with the goldsmith work. In this case, the model can be printed, in different views, including technical and “artistic” information. However, the CAD resources are better used in connection with CAM technology, especially Rapid Prototyping machines to models construction. The main advantage of this technology is the possibility of a controlled result; with sure of the model resultant have the same characteristics of designer conception. Another fundamental advantage is a possibility of adoption of complex and symmetric forms, impossible to a traditional process production, involving a goldsmith work. Finally, it is observed a sensible reduction in the time-to-market, since the design and production process are integrated and the time between conception and production is progressively reduced.

METHODS USED IN JEWELLERY MANUFACTURING

Several techniques have been employed to make jewellery from gold and silver and its alloys are Investment Casting, Die casting, cuttle fish casting and hand fabrication. Many jewelers use CAD/CAM to make jewellery. CAD (Computer Aided Designs) and CAM (Computer Aided Manufacturing) to reproduce a model piece of jewellery that can be mass-produced. Making jewellery requires knowledge and expertise in gold smiting, stonecutting, engraving, mold making, fabrication, wax carving, lost wax casting, electroplating, forging, and polishing. These are the various steps needed to make jewellery. The first step in making a detailed piece is making of a mold (Ray, 2009), it can be made in desk or computer aided.

Mold

A mold is the exact and perfect replica of the piece to be made, copied either from a design or a piece/object. A mold is shaped around the shape/figure with the help of casting process. Molds are made from many materials, including plaster compounds. Some different methods of casting include the lost wax process, centrifugal or investment casting, and sand casting. In jewel manufacturing the process begins with a mold. The casting process involves a number of steps. There are two methods of casting using in jewel and fashion accessory manufacturing; investment casting or die casting each with its own advantages.

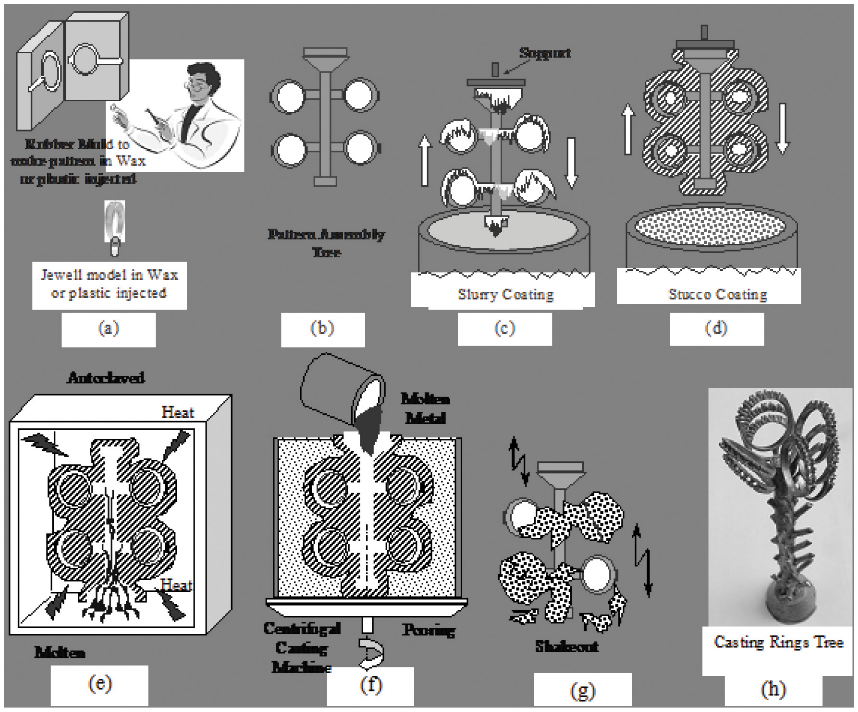
The Investment Casting

The "Investment Casting" or "Lost-wax Casting", also called by the French name of *cire perdue* or the Latin *cera perduta*, is the process by which a bronze, brass or other special alloys are cast from an artist's sculpture and jewels. The casting process is one of the oldest known metal-forming techniques, was first used during the period 4000-3000 B.C. Lost-wax casting was widespread in Europe until 18th century, when a piece-mold process came to predominate. Believed to have been developed by the Mesopotamians, it remains as the most popular process of making gold (metal) jewellery and forms the basis of modern investment casting process. Nowadays, with the appearance of the high-technology waxes, refractory materials and specialist alloys, the castings allow the production of components with accuracy, repeatability, versatility and integrity in a variety of metals and high-performance alloys, thus, in industrial uses, this modern process is called investment casting.

Kalpakjian (1995) said that this process involves dipping a mold into a ceramic mix. Sometimes new materials like plastic or polystyrene foam is used instead of wax. This process has a number of steps involved. The Figure 4 shows a brief description of the Investment Casting process begins by the injection of wax in a metallic mould that has previously built up or plastic hand-made pattern.

a. A primary model can be made in hard alloy like nickel silver or just silver. Surrounding this primary model, using sheet rubber in a mold frame, makes a rubber model. Placing it in a heated press then vulcanizes it. On cooling, it is cut with a scalpel into halves or more and removing the primary model. This rubber mold is used to make many copies of the primary model on wax. Molten wax is then introduced into the mold cavity by using a wax injector. On cooling the wax is removed to get an exact copy of the primary model in wax. Other way is wax or plastic models hand-made by craftsmen.

Figure 4. Steps involved in jewellery manufacturing by investment xasting process



b. Then the wax or plastic models are welded to a structure also in wax, to set up an assembly (tree form).

c. The ceramic mould or negative of the wax pattern is formed up by immersing the assembly (tree) in a slurry coating (babbitt), keeping the finest details as the wax pattern.

d. The assembly is then surrounded by refractory materials (e.g., fine silica) till that a ceramic shell is obtained, also called stucco coating or investment plaster. Thus, form stiff and sturdy molds are produced.

e. The wax is removed in an autoclave by a pressure-temperature process to pattern melt out. The flask is inverted and placed in a kiln/furnace. The wax is melted by steam or air to remove all the wax. The furnace is set in stages and the maximum temperature reached is 750 degrees centigrade. The melting process takes about 12 to 16 hours. This melting down of the wax is called the 'lost wax process'.

f. The ceramic mould is pre-heated at 1000°C and the metallic material is poured into at temperature higher than fusion temperature (e. g., 1550 °C steel or 1100 °C copper, etc) Two types of casting machines can be used; the centrifugal casting machine which is the older technique or the modern technique of static vacuum assist machines.

g. When the assembly is cold the ceramic shell is separated from the steel bye vibration process.

h. The steel parts are then separated for the assembly by mechanical process.

i. The process finishes with all kinds of controls, heat treatments and machining operations to achieve quality and finishing required.

As advantages of casting investment in jewel manufacturing can be said that it is an old age proven method. It allows the jewellery flexibility to create complex designs. The details can be copied perfectly. The control of colour is better. The finished product can be highly polished. It results in very fine surface finish. The metallurgical properties are also excellent. However, some disadvantages of investment casting also can be cited, as that this process can result in porosity. Also the dimensions may not be as accurate as the die struck method. Nevertheless, this process can and is used for almost all gold jewellery and remains a favourite with jewellers even after 6,000 years later.

Die Struck Method

Die struck method is a casting method where the metal to be cast is forced under pressure into a mold which is usually made out of metal. This is an excellent method of producing complex shapes. The earliest recorded history of die casting by pressure occurred in 1800's. Using a plunger or compressed air, molten metal is forced into a metallic die and the pressure is maintained until the metal settles and solidifies. The pressure reaches 300 MPa. The intense pressure causes the atoms in the metal to move closer together and solidify to dies form or molds. Using compressed sheet metal and dies steel mountings are formed with metal parts mechanically stamped out. Each part is matched and fitted into the correct portion of die halved and stamped and shaped. A hydraulic press is used (Ray, 2009).

MODERN MANUFACTURING SYSTEMS

A number of steps are involved in manufacturing a part from its conceptualization to production. They include product design, process planning, production system design, and process control. Computers are used extensively in all these stages to make the entire process easier and faster (Mehrabi et al, 2002). Potential benefits of using computers in jewel manufacturing can include reduced costs and lead times in all engineering design stages, improved quality and accuracy, minimization of errors and their duplication, more efficient analysis tool, and accurate control and monitoring of the machines/processes, etc.

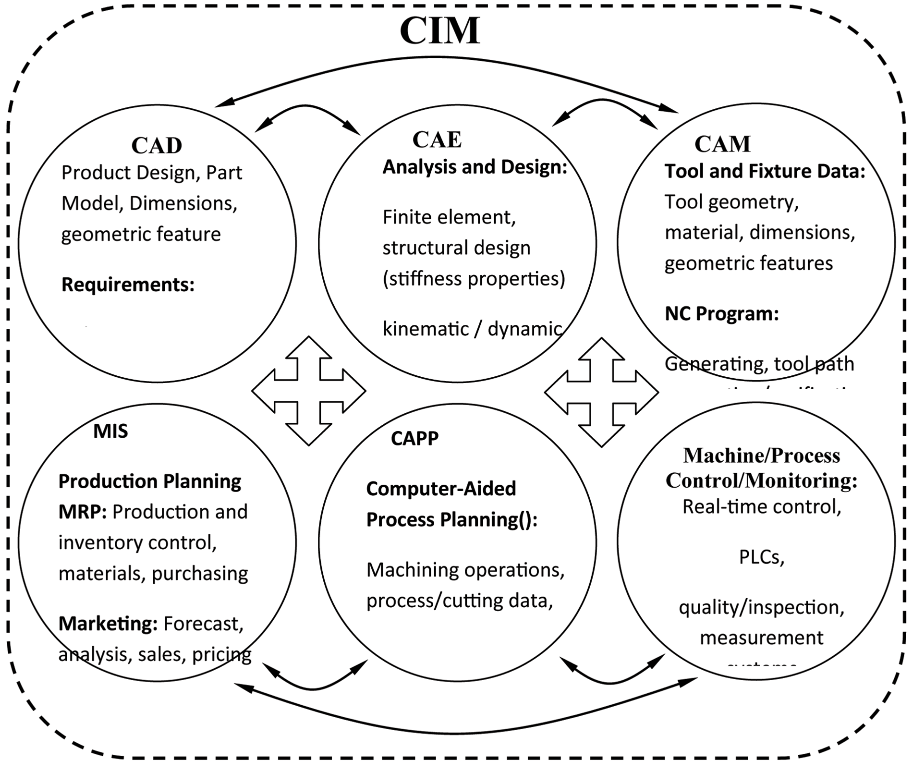
As showed in Figure 5, the applications of computers in manufacturing systems allow development products by computer-aided design (CAD), using computers in the design and analysis of the products and processes. The computer technologies play a critical role in reducing lead-time and cost at the design stages of the products/process. Also, computers may be utilized to plan, manage, and control the operations of a manufacturing system: computer-aided manufacturing (CAM). In CAM, computers are used directly to control and monitor the machines/processes (in real-time) or used off-line to support manufacturing operations such as computer-aided process planning (CAPP) or planning of required materials. Materials Requirement Planning (MRP) determines a schedule for the operations and raw material purchases shows the production requirements for the whole production system.

At higher levels, computers are utilized in support of management. They play a critical role in all stages of decision-making and control of financial operations by processing and analyzing data and reporting the results (Management Information Systems, MIS). Also, computers facilitate integration of CAD, CAM, and MIS (Computer-Integrated Manufacturing, CIM). They provide an effective communication interface among engineers, design, management, production workers, and project groups to improve efficiency and productivity of the entire system. (Mehrabi et al, 2002).

Product Development Life Cycle

Many enterprises have new product development methodologies that provide a standard framework for planning and managing development efforts. It can be discriminated four phases to this life

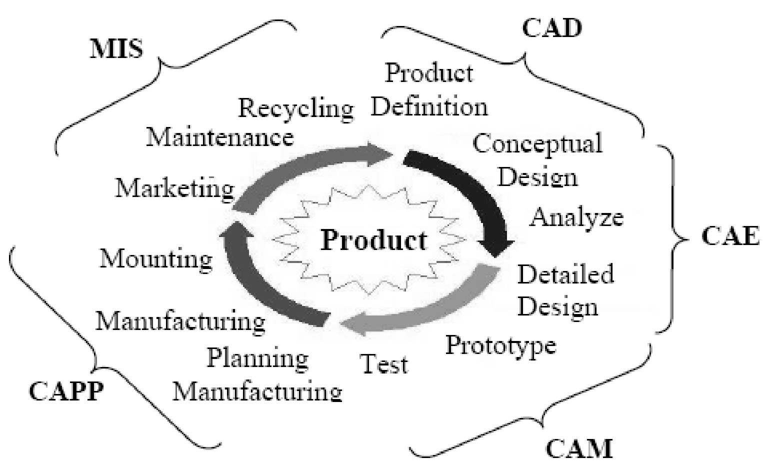
Figure 5. Applications of computer technology in manufacturing



cycle: concept (preliminary ideas), production (including product development and purchasing), use and disposal. The Figure 6 shows the life cycle phases and computer tools that can be using in improvements of the process.

Improvements in jewel manufacturing process are extremely important. Because the jewels and fashion accessories presents a high aggregate value. It is more important when raw material is abounding too. Brazil is a precious metal and

Figure 6. Products life cycle phases and computer technology applications



stones products country, namely gold, silver, diamonds, emeralds, etc. Thus, better products imply in laddering of the market and consolidate designer's names in global market.

An Integrated Method for Jewel Manufacturing

For the last few years, the process of manufacturing jewellery has seen lots of innovation, and particularly in term of Design & Manufacture. CNC machine are adapting to the jewellery industry, as for the laser welder and market, and Design & Manufacture software. For the last one, it has come much slower, and the available solutions offered on the market are not affordable to the majorities of the Brazilian jewelers.

Rapid Prototyping, RP, techniques has a vast application on several fields, such as architecture, art, engineering and industrial design. Using these technologies, and from a CAD3D geometrical file, it is possible in a few hours to build functional prototypes of components or even production tools, known as Rapid Tools or Rapid Manufacturing (RM). Hence, there is no need to build moulds to produce some components, e.g. in the development stage, that are constantly changed by the design teams. The number of RP systems in use, as well as theirs typology, is increasing every day, using different building materials such as waxes, polymers, metals, paper, sand and mix materials. There are already some desktop solutions (Mascarenhas & Esperto, 2006). Using two (2) of these RP techniques it was created a few jewel prototypes, namely Fused Deposition Modeling (FDM) and CNC micro-milling machining.

Rapid Manufacturing is the embodiment of the concept that allows defining elements or modules with well defined interfaces and "hooks" in a way that the process of manufacturing can be: developed in an independent manner, customized based on installation specific data, based on formal models of controller behavior, amenable to automatic generation of control software modules, and reconfigurable to adapt to changes in the environment through changes to data and/or regeneration of control software. Smith (1998) shows that application of RM allows identify time saving opportunities in the product development lifecycle, namely in design and manufacturing phases. As showed in Figure 7, the jewel manufactures may be improved by reducing both the production time and costs by work's superimposing. It is possible by using the computer technology, namely Rapid Manufacturing (RM).

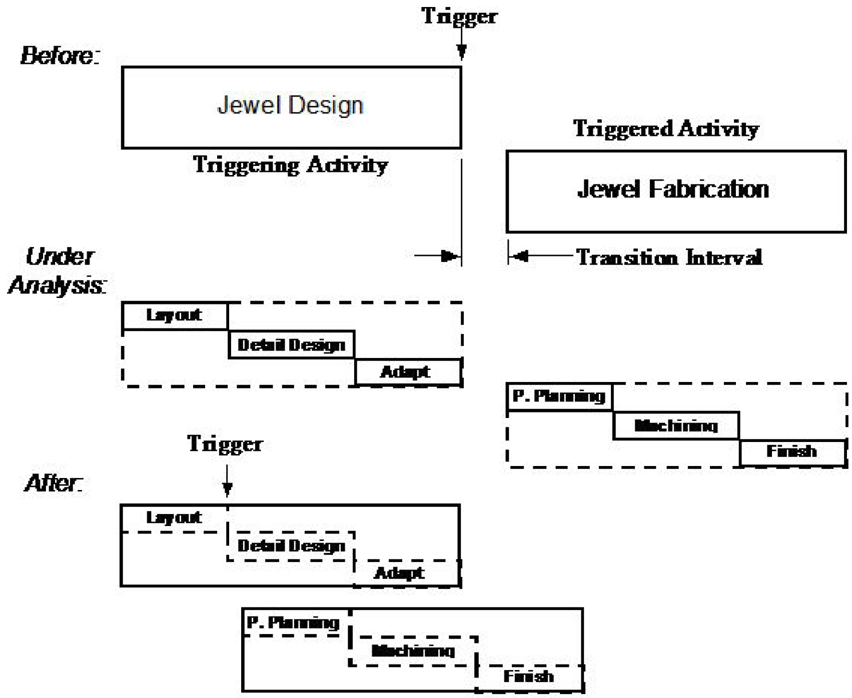
In last year's, artistic design & manufacture software has been developed to the jewellery industry, aimed to reduce production costs and hand process. This technology allows designers to the freedom to development quickly design, modify and view the models. Thus, designers can create new models with the benefit of a parametric construction tree which allows modifying the design at any stage, without going back countless steps or starting from scratch, reducing both the production time and costs. It can use the jewellery specific tools, such as the ring wizard to quickly build a band then change for example, the finger size while keeping the thickness constant.

Once the jewel model is completed, the designer can resize it, reconfigure its dimensions or use it as a component in another design by adding it to a pre-existing library of parts. Another problem is the cost of the jewel designed; the software can alert the designer if it goes under or over the desired weight. Allow a more accurate vision with the production costs. Most of materials are in the software, and designers can also easily create your own material for new jewel or fashion accessories.

Methodology Using in Jewel Rapid Manufacturing

The Rapid Manufacturing (RM) concept can be used when the development of moulds or tools for moderate volume parts or products is required. Among the various RM processes, computer numerically controlled (CNC) machining is rec-

Figure 7. Time saving opportunities in the product development life cycle



ognized as the technology most widely used in industry for the application of CAD/CAM systems. The basic methodology for RM techniques can be summarized as follows:

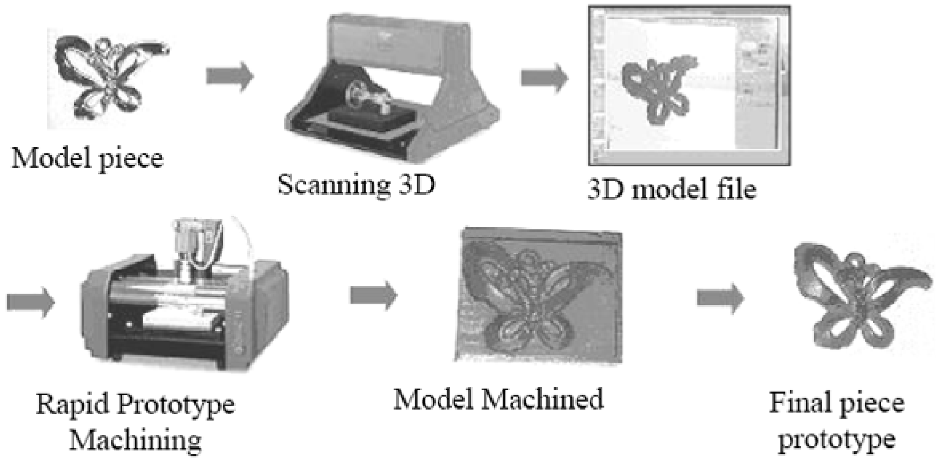
a. CAD jewel model is constructed, and then converted to STL format. The resolution can be set to minimize stair stepping.
b. The RP machine processes the STL file by creating sliced layers of the model.
c. The first layer of the physical model is created. The model is then lowered by the thickness of the next layer, and the process is repeated until completion of the model.
d. The model and any supports are removed. The surface of the model is then finished and cleaned.

Different CNC machines can be used in rapid prototyping aided jewel manufacturing. In Figure 8, a small Roland desktop 3 axis machine was used as RM process, It can machining soft metal, wax or resin that can be vulcanized in rubber moulds. There are two work ways; from the scratch (start drawing) and 3D scanning and modelling (reengineering).

CAD/CAM IN JEWELL INDUSTRY

The use of latest trends in design tools and manufacturing technologies allows jewels design and manufacturing through CAD/CAM technology, from the basic concept to final productions. According to Osgrove (2005), can be cited three (3) advantages of this technology in jewel industry, namely accuracy, time and cost advantages. Among of the accuracy advantages that can be cited are the capability in provides a realistic image of the jewel even before it is made, thus aiding inspection to improve quality. Same, achieve exact symmetry of design, especially for left and right

Figure 8. Diagram illustrating the various methodologies' phases used in jewel rapid manufacturing



earrings. It can create identical looking designs of different diamond weights fasters. Likely, can be created ensembles will have same family looks, described precisely the metal dimensions for gemstone holding areas, no variation in consistency and accuracy, such as provides casting friendly even cross sections, etc.

Regarding to the time advantages in the application of the CAD/CAM technology in jewel manufacturing, can be said that CAD and CAM based technologies help to obtain a silver master models, faster than traditional wax or solid silver based carving methods. One can convert a complex design sketch into a finished silver model in few days time. Modifications in master model are faster and creating identical designs for different diamond weights, earrings and ensembles is possible.

The costs are extremely important in jewel manufacturing, and CAD/CAM technology allows obtaining the uniformity of scoop for maximum removal of excess metal, giving consistent and minimum metal weight. Same, the model making productivity increases many times without increase skilled manpower. As form a contract of high capital involvement, optimum utility of the capacity makes models affordable is allowed when CAD/CAM technology is applied in jewel industry. By using the CAD software in jewel development the designer might creates and produces a bigger range of jewellery models at the same time (family pieces) allowing creating and producing many finished models simultaneously.

In practice, CAD software is written in numerous different programming languages and can be used in many environments and platform (e.g., Windows, Linux, Apple Mac, etc). Some CAD using in jewellery are written in the Java computer, they can also run in any machine, and exchange data with other users. Jewellery's CAD software present friendly and intuitive interface, as well as help box dynamic. There are libraries of precious metals and gemstones with gemmological materials, which can also add too. Thus, a designer with few days of practicing would be able to design nice items, showing that working on the model can be very clear and the final rendering to be easy to use and extremely effective.

Kai et al (2000) presents a methodology to converting scanned data to.STL format. They said that the data modeller is the most important process for the success of jewel making. Its purpose is to convert the scanned image file to editable CAD format. The common converted file formats include IGES, DXF and ACIS. The conversion to CAD readable format is to facilitate correction and rework of the scanned image before converting to.STL format. Figure 9 illustrates the flow chart for converting scanned data to.STL format, followed by Figures 10a and 10b which present the steps to convert the input (scanned file) to the desired output (.STL file) of the ear mould, and finally can be used as a wax jewel model or vacuum cast mould.

All RP systems generally adopt the additive fabrication technique, which is a process that builds a part layer by layer. Each layer is represented and determined by its corresponding slice file. The slice file stores the geometric detail data of the model at that particular slice height. The slice file is created from the.STL file. After specifying the slice height, usually smaller 0.30mm, the RP attached software will slice the. STL file to a slice (.SLI) format. The.SLI file is then used to build the RP model (Osgrove, 2005).

JEWEL MODEL RAPID PROTOTYPING

Rapid Prototyping (RP) can be defined as a group of techniques used to quickly fabricate a scale model of a part or assembly using three-dimensional computer aided design (CAD) data. Rapid Prototyping has also been referred to as solid free-form manufacturing; computer

Figure 9. Steps indicating the conversion of scanned data to.STL format

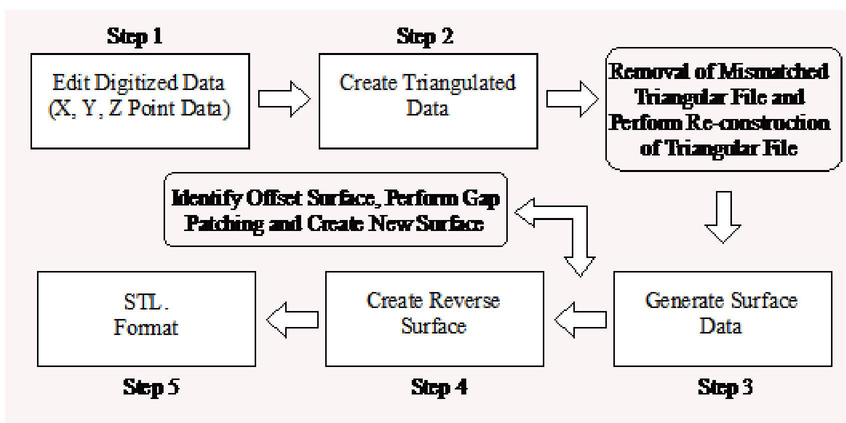


Figure 10. Convert; (a) the scanned image file to (b) editable CAD format

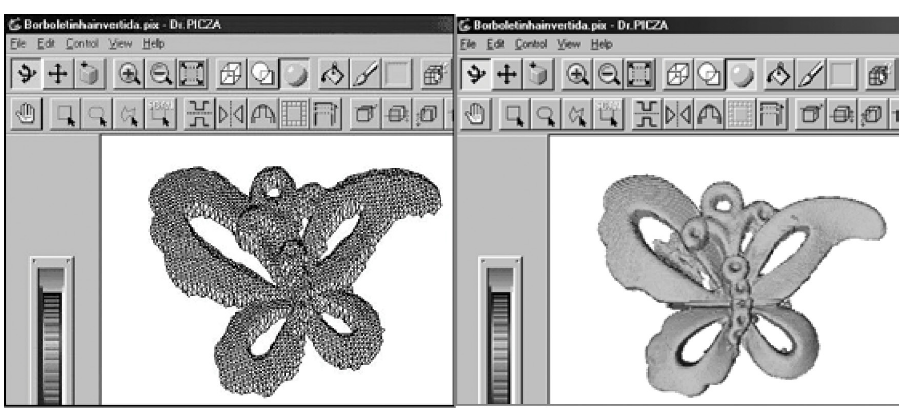

automated manufacturing (CAM) and layered manufacturing. RP has obvious use as a vehicle for visualization. In addition, RP models can be used for testing, such as when an airfoil shape is put into a wind tunnel. RP models can be used to create male models for tooling, such as silicone rubber molds and investment casts. In some cases, the RP part can be the final part, but typically the RP material is not strong or accurate enough. When the RP material is suitable, highly convoluted shapes (including parts nested within parts) can be produced because of the nature of RP.

Why Rapid Prototyping?

The reasons of applied Rapid Prototyping (RP) in jewel manufacturing are:

- Increase effective communication.
- Decrease development time.
- Decrease costly mistakes.
- Minimize sustaining engineering changes.
- Extend product lifetime by adding necessary features and eliminating redundant features early in the design.

Rapid Prototyping decreases development time by allowing corrections to a product to be made early in the process. By giving engineering, manufacturing, marketing, and purchasing a look at the product early in the design process, mistakes can be corrected and changes can be made while they are still inexpensive. The trends in manufacturing industries continue to emphasize the following:

- Increasing number of variants of products.
- Increasing product complexity.
- Decreasing product lifetime before obsolescence.
- Decreasing delivery time.

Rapid Prototyping improves product development by enabling better communication in a concurrent engineering environment.

Different CNC machines can be used in rapid prototyping aided jewel manufacturing. In this work, two RP systems were used to fabricate the jewel and fashion accessories pattern for the silicon mould making or wax model. They are fused deposition modelling (FDM) and CNC Micro-Milling Machining. The first works by material deposition and the second works by material retreat. The two RP systems will be briefly discussed in the following. In addition, SLA and CNC will be used to make the RP jewel mould or model. This is to facilitate the evaluation on the patterns fabricated by each RP system. The evaluation will show which RP systems produce better-finished pattern suitable for investment casting. Figure 11 shows development process of the ring using software oriented to RP machine inside RM environment.

Fused Deposition Modeling (FDM)

The Fused Deposition Modeling (FDM) process was developed by Scott Crump in 1988. The fundamental process involves heating a filament of thermoplastic polymer and squeezing it out like toothpaste from a tube to form the RP layers. The machines range from fast concept modelers to slower, high-precision machines. The materials include polyester, ABS, elastomers, and investment casting wax (Osgrove, 2005). The overall arrangement is illustrated in Figure 12.

Highlights of Fused Deposition Modeling:

- Standard engineering thermoplastics, such as ABS or investment casting wax, can be used to produce structurally functional models.
- Two build materials can be used, and latticework interiors are an option.
- Filament of heated thermoplastic polymer is squeezed out like toothpaste from a tube.
- Thermoplastic is cooled rapidly since the platform is maintained at a lower temperature.

Figure 11. Jewel development process inside RM environment

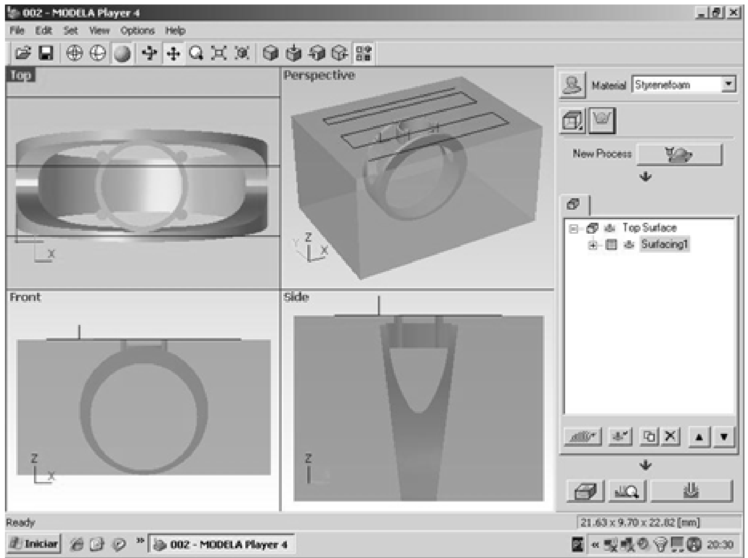

Figure 12. FDM extrusion head

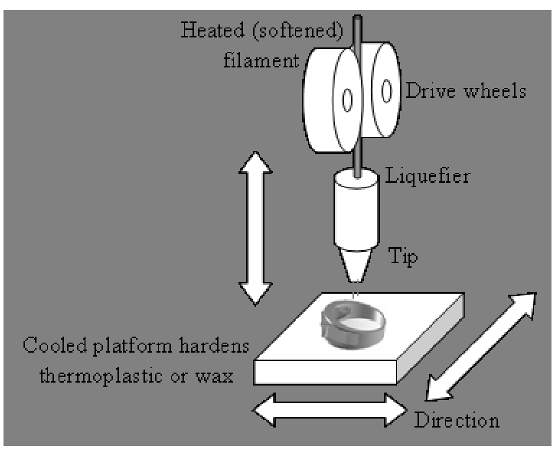
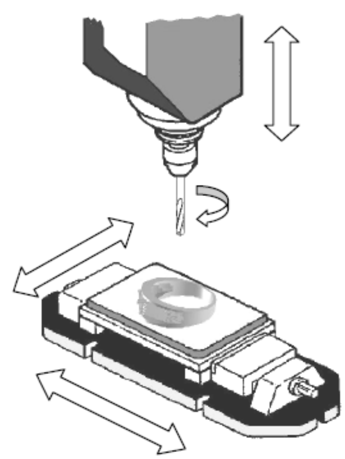


- Milling step not included and layer deposition is sometimes non-uniform so "plane" can become skewed.
- Make rapid progress in past few years and be used widely

CNC Micro-Milling Process

A wax model of a jewel can be produced using CNC machining techniques. The virtual model (CAD) of the jewel created from digital data obtained from the jewel model. The jewel model prototype is then fabricated from the wax model or other plastic materials. On the other hand, the CNC micro-milling process can be used in mold manufacturing. Thus, the virtual model (CAD) is used by coping the replica of the negative piece to be made, The Figure 13 shows CNC micro-milling machine used in jewel model rapid prototyping.

Figure 13. CNC micro-milling machine used in jewel rapid prototyping



Different CNC machines can be used in rapid prototyping aided jewel manufacturing. In this work, was chosen a small Roland desktop 3 axis machine, It can machine soft metal, wax or resin that can be vulcanized in rubber moulds. There are two works ways; from the scratch (start drawing) and 3D scanning and modelling (reengineering). Figure 14 illustrates the stages from scanned jewel model to wax jewel model and finally jewel prototype.

This alternative offers quickly turnaround metal mold prototypes and rapid prototyping for metal parts. Depending on material, timing requirements, critical dimensions and post-machining operations, there are several different methods that can be used to satisfy metal prototyping requirements. CNC machining is the most common method to manufacture rapid metal prototypes. Figure 15 shows a 3D model file and CNC machine cutting tool path using CAD/CAM software.

CONCLUSION

Everything considered, the benefits of CAD/CAM systems in front of the traditional design and production process are clear, and the use of these systems probably will increase in the next years. Notwithstanding the jewel industry modernization is only at the beginning. More and more references about this subject are presented, bringing incentive to entrepreneurs to implement new technologies in the jewel industry. However, the CAD/CAM is not a simple new tool, but it includes some difficulties to learn an adequate application. Problems like communication between designer and production sector, including goldsmith, can be solved with the use of CAD3D. In the same way, the technical characteristics of jewel are necessarily defined in the first stage of design process. This integration between design and production processes is the main benefit of the new technology. On the other hand, it is a great challenge to jewellery industry, especially small and medium enterprises.

KEY TERMS AND DEFINITIONS

Computer Aided Design and Computer Aided Manufacturing (CAD/CAM): Systems are diverse software and hardware technologies, used in many applications in industries like automotive, aerospace, mechanical and others. One of the most important aspects of CAD/CAM implementation is the integration between different areas of enterprise, like product development, production and assembly.

Computer-Integrated Manufacturing (CIM): An engineering approach for manufacturing, where computer technology controls different functions in the enterprise. The use of CIM technology provides an effective communication among design, analysis, planning, purchasing, cost accounting, inventory control, and distribution. However, the CIM can be understood like a management strategy, using the computer resources to integrate functions and people in the corporation.

Fused Deposition Modeling (FDM): Process involves heating a filament of thermoplastic polymer and squeezing it out like toothpaste from a tube to form the Rapid Prototyping layers. The machines range from fast concept modellers to slower, high-precision machines. The materials include polyester, ABS, elastomers, and investment casting wax.

"Investment Casting" or "Lost-Wax Casting": also called by the French name of *cire perdue* or the Latin *cera perduta*, is the process by which a bronze, brass or other special alloys are cast from an artist's sculpture and jewels. The casting process is one of the oldest known metal-forming techniques, was first used during the period 4000-3000 B.C. Nowadays, with the appearance of the high-technology waxes, refractory materials and specialist alloys, the castings allow the production of components with accuracy, repeatability, versatility and integrity in a variety of metals and high-performance alloys, thus, in industrial uses, this modern process is called investment casting.

Mold: The exact and perfect replica of the piece to be made, copied either from a design or a piece/object. A mold is shaped around the shape/figure with the help of casting process. Molds are made from many materials, including plaster compounds. Some different methods of casting include the lost wax process, centrifugal or investment casting, and sand casting.

Rapid Manufacturing: A computer technology, the embodiment of the concept that allows defining elements or modules with well defined interfaces and "hooks" in a way that the process of manufacturing can be: developed in an independent manner, customized based on installation specific data, based on formal models of controller behaviour, amenable to automatic generation of control software modules, and reconfigurable to adapt to changes in the environment through changes to data and/or regeneration of control software.

Rapid Prototyping: A group of techniques, which has a vast application on several fields, such as architecture, art, engineering and industrial design. Using these technologies, and from a CAD3D geometrical file, it is possible in a few hours to build functional prototypes of components or even production tools, known as Rapid Tools or Rapid Manufacturing (RM).

Chapter 47
Cases Illustrating Risks and Crisis Management

Simona Mihai Yiannaki
European University, Cyprus

ABSTRACT

Undoubtedly, the nature of the relationships between business and risk factors in one country or another does not fit exactly into a "model" nor does it have a pure placebo effect. Yet, models' simplicity may appeal to managers and regulators in understanding important business risks and crisis related phenomena. Backed by this idea, this research underpins a comparative study on SMEs handling risk and crisis management according to a new tailored model of a balance scorecard. This new model of a risk and crisis management aims at improving both SMEs management adaptation and performance across all of crisis' stages, something not attempted so far in the literature. The application of such a 'balanced-scorecard' comes from the author's experience as a banker financing various SMEs industries, as a bank consultant on risk management as well as primarily from the results of a survey performed on a sample of 48 Romanian and Cypriot SMEs, equal-proportionally selected from the area of trading, manufacturing, and services. The results of this case study show, coincidently or not, that there is a significant improvement of the financial performance of the SMEs that employed this model compared to those that did not. The monitoring period: 11/2009-06/2010 was employed as a representative one for the latest global financial crisis which affected the entire European Union region, as well.

INTRODUCTION

The last few years brought severe waves of globalisation and several financial and economic crises, where even large, strong, formerly sound corporations did not cope with. In particular, it seems like in the past 20 years there have been several so-called "once-in-a-lifetime events," such as the floods of Hurricane Katrina or any of the financial crisis, including 1987, 1998, 2000, or 2008, and "no one saw that coming." (Hubbard, 2009) Now it seems the moment to realize the need to protect the most 'numerous' of the firms

DOI: 10.4018/978-1-4666-1945-6.ch047

population: the small and medium size enterprises (SMEs). However, the contribution of SMEs varies considerably across countries. In most economies, the share of enterprises with less than 20 persons engaged is more than 70%, ranging between 67% in Ireland and above 95% in Greece. SMEs also account for a smaller share of the total number of employees, ranging between around 11% in the United States and the Czech Republic and more than 35% in Greece (OECD, 2010).

Since SMEs are much more exposed and fragile during and after financial than any other type of companies, whilst they are firmly identified by the EU as the core engine for European economic recovery, growth and innovation,, this chapter looks at a double loop feedback and SME stakeholders' benefit in implementing innovative risk management methods and techniques under a broad Business Socially Responsible strategy.

Subsequently it provides key elements of crisis management resolution not only in times of economic and financial distress but also in times of "black swan" events (Taleb, 2007), such as sudden drops of the National Stock Exchange Index, strong foreign exchange devaluations, sudden and acute raise in unemployment or any other temporary or chronic externality.

Although risk measurement can only be generated by historic data, it has been found that experienced estimators could, using PERT or other well-known models, create usable estimates, which gave usable and effective predictions, with computed standard deviations. One can measure and model risk whatever the risk, static and dynamic, however none can have a crystal ball, as one always have to deal with various levels of uncertainty. This uncertainty is sometimes called error. Any model has also at least 3 inner-errors: model error, parameter error and random error. The task is to minimize them accordingly, but never be able to eliminate them completely. Moreover, the problem of risk management arises further, when the firm doesn't consider any of these.

Others (for example Hubbard, 2010) consider that there are imaginary obstacles that must be overcome, as there are practical measurement solutions that can be applied to any uncertain decision. Hence, one can quantify any uncertainty and then compute the value of reducing that uncertainty by measurement. However one can see during the recent sub-prime crisis that even some of the best quantitative finance modelers at top rating agencies were not able to measure risks of structured products with complicated pay- off's.

Does the picture look though simpler or more effective for the SMEs or not? Except for paying attention at the error and uncertainty part, shouldn't one also look at what is inside the model, before starting measuring?

In pursuing risk measurement, one can learn about the revolutionary thinkers including John von Neumann (inventor of game theory), Harry Markowitz (grandfather of portfolio theory), and the late Fischer Black (Black Scholes option formula), or also find enlightening stories about Fibonacci numbers, chaos theory, the bell curve, regression to the mean, and more (Bernstein, 1996). Yet, despite all the intelligence, computer power, and sophisticated techniques, Bernstein presents us with the growing body of evidence discovered by researchers including the late Amos Tversky's cognitive biases and others who "reveals repeated patterns of irrationality, inconsistency, and incompetence in the ways human beings arrive at decisions and choices when faced with uncertainty." (Bernstein, 1996: pp.271).

In the attempt to model risk, the study employed conditions that can provide indicators of identifiable categories (the five pillars of our proposed model). Once one identifies the patterns indicating the category of risk associated, then one can try to predict when a categorized event might occur. Upon such predictability background, one can attempt to minimize the effects and maximize any recovery efforts. In quantum mechanics, the Heisenberg uncertainty principle states by precise inequalities that certain pairs of physical properties, such as position and momentum, cannot be simultaneously known to arbitrarily high precision. That is, the more precisely one property is measured, the less precisely the other can be measured. Is this paradox trying to teach us a lesson in managing risk and crisis?

The chapter attempts to use though, under a general simplified framework, the key risk evaluation framework which nowadays SME's managers and staff could utilize in reaching their strategic, operational, marketing and financial targets within or not a crisis context.

One big challenge of the study is that we drew under a synthetic five pillar system a balanced-scorecard (herewith BS) which not only can track dawn repeated risk/crisis events and measure their impacts, but it can accommodate further potential risks analysis and mitigation while leaving room for creative improvement at the same time.

In the view of this research, the SMEs are being treated just like any company which needs to support its long-term soundness and profitability in a socially responsible way.

In this light, this study has build a cross-sectoral pool of SMEs from various industries from a particular environment and tested their potential ability to alleviate risk impact and deal with crisis management by utilizing the BS.

BACKGROUND: METHOD ANALYSIS AND CHAPTER FRAMEWORK

Issues, Controversies, Problems: The Balanced Scorecard Concept

This section starts by responding to the question, as why one should utilize the balanced-scorecard (BS) instrument (Kaplan and Norton, 1996) at the base of this model?

Although, there are a few empirical studies linking the use of BS to better decision making or improved financial performance of companies, broadcast surveys of usage have difficulties in this respect, due to the wide variations in definition of 'what a BS is'. Single organization case studies suffer from the 'lack of a control' issue common to any study of organizational change - you don't know what the organization would have achieved if the change had not been made (Lingle & Schieman, 1996), so it is difficult to attribute changes observed over time to a single intervention (the BS), despite obtaining results which demonstrate the usefulness of the BS (Mooraj *et al*., 1999).

Another criticism among others (Schneiderman, 1999), usually from pundits and consultants, is that the BS does not provide a bottom line score or a unified view with clear recommendations: it is simply a list of metrics (Jensen, 2001). Typically however, the unanswered question relates to things outside the scope of BS itself (such as developing strategies) (Rohm, 2004), which in reality could have a decisive impact in the organization change-over and financial existence. For this reason, the suggested BS is designed to incorporate these aspects, under a flexible quantification.

On the other side of the propellers of the BS, according to Kurtzman (1997), it appears that 64% of companies questioned were measuring performance of companies in a similar way to the BS. Yet, again Kurtzman (1997) sees a strong controversy between two schools of thought. He refers to these schools as *the balance people* and *the numbers people*.

A synthetic table format of these two schools is presented in Table 1.

The balance people promote the use of corporate, or BS. Kurtzman utilizes the so called Analog's scorecard, which includes a number of

Table 1. The balance people and the numbers people (Kurtzman, 1997)

The Balance People	The Numbers People
The corporate scorecard should be balanced, including nonfinancial soft matters like employee satisfaction.	The balanced scorecard confuses the issue. Measurements should be purely financial.

nonfinancial measures such as number of new products, the rate of on-time deliveries, product development cycle times. He makes his scorecard link these measurements to financial indicators such as the percentage of sales increase due to new-product introductions or gross margins post introduction of new products.

Kurtzman uses Shell Oil as an example in the numbers people category, which seems to be a good example of a high potential pooled-risks affected corporation. Shell's business model is based on a matrix with four financial measurements as indicated in Table 2.

Shell management's view is that a balanced group of measurements with a number of 'soft categories' leads to confusions. This company's view is an explicit result driven one, where each activity is measured in terms of financial benefit, which in reality is neither a transparent way of sharing the company strategy nor it can differentiate between core activities and corporate social responsibility ones, for example.

At the same time, choosing to calculate a certain financial indicator over another seems to be more or less complicated or fashionable, for example, for finance people the EVA is considered a more accurate measure of control and profitability because it measures an opportunity cost to the money one is investing, and it might yield better returns elsewhere. The calculation allows for an adjustment to compare one project to a hypothetical alternative investment, as well as it is a short term related indicator.(Stewart, 1993). As long as it regards the bonus perspective, in order to be a successful tool, EVA based bonus systems should be long-term, based mainly on changes of EVA and offer considerable bonuses for considerable shareholder value improvements.

Table 2. Shell's business model- (adapted by the author)

Shell's Business Model	
Revenue Growth	Intrinsic Business Value (i.e., Company's Market value)
ROI (return on investment)	EVA (economic value add)

For SME's mangers, who most of the time being SME's owners of vartious background, the understanding of financial indicators takes time. However, more important for them nowadays is having to choose certain indicators over others which may make an important difference in the long run, as decision making is time bound. These schools of thought are putting together several controversial issues related to measurements in management and financial strategy, but they do not give a solution to what is best or why it is so.

Theoretically, Norton and Kaplan (1996) have used such methodology for large corporations not only for bringing in increased success and lessen managerial burdens, but also to reduce the agency conflict between mangers and shareholders (Jensen, 2001). In addition, this instrument will help more in understanding the strategic need for planning, measuring and having operational objectives for any SME, as well as linking budgets with strategy and HRM and constantly reviewing it, which defines the double loop orientation in risk mitigation and risk management.

Under this study, the aim is not the same, since in SME's managers happen to be the owners most of the time, while at the same time strong –cultural patterns may reveal differences in the way of doing business. Moreover, budget wise, SMEs are not as well equipped as large corporations to invest in all necessary risk packages or sustainable activities. First of all, this is due to environment culture, to lack of dedicated organizations and free funding for SMEs as well as lack of governmental support, in brief due to lack of regulation of this sector. Next by regulation, it is meant not necessary the control aspects, in the sense of fiscal or financial ones, but in the sense of business facilitators.

Therefore, this chapter focuses on channeling the attention of SME's management towards a combined 360degree model that does not have to be a burden in its application nor very time consuming in being utilized by the stakeholders involved. The novelty of this tool is that the BS is useful and interpretable not only by managers of SMEs in context, but also to the other stakeholders of the business for the purpose of transparency (www.bis.org).

Moreover, since risk management models are just like big weather forecasting models that predict financial storms, who may happen or not in the predicted timeframe, obviously, the models aren't always right. Even recognizing that the weatherman got it wrong a lot, it was helpful to know that it might rain tomorrow, because then one could make backup plans. This is not an excuse for any model's inaccuracy, but outlines the idea that some things are utterly immeasurable due to three common misconceptions, also called 'COM' (Hubbard, 2010), namely concept, object and method. A strong misconception about measurement is the objective of measurement itself. If "strategic alignment", or "employee empowerment" seem immeasurable, it is only because they are ambiguous. But if they are important to a business, then they must become measurable aims, and so they must be detectable in some manner, directly or indirectly (Hubbard, 2010).

To these, one may add perhaps the versatility of the risk mitigator and his/her interpretation altogether of the results.

Even by utilizing controlled experiments, variations on random sampling methods, and some very simple but non-obvious methods in many practical business situations, their interpretation is at stake when responding to problem solving. At the same time Hubbard (2009), looks at the way risk is measured by the four horseman, The four classes are actuaries, "war quants" economists, and management consultants. For that reason, it seems important to respond to the exact set audience, or have approached important aspects treasured by all these types of audiences. Hence, last, but not least, one could also add the calibration of subjective human inputs.

The Case Study: The Balanced Scorecard Designed for SME Risk Management

The main concerns of this study were if once utilizing the proposed BS model, the SMEs applying it could obtain any competitive advantage versus the ones not using it ? And, thereafter to see if there are any particular country differences?

The research had indeed used a relatively reduced sample and a relatively short period of time (12/2008-06/2009), considering that a crisis is based on three stages, pre-crisis, during-crisis and post crisis. Because of the pertaining status of the recent financial and economic crisis, it is still hazardous to estimate the completion time for the second and third phases. This is why the study can be expanded for a future larger sample for various other countries or regions, as well as considering a lengthier timeframe.

At the same time, as many of the SMEs are operating cross-industry, the sample chosen includes SMEs categorized based on having over 60% of their activity in either trading, manufacturing or services. In the sample, only about 35% of SMEs were operating solely in one of these industries. This is the reason why the research has concentrated the study's results on the overall response of the SMEs.

Starting from the debate of people vs. numbers the proposed BS has been designed under a five pillars system. The main rule SME's directors were given to follow was that risks can be better comprehended by the people/units most capable of understanding them, and then the SME's strategy and decision making may alter or not the existing risk metrics system.

It is important to mention that the results obtained were after the application of all five pillars at the same time and the results collection and interpretation was performed after the end of June 2010. Also, this means that all SMEs applying the BS have implemented during the analysis' period a risk management structure and have designed their own strategy and governance to follow the BS.

The figure next, represents the Conceptual Framework of the study under the BS concept, where the BS elements emerged are based on preliminary discussions with SME managing directors, from the literature review, as well as from the author's experience while dealing with SMEs financing over the past 10 years. Five aspects appeared to be essential in the risk assessment and measurement and they are presented under the following cluster:

Next, the study presents and analyses the five pillars characteristics aiming at integrating them under a Risk Management and Control Centre BS.

Pillar I: The Enterprise Responsible Package (ERP)

The ERP measures:

1. The degree of awareness of the need for having socially responsible stakeholders
2. The ability of the SME to connect and network at all levels with its stakeholders (starting first with the government and corporations and then with customers, employees and eventually with non-trading customers, potential future stakeholders (Jensen, 2001))
3. The ethical response of the SME towards the society
4. The protection of the environment, meaning how green the SME can become in the limits of its business and beyond.
5. The relationship management develops with all stakeholders, including customers

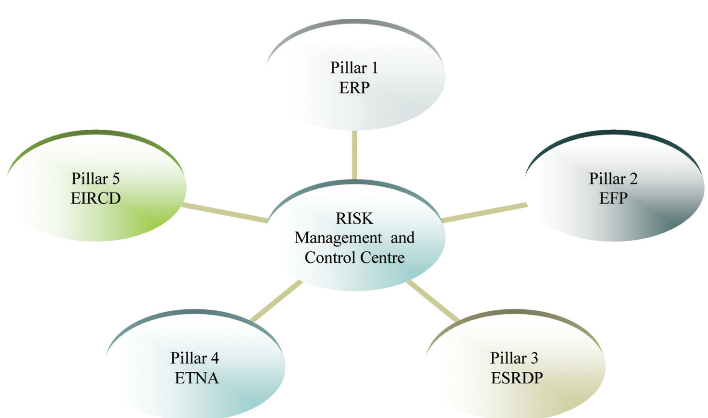
This pillar focus is mainly on measuring: customers' satisfaction, asset turnover, number of green activities per entity, market share increase, operational excellence.

The initiatives and spin-offs brought forth by the SMEs applying the offered risk management tool were: cross-industry partnerships, mergers and acquisitions, managerial and staff training, customers' loyalty schemes and development of corporate social responsibility actions, reinforcing SME-lender relationship (Collier, 2009).

Regarding strategy related aspects of this pillar, a broad outline of risk management at this first level has encompassed:

- Organisational structure definition and implementation or redesign;
- Comprehensive risk management approach;
- Risk management policies approved by the Board or the people in charge which should be consistent with the broader busi-

Figure 1. The conceptual framework of the proposed BS for SMEs



ness strategies, capital strength, management expertise and the overall willingness to assume risk;

- Guidelines and other parameters used to govern risk taking including detailed structure of prudential limits or thresholds of risk for each identified category (Glantz & Mun, 2008);
- Developing a strong Management Information System (MIS) for reporting, monitoring and controlling risks;
- Well laid down procedures, effective control and comprehensive risk reporting framework (Collier, 2009);
- Separate the risk management framework and team/designated body, independent of any operational department and with clear delineation of levels of responsibility for management of risk;
- Periodical review and evaluation not only for risk levels on short term, but also for policies and procedure on a medium to longer term; and
- Redesign checklists – highlighting updated key industry-specific hazards and control measures (Welham, 2003).

Eventually, the results obtained for the Pillar I are those obtained after the application of all the five Pillars of the balanced-scorecard are presented below:

Table 3 interpretations require attention to the major differences obtained, firstly in the area of increased customer satisfaction, which could translate in a serious image change in the eye of the customer for those SMEs approaching the risk management platform. Secondly, the area of green activities seems to have similar high impact in both countries. The audit evaluations eventually seem to have the strongest impact for both countries and in all sectors, mainly because of the international exposure of all of the SMEs within the sample, but also to the strict correlation to the financial success (that is evaluated next in Pillar II).

Table 3. Pillar I: Results per country

Pillar I Parameters Available	**Equivalent Bilaterally set Benchmarks**	**No application of risk management balanced-scorecard**		**Direct application of risk management balanced-scorecard**	
		Romania SMEs	Cyprus SMEs	Romania SMEs	Cyprus SMEs
a. customers' satisfaction increase	50% for all industries	-10%, -20%, and -22% respectively	-12%, -16%, and -22% respectively	60%, 35%, and 38% respectively	55%, 45%, and 18% respectively
b. asset turnover increase	30% for trading, 30% for manufacturing 40% for services.	0%, 0% -10%	10%, 15% 20%	20%, 25%, 28%	35%, 30%, 45%
c. number of new green activities per SME	10	0	2	5	6
d. raise in the market share	30% for trading, 10% for manufacturing and 20% for services.	Difficult to evaluate per SMEs	Difficult to evaluate per SMEs	Difficult to evaluate per SMEs	Difficult to evaluate per SMEs
e. operational excellence grade (Audit evaluations)	Maximum score 10 out of 10.	-1, 2 3	4, 5, 7	7, 6, 7	8, 8, 9

Pillar II: The Enterprise Financial Package (EFP)

Thanks to the simple financial structure, SMEs can respond faster to changing economic conditions and meet local customers' needs, growing sometimes in their size or becoming bankrupt. Here the study analyzes the set of financial indicators that have to be risk associated and treated for proper adequacy. The reason the research introduced this aspect is also due to finding the response to the Kaplan and Norton (1996) question: How should we appear to our shareholders?

In the original Z-score model of Altman (1968) used five out of 22 ratios as decisive in predicting bankruptcy: Working Capital/Total Assets, Retained Earnings/Total Assets, EBIT/Total Assets, Market Value Equity/Book Value of Total Debt and Sales/Total assets.

Despite having many supporters for the application of Basle II Accord to SMEs (Altman & Sabato, 2005), many criticism have been raised by governments and SME associations that high capital charges for SMEs brings closer credit rationing and could reduce economic growth.

Since banks are the main source of finance for SMEs, and since the Basel II accord allow banks to classify SMEs with turnover under EURO 50 million as either retail or corporate for capital requirements calculation, the banks will tend to treat SMEs under a more automated decision methodology, by scoring their financial ratios.

Several studies show that when banks classify SMEs as retail they obtain considerably lower level of capital adequacy than 8%, (www.bis.org) (i.e 4.76% when utilizing Z-Score models), while if they classify them as corporate, they obtain above 8%, (i.e. 8.6% for Z-score model) (Altman & Sabato, 2005). Why is this important? For this reason, banks who tend to split their SME portfolio in 50/50 retail and corporate, will not necessarily win in terms of risk mitigation and they will tend to develop customized risk prediction models for SME, for which reason, financial ratios of SMEs will gain further importance in acquiring bank funding.

However, the study considers only a small package of financial indicators, which are more appropriate to SMEs: Cash ratio (or the company liquidity position), Return on Investment (ROI) (The higher the ROI, the better the performance, and a higher ratio will also improve the firm's ability to find new investors), Return on equity (ROE) and Economic Value Added (EVA) and a Stress Tested Cash Flow ratio (Stress Tested Cash Flow/ Debt Payment+ Preference Dividend+ Interest).

However the example below may show that ROI and EVA results may be contradictory and more accurate interpretation is required.

Let's suppose of a SBU earning currently a return (ROI, ROIC,ROCE) of 30% and that this firm faces an investment opportunity producing a return of 20%

What happens to the ROI of the SBU if the investment is executed?

Before investment: Capital 100, Operating profit 30 or (NOPAT), Capital cost 10%

ROI = 30/100 = 30%, EVA = 30 - (10% x 100) = 20

Investment's capital requirement 20, return 20%/ year: Thus increase in yearly operating profit is 20% x 20 = 4.

After investment: Capital 120, Operating profit 34, Capital cost 10%

ROI = 34/120 = 28%, EVA = 34 - (10% x 120) = 22

In this case decreasing ROI is good for the shareholders, thus ROI should not be maximised and therefore it is problematic controlling tool. Usually large corporations have at least some very profitable units and particularly these units are steered wrongly with ROI.

Due to these contradictions, and for the purpose of having consistent and comparable data and results for interpretation, our recommendation to each SME applying the BS was to stick to its banker's set of financial indicators, as well as to calculate them just like their banker (example: yearend vs. average method of computation, same formulas and periods) (Schoenebeck and Holtzman,2010).

Although ratio analysis is a powerful tool in credit risk evaluation (Bacidore *et al.,* 1997), banks have understood that it is not the only means in this process, as they are other as important parameters for such assessment. Besides, high quality of one ratio may mean a poor quality of another dimension or ratio, as in the box above, also it may not guarantee a sustainable continuous basis of the respective ratio, as they are based on the past.

The results obtained after the application of all the five Pillars of the balanced-scorecard were as presented below and they may represent on average about 20% of the overall credit risk evaluation, where each ratio may have equal strength. The limitation here resides in the calculation of these ratios for the end period and comparison with only the same period a year before not with a trend of at least 5 years.

Last, but not least important, the study employed the stress test of the cash flow from operations, which proved to be also a sensitive issue for the SMEs in Romania, but less sensitive for those in Cyprus. The positive cash flow indicator shows the ability of the SME to satisfy the potential cash flow constraints in case of credit default. At the same time, it is a clear cut indicator compared to meeting just industry adjusted liquidity levels. Although there is no benchmark for the volume, an arbitrary level of 20% was set, which was met by all SMEs applying the risk BS, but not fully by those not applying our risk BS. This may be correlated to the positive results of the other financial indicators, but it proved to be a rather sensitive indicator in this case.

The financial improvement for the SMEs utilizing the risk BS proposed seems overall higher for both countries, which may be or not related to the parallel implementation of the other Pillars' elements, or just as a placebo effect or a noise effect in the market.

The results for these ratios were obtained directly from the SMEs, after being provided with the same formula of calculation. Obviously the element of trust was essential, but also the double calculation based on the companies' key financial statements. However, due to differences in accounting standards and taxation, there are always differences in the input results, hence in the final results. However, since 60% of the firms were medium size companies, they have adopted IAS and therefore the margin of error has significantly diminished, being left only with the input error probabilities. However, to understand risk, one needs to understand the distribution of potential

Table 4. Pillar II: Results per country

Pillar II Parameters Available	Equivalent Bilaterally set Benchmarks	No application of risk management balanced-scorecard		Direct application of risk management balanced-scorecard	
		Romania SMEs	Cyprus SMEs	Romania SMEs	Cyprus SMEs
Cash ratio	0.5 to 1	0.15	0.25	0.35	0.44
ROI	15%	3%	5%	14%	12%
ROE	15%	8%	10%	16%	12%
EVA	15%	2%	4%	12%	10%
Stress Tested Cash Flow	Depends on industry, set up at 20%	No	50% No	Yes	Yes

outcomes and also apply consistently the same calculation/computation formula.

Consequently, it seems there is a definite opportunity to take actuarial type standards to modeling insurance risk for example, and apply them to other operational, financial and strategic risks that organizations face.

As for the stress tests, (Chorafas, 2006) covering stress analysis and the use of scenarios, models, drills, Monte-Carlo simulation, benchmarking, back-testing, and post-mortems, creditworthiness, wrong way risk and statistical inference, probability of default, loss given default and exposure at default, stress testing expected losses, correlation coefficients, and unexpected losses, stress testing related to market discipline and control action, and pillars 2 and 3 of Basel II (www.bis.org)., all these seem to be very complicated to an SMEs, therefore they find their usefulness in banks and the financial sector and rarely in SME sector. For such a reason, the levels were bilaterally settled. This is not only due to their intricate nature and data warehouse needs, but also due to the human factor interpretation or, moreover, response in the business world.

Further stress tests parameters could be added for SMEs performing import-export activities, in order to observe and control associated foreign exchange exposures (Aabo, 2010) and hedging techniques (Woods *et. al.,* 2007).

Pillar III: The Enterprise Supervision and Resource Development Package (ESRDP)

This is a redesigned part of the BS that looks into the development of the learning and growth aspects of the HRM, looking at: employee turnover, investment rate, illness rate, performance pay, gender ratios and frequency of supervision.

Despite arrangements to follow a risk management procedure this part of the BS has encountered difficulties in implementation due to the low level of employment of several firms from our sample, hence results may get a rather poor interpretation.

The only ratios available for Pillar III in this situation are the following:

Before assessing the above indicators the firms applying risk management have acquired several series of knowledge transfer regarding the guidelines for risk management implementation.

There is no clear trend in this series over the analyzed period, except for the decrease of employee turnover for the case of Romania, perhaps due to less people finding opportunities for employment during financial crisis in the SME sector. Interestingly, there is a slight increase of the female employed population versus the male one in the SMEs applying risk BS in both countries, compared to those who do not. But, there is quite a dramatic tendency for unemployment to rise sharply during periods characterized as economic recessions. Both countries have experienced a

Table 5. Pillar III: Results per country

Pillar III. Parameters Available	Equivalent Bilaterally set Benchmarks	No application of risk management balanced-scorecard		Direct application of risk management balanced-scorecard	
		Romania SMEs	Cyprus SMEs	Romania SMEs	Cyprus SMEs
Employee turnover	n/a	20%	5%	5%	4%
Gender ratio	n/a	38% women	30% women	41% women	33% women
Frequency of Supervision	n/a	The same	The same	Increased control and audit	Increased control and audit

superior/effective application of the control and audit function. Indubitably, this last parameter of Pillar III is correlated not only with the other financial and ERP applications of the proposed BS, but also with the way the management empower personnel and allocate the bonus system. Some results also suggest that a firm's incentive or ability to offer fair employee treatment is an important determinant of its financing policy. (Bae, *et al.,*2010).

Also, the relation between incentives and risk is more positive when the manager's effort is more effective in collecting information or in acting upon it. Using data on chief executive officers (CEOs), Shi (2011) found that incentives for CEOs increase with industry-wide risk, a measure of respondable risk. The positive relation diminishes when the CEO is less able to collect information or is less effective in acting upon it. Reason, for which we recommend even more a set up of a tailored scorecard for the Pillar III.

If at bank level, Cash *et. al.* (2010) found only modest evidence that CEO compensation plans promote significant firm-specific heterogeneity in bank risk measures or risky activities, for SME's executives, due to the nature of the activity, this may not be valid.

In this case a SME's general manger or managing director would be in charge to appoint someone to lay down risk parameters and establish risk management control systems. This stage includes the following the below steps:

- Risk Management Architecture / Structure for all risk areas encountered by the industry and the particular firm.
- SME's to get the necessary equipment in getting the ability to identify, measure, monitor and control the various risks.
- Set up an Integrated Risk Management Framework, such as the study's BS or a similar system.
- Move towards Risk based Supervision and Risk focused Internal Audit to enhance risk management functions.
- Set up a Change Management Team or a Crisis Management Team.
- Perform a Risk aggregation and budget allocation for this function and its activities.

Pillar IV: The Enterprise Technological Networking Advance (ETNA)

This particular pillar looks at the technological environment impact on the business and measures indicators such as: level of computerization, number of software packages, number of technological changes in a year time, return on investment in technology.

Regarding ETNA, most SMEs need to build up an Industry Databases which makes available information from an organised centre that offers control for offices and operating levels and help in the risk analysis and in the performance of daily activities.

Table 6. Pillar IV: Results per country

Pillar IV. Parameters available	**Equivalent Bilaterally set Benchmarks**	**No application of risk management balanced-scorecard**		**Direct application of risk management balanced-scorecard**	
		Romania SMEs	Cyprus SMEs	Romania SMEs	Cyprus SMEs
Level of computerization	n/a	The same	Average increase of 2 computers per firm	Average increase of 4 computers per firm	Average increase of 5.5 computers per firm
Software packages	n/a	The same	The same	10% increase	25% increase
ROI in technology	n/a	n/a	n/a	n/a	18% increase

The degree of computerization of the two countries at the sample level have increased, with a larger spur in the Cypriot firms on both hardware and software, and we assume that this was reflected also in the ROI in technology figures. For certain groups of companies operating in manufacturing investment in technology seem to be benefic also in financial terms even on a short term period in Cyprus, while such information is only assumed in Romania, too. In this sense, more explicit details should be obtain as to the purpose of the acquired technology, the business cycle stage of the firm (Hamilton, 2010), if for incremental change, for improvement of daily activity, or for radical change (as in Pillar V), or for facing market demand shifts (despite contraction of demand), or even for future strategic plans.

Pillar V: The Enterprise Innovation and Radical Change Development (EIRCD)

At this stage we assume already that the SME will be exposed to previous learning methods and patterns and we try to identify the possible risk related to implementation of new change processes due to either risks or economic/financial crises. The indicators which may measure this development stage are: employee turnover, investment in innovation, number of radical changes in a year regarding strategy, operational profit margin change post innovation and product leadership per innovation.

This last pillar suggests a high distribution of innovation at the level of SME for both countries, with present both incremental and radical innovations, and with almost double expenditure in Cyprus, but with more results in Romania, although the Cypriot innovations seem to be more profitable. These innovations may account more or less for the employee turnover reduction, where investment in such areas brought a higher stability on freeze of staff on the market, but are certainly provided a cutting edge in the future competitiveness of these firms.

Solutions and Recommendations Based on Discussion of Results

If we consider our model based on a general linear model: Yp=∑ (XB)+εi, where Yp is the study's risk metrics final result or the response variable of each SME applying the suggested model, ∑ represents the sum from 1 to 5 of each pillar's result X, which is the a random discrete variable of almost sure equality that belongs to {0,100} or has an alphanumeric equivalent translated into

Table 7. Pillar V: Results per country

Pillar V. Parameters Available	Equivalent Bilaterally set Benchmarks	No application of risk management balanced-scorecard		Direct application of risk management balanced-scorecard	
		Romania SMEs	Cyprus SMEs	Romania SMEs	Cyprus SMEs
Employee turnover	n/a	20%	5%	5%	4%
Investment in innovation	EUR 50k/ firm	n/a	n/a	EUR20k/firm	EUR40K/firm
Number of radical changes regarding strategy	5/5	0	0	4/5	3/5
Operational profit margin post innovation	20%	n/a	n/a	16% manufacturing 20% services	18% manufacturing 18% services
Product leadership per innovation	Minimum 1 per county	n/a	n/a	2 (service industry)	0

a numerical range belonging to {0,100}, B is a fixed parameter of 0.2 (the equivalent of a equally distributed weight of each pillar), and εi is an unobserved variable that adds noise to the linear relationship between the dependent variable and regressors (X), which for each case we assume it to be close to zero. Eventually the maximum score of the BS will be Yp=100x0.2+100x0.2+100x0.2+100x0.2+100x0.2+0=100.

Where there is no value of the components that make up X, 100 points will be divided for the filled in values only, thus their weight in X become slightly higher.

However, for better interpretation of results, a larger sample together with a more detailed separation of the SMEs according to their representative industries is recommended.

A unique characteristic of this BS is that it can be customized to the specific needs of the company, industry, business cycle, manger and stakeholders, depending also on the emerging risk assessment results and on the capacity to interpret risk of the organisation. This way, the BS will offer the flexibility for the SME's management own judgment and appraisal of the firm's generic and specific risks, as well as offering an adaptable tool to the market change and the technology change in risk management techniques.

A simple Final Rating Model of the BS suggested for SMEs, could look like Table 8.

There is always room for providing a minimum passing grade for each pillar (perhaps 15, depending on industry dynamics) and for the entire scorecard (perhaps 80 instead of 100). However, after getting the score most important becomes the choice of the most appropriate solutions in risk management.

Therefore, in view of the presented results in the above section, one should interpret all these result by correlating both the pillars among them and the indicators within each pillar.

For example on Pillar I, the two countries SMEs obtained mixed results on customer satisfaction on both categories of samples (with no risk and direct risk management application). Although, the results show that Romanian SMEs who have applied risk management as per this study guidelines have obtained higher customer satisfaction on average than the Cypriot SMEs which did so, these results create a paradox interpretation. At the same time we need to understand the results of the following pillars to see if this is a long term or an erratic change.

As for the ratios calculated as per Pillar II, one can notice an improvement of liquidity ratios for the SMEs with risk management in both countries, registration of higher standard deviation for Romania for the SMEs with risk management tools.

This may indicate a higher concentration of risk on a particular industry (manufacturing for Romania) or a different application style and

Table 8. The Balanced Scorecard final rating and interpretation

Pillars	Pillar I	Pillar II	Pillar III	Pillar IV	Pillar V
Overall Score	100	100	100	100	100
Obtained Score	=90x0.2+0= 18	=80x0.2+0=16	=75x0.2+0=15	=50x0.2+0=10	=75x0.2+0= 15
Areas of risk mitigation (example)	Insufficient green activities	Insufficient ROI and EVA	High employee turnover	Identify benchmarks	Increase investment in innovation
Recommendations	Identify ways of implementing more green activities	Seek alternative sources of capital,	Develop or change the performance pay system	Seek industry Database and build up the MIS, perform data mining.	Supervise innovation output and return on investment in technology.

management rigor of the scorecard. The results show also a significant change from inefficient investments to efficient ones, especially in the area of manufacturing, and especially for Romania, and at a lesser extend for Cyprus, where investments in trading seem to be more efficient. These results have a standard deviation at a constant average of 8%, while highest average is obtained in manufacturing in Romania and in services and manufacturing in Cyprus.

Again, Romania sees to obtain the highest value of increase in EVA, perhaps due to the ability to pass through the financial crisis.

However, when correlating ROI, EVA and operating profit results for Romania, it appears that the cost of capital is dearer in this country. At the same time the industry with a higher increase is again the manufacturing one, followed by trading one.

When interpreting the results of Table 9, regarding the four financial ratios calculated for the two types of SMEs in the two countries, one can notice the same standard deviation of EVA as for the ROI for SMEs applying our BS risk model in Romania, which is consistent to the two indicators' controversy presented in section 1, Pillar II. Other discrepancies are seen in random higher standard deviations for the SME which applied our BS, particularly in Romania, except for the case of the ROE indicator, where the standard deviation is higher in the case of SMEs applying no-risk model. The same statistical tool shows relatively lower values variation for the SMEs in Cyprus applying the BS, as well as smaller differences in the average values between SMEs applying the BS and those who did not, compared to the Romanian counterparts.

For Cyprus, the highest spur of average values is obtained by SMEs applying risk management tools in the service industry. Also, for Cyprus there is a higher increase in the average ROI vs. the increase of the average EVA for SMEs applying BS. This could be related to the lower ROE and the higher increase in capital for the Cypriot companies for capital expenditure on innovation, radical change and MIS or on computer and technology acquisitions.

The Cash Flow Stress Test shows the ability of SMEs to pass through liquidity problems. Both countries' SMEs which applied risk management scorecard have passed this test. Those SMEs who did not apply the BS failed the test completely in Romania, whilst only 50% of the Cypriot SMEs non BS risk applicant passed the test. This may be correlated to different market mechanisms and different funding facilities available for SMEs in the two analysed countries, or to each company's economic strength, or to the support of the findings of the literature review (Shi, 2011) regarding executive mangers' compensation packages based on their ability to mitigate risks.

Table 9. Pillar II's ratio averages and standard deviations for the cash ratio, ROI, ROE and EVA

	Cash Ratio		**ROI**		**ROE**		**EVA**	
	Average	STDEV	Average	STDEV	Average	STDEV	Average	STDEV
SME (Romania non risk)	0.15	0.07	0.03	0.05	0.08	0.08	0.02	0.04
SME (Romania risk BS)	0.35	0.10	0.14	0.06	0.16	0.06	0.12	0.06
SME (Cyprus non risk)	0.25	0.09	0.05	0.07	0.10	0.08	0.04	0.06
SME (Cyprus risk BS)	0.44	0.05	0.12	0.05	0.12	0.08	0.10	0.06

In the same manner one can analyse the qualitative indicators, paying attention at meeting the benchmarks, however, there is no exact recipe for getting the best value since one high indicator may mean a possible negative response in another indicator.

Obviously in the end there is a set of the questions that sends us back to Hubbard's literature review of whether we have chosen the right indicators or ratios and if we have calculated them consistently, if the interpretation is the same or if the strategic objectives are met or not eventually. For this issue the fact that the SME develops procedures and involves cross-departmental teams in the area of risk management proves to be an additional risk mitigator, if not even a performance enhancer.

FUTURE RESEARCH DIRECTIONS

It is worth trying to make an analysis as a separate research that crosses the borders of a case study and adds in a large number of SMEs from various countries or regions and upon a larger number of defined indicators to be able to draw a more accurate combination of ratios that are more appropriate in risk evaluation and mitigation for the future generation of SMEs.

Another issue is related to the potential cultural aspects in the way risks are dealt with or risk management is applied in general, the level of uncertainty acceptance, the entrepreneurial spirit in each country, as well as the trends regarding particular reasons for defaulting in one country or another, if any. This may be related to other structures of externalities beside the common affecting ones, such as corruption levels, red-tape level, political implication of actions and others.

From the point of view of comparison against benchmarks or benchmarks translation may be required. It could be mentioned also that a better approach may to set benchmarks not only for periods of boom, normal growth, but also for recession times.

This approach has not been used within this study, the benchmarks being commonly agreed with all the participating subjects (i.e. the managers of the SMEs' sample).

Regarding the fine tuning of the ratios calculation or even choice or the sets of qualitative indicators, the advantage of this balanced-scorecard is that it provides room for adaptation to any industry and it shows how to use and measure or put together under a flexible rating system the obtained results.

CONCLUSION

Upon the analysis of a representative number of SMEs in Cyprus and Romania in the area of trading, manufacturing and services, the findings show the areas where the two countries provide stronger versus weaker appraisal indicators. The strong areas for Romania seem to be manufacturing and trading, while for Cyprus the service industry, all these neglecting the level of the cost of capital in both countries.

The BS utilised indicators have been analyzed from both quantitative and qualitative perspectives and could provide a feedback loop for improvement of SMEs activities as well as for paying attention to other uncovered areas of risk management, such as measuring the impact of a "once in a lifetime" event.

If risk management programs really do work, then it seems logical to assume that companies in a given industry with a (self proclaimed) "highly effective" risk management program would show greater shareholder returns, less earnings volatility, and better safety and regulatory compliance records (Mihai-Yiannaki, 2010) than other companies in their peer group who lack such a program. Yet, there appears to be no valid evidence that current risk management practices, taken as a whole, serve to improve overall corporate performance. The evidence just isn't there, and the research thus has to agree with Hubbard (2010).

The calibration on the rating scale or a balanced-scorecard for SMEs is expected to define also the future deals pricing and other related terms and conditions for the undertaken transaction or operational exposures. Also by tracking down previous transactions' risks, any SME can find resources to discover new business relationships and/or deals, or to improve existing ones, renegotiate or give up certain business relationship or even take legal actions in due time.

Such a prediction or simulation is important not only for forecasting and planning purposes in operational management of the firm, but for accounting and provisioning purposes, as well as for future capital budgeting or even for strategy redesign and resources redeployment.

Moreover, by having such a risk management system in place in parallel with a sound firm strategy, the SME becomes more equipped for the future, its management and human resources more astute on risk mitigation techniques, overall being capable to control better the company and to adapt to crises conditions and adverse risks, altogether creating a cultural-cognitive pressure for environmental sustainability.

Whatever measurement of risk derived out of models especially in operational risks, it is difficult to do back- testing or stress testing. The measurement may be correct (not the absolute figure) in some cases for predicting the trend if other things remain constant. Hence, measurement of tail events does not reflect the true picture of uncertainty in short term (within a year). Therefore, measurement of risks shall provide some strategic inputs towards the direction/movement of risks not in absolute terms.

Thus, it's not just a case of accurately assessing and management individual risks, associated to each SME's activity but also in considering the extent to which there might be a "domino" or "contagion" effect among different risk factors, or among the risk pillars, and how can the SME interpret and integrate the results.

Eventually, this study does show significant improvement in the results obtained by risk management lead SMEs in both countries, compared to those not operating by this norm.

KEY TERMS AND DEFINITIONS

Balanced Scorecard: The balanced scorecard in general is a strategic planning and management system that is used widely in any business activity worldwide to attain vision and strategy of the respective organization, improve information flows, monitor organization performance against strategic goals. It was originated by Drs. Robert Kaplan (Harvard Business School) and David Norton as a performance measurement framework that added strategic non-financial performance measures to traditional financial metrics to give managers and executives a more 'balanced' view of organizational performance.

Crisis: 'Negative impact turning point', while from a business perspective, it might be a substantial, unforeseen circumstance that has a higher probability than usual to jeopardize a company's stakeholders, products, services, fiscal or legal situation, or reputation. Both definitions contain an element of urgency that requires immediate decisions and actions from management and employees involved and most possibly from other stakeholders.

Crisis Management: The process of preparing for and counteracting an irregular negative event in order to prevent eventually the organization to fall apart. Crisis management resides in a set of well-coordinated actions to implement thorough control of any potential damage and preserve or re-establish public confidence in the system under crisis.

Entrepreneurship: We refer in the chapter text to entrepreneurship regarding SMEs, as its most obvious form of starting a new business, including its recent association to its terms of social and political forms of entrepreneurship.

Operational Risk: The risk of direct or indirect loss resulting from inadequate or failed internal processes, people and systems or from external events. We define SMEs Operational Risk as any risk which is not categorized as the risk of loss arising from various types of human or technical error either internally or externally triggered.

Risk Assessment: As a component of risk analysis, it involves identification, evaluation, and estimation of the levels of risks or hazards that have a certain probability to get involved in a situation, their comparison against benchmarks or standards for a particular industry or category of business, and its determination of an acceptable level of risk for the business.

Risk Management: We considered risk management for SMEs, as that particular combination of strategies, policies, procedures, and practices involved in the identification, analysis, assessment, control, and avoidance, minimization, or elimination of unacceptable risks emerging from future events. A company can use risk assumption, risk avoidance, risk transfer, risk retention or any other strategy in risk management. Risk Management is a planned method of dealing with uncertainties to estimate expected and unexpected losses. Risk Management essentially implies identification, measuring, monitoring and controlling risks. Identification of risk is the first and essential step in risk management to assess the extent to which risk could or should be taken and put in place risk mitigation measures. Risk Management is an on-going process as the dynamics change with time. Guidelines on risk management provides broad parameters and each firm may evolve their own systems compatible to their risk management architecture and expertise.

Risk Measurement: Choosing to ignore risk is the riskiest thing a firm can do. One does not measure risk as a stand-alone metric, instead continually analyses the environment to anticipate and avoid situations that may potentially damage the organisation. Some things are thought to be immeasurable only because it is believed that measurement must be some exact value. But the more pragmatic scientific approach to the term measurement is to treat it as quantified uncertainty reduction based on observation (Hubbard, 2010).

Risk Mitigation: We considered risk mitigation or risk reduction the systematic and managed decline in the level of exposure to a risk and/or to the odds of its occurrence.

Sustainable Innovation: The term of sustainable innovation in connection to the risk management of SMEs relates to that particular management approach that leads any new product or service, companies to analyse the benefits, risks and impacts of not only economic factors, but also social and environmental ones.

Chapter 48
Aircraft Development and Design:
Enhancing Product Safety through Effective Human Factors Engineering Design Solutions

Dujuan B. Sevillian
Large Aircraft Manufacturer, USA

ABSTRACT

Effective Human Factors Engineering (HFE) has provided the aerospace industry with design considerations that promote aviation safety in the development of complex aircraft systems, as well as the operators and maintainers that utilize those systems. HFE is an integral aspect within the systems engineering process. Measuring the effectiveness of Human Systems Integration (HSI) in the research & development stage is critical for the design of new and modified systems. This chapter focuses on how providing effective HFE design solutions enhances product design and system safety. Providing the customer with safe and reliable products augments mission capabilities throughout the product lifecycle.

INTRODUCTION

Multi-modal transportation such as aviation, marine, rail, transit, cycle, pedestrian, and motor vehicles all provide the general public with choices for determining which mode they prefer to utilize. The cost of travel, safety, and transportation reliability are all factors the public uses to determine their travel choices. From a safety perspective, federal agencies have provided the general public with safety statistics for all modes of transportation.

The National Highway Traffic Safety Administration (NHTSA) released data on fatal car crashes in 2008. According to the Fatality Analysis Reporting System (FARS) of the NHTSA, there were

DOI: 10.4018/978-1-4666-1945-6.ch048

more than 34,000 people killed in vehicle crashes in the U.S. (Administration, 2008). The Bureau of Transportation Statistics (BTS)-Transportation Statistics Annual Report-2008 report indicated that there were 4,654 fatalities as a result of pedestrians struck by highway vehicles, and 16,520 passenger car occupant fatalities in 2007 (Statistics, 2008). The public continues to manage their personal risks regarding travel choices and determining which mode of transportation is the safest.

Studies conducted by the National Transportation Safety Board (NTSB), a U.S. independent federal agency that investigates transportation accidents, have shown that commercial aviation transportation is a vital asset to the U.S. economy and is one of the safest modes of transportation. According to former NTSB chairman Marion C. Blakey, "The U.S has long depended on aviation, not just as a means of point-to-point travel, but as the hinge on which the door of commerce depends to stay open". "Literally, aviation keeps America open for business" (Blakey, 2007, p.1). Aviation accidents declined between 2008 and 2009. The NTSB conducted a study that demonstrated a reduction of aviation accidents in 2009—where "The total number of U.S. civil aviation accidents decreased from 1,658 in 2008 to 1,551 in 2009". "Total fatalities also showed a decrease from 566 to 534". "On-demand Part 135 operations reported 47 accidents in 2009, a decrease from 58 in 2008". "The accident rate decreased to 1.63 per 100,000 flight hours in 2009 from 1.81 in 2008". The NTSB have also been able to pinpoint that the "the majority of these fatalities occurred in general aviation and scheduled part 121 operations" (Board, 2010, p.1).

Even though commercial aviation transportation is considered a safer way of traveling, incidents and accidents continue to occur within the industry. From an international aviation perspective, high accident rates in Africa and Indonesia continue to be a critical factor in the general public's perception of air transportation safety. Consequently, federal agencies across the globe have made substantial progress in determining influential factors that cause aviation incidents and accidents. In particular, the goal has been to reduce the rate of occurrences and provide the public with a positive image of aviation safety.

The military and civilian air transportation sectors have developed robust strategies of aviation safety management. Federal government officials, manufacturers, airlines, and independent consultant agencies have implemented aviation safety management methods for the continuous surveillance of safety in flight operations and maintenance. These methods were created to reduce the rate of incidents and accidents through various systematic processes. These systematic processes were developed to manage the 'common threads' in incident and accident causation.

After the crash of ValuJet flight 592 on May 11, 1996, the U.S. implemented the Air Transportation Oversight System (ATOS). The ATOS is an inspection system that was designed to systematically manage safety in flight operations and maintenance in the airline industry. Other reliable methods have all provided the airline industry with structured systematic ways of managing aviation safety. Some of these methods are as follows: Aviation Safety Action Program (ASAP), Maintenance Safety Action Program (MSAP), Dispatch Safety Action Program (DSAP), Safety Management Systems (SMS), and the Aviation Safety Information Analysis and Sharing System (ASIAS). Accident investigation, empirical, and theoretical research continues to provide data useful for determining the causal factors of incidents and accidents.

Aircraft design, weather, and human factors have been a constant trend of incident and accident causation throughout the history of the air transportation system. On February 12, 2009, Colgan Air flight 3407 crashed outside of Buffalo, NY with no survivors. The probable cause of this crash was "the captain's inappropriate response to the activation of the stick shaker, which led to an aerodynamic stall from which the airplane did not recover" (Board, Loss of Control on Approach, Colgan Air, Inc., Operating as Continental Connection Fight 3407, 2010, p.1). On August 27, 2006, a Comair Regional jet crashed in Lexington, KY with only one survivor. The probable cause of this accident was "the flight crewmembers' failure to use available visual cues and aids to identify the airplane's location on the airport surface during taxi and their failure to cross-check and verify that the airplane was on the correct runway before takeoff" (Board, Attempted Takeoff From Wrong Runway; Comair Flight 5191, 2007, p.1). The NTSB investigations revealed that the ValuJet, Colgan Air and Comair crashes were considered to be related to the concept most often referred to as 'Human Factors'. According to the Human Factors Accident Classification System (HFACS) Analysis of Military and Civilian Aviation Accidents: A North American Comparison; "Between 70-80% of aviation accidents are due, at least in part, to human error" (Wiegmann, 2004 p. 2).

Historically, Human Factors related deficiencies in air transportation have influenced incidents and accidents across the global airline industry. In December 2003, a ramp worker lost his life while preparing to push back an aircraft. According to the report, the tractor operator's foot accidently hit the accelerator and "the tug jumped forward striking the radome of the aircraft fatally pinning the driver". The investigation revealed that the ramp agent did not set the parking brake (Matthews, 2004 p.6).

The constant trend of human factors related incidents and accidents in the aviation industry appear to be a parallel theme in other modes of transportation such as the railroad, chemical, highway, and marine industries. On June 11, 1997, a bus collision with pedestrians in Normandy, Missouri occurred. The causal factor in this crash was, "The driver trainee's misapplication of the accelerator resulting in the bus's override of the curb and travel onto the occupied pedestrian platform" (Board, Bus Collision with Pedestrians, 1997). On October 12, 2003, a Northeast Illinois Regional Commuter Railroad train derailed. The probable cause of the derailment was "the locomotive engineer's loss of situational awareness minutes before the derailment because of his preoccupation with certain aspects of train operations that led to his failure to observe and comply with signal indications" (Board, Derailment of Northeast Illinois Regional Commuter Railroad Train, 2003). Even in the design of Unmanned Air Vehicles (UAVs), "the Air Force Scientific Advisory Board (AFSAB) identified the human system interface as the greatest deficiency in current UAV designs" (Williams, 2006 p.1).

The term Human Factors is frequently utilized in the aviation industry. Human Factors can be operationally defined in this chapter as factors influencing the behavior of the human based on several dynamic critical interfaces. Generally speaking, the interfaces that affect human performance include: environmental conditions, software/hardware factors, and interactions with other humans. HFE is the application of human capabilities and limitations as they relate to the design of systems. HSI is the systematic process of integrating the human with the system so that the human has the ability to operate, maintain, and support personnel needs within the applicable environment. HSI is needed to reduce possibilities of human performance related errors and to promote aviation safety. These definitions will be further explained throughout the chapter. Additionally, HFE and HSIs relationship to overall aircraft systems design will be discussed.

Reducing the possibilities of human error can be a rigorous task. The industry has developed several methods to aid in the reduction of human performance based errors. Some methods such as: HFACS, Maintenance Error Decision Aid (MEDA), and the Ramp Error Decision Aid (REDA) are internationally accepted methods designed for human error reduction. Essentially, these methods are utilized to help manage the risk of human error and to better prepare the human for the tasks and environmental conditions they will experience.

Several years ago, the term 'pilot error' was commonly used by air safety investigators to describe an individual(s) flying an aircraft that was involved in an aircraft incident or accident. It is paramount to understand that 'pilot error' is not synonymous with the term human factors. The refined definition of human factors requires a complete understanding of the 'human element' as a system interfacing with a series of systems. The process of integrating the 'human element' within a system is not a parallel process within the systems engineering discipline. Therefore, understanding the dynamics of the human system interface continues to be a challenging and critical aspect in the development and design of complex aircraft systems. Nevertheless, one might ask the question, 'How is a system designed without human error?' It is impossible to design a system without the possibilities of human error. In fact, as long as there is human interface with a system, there will be the potential for errors. As engineers, investigators, scientists, and specialists, we must determine the impact of the system design on human performance, while minimizing the potential risk associated with the hazards.

The goal of this chapter is to provide the reader with a clear understanding of the need for human factors considerations at the design stage, and to examine the factors that influence safety throughout the product lifecycle. This chapter will provide case scenarios related to human factors and system design; to further demonstrate the relationship between the human and its interfaces. Furthermore, there will be a discussion of human factors issues. Finally, solutions, industry recommendations, and future research directions will be provided. An outline of topics that will be covered throughout the chapter are as follows:

- General understanding of system engineering and design architecture
- Human integration vs. system design
    - Cognitive interfaces on system design
    - Physical interfaces on system design
- Enhancing product integrity through promoting effective system safety management
    - Hazard Identification
    - Hazard Analysis
    - Hazard Mitigation
    - Hazard Monitoring

BACKGROUND

Since the Wright Brothers flight on December 17, 1903, the aviation industry has learned from, scientists, pilots, engineers, and other aviation professionals, the need to develop safe technologically advanced aircraft systems. Since World War II, the design of aircraft systems, and the apparent human factors influence on these systems has increased the ability for research and development in the human performance domain.

The aerospace industry has learned how to design aircraft systems that are reliable, safe, cost effective, and efficient for the crewmembers that utilize those systems. Recent developments in aircraft design and test, such as the Boeing 787 Dreamliner and the Boeing 747 Large Cargo Freighter (LCF)-Dreamlifter further re-iterates the continuous strategies and perspectives of safety through constant innovative new technologies. However, the design of complex aircraft systems can be a challenging effort. An abundance of engineers are required to produce quality products that are safe, human compatible, reliable, and meet the customer mission requirements. As the complication and interdependence in systems grow, the certification and testing of those systems continues to be a crucial factor in aircraft system development (Abbott et al., 1999).

It is inevitable that when engineers design a system, there will be some type of human interface with the product. Whether the system is a manned or an unmanned crew station, human system interface continues to be a persistent issue when designing any aircraft system. Software and hardware technological advances have provided the industry with the opportunity to design systems that have components that are interconnected. However, these systems have the potential to fail (Abbott et al., 1999). These failures can be considered systematic failures, those related to the aircraft system functions and human system interface failures, and those related to the integration of the human with the system.

Failures related to the system reflect deficiencies in the way a system was executed. These insufficiencies are due to lack of training, personnel selection, operating policies, maintenance and organizational support issues. Human system interface failures are design errors which include hardware, software, environment, and training factors. These design errors are the result of insufficient integration of the human with the system. In particular, Graphical User Interface (GUI), and other ergonomic equipment design related issues are some of the factors that influence the user interface (McSweeney and J.Pray, 2009).

It is important to understand that having a technologically advanced system does not constitute a safe and user-compatible product. The human utilizing the system has to be able to effectively operate and maintain the system. If the operators and maintainers cannot effectively utilize the system, then the potential of human error exists and the design becomes incompatible for the user. In order to reduce the possibilities of design human incompatibility that could lead to induced human error, an understanding of the system design architecture becomes a crucial aspect at the design inception stage. During this stage, both systems engineers and design engineers work together to understand the system fundamentals.

A system is defined as an interactive integrated composition of architecture that work together to achieve a specific mission. According to Chapanis (1996), there are three views of a system: the physical view, functional view, and the operational view. The physical view is based on the population of people that the system will contain. Next, the functional view focuses on how the system should work from an operational perspective. Last, the operational view is based on how the users interface with the system. Systems engineering is the iterative integrated process of managing the development of complex systems throughout the product design lifecycle. Without systems engineering, it would be difficult to manage the development of any aircraft system because systems engineering provides the framework for managing the design.

MAIN FOCUS OF THE CHAPTER

"The Iterative Process of Aircraft Development & Design"

When a customer solicits participation in an aircraft design contract, they want a contractor that can provide customer service that will support their mission needs. Whether these customer mission needs are to fly passengers from point A to B, or to fly a secret mission, it is paramount when designing any aircraft system to implement a 'systems thinking' tactic to design. A 'systems thinking' approach to product design is a disciplined scheme to problem solving. Typically, this process can be defined as how certain systems influence the aircraft as a whole. The approach also focuses on how the human interfaces with a system and its components. Utilization of 'systems thinking' should occur when determining the purpose of the system, functional capabilities, and operational capabilities. Finally, this approach requires knowledge of five general integrated areas related to systems engineering. The five taxonomies are as follows:

- Product definition
- System and mission requirements
- Functional Analysis/Functional Allocation
- System Design
- System Test

When designing an aircraft system, it is important to understand the conceptual design stage, which is most commonly referred to as the product definition. At this stage, the forecasting of engineering strategies, business planning development, and proposal planning are considered and executed. Reputable competition strategies are a key asset within the product definition stage. While competition strategies are key to the development and design of aircraft systems, system engineers create program plans to effectively collaborate and manage the process of design. The HSI Program Plan, Human Engineering Program Plan (HEPP), System Safety Program Plan (SSPP), Reliability/Maintainability Program Plan, and System Engineering Management Plan (SEMP) are just some of the program plans that should be developed at this stage. These collaborative program plan approaches to engineering design should be reviewed with the customer. These plans are needed so that the customer has a clear understanding of how the engineering process will be managed.

The contractor Statement of Work (SOW) provides the foundation for understanding baseline level customer requirements. From a system engineering perspective, a requirement defines a necessary element or characteristic that must be satisfied in order to achieve operational capabilities. A requirement should be further emphasized in order to determine how it applies to the system and the environment.

System and mission requirements are essential components within the systems engineering process. System requirements describe 'what' a system shall do from a hardware and software perspective. Mission requirements are performance specifications and they relate to 'how' the system shall perform in a particular environment. For example, a system requirement may be, 'the software shall be compatible for the display user interfaces'. A mission requirement may be, 'the satellite shall be capable of differentiating between various types of surface matter'. The impact of these requirements must be further explained and reviewed by the customer and contractor. Trade studies help systems and design engineers understand how the system and mission requirements impact the user operational and environmental characteristics. It is imperative that these requirements are thoroughly examined in order to ensure consistency in the application of the requirements in system design; this is needed to ensure the requirements are attainable, verifiable and valid.

The functionality of a system drives certain requirements. Whether the system is electrical, hydro-electrical, mechanical, or pneumatic, a complete understanding of how the system functions relative to the requirements assists the designer with developing the system. Furthermore, the function of the system assists the designer with how the system will perform in an operational environment. Examples of system functionality in an operational environment are the aircraft phases of flight. Typically, the aircraft phases of flight are as follows: pushback, taxi, takeoff, climb, cruise, decent, and landing.

The function of an Aircraft Communications Addressing Reporting System (ACARS) is to provide the aircrew with a digital data link utilized as an interface between dispatch and crewmembers. Some of the characteristics of the ACARS system are the capability to send information such as aircraft system performance data characteristics, generation of weather reports, flight plan management, and maintenance message communications. The data generated from the ACARS ease communication with airline System Operational Control Centers (SOCCs). SOCCs are the communication command centers at the airline base of operations that ensure the aircraft and crew members are operating adequately throughout the phases of flight. To ensure that the crew is operating satisfactorily, maintenance control, dispatch, and other related airline functions are communicated through the use of the ACARS. The ACARS system is utilized in all phases of flight.

Another system that is utilized in flight as a power generator is the Auxiliary Power Unit

(APU). The function of the APU is to provide the aircraft with an additional power source. This power may be used for transferring air to the cabin for air-conditioning purposes or electrical power distribution. The APU also assists the crew in an emergency situation (engine loss, or failed power generator) by providing the crew with an alternative means of power. Moreover, the function of the system must be evaluated so that the system engineer understands how to meet customer requirements and the impact of system operations.

Typically, after the functions of the system have been defined and analyzed, the allocations of the functions are evaluated. Functional allocation is "a procedure, for assigning each system function, action, and decision to hardware, software, human operators, or maintainers or some combination of them" (Chapanis, 1996, p.101). Functional allocation is an important concept because it assists the designer with an understanding of the viability of technology related to software and hardware interfaces. Additionally, the software and hardware interfaces should be reviewed by HFE to determine the practicability in meeting the requirements. The data evaluated at this stage of the process are previous experiences with systems, technologically advanced performance capabilities or mechanical systems and software systems related to human limitations. Functional flow diagrams help facilitate and understanding of the functional allocation process (Chapanis, 1996).

The system and mission requirements are reviewed by the contractor and customer. These requirements are derived and further delineated through a series of customer reviews. These reviews help the customer and contractor understand the feasibility of the design for future product developments. Depending on the mission, the customer may choose how they want certain requirements implemented in particular stages of the system design; this is normally based on current and future design strategies.

An Operational Readiness Review (ORR) determines the feasibility of proceeding to the concept exploration. The inputs to this review are the operational need analysis and the operational concept analysis (Chapanis, 1996). The contractor develops the concept document to determine if customer needs are satisfied.

A System Requirements Review (SRR) is then conducted with the customer to determine how the requirements will be utilized to design the system. Depending on the program, there may be a series of SRRs developed to further delineate the requirements through incremental stages of the contract. The SRR also examines the various methods of compliance to the requirements and the methods the contractor has chosen to perform analyses to meet the requirements.

Normally, the System Design Review (SDR) is conducted after the system specifications have been reviewed. This review is required to determine if the integrated system will meet the requirements (Chapanis, 1996). The human factors requirements that are ordinarily reviewed (as they relate to the overall system) are as follows: Human Computer Interaction (HCI), ergonomics, safety, operations, maintenance, personnel requirements, and training.

During the Preliminary Design Review (PDR), the customer, program management, and various engineers are assembled to review the current design philosophy. The PDR includes the approach to various design configurations such as hardware component specification, software specifications, and detailed requirements for future test evaluations. Specialty engineers provide support to the PDR approach and they include: Reliability Maintainability & Testability (RM&T), Electrical, HFE, and system safety engineering.

After the PDR, the Critical Design Review (CDR) is coordinated. This review is the final review before the production stage of the system. The purpose of this review is to compile all of the detailed engineering data related to software and hardware configurations. At this stage, engineering drawings, mockups, HFE, safety, reliability & maintainability analyses are reviewed. Engineering data is provided to the logistics team in order to update or develop new training methods and procedures to support crewmembers in the operational environment.

Last, the Test Readiness Review (TRR) is conducted to review the design integration as it relates to the capability of the system to operate effectively in the operational environment. The design is tested in regards to the interface between the human and the system to ensure user compatibility and safety; various test plans are developed to test system effectiveness. Test reviews are performed to ensure that the contractor has met all of the customer requirements and that the system is suitable for the operational environment.

"The Human Integration Strategy"

Historically, the systems engineering process has been portrayed as a complex integrated approach to product design. The process has worked for several years in the development of aircraft systems. Each stage of the system engineering process conveys a common theme. This theme is related to the continual need to ensure 'system compatibility' so that the system can function in the operational environment. It is pertinent for design engineers to develop systems utilizing their knowledge of engineering design. However, a more important aspect is the design of the human into the overall system design.

Most of the literature related to system design covers a wealth of information regarding overall system design effectiveness and operational support. However, it is argued that there is a consistent issue with the value, understanding, and the application of implementing a HSI approach to engineering design. In addition, HSI is often considered an 'excess cost agent' to program management and to the customer. How should a system be designed to encompass program and customer requirements, and cost dynamics, while also providing the customer with a safe and effective integration of human system interfaces? This is the primary question that most human systems integration engineers, human factors engineers and specialists ask themselves when participating in any program.

The U.S Air Force, Federal Aviation Administration (FAA), U.K. Ministry of Defense and the Canadian armed forces have all incorporated HSI within their Human Factors commercial and defense programs. HSI is the comprehensive management strategy for effectively implementing the human with the system, in order to fully support the human interfaces considering various conditions.

This strategy provides, tools, techniques, to help facilitate a more robust effort for human integration within systems. Previous approaches only focused on hardware and software integration issues. This strategy focuses on the end user and the relative operational dynamics (Reinach, 2007). Qualitative and quantitative realistic approaches should be utilized to evaluate the risk and to measure the need to utilize a HSI approach in the program development stage. In particular, trade studies should be used to provide evidence to the program regarding the need to implement a HSI program.

Customer program management, contractor program management, design engineers, and system engineers should all interface with HSI. According to the Defense Acquisition Guidebook (DAG), there are seven domains applicable to supporting the integration of the human with the system. The seven domains are:

- Manpower
- Personnel
- Training
- Environment, Safety, and Occupational Health
- Survivability
- Habitability
- HFE

"Manpower can be a major determinant of program cost and affordability" (Guidebook, 2010, p.2). Manpower focuses on operations and maintenance tasks and conditions in the operational environment that are associated with workload. Moreover, the manpower perspective focuses on the need to support military and civilian manpower. Manpower considerations are important to the customer. Program management should consider developing case studies and engineering analyses to optimize manpower and reduce costs to affordable levels. Effectively utilizing manpower considerations in system design can reduce the cost associated with design and operations. One factor that reduces the cost of manpower is an understanding of user tasks as they relate to the system functional allocation processes. If the engineer understands the user tasks, then only relevant tasks will need to be evaluated. These tasks are unique to the system design, and are related to cognitive, physical, environmental, and other related conditions. Evaluating these parameters helps the customer determine proper manpower considerations for their program.

"Our uniqueness as individuals--the way we were raised and educated, our work experiences, and genetic compositions--affect the way we perceive the world and act upon it" (Strauch, 2005, p. 47). Personnel considerations are developed based on the Knowledge, Skills, and Abilities attributes (KSAs) of individuals. The KSA attributes are related to the cognitive and physical demands of the system versus the demands for personnel needed to perform the jobs (Guidebook, 2010). These factors are used to determine the experience levels that operators and maintainers need to perform their job task. KSAs help engineers understand human capabilities and limitations as they relate to system design and personnel qualities. Lastly, personnel selection helps engineers design tasks properly in order to reduce the possibilities of human error.

"Training is the learning process by which personnel individually or collectively acquire or enhance pre-determined job relevant KSAs by developing their cognitive, physical, sensory, and team dynamic abilities" (Guidebook, 2010, p1). When the customer and program management have completed the CDR and the customer is satisfied with the design, training factors need to be discussed with the customer as they relate to the new/modified design. These factors include simulation training, On-the-Job-Training (OJT), or Computer Based Training (CBT). After these factors have been addressed, it is paramount that when personnel are trained, they understand the new or modified system functions and their components. Ongoing training should assist personnel with the new/modified operating procedures and new or modified system capabilities (Strauch, 2005). Essentially, documents such as Aircraft Maintenance Manuals (AMMs), Flight Crew Operations Manuals (FCOMs), and Technical Orders (T.O.s) are just a few of the documents that may need to be updated as a result of the new/modified system design. These updates are needed to ensure that the new/modified equipment design aligns with the nucleus of the training program curriculum.

Environment, Safety, and Occupational Health (ESOH), are essential components to the HSI process. Understanding the factors that influence the surroundings of the human when operating and maintaining a system can provide designers with an understanding of how to accommodate the user with the system. The environment includes "the conditions in and around the system and the operational context within which the system can be operated and supported" (Guidebook, 2010 p.1). In particular, certain environmental issues should be evaluated by engineering. Some of these issues include acoustical noise, vibration, and electric shock. Engineers need to determine the safety impact on the human and the mission as a result of environmental conditions. Safety related issues such as workspace design, Personal Protective Equipment (PPE), hazardous waste, and radiation need to be evaluated to determine the impact on the human and the mission. Warnings and cautions that are depicted on systems or within workspace areas should be clear and concise. These placards should provide the user with enough information to understand the warnings or cautions and provide meaningful information for the user to make the most practical decisions. Warnings and cautions should be effectively communicated in training manuals, test procedures, and OJT. While understanding the impact of safety on the human and mission is practical, it is also important to realize the effects of unsafe designs on the human in a particular environment. The occupational and health perspective is incorporated within the design to explain the potential risk of the design on the human body that could lead to musculoskeletal issues, injury, illness, or disability.

Providing the program and customer with an assessment of the occupational hazards as well as a, relative cost benefit analysis helps the customer with evaluating the risk. This evaluation can be used to determine if a design is suitable for the user population. Data presented by occupational safety specialists at the CDR provide the customer with an early indication of the hazards and the applicable mitigation processes.

The survivability domain is most often related to the military or defense environment. Survivability factors are related to design features that reduce the risk of man-made hostile environmental conditions. Survivability design and operational techniques should be outlined in the program requirements. All requirements should be further defined to provide the engineer with an understanding of the type of environment the human will be susceptible to versus the system design. Certain clothing and survivability gear may be utilized to prevent the possibilities of death or the abortion of a mission. An example of survivability gear is the Nuclear, Biological, and Chemical (NBC) gear. This gear should be designed so that the user can perform the mission operations while minimizing the potential risk of injury or fatigue. In particular, some factors to consider when designing NBC gear are egress capabilities, and extreme environments. It is important that the crewmember has the ability to exit the aircraft immediately and survive conditions on the land or sea. HFE assists with making decisions that may affect the design of the user interfaces.

Habitability focuses on the living and working conditions for the user population, in order to effectively accomplish a mission. Depending on the mission, the customer may require only certain aspects of habitability. Some characteristics of habitability are as follows: ambient lighting, food servicing, lavatory service, and medical support. HFE and other related specialists should determine the effect of the design on the user, and develop methods for evaluation to optimize user performance in the habitability environment.

HFE is the application of human capabilities and limitations as they relate to the design of systems. HFE should be implemented within a program to reduce manpower and provide effective crew training. Previously stated, when the system functional allocation is performed, the user interfaces should be identified and evaluated by HFE. HFE should be applied during the development stage of equipment design; this application provides the customer with an understanding of the human machine interfaces. Any related tools (modeling, prototyping, simulation) or techniques (Crew Station Working Groups (CSWGs), workload analysis, strategic processes) should be outlined in the HEPP to address how the user interfaces will be managed throughout the product design stages. Generally speaking, user interfaces include: display design, GUI, maintainability, training systems development, training manual development, workload analysis, and Ground Service Equipment (GSE) support. All interfaces should be reviewed with the customer and program management to understand the cost, and design impacts. A meticulous technology strategy review should be utilized when determining the best method to reduce cost associated with modeling and simulation because these cost drivers could affect the program budget. Understanding the customer requirements for HFE prior to development can reduce the cost of design by eliminating extraneous methods of analysis and evaluation. HFE should be cost effective for the program while enhancing user interface capabilities. If a HSI program is developed, a complete understanding of the HSI domains helps with system development and design, thus providing the customer and the program with data for managing the factors influencing system design.

HFE: "Indispensable Solutions in Design"

So far, the issues relative to transportation safety, system design, and the interfaces related to HSI have been acknowledged. Within the confines of HSI, the remainder of this chapter will focus primarily on the HFE domain of HSI. Also included will be a discussion regarding product safety as it relates to managing system design.

HFE can be separated in to two distinct integrated categories: cognitive engineering, and hardware/human physical ergonomics engineering. To understand the context of cognitive engineering, one must first understand the definition of cognition. Cognition is the study of how the human thinks, perceives and remembers information in a certain environment. Cognitive engineering is a multidisciplinary field focused on the design and evaluation of systems technology as it relates to human interfaces and cognitive processes (Gersh, 2005). Since the Three-Mile Island nuclear power plant incident in 1979, a focus on how the human interfaces with workplace design and socio-technical systems continues to be evaluated by scientists and engineers. In addition, human interface with system controls and displays has been on the vanguard of cognitive scientific research. Cognitive engineering may focus on HCI as it relates to GUI or other cognitive demands on the human in a particular environment. Cognitive engineering also focuses on workload and human performance in specific environments. Hardware/physical ergonomics engineering is the application of human dimensions, physics and biomechanics on human system design integration in a specific environment.

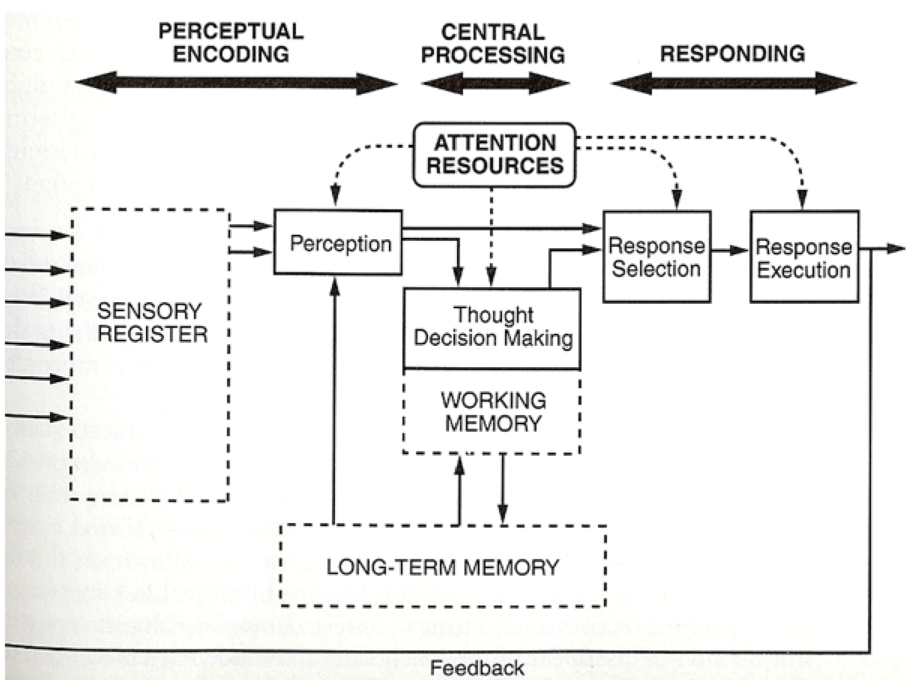
From a cognitive perspective, when functional allocation decisions are considered, HFE should assist the program with making those decisions. It is imperative that once the functional allocation decisions have been made, that HFE outlines how those functions interface with the existing requirements. HFE should provide the program with an overview of how the system functional allocation may affect the human capabilities and limitations. For example, if the requirement is for the human to be able to control system functions, then HFE has to determine the impact of those functions and how they influence the ability of the human to perform certain tasks. These tasks should be based on data obtained from a system functional analysis. The data should be utilized to determine if the functions of the system interface are compatible with the user prospective environments.

After determining the impact on the user and system functional capabilities, the HFE should perform a task analysis. A task analysis is utilized to identify tasks and sub-tasks related to the user environment, and comparing those tasks to the operator and maintainer cognitive processes in order to achieve a goal. Essentially, the task analysis is utilized to: reduce potential hazards and errors, increase human reliability in system interface, evaluating user-system processes, and analyzing personnel needed to perform certain tasks such as operator related tasks or maintainer related tasks. The data generated from task analyses provides information to logistics for developing training documents and other related OJT. The task analysis should describe the human system interactions as they relate to human capabilities and limitations. The results from a task analysis drive new personnel and manpower requirements; these requirements may indicate a need for additional crewmembers or a reduction in crewmembers. A task analysis would be practical if the HFE is evaluating HCI on an operator aircraft display at a particular crew station. The HFE should evaluate the ability of the user to process information on the display screen while performing a task. Whether the task is evaluating the integration of overlays on a display or determining the color and text size, it is important to evaluate how the human processes this information. In order to perform the task analysis, the HFE should have a clear understanding of the Human Information Processing System (HIPS) theory.

According to Wickens (1998), there are three stages in the HIPS theory. The perceptual stage focuses on how the human perceives stimuli and compares it to memory and knowledge to give it meaning. The cognitive stage focuses on how we relate new information to memory or goals to solve problems or make inferences. The action stage is the final stage of the HIPS theory that focuses on how the central processing unit (brain) responds and coordinates utilizing certain motor signals. Once the HFE understands the HIPS theory, the HFE should utilize the Information Processing Model (IPM) to examine all human system interactions to clearly understand how the human processes information related to the system design in a particular environment. The IPM is a model that portrays how the human interprets a stimulus and responds to certain system inputs in a particular environment. Figure 1 illustrates the IPM; this is a generic model used for human information processing.

Hardware/human physical ergonomics engineering focuses on human anthropometry as it relates to the system interface. Generally speaking, HFE integration should support at least the 5th percentile (typically who are female) and at most the 95th percentile (typically who are male) as the critical human dimensions. Critical human dimensions such as: stature, weight, chest breadth and depth are utilized when integrating the human with the system. Designing systems for the 5th and 95th percentiles provides a baseline approach for accommodation of the user population. However, depending on the user population (Army, Navy, Air-Force, Civilian), certain case scenarios

Figure 1. Information Processing Model (Wickens, 1998)



may need to be further evaluated to ensure user-system accommodation. These case scenarios are related to certain body dimensions that may be on the outside boundary of the targeted user population for a particular environment such as chest breadth and stature. Figure 2 illustrates the 5th and 95th percentiles and Figure 3 illustrates critical body dimensions.

Locations of controls and displays, workspace design, and system maintainability are just some of the general areas that must be analyzed by HFE to determine the best method to optimize the user interface. HFE industry standards assist HFE with determining the best method for optimizing usability.

The Department of Defense (DOD) and the FAA publish numerous design standards, and design approaches to provide HFE best practices for accommodating the user with the system. If utilized early in the engineering design process, these standards can reduce the cost associated with the development and design of hardware and software systems. These standards and approaches should be outlined in the HEPP to provide the

Figure 2. CATIA V5 5th and 95th percentile Manikins (National Institute of Aviation Research (NIAR) Laboratories)

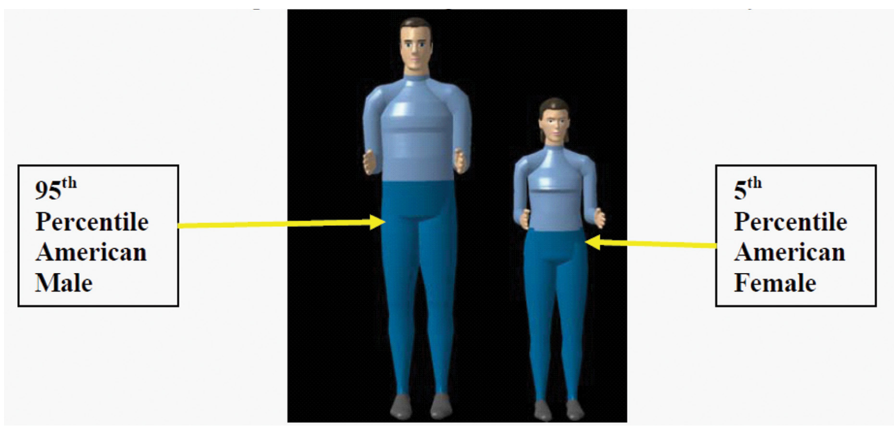


Figure 3. CATIA V5 Manikins critical body dimensions (National Institute of Aviation Research (NIAR) Laboratories)

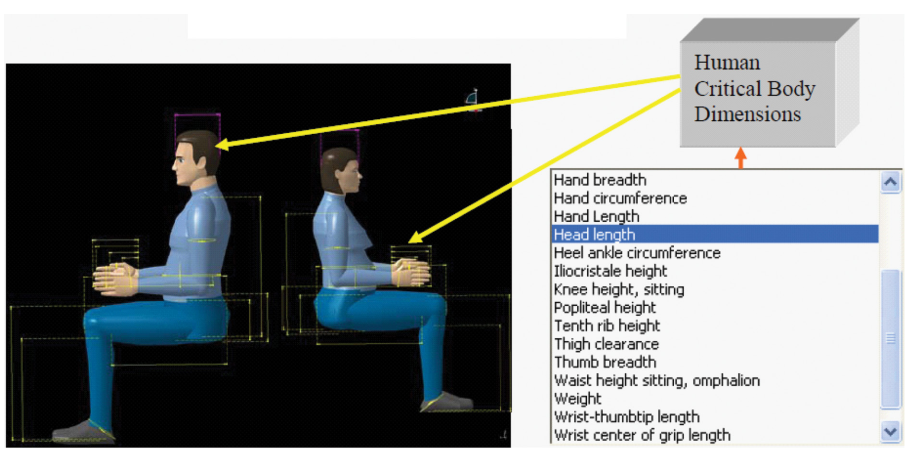

program and customer with and understanding of how the standards and approaches relate to the system requirements. Furthermore, these standards and approaches provide objective data that can be utilized to substantiate issues related to engineering drawings, computer models and the overall systems integration.

MIL-STD 1472 (DOD Human Engineering Design Criteria Standard) is one of the most common utilized standards by HFE for hardware design. Many of the supplemental HFE industry standards are derived from MIL-STD 1472. From a hardware perspective, this standard provides an abundance of data related to the design of certain hardware such as: knobs, dials, pushbuttons, joysticks, pedals, toggle switches, and commonality in systems, just to name a few. The standard also provides information regarding safety, human visual fields, system color coding, and lighting. MIL-HDBK 759 (Human Engineering Design Guidelines) is utilized for determining various anthropometric variables that can be used for the design of systems. Variables such as arm length and chest breadth assist the design engineer with understanding the impact of human dimensions on system spatial integration.

HFE often utilizes design approach documents to help facilitate robust methods for human design integration. Two of the most common design approach documents are the Human Engineering Design Approach Documents-Operator and Maintainer (HEDAD-O/M). Both documents outline HFE methods to assist the HFE with understanding how to evaluate the human interface with the equipment. These documents provide information on how to meet HFE requirements and HFE design criteria. The approaches should be communicated with the customer during SRR and PDR. Communicating these approaches gives the customer a better understanding of how the operator and maintainer systems will be evaluated.

MIL-STD 1472, MIL-HDBK 759, and other applicable standards should be utilized when creating computerized engineering models. These standards provide the HFE with data to support his/her modeling activities. One of the most common systems utilized by HFE for hardware human integration is the Computer Aided Three-Dimensional Interactive Application (CATIA). CATIA is an iterative process application, utilized to develop human engineering models that predict human performance in system design. Rather than having physical prototypes, human engineering models reduce the cost of human factors analysis by providing the customer with an early indication of possible human factors related integration issues prior to CDR. CATIA software provides the HFE with various workbenches to support HFE analysis. Two of the most common workbenches related to HFE analysis are ergonomics and kinematics. These workbenches aid the HFE with developing digital human static models (manikins) and motion activated models that support maintainability and human crew station compatibility.

Digital human static models are utilized to provide multiple case scenarios related to maintainability and crew station compatibility. These models can be manipulated to show human performance issues in system design. The motion activated models provide the customer with an analysis that conveys the relationship between engineering models (system models) and how they are put in to motion (kinematics) relative to the manikin simulated motion. A Digital Maintainability Analysis (DMA) via CATIA would be practical if there is a need to analyze the human access abilities for Removal and Replacement (R&R) of Line Replaceable Units (LRUs). It is important to ensure that the user can access, inspect, and opt for the R&R of LRUs. This analysis is also needed to meet applicable maintainability requirements. Depending on how long it takes maintenance personnel to R&R, access, or inspect a LRU, this analysis could determine the need to allocate certain personnel or manpower for the task. A tooling analysis provides an evaluation of the types of tools needed to access the equipment and the ability to R&R the system and its components; virtual tools (wrenches, screwdrivers, hammers, etc.) are utilized to determine system accessibility.

The force required to remove a LRU is computed utilizing a Push-Pull Analysis; this helps the HFE understand the effort needed to remove an LRU. A carry analysis is used to ensure the user can carry an LRU with respect to system weight and system lifting characteristics. Variability in system weight should be outlined in the system description document or other applicable equipment detail documents. It is imperative that a thorough evaluation of the effects of system weight on human performance is analyzed. User population and system weight characteristics should be identified and defined prior to PDR to ensure these factors are addressed. Depending on the type of environment, cold weather gear may need to be evaluated to determine user compatibility in maintenance operations. Arctic gloves/mittens may be tailored for a certain user population by simulating certain measurements to the hand. Applying specific measurements to the hand utilizing CATIA helps accommodate the design of arctic gloves/mittens.

A Crew Station Compatibility Analysis (CSCA) via CATIA is utilized to ensure crewmembers are able to operate the systems effectively and that they possess the ability to work in their environment. A CSCA should be utilized when determining the user's ability for grasping controls, reaching display screens, or any other applicable hardware at the crew station. For example, if an automated warning, caution, or advisory display message requires crew input to retrieve information regarding a display message, it is important that crew's ability to access the information is optimized. In other words, this means that the display needs to be designed so that the user has access to the display and has the ability to operate the controls effectively. Hand size dimensions should be evaluated with respect to control system design to ensure that the human has the ability to grasp or press certain buttons.

Line of sight and visual field evaluations are utilized to determine human system visual compatibility. Certain equipment such as Helmet Mounted Displays (HMD) may be evaluated to determine operator spatial orientation and the ability to recognize objects in the operator Field of View (FOV). Essentially, the HMD analysis should be evaluated to ensure the user's ability to effectively perform a particular mission. Additionally, the customer mission requirements may dictate a need to accommodate a certain user population in regards to the design of the HMD.

A human posture analysis should be utilized to determine the need for the operator to maintain a certain posture while operating a system at a crew station. In regards to pneumatic systems, such as crew oxygen, it is important to evaluate the crew's ability to reach oxygen masks while maintaining a certain posture. Furthermore, variability in seat designs such as the ability of the seat to be elevated or lowered is critical to understanding how the seat design affects the user's ability to reach the oxygen mask. In particular, the stature of the human could affect the ability to operate certain controls at the crew station. The analysis should provide the designer with information to develop or modify a seat configuration so that it is compatible for the user.

Table 1 illustrates the types of analysis that HFE should conduct utilizing CATIA in order to

Table 1. CATIA/human system interface design considerations

measure the efficiency of hardware human system interfaces related to human performance.

CATIA models should be utilized to communicate with the program and the customer during the PDR and CDR. Providing these analyses assists the program with understanding the impact of HFE on the operator and maintainer interfaces. Lastly, CATIA models help facilitate the integration of system design, while providing assistance with determining the safety impact on system design.

Product Safety: 'A Management Perspective'

Thus far, various meaningful methods for accommodating the user from a cognitive and hardware engineering perspective have been mentioned. These methods are paramount for evaluating user interfaces. However, the need to evaluate user and system compatibility are not the only methods for ensuring product user efficiency.

Product safety management is the ability to manage safety related risks by providing reliable safety analysis suitable for the operational environment. Product safety management is imperative when certifying any aircraft or system. Safety risks are evaluated to determine if an aircraft and system can meet certification requirements to be certified. Various methods of reducing the risks associated with system hazards prior to system design have provided the industry with the ability to engineer-out or to provide other solutions to mitigate certain hazards. These hazards could have a direct influence on the aircraft, system/subsystem and the user. Hazards associated with the aircraft, or system/subsystems could affect mission capabilities, and hazards associated with the system/subsystem user could affect personnel life and work environments.

The most common way of reducing risks associated with a system/subsystem and the user is through the application of system safety engineering. System safety engineering provides the program and the customer with an early identification of risks. A risk is defined as the probability and severity associated with a particular hazard. System safety engineering identifies latent and active failures to reduce the potential of a hazard. Latent failures are related to system/subsystem deficiencies which may be undetected. An active failure is the result of failing to detect system/subsystem deficiencies in which case, the possibilities of an incident or accident are likely. Although latent and active failures occur in system and subsystems, the result of the failure could have an effect on the human. Thorough analysis techniques should be utilized to disclose the risk associated system and subsystem failures and their possible effects on the human. Through the use of fault tree analysis, Failure Modes and Effects Analysis (FMEA), and other related system safety analysis techniques and philosophies, the program and customer have a realistic view of potential risks on the system, subsystem and the human.

During the product definition phase, a SSPP should be utilized to outline the system safety organization plan on managing safety related program risks. The customer should provide the safety requirements to the contractor so that the contractor has an understanding of how the safety requirements may affect the system design. The system safety engineer should determine the best methods to meet those requirements. During the PDR, the system safety engineer provides a preliminary evaluation of the system/subsystem risks during certain phases of flight; risks associated with system human integration are also identified. It is essential that the system safety engineer analyzes the risk from the system component and aircraft level, in order to understand the impact of the risk for the proposed design configuration. From a military perspective, MIL-STD 882 (DOD Standard Practice for System Safety) is used to determine the levels of risk associated with certain designs and operations. ARP-4761 (Guidelines and Methods for Conducting the Safety Assessment Process on Civil Airborne

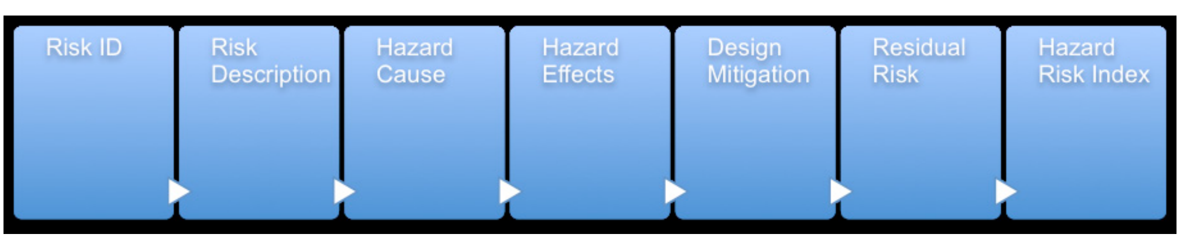
Systems and Equipment) is normally utilized for commercial aircraft or systems. The techniques utilized for identifying risks may be different, but the philosophy of risk identification and mitigation should be transparent and support customer and program goals.

Classically, a preliminary risk assessment starts with the identification and description of the risk. This provides the program and customer with an understanding of the issue. For example, the risk description may be characterized as: 'Possible insufficient installation of LRUs' (Risk Identification #1). All risk descriptions in the preliminary risk assessment should be related to the proposed design configuration and must be clear and concise. The system safety engineer must have a clear understanding of the system description and the system function in order to proceed to the next step of the preliminary risk assessment. The next step of the assessment is to identify the causal factors and the effects of the risk. In this case, the causal factors could be related to the design of the LRUs and the integration in to the aircraft. The effect may be the LRU falling off an equipment support rack, leading to maintainer injury. As a result of the LRU falling off the rack and depending on the LRU location on the aircraft, the potential for inhibiting egress operations for the operator and passengers may exist. Next, the design mitigation strategy and any residual risks are identified. In this case, the design mitigation may be to re-design or relocate the LRUs to ensure the LRU installation configuration is optimized. To ensure the design is optimized, engineering drawings and CATIA models will need to be modified. Customer and program management must understand the engineering change and the potential effects on the mission. Any residual risks (risks left after design mitigation) should be identified and communicated with the customer at PDR. Finally, a preliminary hazard risk index should be provided to identify the probability and severity associated with the hazard. Figure 4 illustrates a typical preliminary risk assessment table outline.

All new or modified risks should be identified as the design develops. As the design matures, certain risks may need to be further communicated with the contractor, program management and the customer prior to CDR. For example, certain risks that could affect mission capabilities or relatively high risks such as radiation hazards should be effectively communicated. It is the responsibility of program management to adhere to recommendations provided by system safety engineering and incorporate certain design features to reduce the potential risk of a hazard. As the program transitions in to test and operations, a thorough evaluation of the hazards should be communicated through a series of safety assessment reports. The reports generated should be inclusive and provide conclusive evidence for the reporting of potential risks. Any analysis relative to potential system level, aircraft level or personnel hazards should be documented and monitored through a tracking system. It is up to the contractor to effectively monitor and provide updates to the customer regarding new or modified hazards.

The overall goal of safety management is to ensure that incidents and accidents do not occur

Figure 4. Typical preliminary risk assessment



within the lifecycle of the product. By implementing a product management safety perspective on system design, the user is provided with the necessary mitigation techniques in order to maintain safety in maintenance and flight operations.

Throughout this chapter, the framework for understanding the need for Human Factors design integration perspectives in the early stages of system design have been provided. There has been the discussion of the need to provide safety management perspectives in the early stages of design in order to reduce the potential for hazards in the maintenance and flight operations environment.

Theoretical perspectives in human factors and safety are important facets in understanding the core of user-system compatibility. However, theoretical perspectives are not the only methods of communicating issues in the industry relative to human factors and safety. Illustrating practical solutions provide the industry with a clearer understanding of the issues pertaining to product system safety and system usability. Three case scenarios related to human factors and system safety engineering are provided below. These case studies will provide the reader with realistic approaches to integrating the human with the system design effectively while providing safety considerations needed to optimize human performance. The case studies are organized as follows:

- Issue
- Effect
- Engineering Analysis
- Recommendations

CASE STUDIES

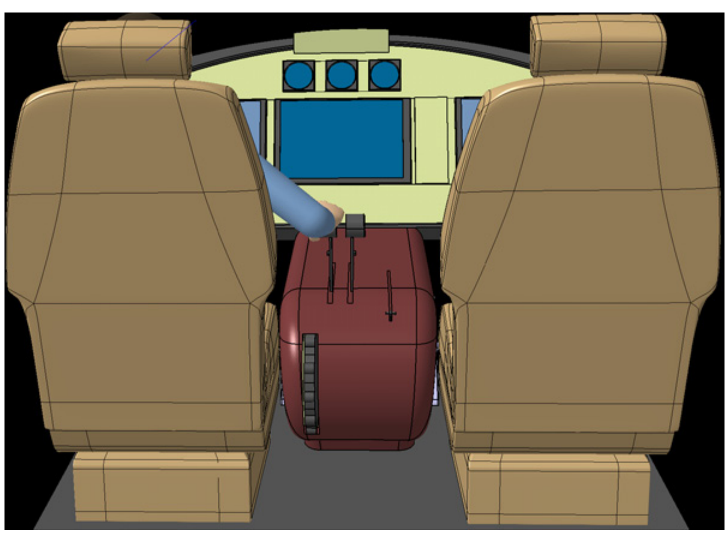
Figure 5.

Case Study# 1

Issues

- The flight crew's inability to reach and read display due to seat configuration (95th percentile male is 1.17 inches away from display and the 5th percentile female is 4.68 inches away).
- Crew's inability to respond to warnings and cautions due to the seat configuration. Program management is concerned with

Figure 5. Crew Station Prototype, National Institute of Aviation Research (NIAR) Laboratories



the ability to meet the aircraft transport category airworthiness standards in 14 CFR 25.1322 (flight crew alerting-warnings, cautions, and advisory lights).

- Need to ensure that the design eye angle position is compatible with user display interface in order to effectively respond to the warning and caution lights. This is also needed to meet the requirements set forth by 14 CFR 25.1321 (arrangement and visibility)
- The display characters and color scheme needs to be evaluated to ensure user system interface compatibility.
    - Need to evaluate the flashing rate of the warnings and cautions on the display

Effects

- May affect the crew's response in the critical phases of flight
- Mission critical and safety critical
- Could affect flight deck certification requirements
- Increased workload

Engineering Analysis

- Determine applicable methods to integrate the human with the system and to meet safety/flight deck certification requirements (Figures 6 and 7).

Case Study #1 Recommendations

- A physical hardware engineering analysis is needed to ensure user system interface compatibility. Change seat position or crew station to accommodate the 5th and 95th percentile population. The seat position change should provide the ability for both percentiles to reach and read the display. If this analysis is not sufficient, HFE many need to provide an analysis based on operator population boundary cases.
- Change seat geometry to accommodate the 5th and 95th percentile population posture. The seat change is needed to ensure the crew members can respond to warnings and cautions annunciations. This change will reduce the system safety risk and increase

the likelihood of meeting flight deck certification and airworthiness requirements.

- A cognitive engineering analysis is needed for the Flight Management System (FMS). The display needs to be re-designed to ensure crew members can read the information and interpret the data effectively to ensure mission success. If a software change is not immediately available during flight test operations, a temporary bulletin will need to be implemented in to the FCOM. This is needed to assist the crew members with an alternate means of understanding how to set up the flight plan via the FMS during flight test.
- Need to relocate the FMS system from the throttle quadrant area to an optimal viewing angle to accommodate the human vertical and horizontal visual fields. This analysis is needed to ensure compatibility with user system view angle and to ensure the user can see the FMS system at the optimal viewing distance.
- HFE needs to provide software engineering with standards for display character size and color logic. Also, provide software engineering with display overlay flash rate standards. Last, HFE needs to evaluate the feasibility of integrating aural warnings with the textual terrain and traffic visual

annunciations to provide the user with an increased situational awareness.

Case Study #2

Issues

- Need to ensure the design eye position is evaluated with new seat design, also need to ensure the operator can still see the display
- Need to ensure the applied weight/cushion compression on the seat does not affect the eye position or the seat reference point

Effects

- Inability to meet safety/certification requirements. Crew members may not be able to respond to an emergency effectively
- Safety and mission critical issue
- Could affect the program schedule

Engineering Analysis

- Determine most effective solution to comply with certification and safety requirements (Figures 8 and 9).

Case Study #2 Recommendations

- Ensure seat length and width corresponds with the human physical dimensions. This is needed to ensure compliance with MIL-STD 850.
- Ensure that the change in seat geometry does not affect the eye position or the ability to read and interpret information on the aircrew display.
- Ensure seat geometry change does not affect the ability to meet certification and airworthiness standards.
- Perform a simulation study to determine human body movement limitations within the seat configuration.

Figure 8. Case Study 2: Seat Schematic (MIL-STD 850-Aircrew Station Geometry for Military Aircraft)

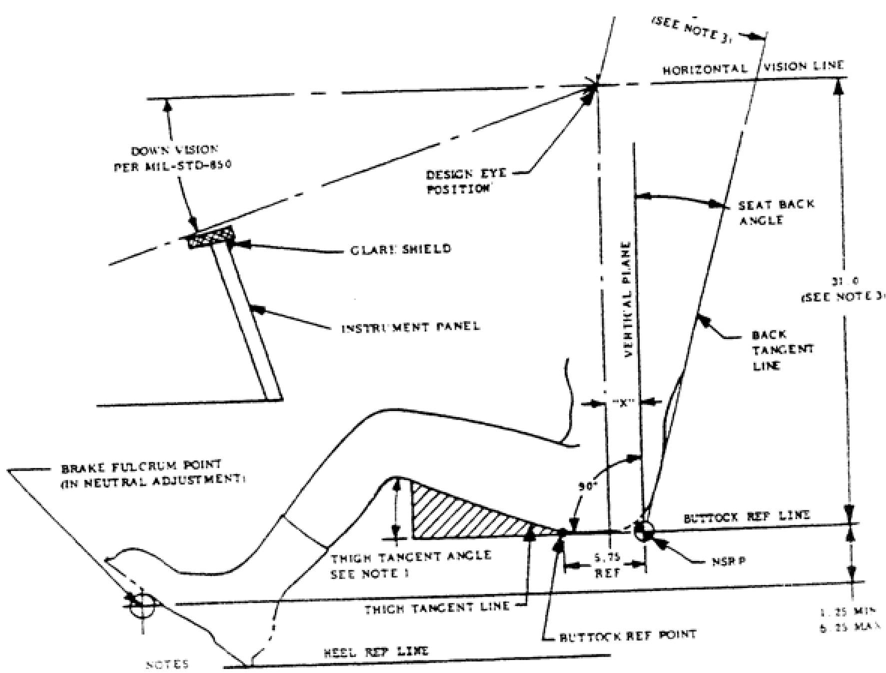

Figure 9. Case Study 2: Sevillian, Dujuan (Ph.D. candidate-Cranfield University, UK) Crew Station Human Modeling [Seat Analysis-Wireframe Configuration] NIAR Laboratories

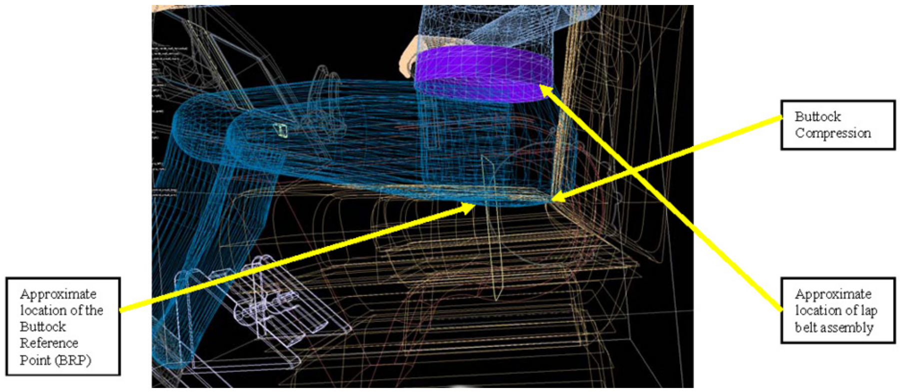


Case Study #3

Issues

- Flight crew posture and stature inadequate for flight test operations
- Human must remain strapped in lap belt in order to effectively reach rudder pedals but cannot reach pedals - (5^{th} and 95^{th} percentiles issue)

Effects

- Inability to reach rudder pedals
- Possible knee contact/strike with crew station
- Safety and mission critical issue

Engineering Analysis

- Determine most effective way to accommodate crew and meet MIL-STD 1472 and the FAA Human Factors Design Standards (HFDS). Need to utilize MIL-HDBK 759C for anthropometric dimensions (Figures 10 and 11).

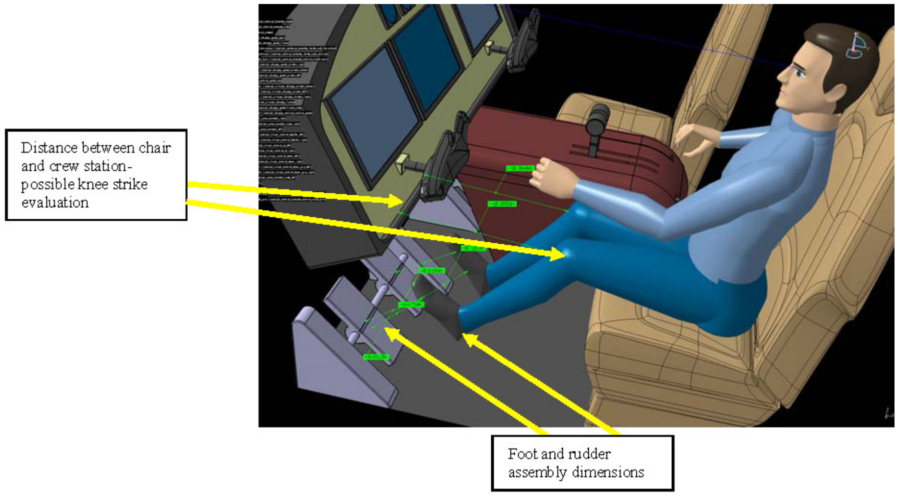
Case Study #3 Recommendations

- Ensure that the dimensions of the human leg and foot integrate with the design of the rudder pedal assembly.
- Ensure the posture of the human is not affected due to the change in rudder pedal configuration.
- Ensure the ability to move seat lateral and vertical to reach rudder pedals. This is needed to accommodate and optimize human abilities to operate the systems within the flight deck.
- Ensure the design configuration does not induce the possibilities of crew member's knees striking the flight deck control panel due to the new engineering design.
- Reduce the system safety risk to an acceptable level for the program and customer.

SOLUTIONS AND RECOMMENDATIONS

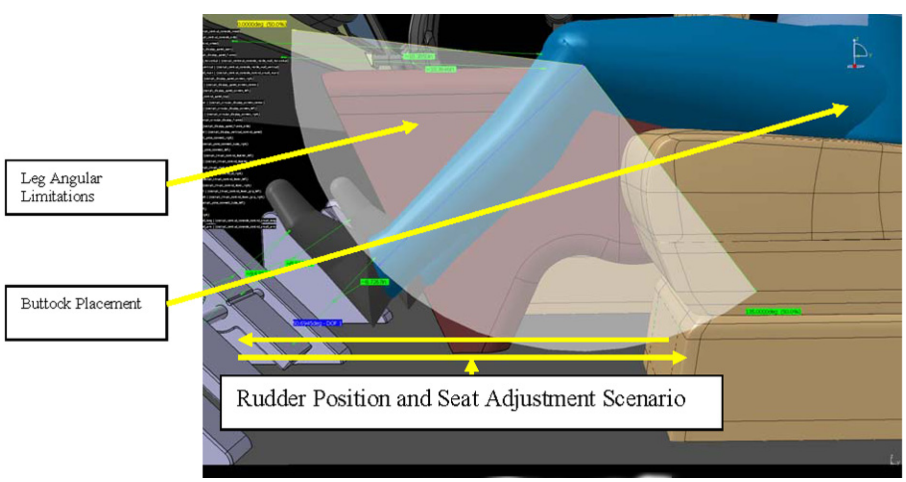
This chapter discussed several methods on human integration philosophies and strategies related to system design. Ensuring effective product safety management is an integral aspect in system design. Risk management is a systematic and collabora-

Figure 10. Case Study 3: Sevillian, Dujuan (Ph.D. candidate- Cranfield University, UK) Crew Station Human Modeling [Rudder/Knee Strike Analysis, Vision, Seat Analysis] NIAR Laboratories



tive effort between program management and the customer which can lead to safe maintenance and flight operations. Implementing effective design solutions provides a practical approach to integrating the human with the system. Understanding program requirements is essential to program success. The program must understand the effects of the requirements on system design. These requirements affect the system design and ultimately the user in their prospective environments. Processes and procedures help facilitate robust strategies for system design management. However, this is not an easy task and it requires a complete understanding of the systems engineering process and how the process interfaces with HFE and safety. Whether the program goal is to implement a HSI program or a HFE program, the program scope and cost dynamics must be further

Figure 11. Case Study 3: Sevillian, Dujuan (Ph.D. candidate-Cranfield University, UK) Crew Station Human Modeling [Rudder and foot dimensions analysis/knee strike analysis, seat analysis] NIAR Laboratories



researched to determine the most effective way to integrate the human with the system. In view of the fact that the overall goal of HFE is to reduce the possibilities of human error in design, strategies must focus on influencing system design concepts with a desire to optimize human system interfaces at the beginning of the program acquisition. In theory, there are seven general recommendations for effective human integration in system design that are recommended. The seven recommendations are as follows:

- Understand the design concept
- Understand the requirements
- Understand the system functions
- Identify the user system interfaces
- Analyze the user system interfaces
- Provide effective human engineering design solutions
- Understand the impact of system design on the user operational environment

FUTURE RESEARCH DIRECTIONS

There is a perpetual need to discover new and more effective methods for integrating the human with the machine and the environment. Research in the field of cognitive engineering appears to be a primary focus within the field of Human Factors Research and Development (HF R&D). New aircraft (unmanned and manned) are continuously being developed and the need to ensure user system compatibility is still a prominent focus.

Pivotal changes in software technology development, such as automation continue to affect human performance in aviation. There have been an abundance of airline and military incidents/accidents related to automation in the flight deck. On June 30, 1994 an A330-300 crashed in Toulouse, France killing seven people. One of the causal factors was the issue related to the user interface with the automation within the flight deck. Automation technology has been a factor influencing the ability for crewmembers to effectively communicate issues within the flight deck. There is a constant need to understand how new automation technology affects Situational Awareness (SA). In particular, CRM in flight deck operations continues to be an issue as more technology is developed for the user community. Questions are asked often by operators, engineers, and scientists regarding automation technology, and the impact on the user interface. 'Does more automation distract the operator'? 'Does more automation provide the operator with the ability to monitor the system better'? Dr. Micah Endsley provides theoretical approaches that can be utilized to understand the impact of automation on the operator interface. According to Endsley, (2000), there are three levels of SA. The three levels are Perception (Level 1 SA), Comprehension (Level 2 SA), and Projection of the Future Situation (Level 3 SA). Understanding these levels provide the framework for determining how to design certain systems that are compatible for the user while increasing SA. There is a constant need to research the impact of new software automation technology on the operator interface during the development and design phases of aircraft systems.

Another focus in HF R&D has been Virtual Reality (VR) and Augmented Reality (AR) applications. Human Factors research in VR & AR environments has provided techniques and strategies to increase human performance. For example, the ability to convey HCI influences on human performance in virtual environments provides the HFE with an understanding of the factors that should be addressed prior to product concept. According to Stanney (1995), an understanding of human sensory and motor physiology is the foundation for understanding the compatibilities and incompatibilities of the human in virtual environments. Human Factors issues such as: Haptic, visual, and auditory perception impact system design in virtual environments (Stanney, 1995). These factors are continuously investigated and are used to determine the impact on human performance.

The book "Technology Engineering and Management in Aviation: Advancements and Discoveries" provides the blueprint for understanding 'how' aviation and aerospace challenges should be managed and executed. Essentially, this chapter illustrates the constant need to effectively manage the human system interface while providing indispensible solutions to development and design.

CONCLUSION

It is common knowledge that air transportation safety is a legitimate reason to design aircraft systems that do not impinge on the user's abilities to perform effectively in particular environments. Designing aircraft systems with the 'Human Element' in perspective provides the foundation for safe maintenance and flight operations. Whether performing maintenance on a landing gear assembly or flying from New York to Japan, it is important that mechanics and pilots have a suitable user interface that enables them to have the ability to effectively communicate and perform their job duties with the highest degree of safety. Therefore, aircraft systems must be developed to optimize the user interface. Expectations of incidents and accidents are likely to occur throughout the lifecycle of a product. However, system designs that optimize human performance can lead to a reduction of human error. Early detection of human performance errors in aircraft design leads to safe and effective maintenance and flight operations.

KEY TERMS AND DEFINITIONS

Critical Design Review: (CDR): The CDR is the final review before the production stage of the system. The purpose of this review is to compile all of the details regarding software and hardware configurations.

Federal Aviation Administration: (FAA): U.S. Government agency charged with developing regulatory standards providing regulatory oversight to the aviation aerospace industry.

Human Factors Engineering (HFE): Is the application of human capabilities and limitations as it relates to the design of systems.

Human Factors: Human Factors are the factors influencing the behavior of the human based on several dynamic critical interfaces.

Human Systems Integration (HIS): Is the systematic process of integrating the human with the system so that the human has the ability to operate, maintain, and support personnel needs within the applicable environment.

Information Processing Model: (IPM): The IPM is a model that portrays how the human interprets a stimulus and responds to certain system inputs in a particular environment.

Line Replaceable Unit (LRU): A system designed to be removed and replaced expeditiously.

National Transportation Safety Board: (NTSB): Agency charged by U.S. Congress to investigate all U.S. transportation related accidents.

ORR: The ORR is a review that determines the feasibility in proceeding to the concept exploration.

Preliminary Design Review: (PDR): The PDR is a review with the customer, program management, and various engineers to review the current design philosophy. The PDR includes the approach to various design configurations such as hardware component specification, and detailed requirements for future test evaluations.

System Design Review: (SDR): The SDR is a review developed to determine if the integrated system will meet the requirements.

System Requirements Review (SRR): The SRR is conducted with the customer to understand how the requirements will be utilized to design the system.

Test Readiness Review: (TRR): The TRR is conducted to review the design integration as it relates to the ability for the system to operate effectively in the operational environment.

Chapter 49

Adoption of Information Technology Governance in the Electronics Manufacturing Sector in Malaysia

Wil Ly Teo
Universiti Teknologi Malaysia

Khong Sin Tan
Multimedia University, Malaysia

ABSTRACT

Past studies and surveys of top management in business and information technology (IT) have shown the importance of strong IT governance in delivering results to the business. This research investigates the extent to which empirical results from past studies is applicable to the electronics manufacturing sector in Malaysia. Empirical evidence from 33 organisations in this sector indicates that having the right decision owners making appropriate decision types lead to better IT governance performance. Organisations with growth as their primary goal demonstrate marginally higher IT governance performance, contrary to expected outcomes. The research also shows that awareness of industry IT governance frameworks is not related to IT governance performance. We conclude that adoption of IT governance is on track, though familiarity with technicalities of the available frameworks should be improved.

INTRODUCTION

Overview

Governance, in general terms, can be understood as the act or process of governing, specifically on the authoritative direction or control. The term "IT governance" as it is known today surfaced in the early 1990s with Loh and Venkatraman (1992) and Henderson and Venkatraman (1993) using the term to describe the mechanisms to ensure attainment of necessary IT capabilities.

In this paper, the terms IS and IT are used interchangeably. The definition of IT governance in this context is based upon the following:

DOI: 10.4018/978-1-4666-1945-6.ch049

1. Van Grembergen (2002) terms IT governance as the role of Board, executive management and IT management to achieve alignment of business and IT strategies through control over formulation and implementation of IT strategy.
2. IT Governance Institute (2003) defines IT governance as "the responsibility of the board of directors and executive management" and "is an integral part of enterprise governance and consists of the leadership and organisational structures and processes that ensure that the organisation's IT sustains and extends the organisation's strategies and objectives" (p. 10).
3. IT governance is "specifying the decision rights and accountability framework to encourage desirable behaviour in the use of IT" (Weill & Ross, 2004, p. 8).

Research Context

Various studies and surveys of top management from business and IT have shown the importance of strong IT governance in delivering results to the business. Of significant importance is the study of IT governance in 256 companies in 23 countries conducted by Weill and Ross (2004). The study provided empirical evidence that strong IT governance leads to more successful business outcomes. This research intends to validate the empirical evidence in the context of electronics manufacturing sector in Malaysia. The motivating factors behind such a research context will be discussed shortly.

Malaysian Industry Development Authority reported that the electronics industry (in combination with electrical industry) achieved a 10.8% increase in sales value to RM195.7 billion. The production index of the industry expanded by 8.7%. Specifically for the electronics industry, the production of semiconductors and other electronic components expanded by 10.4% in tandem with the growing global semiconductor market (Malaysian Industrial Development Authority, 2006).

In addition to the economic significance of this sector to the national economy, there are two other factors behind the choice of research context. Firstly, distinguishing from financial sector where IT governance implementation is often mandated by statutory requirements, such initiatives in the electronics manufacturing sector are likely to be voluntary and driven by business benefits.

Secondly, the use of technology, including IT, is pervasive as the industry moves up the value chain after more than three decades since the first foreign investment started operation locally. The maturity of IT usage means the focus has shifted from basic infrastructure initiatives towards effective use of IT, hence more likely to have emphasis on elements of IT governance.

Problem Statement

With the motivating factors described above, this research was carried out in late 2006 to validate the empirical results from Weill and Ross (2004) in the organisational context of electronics manufacturing sector in Malaysia. Specifically, the research questions are:

1. What is the as-is IT governance level?
2. Why do organisations implement IT governance?
3. How successful has IT governance contributed to the intended outcomes?
4. What are the factors affecting IT governance performance?

The research intends to explore the as-is situation of structure, awareness and performance of IT governance, understand the motivation of IT governance initiatives and assess the alignment of IT governance with business strategies.

Significance of the Study

This research is beneficial to academic researchers, practitioners and policy makers who are interested to understand the as-is situation of IT governance level in electronics manufacturing industry in Malaysia. There is limited prior academic research on IT governance in Malaysia, particularly empirical-type and within this industry. This paper extends the earlier preliminary conference paper (Tan, Eze, & Teo, 2008) in the sense of depth and coverage of the results.

Organisation of the Paper

The relevant theoretical background in IT governance especially in aspects related to this research will be briefly covered, followed by research design, data analysis and discussion.

LITERATURE REVIEW

Boundaries of IT Governance

IT Governance Institute (2003) describes the two fundamental concerns of IT governance as:

- IT's delivery of value to the business, driven by strategic alignment of IT with the business
- Mitigation of IT risks, embedding accountability into the enterprise

In a general sense, Sohal and Fitzpatrick (2002) distinguish governance as the creation of a setting in which others can manage effectively, from management domain where operating decisions are made. Taking this distinction to the IT field, hence IT management focuses on operational aspects, whereas IT governance deals with strategic issues (Van Grembergen, 2003).

Each day, IT managers are faced with a myriad of issues requiring them to make decisions. To remain focused on issues of strategic importance, it is necessary to distinguish:

- Key strategic issues and daily operational issues.
- IT-relevant issues and the business domain

The key IT decision model from Weill and Ross (2004) classifies IT decisions into 5 areas:

- IT principles
- IT architecture
- IT infrastructure
- Business applications needs
- IT investment and prioritisation

IT Principles

IT principles are the high-level statements about how IT is used in the business (Weill & Ross, 2004) or referred to as maxims by Broadbent and Kitzis (2004). Organisations are often confronted with two contradictory dilemmas (Kayworth & Sambamurthy, 2000). IT is expected to respond quickly and flexibly within individual business units. At the same time, enterprise-wide integration depends on the ability of IT to exploit cross-unit synerties. A set of IT principles will clarify the priorities consistent with the organisation's goals.

IT Architecture

Solution architecture addresses both business processes and technological aspects of solution implementation. Effective information architecture is the answer to the dual challenge of "speed and flexibility" and "low cost and efficiency (Allen and Boynton, 1991). Consistent execution is a benefit of standardisation, which in turn results predictability and efficiency.

IT Infrastructure

IT infrastructure is the foundation of planned IT capabilities available throughout the business as shared and reliable services and used by multiple applications (Weill, Subramani, & Broadbent, 2002). The study by Weill, Subramani and Broadbent (2002) found significant correlation between strategic agility and IT infrastructure capability. Managers use IT principles to identify IT infrastructure services that enable the organisation to achieve competitive advantage.

Business Application Needs

The business value of IT is most directly delivered through fulfilment of specific business needs. However, identification of business needs for IT applications often has two conflicting objectives of being creative while remaining disciplined (Weill & Ross, 2004). Both business and IT need to have a common agreement that new functionality might need to be sacrificed if they cause deviation to architectural principles.

IT Investment and Prioritisation

IT investment and prioritisation process determines the amount to be spent on IT, identifies the IT initiatives to be undertaken, and reconciles conflicting needs of individual business units. There is no specific framework to determine the amount to be spent on IT. Departing from the conventional business case and discounted cash flow techniques on IT investment decisions, Ross and Beath (2002) and Irani and Love (2002) propose alternative approaches to justify IT investments and expenditures.

Identifying the Decision-Makers

The study of IT governance from the perspective of who has the power to make decisions is as old as the use of computer systems itself. The simplest form of such study considers only either centralised or decentralised decision-making structure began with Garrity (1963) and continued into late 1990s in various forms (Boynton & Zmud, 1987; Brown, 1997; Olson & Chervany, 1980).

The expansion into vertical form considers multiple degrees of centralisation/decentralisation in the form of continuous classification (Ein-Dor & Segev, 1978; King, 1983; Olson & Chervany, 1980; Tavakolian, 1989), discrete nominal classification and redefinition of extremes within a decentralised form. (Boynton & Zmud, 1987; Dixon & John, 1989; Rockart, 1988). In addition to that, horizontal expansion considers varying degrees depending on the type of decision, rather than the entire IT organisation (Sambamurthy & Zmud, 1999). In this area of study, the focus was on the use of technology (Allen & Boynton, 1991; Brown & Magill, 1994; Dixon & John, 1989; Zmud, Boynton, & Jacobs, 1986).

The pragmatic approach taken in this research follows the ownership of decision-making classification by Weill and Ross (2004, p. 27):

- Business Monarchy: A group of business executives or individual executives (CxOs). Includes committees of senior business executives (may include CIO). Excludes IT executives acting independently.
- IT Monarchy: Individuals or groups of IT executives
- Feudal: Business unit leaders, key process owners or their delegates
- Federal: C-level executives and business groups (e.g. business units or processes); may also include IT executives as additional participants. Equivalent of the central and state governments working together.
- IT Duopoly: IT executives and one other group (e.g., CxO or business unit or process leaders)
- Anarchy: Each individual user

The Execution Stage

Formal Governance Mechanisms

Horizontal mechanisms encourage contacts between individuals in order to coordinate the work of two units (Brown, 1999). These can be task-specific groups (e.g. ad hoc task forces), permanent teams with cross-unit representatives or formal roles responsible for collaboration across units. Commonly found mechanisms include steering committee with membership from IT or mixture of both business and IT, account management teams, and programme and project office (Weill & Ross, 2004).

Once decisions are made, monitoring and periodic reviews are necessary to ensure the execution is on the right path. The mechanisms for monitoring execution include standard operation management processes, service level agreements (SLA), organisation-wide project management methodology and key performance indicators or balanced scorecard (Grembergen & De Haes, 2005; Van Grembergen & Van Bruggen, 1997).

Communication includes formal announcements, information channels and education efforts that propagate IT governance principles, policies and as reflected in the outcome of IT decision-making proceses (Weill & Ross, 2004). In this research, only formal communication mechanisms are considered whereas soft aspects of personal contacts and relationships between the IT management and business are excluded.

Governance Frameworks

There are various frameworks related to IT governance in one way or another. The three common governance frameworks are briefly described here.

Control Objectives for Information and related Technology (COBIT) was first released in 1996. COBIT is organised into four domains: Planning and Organisation, Acquisition and Implementation, Deployment and Support, and Monitoring, 34 high-level processes and 210 control objectives (IT Governance Institute, 2007).

IT Infrastructure Library (ITIL) was developed in the late 1980s by the UK's Office of Government Commerce (OGC). ITIL is intended to increase IT business effectiveness, reduce costs and improve IT services. IT service management practices from ITIL are formalised as the British Standard 15000 and later followed by ISO 20000:2005 Standard (Office of Government Commerce, 2007).

Capability Maturity Model Integration (CMMI) for software development was established in 1986 at Carnegie Mellon University by the Software Engineering Institute (SEI). CMMI defines five stages of organisational maturity with respect to software development. The objective is to improve predictability, effectiveness and control of an organisation's software processes (Software Engineering Institute, 2005).

Effects of Organisational Context

A framework of organisational context predicting the success and failure of IT was proposed by Ein-Dor and Segev (1978). However, no empirical evidence was provided to test the validity of the framework.

Empirical studies relating organisation context and IT governance finally emerged in 1980s through 1990s. These studies were mostly done on organisations in the United States (Clark, 1992; Ein-Dor & Segev, 1982; Olson & Chervany, 1980; Tavakolian, 1989), Europe (Earl, 1989, as cited in Brown, 1997) and Israel (Ahituv, Neumann, & Zviran, 1989).

The most commonly studied organisational context variables were:

- Organisation size (employees or revenue)
- Governance form
- Competitive and business strategy
- Diversity in business
- Industry

Organisation Size

Olson and Chervany (1980) found no differences by organisation size. Interestingly, Ein-Dor and Segev (1982) discovered inverse relationship between organisation size and degree of centralisation (however this study was limited to one city in the United States).

Governance Form

Ein-Dor and Segev (1982) found positive relationship between organisation structure and IT governance. Such finding was also found to be true for organisations in Israel where the only significant determinant in distributing computing resources was the decision-making process of the organisation (Ahituv et al., 1989).

Competitive and Business Strategy

Tavakolian (1989) studied competitive strategy (defender, prospector, and analyser) as the organisational variable relating to IT governance. The study found that companies with defender strategy have more decentralised structure of IT governance compared with prospector strategy. This was extended by Henderson and Venkatraman (1993) on the range of competitive strategy to what was termed as "fundamental domains of strategic choice". The four strategic choices identified in the study were business strategy, information technology strategy, organisational infrastructure and processes, IT infrastructure and processes.

Diversity in Business

Business synergy is found not to be a dominant contingency for IT governance mode or IT synergies of multi-business firms (Sambamurthy & Zmud, 1999). However, Tanriverdi (2006) argues that IT resources can create an IT-based coordination mechanism in a multi-business firm and enhance boundary-spanning organisational capabilities that exploit cross-unit business synergies.

Industry

Of all the organisational context variables discussed, industry is the only one with common agreement by authors of past studies. Olson and Chervany (1980), Ahituv, Neumann and Zviran (1989) and Clark (1992) found no relationship between industry and IT governance. Furthermore, Brown and Magill (1994), in their study of predictors for movement from one to another form of governance, found that industry type is not a strong predictor.

RESEARCH METHODOLOGY

Construct

The theoretical framework is built upon the three key considerations of IT governance outlined by (Weill & Ross, 2004) discussed in the theoretical section: what decisions should be made, who should make these decisions, and how will these decisions be made and monitored.

The questions of "what" and "who" lead to ownership of decision-making as the first construct, while "how" naturally leads to formal governance mechanisms as another construct.

Construct 1: Ownership of decision-making
Construct 2: Formal governance mechanisms

Further, it is imperative that we do not lose sight of the fundamental concerns of IT governance: strategic alignment of IT with the business, and mitigation of IT risks. Thus, the discussion of IT governance is incomplete without considering the business context in which IT operates.

Construct 3: Organisational context

Finally, these 3 constructs lead to the outcome of IT governance.

Construct 4: IT governance performance

Variables

IT Decisions

Each of the decisions can be made by any of the following groups of decision makers, as classified by Weill and Ross (2004).

Decision Types:

- IT principles
- IT architecture
- IT infrastructure
- Business application needs
- IT investment and prioritisation

Decision Makers:

- Business Monarchy
- IT Monarchy
- Feudal
- Federal
- IT Duopoly
- Anarchy (Weill & Ross, 2004, p. 59)

The resultant variable set consists of five variables (one for each type of decision). The value of each variable is reclassified from the six categories listed above into three broad categories, i.e. business, IT or joint decisions. Reason for this reclassification will become apparent in the section on formulation of hypotheses.

Taking into account that one group might not be consistently used for the same type of decision, a 5-point Likert scale representing frequencies from "Never" to "Always" is used.

Variable 1a: Extent of joint business-IT involvement in decision-making on IT principles (scale)

Variable 1b: Extent of independence of IT in decision-making on IT architecture (scale)

Variable 1c: Extent of independence of IT in decision-making on IT infrastructure (scale)

Variable 1d: Extent of joint business-IT involvement in decision-making on business application needs (scale)

Variable 1e: Extent of independence of business in decision-making on IT investment and prioritisation (scale)

Formal Governance Mechanisms

The variables used to measure this construct are derived from the three aspects of making and monitoring IT decisions, again basing upon (Weill & Ross, 2004, p. 86):

- Coordinating the decision-making process.
- Monitoring to ensure decisions are executed as agreed upon.
- Communicating constantly with stakeholders.

Similar to the previous set of variables, a 5-point Likert scale representing frequencies from "Never" to "Always" is used to take into account the fact that a mix of different mechanisms is possible for each aspect.

Variable 2a: Extent of usage of formal governance coordination of decision-making mechanisms (scale)

Variable 2b: Extent of usage of formal governance execution mechanisms (scale)

Variable 2c: Extent of usage of formal governance communication mechanisms (scale)

In addition, one of the research objectives is to "explore the as-is situation of structure, *awareness* and performance of IT governance". The extent of awareness is measured as awareness of industry of frameworks related to IT governance, which in turn implies clarity of direction taken by the IT organisation with respect to IT governance.

Variable 2d: Extent of awareness of industry frameworks related to IT governance (scale)

Organisational Context

In this research, the organisational context variables of interest are organisation size as characterised by revenue and strength of workforce, and the primary goal of an organisation (profit or growth orientation)

Variable 3a: Revenue (ordinal)
Variable 3b: Strength of workforce (ordinal)
Variable 3c: Primary goal of organisation (nominal)

Governance Performance

Organisations have different expected outcomes for implementing IT governance. The objectives could be one or more of the following:

- Cost-effective use of IT
- Effective use of IT for growth
- Effective use of IT for asset utilisation
- Effective use of IT for business flexibility (Weill & Ross, 2004, p. 121)

Governance performance is a weighted average of the importance of outcome and contribution of IT governance to achieve them.

Variable 4: IT governance performance (scale) is calculated using the equation in Box 1.

Theoretical Framework

Figure 1 depicts the relationship between variables constituting the theoretical framework.

Hypotheses

Ownership of Decision-making

IT principles are defined as basic philosophies about IT, articulated through a set of IT management principles that summarise how the company would use IT to achieve its goals. Davenport, Hammer and Metsisto (1989) argue that keeping with the corporate strategy means technology decisions must be guided by agreed principles.

However, principles are by no means static statements. Periodic review is required, not only for alignment with changing corporate strategy, but also to harness new possibilities arising from technology development. Therefore, it is imperative that both business and IT are jointly involved in the formulation and review of IT principles, both from perspective of corporate strategy and technology development.

H1a: Joint decision-making by business on IT for IT principles is correlated with high governance performance.

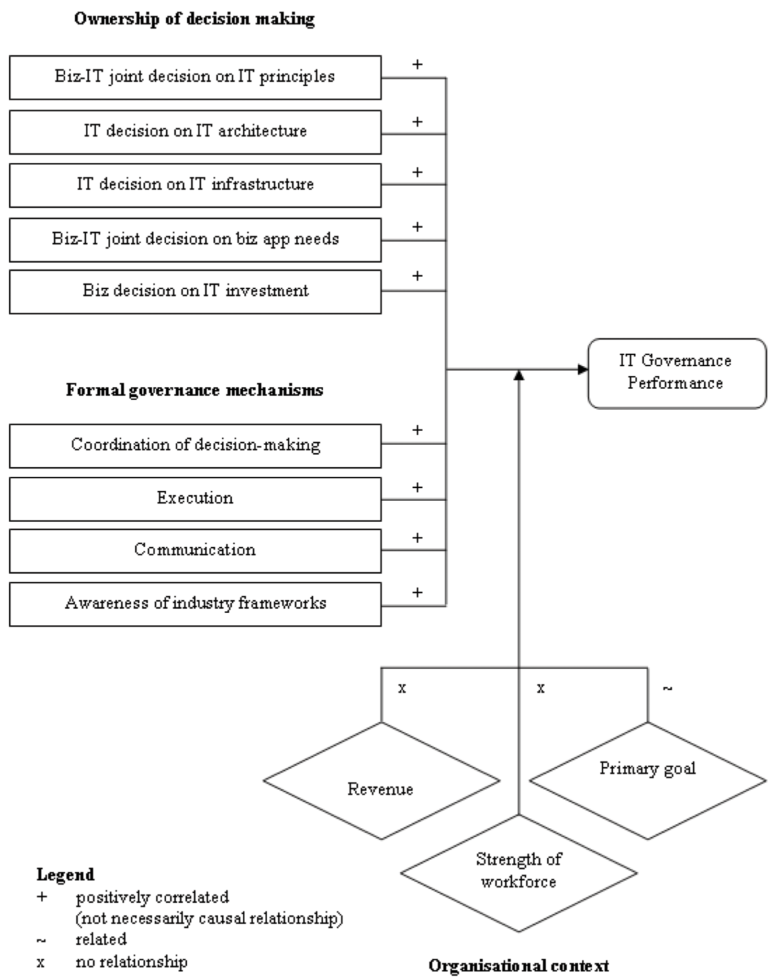
Business process integration and standardisation are key responsibilities of the process

Box 1.

$$\frac{\sum_{n=1 \text{ to } 4}\left(\text{importance of outcome X influence of IT governance}\right)}{\sum_{n=1 \text{ to } 4}\left(\text{importance of outcome}\right)}$$

(Weill & Ross, 2004, p. 240)

Figure 1. Theoretical framework



owner from the business side. A pre-requisite for integration and standardisation is the formulation of IT architectural decisions. These provide the foundation for IT capabilities of the organisation (Weill & Ross, 2004). Similarly, IT infrastructure capability is a key contributor to strategic agility (Weill et al., 2002).

Although IT architecture and infrastructure are based upon requirements articulated as part of IT principles, these are technical decisions within the domain of IT specialists. Therefore, effective decision-making is best left to IT specialists guided by objective criteria, independent of input from non-specialists.

H1b: Sole decision-making by IT on IT architecture is correlated with high governance performance.

H1c: Sole decision-making by IT on IT infrastructure is correlated with high governance performance.

Creativity in delivering customer value through IT and disciplined execution consistent with architectural principles are two key considerations in deciding business application needs. As such, both business and IT have to agree on the trade-off between fulfilment of business needs and compliance with architectural principles.

H1d: Joint decision-making by business and IT on business application needs is correlated with high governance performance.

The IT investment justification model proposed by Ross and Beath (2002) categorises investments as one of transformation, renewal, process improvement or experiments. Except for renewal, the other three categories of IT investment are usually directly driven by business needs, including the need to support a new business model, improve operational performance and enable new technologies or ideas.

Organisations undertake technology renewal to reduce cost or raise quality of IT services. In addition, end of product life or vendor ceasing their services are two externally-driven reasons to embark on technology renewal. The IT organisation's annual budget allocation is usually used to fund renewal activities. In spite of this, we must not overlook the fact that such allocations are decided by business, considering financial standing of the organisation and input from IT with regards to mandatory renewal activities.

H1e: Sole decision-making by business on IT investment is correlated with high governance performance.

Formal Governance Mechanisms

Good IT governance does not happen by chance. Therefore formal governance mechanisms are necessary to achieve it.

H2a: Organisations with formal governance coordination of decision-making mechanisms have high governance performance.
H2b: Organisations with formal governance execution monitoring mechanisms have high governance performance.
H2c: Organisations with formal governance communication mechanisms have high governance performance.

Rising awareness of industry frameworks related to IT governance, such as COBIT, ITIL and CMMI, is expected to lead to widespread activities to improve IT governance. Availability of these industry-wide frameworks means organisations starting out on this journey do not need to reinvent the wheel and reduce implementation risks, thereby increasing chances of success.

H2d: Awareness of industry frameworks related to IT governance is positively correlated with governance performance level.

Organisational Context

IT governance is not limited to large corporations, just as corporate governance applies to all joint-stock corporations. IT governance affects big and small, profit and non-profit organisations. The difference lies in how rigorous the implementation is, but not how successful IT governance contributes to the intended outcome.

H3a: IT governance performance is not affected by annual revenue (organisation size).
H3b: IT governance performance is not affected by strength of workforce (organisation size).

In the quest for a new customer base and product innovation, growth-oriented organisations require extremely agile IT systems and flexible IT services to deal with fast-changing business requirements. On the other hand, organisations with profit as the primary goal strive to maximise profit through operational efficiencies and economies of scale through standardised and tightly controlled processes and tools. This could be translated to a more immediate improvement in IT governance performance.

H3c: Organisations with profit as the primary goal have a high IT governance performance compared to organisations with growth as the primary goal.

Research Design

This research engages in hypotheses testing. It attempts to explain the relationship between ownership of IT decisions, formal governance mechanisms, organisational context and IT governance performance. In this research, data collection is done mainly via survey. In administering the survey, minimal researcher interference is applied, limited to providing clarification to respondents where necessary. Every company in the survey forms a unit of analysis.

Data Collection

This research is carried out using a set of questionnaire structured in 5 sections:

- **Section A:** Organisational context
- **Section B:** IT decision-making
- **Section C:** Coordination, monitoring and communication mechanisms
- **Section D:** IT governance framework
- **Section E:** IT performance governance

Section A uses dichotomous and interval-scale. For sections B and C, 5-point Likert scale is used (1=Never, 2=Rarely, 3=Sometimes, 4=Often and 5=Always). The 4-point Likert scale is used for section D (1=Currently Used, 2=Intend to Use, 3=No Intention to Use, and 4=Never Heard of). Finally Section E uses two different 5-point Likert scales are used for different questions in this section (1=Totally Not Important, 2=Not Important, 3=Quite Important, 4=Important and 5=Very Important; 1=Totally Not Successful, 2=Not Successful, 3=Quite Successful, 4=Successful and 5=Very Successful). Respondents are also provided the opportunity to provide response in free text.

Respondents have the option to complete the survey through one of the following methods:

- Web-based survey
- E-mailing the completed questionnaires
- Posting the completed questionnaire using the postage-paid reply envelope

Unique identification numbers are attached to survey invitations to ensure no duplicates in data collection.

Sampling

The population of this research is determined primarily using the member directory of the Federation of Malaysian Manufacturers (FMM), as well as through industry contacts. FMM represents more than 2,000 manufacturing and industrial service companies of various sizes in Malaysia (Federation of Malaysian Manufacturers, 2006).

The organisations included in this research are involved in the manufacturing of one or more of the following products: diode, electronic, integrated circuit, memory product, resistor, semiconductor, sipmos, transistor, and wafer. Care was taken to clean the population frame by removing obvious mismatches (e.g. “wafer” as a product of the food industry, as opposed to “wafer” fabrication in the semiconductor industry).

The finalised population frame consisted of 84 organisations. No sampling was done as the number is relatively small. All organisations in the list were invited to participate in the survey which ran for approximately one month.

DATA ANALYSIS

Sample Characteristics

Out of 84 surveys distributed, 30 respondents answered the questionnaires online, 3 responded by returning the completed paper-based survey form through postal mail, while 2 declined to participate citing confidentiality as a reason. 33

usable survey responses were collected which represented almost 40% response rate (N = 33).

Reliability Analysis

The questionnaire section on ownership of decision-making consists of five main questions, each corresponding to IT principles, IT architecture, IT infrastructure, business application needs and IT investment and prioritisation. Each main question consists of seven sub-questions (items) representing possible combinations of the decision owner. Respondents were asked to rate how often each group makes the decision. Reliability analysis for inter-item consistency of the recoded answers is tabulated in Figure 2. Cronbach's Alpha value of 0.7 is used as reference value for assessing item consistency (Nunnally, 1978).

Descriptive Statistics

Ownership of Decision-Making and Formal Governance Mechanisms

The descriptive statistics are shown in Figures 3 and 4 respectively.

Organisational Context

The distribution of annual revenue (variable 3a) is skewed towards large corporations with significant representations of small and medium-sized companies. Similarly, the distribution of strength of workforce (variable 3b) is also skewed towards medium-sized companies and large corporations having more than 100 and 1000 employees respectively. Finally, distribution of primary goals of the companies (variable 3c) is almost equally distributed between profit and growth.

Figure 2. Inter-item consistency

Item	Cronbach's Alpha	Remarks
IT principles	0.662	Marginally lower (acceptable)
IT architecture	0.694	Marginally lower (acceptable)
IT infrastructure	0.722	2 cases were found to contribute to initial low value of 0.455, revised calculation resulted in acceptable value of 0.722.
Business application needs	0.722	
IT investment and prioritisation	0.702	

Figure 3. Descriptive statistics for ownership of decision-making

Variable	Scale	Mean	Standard Deviation	Range
1a	1–5	3.36	0.30	3.00 – 3.86
1b		2.99	0.33	2.14 – 3.43
1c		3.09	0.27	2.57 – 3.57
1d		3.40	0.38	2.86 – 3.86
1e		3.19	0.38	2.57 – 4.29

Figure 4. Descriptive statistics for formal governance mechanisms

Variable	Range	Mean	Standard Deviation	Range
2a	1–5	3.47	0.58	1.40 – 5.00
2b		3.62	0.63	2.00 – 5.00
2c		4.12	0.44	3.67 – 5.00
2d	1–4	2.09	0.60	1.00 – 3.00

IT Governance Performance

IT governance performance is measured as how important the outcomes are to them and how successful IT governance has contributed to each outcome. The mean IT governance performance is 3.42 with a standard deviation of 0.44 (on a scale of 1 to 5). The values range from 3.00 to 4.56.

Inferential Statistics

Correlation between Ownership of Decision-Making and Governance Performance

Pearson Correlation test shows significant correlation between the abovementioned variables (p-value of less than 0.01):

- Extent of joint business-IT involvement in decision-making on IT principles
- Extent of independence of IT in decision-making on IT infrastructure
- Extent of joint business-IT involvement in decision-making on business application needs
- Extent of independence of business in decision-making on IT investment and prioritisation

The extent of independence of IT in decision-making on IT architecture showed significant correlation with IT governance performance (p-value of less than 0.05). Details of inferential statistics are shown in Figure 5.

Therefore, the following hypotheses pertaining to ownership of decision-making and governance performance are not rejected.

H1a: Joint decision-making by business on IT for IT principles is correlated with high governance performance.
H1b: Sole decision-making by IT on IT architecture is correlated with high governance performance.
H1c: Sole decision-making by IT on IT infrastructure is correlated with high governance performance.
H1d: Joint decision-making by business and IT on business application needs is correlated with high governance performance.
H1e: Sole decision-making by business on IT investment is correlated with high governance performance.

Correlation Between Formal Governance Mechanisms and Governance Performance

Formal governance mechanisms for communicating IT issues also shows very significant correlation with IT governance performance (p-value of less than 0.01), while formal governance mechanisms for coordinating IT decision-making activities and monitoring execution of IT decisions show significant correlation with IT governance

Figure 5. Pearson Correlation between ownership of decision-making and governance performance

Correlations

		IT principles	IT architecture	IT infrastructure	Business application needs	IT investment and prioritisation	IT governance performance
IT principles	Pearson Correlation	1	-.047	.243	.663**	-.075	.483**
IT architecture	Pearson Correlation	-.047	1	.876**	.105	.282	.348*
IT infrastructure	Pearson Correlation	.243	.876**	1	.210	.238	.505**
Business application needs	Pearson Correlation	.663**	.105	.210	1	-.139	.509**
IT investment and prioritisation	Pearson Correlation	-.075	.282	.238	-.139	1	.494**
IT governance performance	Pearson Correlation	.483**	.348*	.505**	.509**	.494**	1

**. Correlation is significant at the 0.01 level (2-tailed).

*. Correlation is significant at the 0.05 level (2-tailed).

Figure 6. Pearson Correlation between formal governance mechanisms and governance performance

Correlations

		Coordinate IT decision-making activities	Monitor execution of IT decisions	Communicate IT issues	IT governance framework	IT governance performance
Coordinate IT decision-making activities	Pearson Correlation	1	.813**	.420*	.267	.353*
Monitor execution of IT decisions	Pearson Correlation	.813**	1	.166	.162	.364*
Communicate IT issues	Pearson Correlation	.420*	.166	1	.185	.467**
IT governance framework	Pearson Correlation	.267	.162	.185	1	-.059
IT governance performance	Pearson Correlation	.353*	.364*	.467**	-.059	1

**. Correlation is significant at the 0.01 level (2-tailed).

*. Correlation is significant at the 0.05 level (2-tailed).

performance (p-value of less than 0.05). Details of inferential statistics are shown in Figure 6.

Therefore, the following hypotheses pertaining to formal governance mechanisms and governance performance are not rejected.

H2a: Organisations with formal governance co-ordination of decision-making mechanisms have high governance performance.

H2b: Organisations with formal governance execution monitoring mechanisms have high governance performance.

H2c: Organisations with formal governance communication mechanisms have high governance performance.

No significant correlation exists between awareness and usage frequency of various industry frameworks with IT governance performance. Therefore, the following hypothesis is rejected.

H2d: Awareness of industry frameworks related to IT governance is positively correlated with governance performance level.

Relationship between Organisational Context and Governance Performance

Results from the ANOVA test show that, with governance performance as dependent variable, the p-values for annual revenue (AR) and strength of workforce (SR) are more than 0.05. This indicates that there is no significant difference in governance performance across companies with different annual revenue and strength of workforce. However, effect size and power are both low, implying that there could be some differences in governance performance if a larger sample size is used. Details of inferential statistics are shown in Figure 7.

The following hypotheses are not rejected.

H3a: IT governance performance is not affected by annual revenue (organisation size).

H3b: IT governance performance is not affected by strength of workforce (organisation size).

As for primary goal (PG), the p-value is less than 0.05 with effect size of more than 0.14 and moderate power. Based on Cohen's (1984) criteria, effect size of more than 0.14 is considered important. This indicates there are some differences in governance performance between companies with primary goals of profit and growth. Further analysis revealed that governance performance for companies with growth as the primary goal is higher than that of profit.

Figure 7. ANOVA table for organisational context with governance performance as dependent variable

Tests of Between-Subjects Effects

Dependent Variable:IT governance performance

Source	Type III Sum of Squares	df	Mean Square	F	Sig.	Partial Eta Squared	Noncent. Parameter	Observed Power[b]

Error	4.304	26	.166					
Total	392.799	33						
Corrected Total	6.061	32						

a. R Squared = .290 (Adjusted R Squared = .126)

b. Computed using alpha = .05

Therefore, the following hypothesis is rejected.

H3c: Organisations with profit as the primary goal have a high IT governance performance compared to organisations with growth as the primary goal.

DISCUSSION AND CONCLUSION

Research Findings

Ownership of Decision-Making

Research data show that IT governance performance is related to who makes the IT decisions. The right decision owner(s) making appropriate decision types lead to better IT governance performance. Specifically, it is recommended that:

1. Business and IT jointly make decisions on IT principles.
2. IT makes decisions on IT architecture, independently from business.
3. IT makes decisions on IT infrastructure, independently from business.
4. Business and IT jointly make decisions on business application needs.
5. Business makes decisions on IT investment, independently from IT.

Recommendations #1 to #4 are consistent with the pattern of top governance performers as recommended by Weill and Ross (2004). The slight divergence in the last recommendation will be discussed shortly (the reference study ranks this arrangement not as the best performer, but 2nd and 3rd best performers).

Once defined, IT principles require periodic review to align with changing corporate strategies and new possibilities arising from technology development. Joint ownership of business and IT in the formulation and review of IT principles ensures a balanced perspective of corporate strategy and technology development.

IT architecture and infrastructure are technical decisions based upon requirements articulated as part of IT principles. IT specialists are in the best position to make effective decisions based on technologies available in the market. It is important that IT specialists do not succumb to specific wants (not needs) of "IT-savvy and power users" of the organisation. Instead, they should make objective judgments in the interest of the organisation.

Fulfilment of specific business needs is the most obvious business value of IT. This explains why this is also the area where business exerts great pressure on IT to deliver value. It is important that IT actively participates in decision-making of business application needs. Creativity and discipline, though conflicting in nature, are important to guide IT when to turn down specific requests for functionality that deviates from architectural principles. What seems to be a short-term loss to the organisation will prove itself as the right decision in the long run. Compliance with architectural guidelines ensures integrity, flexibility and scalability to meet future business needs.

In almost all organisations, IT remains as a service centre with budget allocated from business. Investment and prioritisation decisions are best made by the business with input from IT. The only exception is technology renewal investments which are funded through periodic budget allocation from business, leaving the individual spending under discretion of IT executives/managers. The empirical results show that organisations are not ready to share investment decision-making powers with IT. Having businesses to make investment decisions will avoid potential problems of IT being caught in the middle when business units/processes dispute over the priority of IT projects, however it implies that IT has not gain the respect to be considered an equal decision-making partner.

Formal Governance Mechanisms

In deriving the hypotheses relating formal governance mechanisms to high governance performance, it was argued that good IT governance does not happen by chance. Coordination of decision-making process, execution monitoring and communication are the three categories of governance mechanisms.

Whether IT governance mechanism is viewed from a generic perspective, or based on specific COBIT control objectives, findings from this research showed that formal governance mechanisms are necessary to achieve good governance.

Contrary to the expected outcome, awareness of industry frameworks was found not to be related to IT governance performance. The level of awareness of IT governance was also not encouraging. Out of the 33 respondents, 12 (36.4%), 10 (30.3%) and 6 (18.2%) have not heard of COBIT, CMMI and ITIL respectively. COBIT and CMMI are currently used in only 5 (15.2%) organisations, while ITIL trailed closely with 4 (12.1%) organisations. Obviously more initiatives in this aspect are imperative.

On a positive note, when asked to describe what the term "IT governance" means, a significant number of respondents could accurately describe the issues underlying and goals of IT governance.

3 respondents stated precisely the fundamental concerns of IT governance: IT's delivery of value to the business and mitigation of IT risks. In their own words:

- *"IT governance means to measure, monitor and optimize the business value from investment in IT."*
- *"Management of IT performance and risk"*
- *"Compliance of IT department to rules and regulations set forth to ensure companywide risks and costs are minimized."*

Comments from several other respondents describe one or more objectives of IT governance, in terms of strategic alignment, value delivery, risk management, resource management and performance management. Quoted directly from the survey responses:

- *"Centralized Controlling for IT Cost, Headcount, and investment."*
- *"Control of flexibility of expanding"*
- *"Management of IT investment, service delivery, change of projects and etc"*
- *"Ensuring security and meeting requirements or compliance necessary for IT system within the corporation"*
- *"With the IT governance, It can bring the tool and knowledge used to benchmark and measure IT function to meet those needs with confidence and asurance."*
- *"Control and policies of IT & implementation"*

Organisational Context

The research findings show that organisational size is not a predictor of IT governance performance. This is consistent with the notion that IT governance affects big and small, profit and non-profit organisations.

However, it must also be noted that the distribution of annual revenue is skewed towards large corporations with significant representations of small and medium-sized companies. In addition, the distribution of strength of workforce is also skewed towards medium-sized companies and large corporations having more than 100 and 1000 employees respectively.

Furthermore, a surprising finding was made pertaining to influence of profit/growth-orientation towards IT governance performance. The research initially predicted that organisations with profit as the primary goal would implement standardised and tightly-controlled processes and tools, leading to higher IT governance performance. However, the research findings showed otherwise. Organisations with growth as the primary goal showed marginally higher IT governance performance. A bigger sample size is necessary to make further conclusions.

Governance Performance

Organisations in this research achieve a mean IT governance performance score of 3.42 with a standard deviation of 0.44 on a scale of 1 to 5. The lowest score is 3.00 while the highest is 4.56. This seems to be contradictory to the level of awareness concerning industry frameworks related to IT governance. The score was calculated independently, based only upon how important the outcomes are to the respondents and how successful IT governance has contributed to each outcome. A conflicting result indicates that the understanding and implementation of IT governance is on track, though familiarity with technicalities of the frameworks should be improved.

Limitations of Research

There are two major challenges faced throughout the research. Firstly, availability of data was a big hurdle. A number of organisations explicitly declined to participate in the survey, even though anonymity was assured. The number of responses received is sufficient to provide a preliminary view of the as-is situation of IT governance, but could be challenged statistically.

Secondly, IT governance itself is a relatively new topic in Malaysia. Some respondents reported confusion with usage of certain terms (e.g. corporate executives vs. business unit managers). Such clarity could only be achieved using case study research methodology with interviews and investigation of archival records in multiple organisations.

Generalisablility of Research Findings

This research was targeted at the electronics manufacturing industry in Malaysia, as the nation's leading industrial sector and having pervasive usage of IT in manufacturing process.

It is possible to generalise the research findings and empirical results to other industries. Past studies by Olson and Chervany (1980), Ahituv, Neumann and Zviran (1989), Clark (1992) found no relationship between industry and IT governance. In addition, industry type is found not to be a strong predictor in the study by Brown and Magill (1994).

Managerial Implications

The reality is that IT governance is neither a technical issue confined to the IT organisation, nor is the IT organisation solely responsible for success of IT service. Empirical results demonstrating that strong IT governance result in successful business outcomes have stood the test of time.

The best practices of who should make what IT decisions have been established through this research. Formal governance mechanisms have been shown to be necessary for good governance. IT governance does not just happen by chance or as an afterthought.

ABSTRACT

This chapter presents an environmentally integrated manufacturing system analysis for companies looking for the benefits of environmental management in achieving high productivity levels. When the relationship between environmental costs and manufacturing decisions is examined, it can be seen that the productivity of the company can be increased by using an environmentally integrated manufacturing system analysis methodology. Therefore, such a methodology is presented and the roadmap for generating environmentally friendly and economically favorable alternative waste management solutions is elaborated. The methodology combines data collection, operational analysis of the manufacturing processes, identification of wastes, and evaluation of waste reduction alternatives. The presented methodology is examined in a car battery manufacturing plant, which generates hazardous wastes composed of lead. It is aimed to decrease the wastes derived from the production so that the efficiency in raw materials usage is increased and the need for recycling the hazardous wastes is decreased.

DOI: 10.4018/978-1-4666-1945-6.ch050

INTRODUCTION

Manufacturing companies are now aware that whether to implement sustainable environment and resource management practices or not is no longer a choice for them. Companies operate in a world of dynamic competition in which technology, production and manufacturing processes, customer needs and, environmental regulations are constantly changing. Therefore, companies should constantly find innovative solutions to survive under the pressure of competitors and regulators. The increasingly strict environmental regulations combined with the improving consciousness of consumers for environmentally friendly products have put manufacturers in a precarious situation. Consequently, not only researchers, but also manufacturing managers are recognizing the importance of environmental management systems used for managing environmental practices (Angell and Klassen, 1999; Claver et al., 2007; Gupta and Sharma, 1996; Klassen, 2000; Porter and van der Linde, 1995; Sroufe, 2003; Xigang and Zhaoling, 2000).

A major barrier to the adoption of environmental management systems is that companies often do not know the environmental costs of operating their business and therefore do not know the financial benefits that can be obtained by reducing their environmental impacts. Previously, environmental costs were generally defined as costs dealing with environmental laws, regulations, and taxes. It is now recognized that the true environmental costs includes: costs of resources, waste treatment and disposal costs, the cost of poor environmental reputation, and the cost of paying an environmental risk premium. The calculation and evaluation of environmental costs provide better understanding of the production cost of a product, and that it properly allocates costs to product, process, system or facility. Measuring environmental costs also improves the correctness of the pricing and gives profitability and competitive advantage, therefore increases the overall management system of a company. For this reason, environmentally integrated manufacturing decisions require for the consideration of technical, economic, and ecological aspects of the manufacturing processes simultaneously. Especially the companies using hazardous materials in their production have started to consider environmentally integrated manufacturing systems to decrease their impacts on environment and to prevent pollution at source directly.

This chapter presents a methodology for the environmentally integrated manufacturing system analysis for companies aiming to achieve the benefits of environmental management in obtaining high productivity levels. The aim of the methodology is the reduction of wastes derived from the manufacturing processes. The wastes produced during the manufacturing process are important cost issues for manufacturers. Waste of raw material creates important costs and environmental effects, especially when it is hazardous. For the case of using hazardous raw materials, the wastes derived from the manufacturing processes can not be sent to trash, instead they are sent to the recycling or treatment facility. Obviously, wastes that can not be used within the facility create inefficiency in the usage of raw materials. Therefore, the problem considered is to decrease the formation of wastes in order to decrease waste management costs and improve raw material usage. One solution to this problem is to use an environmentally integrated manufacturing system point of view aiming to decrease product losses, while reducing costs and improving profitability. The presented methodology is examined in a car battery manufacturing plant since any improvement to reduce wastes in this company will be yielding immediate environmental benefits since the waste usually consists of lead, which is hazardous. This application forms also an example about the achievability of "cleaner" production philosophies in the manufacturing sector using hazardous raw materials. The presented methodology is designed in a way that its implementation in different sectors is also possible. The presented methodology is the combination of data collection, manufacturing system analysis, identification of wastes, and evaluation of alternative waste management solutions. The objectives of the presented methodology are

- to create a point of view about the types of alternative waste management solutions that can be determined and to show their benefits,
- to discuss how the operations management functions of the facility will be affected by the implementation of an alternative waste management solution,
- to discuss what types of limitations can be encountered in a facility while implementing an alternative waste management solution,
- to give an example about the practicability of pollution prevention philosophies to the manufacturing sector.

The presented methodology intends the integration of environmental management principles with the operations management. In the next section, the need for adopting a sustainable development perspective is made clear by analyzing the relationship between environmental costs in manufacturing decisions. In addition, environmental operations management principles and criteria affecting the environmental operations management strategy are described. Next to this section, the methodology for the environmentally integrated manufacturing system analysis is presented. After description of the methodology, the manufacturing system of a car battery manufacturing plant is analyzed by using the given methodology. Finally, the conclusion and summary of the chapter is given.

BACKGROUND

In the last few decades environmental problems have received increasing attention. Protection of the environment has become an issue at all levels of society. Within the field of operations management, attention for environmental issues is now growing rapidly. Operations management is the process of managing people, resources and production systems in order to convert inputs into outputs. The inputs of the system are energy, materials, labor, and capital. The outputs of the system are the products demanded by customers (Nahmias, 2004). Wastes can be produced when converting raw materials into products and are considered as non-value-added outputs that create extra costs to the production of the product. The reduction or elimination of wastes in the production has always been a goal in operations management e.g., lean manufacturing. In order to provide the best use of raw materials, operations managers have to minimize the amount of the waste produced, namely, to reduce the cost and impact of the waste. An efficient approach undertaking this target is to integrate waste management into the operations management decision. Operations management deals with the optimization of the manufacturing process and covers decisions involving production planning, scheduling, capacity planning, inventory management, material management, workforce management, and quality management. It can be remembered that the traditional objective of inventory control, scheduling and production planning is to minimize production costs and improving measures such as worker idle time, work-in-process inventory levels, and production lead times while recognizing constraints such as limited space. Undoubtedly, by the integration of waste management into the operations management, the objective function should include not only the cited objectives but also environmental ones. It is obvious that an operations management team is not only responsible of the achievement of the desired products in terms of quality and quantity, but also has to control working practices, resources consumption, emissions, and the flow of hazardous materials. Thus, operations managers are directly concerned with environmental issues in their operational responsibilities and play a critical role in developing management systems that affect environmental performance (Angell and Klassen, 1999; Gupta and Sharma, 1996).

Environmental Operations Management (EOM) is a concept of integrating environmental management principles into the operations management process for the conversion of resources into usable products. Due to EOM principles, instead of looking at environmental management as a "cost", companies can use EOM as an opportunity to improve their position by eliminating waste, removing non-value added materials and equipment, and reducing both short-term cost and long-term liability. The company will be able to plan and design products that do not create toxic wastes or require environmentally hazardous processes – from the introduction of the product to its final disposition. A long-term competitive advantage can be obtained by setting EOM principles to the production process. In order to create an environmental operations strategy, the operations management team is constrained by criteria such as: dependability, efficiency, flexibility and quality. The quality of the environmental attributes of the products is important criteria for consumers willing to buy. The dependability of a company is affected by the use of hazardous materials and processes. Accidents involving the shipment, transfer, and use of hazardous materials often result in temporary shutdowns of manufacturing plants. In addition, the capital investment needed to process and dispose hazardous materials is often high and affects the dependability. The flexibility of the company is limited by the materials and processes necessary for the production and by the types and quantities of hazardous materials discharged into the environment. Efficiency can be achieved by finding less expensive and less environmentally hazardous materials and processes to manufacture the desired products (Gupta and Sharma, 1996).

As mentioned before, one major barrier to the adoption of environmental management systems is that companies often do not know the environmental costs of operating their business and therefore do not know the financial benefits that can be obtained by reducing their environmental impacts. Until only a few decades ago, there was a belief that any investment in improved environmental performance would contribute to increased costs, which will finally reduce profits. Previously, environmental costs were generally defined as costs dealing with environmental laws, regulations, and taxes. Firms have tended not to measure environmental costs because management accounting systems have focused on clearly identifiable costs but not on the costs and benefits of alternative actions. In 1991, Porter put forward a new standpoint to the interaction between profitability and pollution prevention (Porter, 1991). This interaction has increased the theoretical and practical interest in the possibility that profitability and pollution reduction were not conflicting goals. According to Porter, pollution was simply a diminishing value in the production and was an indication of problems in products and/or processes. Therefore, contrary to previous opinions, reducing or eliminating pollution would not weaken but strengthen corporate competitiveness. After Porter's study, a radical change has come in management's views on pollution reduction and better environmental management. Companies became aware of the important role that environmental costs play in the calculation of total costs of production. It is now recognized that the true environmental costs includes: costs of resources, waste treatment and disposal costs, the cost of poor environmental reputation, and the cost of paying an environmental risk premium. With this point of view, environmental costs are transferred from overall (or indirect) costs to direct costs. As a result, the calculation and evaluation of environmental costs provide better understanding of the production cost of a product, and that it properly allocates costs to product, process, system or facility. Measuring environmental costs also improves the correctness of the pricing and gives profitability and competitive advantage, therefore increases the overall management system of a company. Thus, environmentally integrated manufacturing decisions require for the consideration of technical, economic and ecological aspects simultaneously (Melnyk et al., 2003; Spengler et al., 1998; Wu and Chang, 2004). Additionally, companies try to avoid inefficiencies in the production and waste removal charges as a result to decrease the cost of unit production. Especially the companies using hazardous materials in their production have started to consider environmentally integrated manufacturing systems to decrease their impacts on environment and to prevent pollution at source directly.

Manufacturing decisions should not be made in isolation from decisions in environmental management. In recent years, many production planners and decision makers have started to recognize the role and significance of the integration of economic and environmental efforts in a single production-planning program. New concepts connecting manufacturing practices, pollution control and prevention and operations are recently being used in order to increase the efficiency of converting raw materials into products. Specifically, studies are carried out in order to create decision support tools for analyzing the effects of planning decisions on the amount of product losses. Companies are willing to organize their production systems to enhance resource productivity by adopting an environmental approach. Based on this kind of approach, a company can include environmental principles in the mission statement, incorporate the cleaner production philosophy into product and process design and, consequently, develop an environmental business strategy in order to gain competitive advantage. At this point, it is important to understand the difference between pollution prevention and pollution control. Pollution control covers the elimination of pollution after the waste is generated. On the other hand, pollution prevention covers the modification/redesign of the production process and the introduction of new technologies throughout the product life-cycle to identify the source of the problem. A company adopting traditional pollution control methods focuses on its activity on the short term. In this context, the company sets as its main aim to carry out environmental impact correcting actions that do not entail the development of new skills needed to manage new environmental processes. Therefore, it is seen that traditional pollution control methods are practically inefficient compared to prevention methods. Therefore it is clear that preventing environmental damage is cheaper and more effective than attempting to manage or fix it. Pollution prevention has replaced the traditional pollution control methods and has become an important research topic for the process design (Claver et al., 2007; Xigang and Zhaoling, 2000). There are many studies demonstrating that pollution prevention is almost the most cost-effective constituent of integrated waste management strategies in different manufacturing systems (Akkerman and van Donk, 2006; Dahab et al., 1994).

One step forward of pollution prevention is the concept of cleaner production (CP). CP can be described as the continuous application of an integrated preventative environmental strategy to processes, products and services to increase efficiency and reduce risks to humans and the environment. For production processes, CP includes conserving raw materials and energy, eliminating toxic raw materials, and reducing the quantity and toxicity of all emissions and wastes before they leave a process. For products, the CP strategy focuses on reducing impacts along the entire life cycle of the product, from raw materials extraction to ultimate disposal of the product. In CP applications, savings are often achieved with little or no capital expenditure by simply changing management practices. Many successful case studies show that CP can provide opportunities for making sound choices for both environmental concerns and economic benefits (Dahodwalla and Heart, 2000; Jia et al., 2005). One of the most basic reputations of CP is that it improves efficiency and productivity in industry. These improvements result in lower expenditure on resources such as energy and water, increased efficiency in production, fewer risks associated with environmental impacts, and decreased waste generation that leads to savings in landfill fees and pollution licenses. Due to the CP context, continuous improvement is required not only in technology and know-how, but also in managerial skills and policies. CP offers much for operations management researchers to draw on as they explore the linkages between process and product technology, environmental management and performance.

The car battery manufacturing industry is one of the critical industries in the implementation of pollution prevention and CP studies because of the lead (Pb) used in production. Wastes should be decreased in order to prevent the hazardous effects of Pb to the environment and human health. Many studies involving technology changes and pollution prevention options are accomplished for the battery manufacturing industry (Boden and Loosemore, 2007; Dahodwalla and Heart, 2000; Ferreira et. al. 2003).

THE ENVIRONMENTALLY INTEGRATED MANUFACTURING SYSTEM ANALYSIS

The environmentally integrated manufacturing system analysis provides a roadmap for companies willing to apply an integrated preventive waste management approach in their manufacturing plant. Many possible working areas and information to be collected are given so that this methodology can be applied in different manufacturing sectors and companies. The design of the methodology firstly involves the investigation of techniques aiming the reduction of wastes in the manufacturing area. Waste auditing methodologies are examined in this context. Operations management techniques involving the reduction of material losses are then analyzed. The problem solving techniques are used for the identification of manufacturing problems, the investigation of possible solutions and the selection of the best solution. The methodology is established by integrating operations management perspectives to the classical waste auditing methodology. Waste auditing generally covers three steps. The first step, which is the pre-assessment, covers the division of the processes into unit operations and the construction of the process flow diagram. The second step, which is the material balance, covers the identification of inputs, outputs and the current reuse and recycling methods. The final step which is the synthesis, deals with the evaluation of waste reduction options and the creation of the waste reduction action plan. The presented methodology, different from the classical waste auditing, cautiously focuses on the operations of the manufacturing facility. Processes are analyzed based on the inputs used, working practices, capacities of machines, and byproducts and outputs derived from the processes. Steps of the presented methodology can be summarized as follows:

- **Step 1:** Analysis of the system
    - Data collection
    - Manufacturing system analysis
    - Construction of a process flow diagram
    - Current waste management practices
    - Environmental impacts of materials used in production
- **Step 2:** Identification of Alternative Waste Management Solutions
    - Investigation of Waste Management Technologies
    - Investigation of Alternative Waste Management Solutions

- **Step 3:** Evaluation of the Alternative Waste Management Solutions
  - Operational Analysis of Alternative Waste Management Solutions
  - Technical Analysis of Alternative Waste Management Solutions
  - Economical Analysis of Alternative Waste Management Solutions
- **Step 4:** Comparison of Alternative Waste Management Solutions

Analysis of the System

In the first step of the methodology, the analysis of the manufacturing system should be accomplished. This analysis will provide the information about the current manufacturing and waste management system. The data collection phase involves a thorough assessment of the company, from the purchase of various inputs (e.g., raw materials, energy and water) to the output itself (products). This phase implicates the collection of data such as: product types, raw materials used and their prices, the demand of products and their prices, material requirement planning, and supply chain partners. By analyzing the data collected, it will be possible to find the processes operating with low efficiencies. The manufacturing process is considered as one of the important sources of environmental impacts of the industrial production. Therefore, it is essential to analyze in detail all the elements of the manufacturing system in order to prevent the pollution at the source. The information about the system as a whole is gathered in this phase by combining the data collected about processes and their operational conditions, material management, capacity planning, production planning and scheduling, quality management, workforce management, supply chain management, and logistics. The operations forming wastes are determined in this phase of the system analysis. It is important to obtain real data in this step, because even if it is not optimal, the current manufacturing system of the company will be a basis for a comparison. With the aid of data collected in the first and second phases, it is now possible to generate a process flow diagram for a complete manufacturing process including sequence of operations, raw materials, semi-finished products, products and wastes.

In the next phase, the investigation of current waste management practices in the company is accomplished. The waste management system of a company involves the entire procedure of collecting, transporting, processing, recycling or disposal of waste materials. Waste management can involve different methods and fields of expertise for solid, liquid, gaseous or radioactive substances, with the aim of reducing the effects of these wastes on the health and environment. During this phase, data such as the quantity and rate of generation of production wastes are collected. The content of wastes and the waste management costs are also investigated. Current waste management practices in the company should be determined correctly and then analyzed with respect to their appropriateness. A waste management application may be efficient in treating a waste completely, but it may be very costly or may cause extra usage of raw materials. On the other hand, a simple and inexpensive application may be financially welcomed but may gradually create serious damages in worker's health or environment. As a result, measurements should be made to find out the real needs of the system in order to solve each problem efficiently. For the last phase of the first step, investigating the environmental impacts of raw materials, production processes and products is important. Investigations may give ideas about the substitution of hazardous raw materials with non-hazardous materials. These kinds of substitutions may give benefits such as the decrease in employee exposure to pollution and decrease in costs due to the hazardousness of the material, such as special transportation costs, fees, etc. Making detailed analysis about the environmental impacts of materials is also an important action for convincing people to implement the alternative waste management solutions suggested. The workers and the management of the company can be influenced to take environmental precautions by informing them about impacts of products produced or materials used. After clarifying the environmental impacts of raw materials, production processes and products, it will be effective to suggest alternative waste management solutions as a new way of achieving better working conditions in the facility.

Identification of Alternative Waste Management Solutions

In the second step of the methodology, the investigation of possible alternatives aiming to reduce or reuse waste should be performed. Once the production wastes and inefficient processes in manufacturing system are identified, the next move is to investigate the available waste management technologies or practices in the literature. Current operational conditions of the company must be compared with the conditions reported in the relevant literature. The investigations may draw upon basic research results, literature searches, field research, and discussions with industry experts and technology-users. This process will make it possible to recognize environmentally friendly methods, the best available technologies, and the newest technologies. Alternative waste management solutions are prepared by using information about wastes and processes operating with low efficiencies. Alternative waste management solutions involving the integration of economic and environmental efforts are investigated. According to this integrated point of view, waste is accepted as a resource that can be used in the production process. The investigation of alternative waste management solutions will pursue the following hierarchy:

1. Reduction at source
2. Internal (on-site) and external (off-site) recycling
3. Treatment of waste streams
4. Controlled disposal when there is no other solution.

The reduction of wastes at source may be accomplished by the purchase of new equipments or materials, or may simply involve small changes in the production process. Pollution prevention alternatives aiming the reduction of waste at the source are at the first priority. The environmental and economic benefits of reducing waste at source are much higher than other alternatives because the raw material usage and the waste management costs can both be reduced. If the formation of waste can not be prevented at source, internal and external recycling alternatives must be considered in order to minimize the waste treated/disposed. With the recycling opportunities, wastes from one industrial process can serve as a raw material for another, therefore the impact of the industry on the environment is reduced. Specifically, on-site recycling is very valuable because it eliminates the cost of sending the waste to an off-site facility, therefore increases the productivity of the company. In cases where the waste can not be prevented or can not be reused within the facility, off-site recycling is a choice allowing to send out the waste from the facility and to allow its reuse by other industrial processes. Therefore, the impact of the waste to the environment is diminished. However, off-site recycling creates a cost due to the transportation of wastes to the recycling facility, and more importantly, due to the inefficient use of raw material that can not be converted into a product.

The treatment of waste streams is accomplished to remove the hazardous portion of a waste from the non-hazardous portion, such as water. Various techniques are available to reduce the volume of a waste through physical treatment. For example, concentration techniques including vacuum filtration, filter press or heat drying are commonly used to dewater the sludge. These techniques are used to reduce the volume, and thus the cost of disposing a waste material. Moreover, once the material is concentrated, there is a greater likelihood that the materials in the waste can be recovered. This allows the potential use of the waste streams as a raw material for other companies or for the company itself (Freeman, 1988, p. 5.13). Controlled disposal is a solution for wastes which can not be treated by pollution control technologies. Disposal is the last preferred waste management option. Nevertheless controlled disposal is an important part of environmental management; even though it is the least effective one.

Evaluation of Alternative Waste Management Solutions

Each investigated alternative waste management solution in the previous steps of the methodology must be analyzed in order to evaluate how beneficial or practical the implementation of this alternative will be. It is important to use an interdisciplinary point of view while evaluating each alternative waste management solution since the entire production system is aimed to be optimized. By this integrated point of view, it will be possible detect the positive and negative results of each alternative waste management solution proposed. The scope and complexity of an apparently feasible alternative waste management solution can change after the analysis of the initial problems or after the design of the system. An alternative waste management solution is feasible if it works with available or obtainable resources, produces better results in both environmental and economical point of view and if it does not conflict with other management functions. For example, while an alternative waste management solution may be feasible due to machine schedules, it may be infeasible due to the demand pattern of the products. As a result, it may not be possible to implement this alternative. It is also important for an alternative waste management solution to have a reasonable reimbursement time. Evaluations of solutions alternatives are made under the title of the following measures.

Operational Analysis of Alternative Waste Management Solutions: Each alternative waste management solution should be analyzed in order to see if it is operationally feasible. The operational viability generally consists of measures such as the applicability of an alternative. In order to see if an alternative waste management solution is desirable in an operational sense, it should be proved that the alternative is practical and efficient. In other words, it should be demonstrated that the alternative makes maximum use of available resources including raw materials, people, and time. Before evaluating an alternative waste management solution, it should be verified if the current work practices and procedures support a new system. This verification also covers the adaptation of end users and managers to the change. The flexibility and expandability of the alternative must also be taken into account because capacity changes can take place in the company as a result of future needs and projected growth.

Technical Analysis of Alternative Waste Management Solutions: Each alternative waste management solution should be analyzed in order to see if it is technically feasible. The technical viability generally consists of measures such as the practicality of an alternative and the availability of technical resources and expertise within the facility. An important aspect identifying if the alternative waste management solution is technically feasible is the availability of the required technology. Some alternatives may involve solutions that can be applied without the need of a new technology or equipment. Conversely, there may be alternative waste management solutions that need the investigation of the market availability of the required technology or equipment. If the required technology is produced or sold within the country, it is needed to compare the different sellers and selling prices. On the other hand, if the required technology is exported, it is needed to investigate the different countries, selling prices and transshipment rates. In order to see if an alternative waste management solution is desirable in a technical sense, the company should verify if the technical requirements, impediments and competing technologies are identified. By evaluating current technology options and limitations, the company can define how difficult it will be to build the new system. For some alternative waste management solutions, there may be critical elements that require feasibility demonstration. Therefore the company may require making tests and experiments in order to see if the considered alternative waste management solution is technically feasible. By this way, the performance of experiments and tests can be compared with preliminary technical requirements and objectives. The experiments and tests will enable the presentation of a path forward for the next stage of the alternative. Moreover, written results, models, or laboratory process outputs demonstrating technical concepts and benefits will improve confidence that the alternative waste management solution will successfully meet the goals of the company.

Economical Analysis of Alternative Waste Management Solutions: If an alternative waste management solution is operationally and technically feasible, then the economical analysis of the alternative should be carried out to examine if it is affordable or not. The economical viability generally consists of measures such as the quantitative estimation of benefits of an alternative waste management solution, which are typically reduction in costs or risks. An alternative waste management solution that is economically desirable is regarded as justified because the economic aspects are generally the bottom line of many projects. In the economical analysis phase, the costs, benefits and incomes of the current system should also be identified. By this way, it will be possible to compare the economic aspects of the current system and the suggested alternative waste management solution. This will allow realizing the cost of not developing the new system. In order to see if an alternative waste management solution is desirable from an economical point of view, the cost-benefit analysis should be made and the cost-effectiveness of the alternative should be proved. By this analysis, it will be demonstrated if the benefits outweigh the estimated costs of development, installation, operation and maintenance. When making an economical analysis, it is important to predict tangible and intangible benefits. Furthermore, the timing of costs and benefits is an important factor determining the payback period, which is also an important decision criterion affecting the applicability of an alternative waste management solution.

Comparison of Alternative Waste Management Solutions

As it is known from operations research, optimizing a variable may not always give the overall optimal solution, especially when several aspects such as productivity and environmental performance are both aimed (Nahmias, 2004, p. 671). Therefore, the consequences of the alternative waste management solutions and their effects on the overall performance should be discussed. If an alternative waste management solution is found to be feasible, the company may decide to proceed with this solution after comparing it with other alternatives generated for the considered problem. In selecting the best alternative, a company often considers trade-offs. The final decision can be determined by working with end-users, reviewing operational, technical and economic data. On the other hand, decisions criteria such as dependability, efficiency, flexibility and quality may be used for creating an environmental operations strategy. Therefore, if a company aims to accomplish an environmentally integrated manufacturing system analysis, a multi-disciplinary team should be formed and operational, technical and economic aspects should be compared for each alternative waste management solution by taking account the criteria mentioned above. It is also essential that the company reviews and changes its environmentally integrated manufacturing plans dynamically to assure high environmental standards. An important issue in improving the manufacturing system is the use of feedback information in order to continually adjust the mix of inputs and technology needed to achieve desired outputs. Information derived from environmentally integrated manufacturing system analysis will continually change production planning decisions such as demand forecasting, purchasing, production and personnel scheduling, quality control, and inventory control issues. The team leader should constantly monitor the manufacturing system and its environment in order to plan, control and improve the system.

IMPLEMENTATION OF THE ENVIRONMENTALLY INTEGRATED MANUFACTURING SYSTEM ANALYSIS IN A CAR BATTERY MANUFACTURING PLANT

The implementation of the methodology is accomplished in a car battery manufacturing plant working with hazardous materials such as lead and sulfuric acid. The lead-acid battery manufacturing company occupies a total space of 22,500 m2 in its manufacturing plant in Ankara. The company produces different types of lead-acid batteries and also supplies different types of semi-finished products like grids, raw plates, charged plates as well as lead monoxide. The production capacity is 1,500,000 batteries per year and there are 50 white-collar and 250 blue-collar workers. The following assumptions are considered in the context of the study:

- The manufacturing process of wet-charged batteries is considered.
- Prices of products are assumed to be constant for every customer.
- Data collected about the manufacturing system is considered as input data.
- The unit waste management cost of an on-site recycled waste consists of its raw material cost. Labor and overhead costs associated to the considered waste are included if a change in these costs is obtained according to the evaluation of alternative waste management solutions.
- The unit waste management cost of an off-site recycled waste consists of its raw material cost and transportation cost, apart from the selling price to the recycling facility.
- The unit waste management cost of discarded wastes consists of the raw material cost.
- The unit waste management cost of wastewater consists of the raw material cost. Energy usage in the wastewater treatment facility is ignored. Chemical usage costs are included to costs calculations if a change in chemical usage is obtained according to the considered alternative waste management solution.
- In the net present value calculations, the costs are assumed to derive at the end of each month and the monthly interest rate is assumed to be 1.6%.
- The company works 6 days a week. Each day consists of 3 shifts, which are 8 hours each.
- The company does not hold end-product inventory and there is no cost associated to inventory carrying.
- There is no problem associated to the limited storage area.

With the use of the methodology, the manufacturing system of the company is analyzed and the alternative waste management solutions are investigated and evaluated.

Analysis of the System

The analysis of the system provides information about the current manufacturing and waste management system. The data collection phase involves a thorough assessment of the company, from the purchase of various inputs to the output. Data such as the types of batteries, demands and prices of each product, raw material prices and material requirement plans are obtained in this phase of the study. The demand forecasting procedure and bill of material of a car battery are obtained. The current production planning and scheduling system are analyzed. Each manufacturing process is analyzed in detail to determine the operations forming wastes. The manufacturing process of a car battery and wastes derived from each unit process are shown in Figure 1. The waste management system of the company involves the entire procedure of collecting, transporting, processing, recycling and disposal of waste materials. Information about the production wastes (quantity and rate of generation) is collected. The composition of wastes and waste management costs are investigated. Current waste management practices in the company are determined and analyzed with respect to their appropriateness in terms of environmental and economical benefits. Making detailed analysis about the environmental impacts of the wastes is also important for convincing people to implement the suggested alternative waste management solutions, which can be considered as a new way of achieving better working conditions in the facility. This study focuses on the wastes produced in three manufacturing processes as shown in Figure 1: grid casting, battery closing, wet-charging. Due to the current waste management system of the company, the identified wastes are considered as:

- On-site recycled wastes: Wastes used within the facility.
- Off-site recycled wastes: Wastes sent to recycling facilities to recover the raw material.
- Wastewater: Contaminated water treated in the wastewater treatment facility of the company

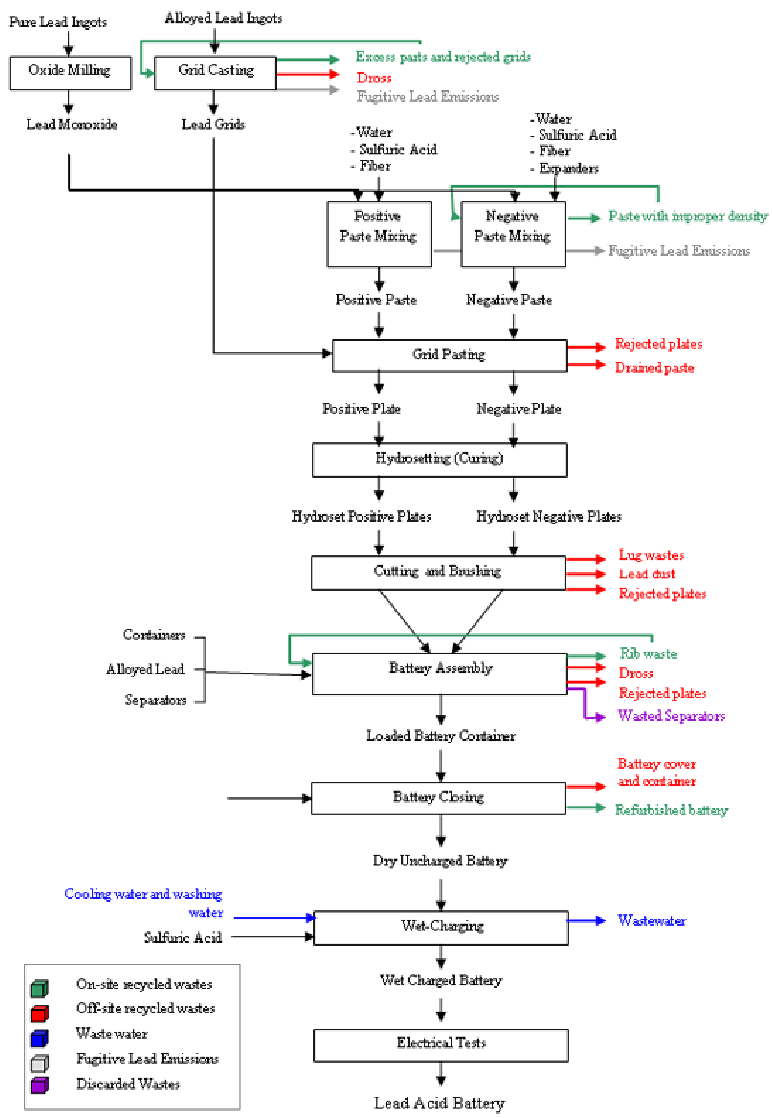
Identification of Alternative Waste Management Solutions

The alternative waste management solutions are identified by investigating waste management technologies and alternative waste management solutions. The possible waste management technologies in the battery manufacturing plant are identified and the benefits of implementing pollution prevention techniques in the considered sector are investigated. The best available technologies aiming the decrease of particular types of wastes are described in detail in the evaluation of alternative waste management solutions investigated for the considered wastes. Additionally, two case studies concerning a general pollution prevention study in the car battery manufacturing industry are examined. The applicability of each alternative waste management solution is evaluated in order to show the type of problems that could derive from their applications. By making an operational, technical and economical analysis for each of the alternatives, it is possible to present realistic propositions. Therefore, the possible benefits and limitations are identified for each solution alternative.

Alternative Waste Management Solutions: Wastes from Grid Casting

Dross obtained from the grid casting process is the waste that causes the highest lead loss in the company. In the grid casting process, the excess parts of each grid are cut automatically and transferred to the melting pot by a conveyor belt located behind grid casting machines. Additionally, the rejected grids detected by operators are added to the melting pot immediately after their detection. Therefore, the grid casting process involves continuous addition of wastes into the melting pot. The formation of dross is the result of molten lead alloy and air contact. It is simply the oxidation of lead alloy. Therefore, the formation of dross is inevitable on the surface of the molten

Figure 1. Process Flow Diagram of a Car Battery



lead alloy in the pot that is open to atmosphere. In fact, the dross formed may act as a protective passive film preventing further dross formation if it is not disturbed. But, when wastes deriving from the grid casting machine are added to the melting pot continuously, the surface covered by dross collapses, and this procedure causes an increase in contact area of lead alloy with air. As a result, the amount of dross increases continuously when wastes are added to the pot. There are two alternative practice identified for the reduction of dross amount in this study as explained and analyzed below.

Addition of Excess Parts and Rejected Grids in Batch Mode: The practice of adding excess parts and rejected grids may be changed from continuous to batch. In other words, the parts and grids may be collected and then added at specific time intervals, so that the contact time of the molten lead alloy with air can be decreased.

This practice is experimented in the grid casting procedure to observe any change of dross formation rate in this study.

Two experiments are accomplished for observing the relationship between dross formation and time interval adopted for the collection of rejected parts and grids. Two different time intervals were tested as 1.5 and 3.0 hour. The current grid casting procedure was also observed for comparison. Before the experiment, the dross layer from the surface of the molten lead alloy was completely removed from the melting pot by the use of a ladle with holes in it. The amount of dross formed in the melting pot during 1.5 and 3.0 hour periods was observed under the conditions in which the excess parts and rejected grids were collected. At the end of the collection period, the production of grids was stopped and the dross formed on the surface was removed and weighed. Following this, the collected excess parts and rejected grids were weighed and added to the melting pot. Since the excess parts and rejected grids weighed about 700 kg, the manual addition of the rejects to the pot took approximately 25 minutes. Then, the formation of dross for an hour was allowed under the conditions of no production. Finally, the dross formed in an hour was collected and weighed. The summation of the dross collected before and after the addition of rejects is considered as the total weight of dross obtained from the experiment with the considered time interval. The results from this experiment show that the ratio of rejects to the ratio of product produced is about 58-60%, which is considerably high.

Following up these steps, the current grid casting procedure was observed for the same time intervals; specifically 1.5 and 3 hours time periods. Accordingly, the production of grids was started with continuous feeding of the melting pot with the excess parts and rejected grids by conveyor belt. The amount of dross formed at the end of the time interval was measured by collecting and then weighing the dross. During this step, the amount of excess parts and rejected grids could not be measured since they are automatically added to the melting pot.

According to the results obtained from the two experiments with different time intervals, it is proved that the suggested work practice reduces the amount of dross significantly. It has also been shown that decreasing contact time decreased the amount of dross formed. Therefore, the longest possible time period for collection is expected to decrease the dross amount most. The cash flow analysis of the batch mode and the current system are compared in Table 1. The calculations in Table 1 take into basis that dross is reduced by 48% with the use of the batch mode alternative. The cost of raw material loss is calculated based on the unit cost of dross, which is 1.18 $/kg. Since it took 3 hours to obtain 41 kg of dross in the experiment, the production of dross is assumed to be 13.6 kg/hour. Additionally, the unit labor cost for the company is calculated to be 1.63 $/hour, based on the base wage rate. Given the unit labor cost and unit production rate of dross, it can be concluded that the unit direct labor cost of dross is 0.11 $/kg. Based on the monthly quantity of dross, the direct labor cost associated to dross in the current system is:

Direct Labor Cost of Current System= 0.11 $/kg x 12,299 kg/month = 1352 $/month.

In the production cost of a battery, it is known that the direct labor occupies a percentage of 14%, and the overhead occupies a percentage of 26% of the total cost. The overhead cost associated to dross can be calculated by using these ratios and the direct labor cost as calculated above. Knowing that the 14% of the total cost is 1,337 $/month, it can be calculated that the 26% of the total cost, which corresponds to the overhead cost associated to dross, is 2,712 $/month, as shown in Table 1. The direct labor and overhead costs of the batch mode are calculated similarly. In addition to the current system, in the batch mode there is a need of labor when collecting excess parts and rejected

Table 1. Comparison of cash flow analysis of the current system and the batch mode for t=3.0 hours

	Current System	**Batch Mode**
Quantity of dross (kg/month)	12,299	6,396
Cost of raw material loss ($/month)	14,605	7,593
Direct labor cost associated to dross ($/month)	1,352	759
Overhead cost associated to dross ($/month)	2,712	1,410
Labor cost associated to the collection of parts ($/month)	-	285
Net Present Value ($/year)	**203,552**	**108,920**

grids. In the experiment, it is seen that a total of 45 minutes is spent for a production of 3 hours. Taken into basis that the company works 24 hours during 29 days/month, it is calculated that the monthly labor spent for this alternative is 174 hours. Since the unit labor cost is 1.6 $/hour, the labor cost associated to the collection of parts is:

C Labor Cost of Collecting Parts= 1.6 $/hour x 174 hours/month = 278 $/month.

The net present values of the current system and the batch mode are calculated for one year, as seen in Table 1. The costs are assumed to derive at the end of each month and the monthly interest rate is taken as 1.6%. When comparing net present values, it can be seen that the batch mode decreases costs by 46% compared to the current system. This alternative obviously will reduce the quantity of lead alloy required to produce the same amount of grid since the raw material loss in dross will be minimized. Therefore, it will clearly improve the productivity by reducing raw material consumption. This alternative is also advantageous because the waste is reduced at source. As a result, the environmental impact of the company can be considerably reduced by using this alternative.

Separation of Pure Lead from Dross Using Vitaflux™: The dross collected from the melting pot is high in its lead (Pb) content. It is observed that dross formed in the current system contains a quantity of 41% of lead in a purity of 99.92%. As mentioned before, the dross is currently collected and sent to the recycling facility. However, if the pure lead can be extracted from the dross inside the facility, it will be a very beneficiary practice since it will be possible to reuse the pure lead as a raw material. Drossing-off fluxes are used for this purpose in order to accumulate the oxides and allow easy removal from the surface of the molten lead (Brown, 1999, pp. 56-62). Specifically, there is a material called Vitaflux™, which is used to recover the lead from dross at source (NA Graphics, n.d.). Application of the material is very simple. Vitaflux™ is added on the surface of the melting pot before dross is collected. The lead alloy begins to burn with the addition of Vitaflux™ and the pot is mixed until dross becomes fine powder. At the end of the reaction, the dross in fine powder form is accumulated on the surface of the molten metal. Vitaflux™ has been tested in the company and lead was recovered from the dross successfully.

The grid casting department consists of two melting pots. Due to the lead alloy load of the pots, six tubes of Vitaflux™ is needed for each melting pot every time dross is collected. Since dross is collected once a day in the grid casting department, one box containing a dozen of Vitaflux™ tubes is needed every day. In the calculations, it is assumed that one year consists of 350 working days. Therefore, about 350 boxes of Vitaflux™ are needed per year. Results from test showed that the use of Vitaflux™ does not influence the composition of the lead alloy in the melting pot. Besides, when the dross collected after the use of Vitaflux™ is analyzed in the laboratory of the company, it was observed that the pure lead is totally removed from the dross. Therefore, it can be concluded that the use of Vitaflux™ creates significant amount of recovery of lead from the dross.

Experiments conducted in the company for recovering lead from dross showed that the quantity of the dross decreases by 30% when pure lead is separated from dross with the help of Vitaflux™. In other words, this alternative involves 30% of reduction of dross at source. Therefore, even if the impact to the environment can not be quantified, the company's damage to the environment is certainly decreased on a large scale since the dross deriving from grid casting is the highest amount of waste in the company. In addition and more importantly, a significant quantity of pure lead is going to be saved and will be used in production. As a result, this alternative allows a more efficient use of raw materials and a decrease in total recycling costs. The net present values of the current system and the Vitaflux alternative are calculated for one year in Table 2.

In addition to the current system, in the Vitaflux alternative there is a need of extra labor time when mixing the pot and collecting the dross after the addition of Vitaflux. Dross is collected once in 24 hours from 2 melting pots. In the current system, the collection of dross from one pot takes 10 minutes. Taken into basis that the company works 24 hours during 29 days/month, it is calculated that the monthly labor spent for in the current case is 10 hours. Since the unit labor cost is 1.6 $/hour, the labor cost associated to this alternative is: C Labor Cost of Current System= 1.6 $/hour x 10 hours/month = 16 $/month.

The same calculation is made for the Vitaflux alternative taking into basis that the collection of dross from one pot takes 20 minutes. On the other hand, the period in which Vitaflux™ is bought and the quantity of Vitaflux™ needed in this time period is important. It is calculated that 3 month purchasing period gives the minimum net present value. The monthly interest rate is taken as 1.6%. When comparing net present values, it can be seen that the Vitaflux alternative decreases costs by 17% compared to the current system. Since the amount of dross is assumed to be equal to the lead alloy loss, it can be concluded that 3,690 kg/month of lead can be recovered and used in production with the Vitaflux™ application.

Alternative Waste Management Solutions: Setup Wastes Generated From Battery Closing Operation

Minimization of setup time may correspond to reduction of setup wastes for the industries producing sequential products requiring similar production techniques. One way of decreasing setup waste may be to decrease the number of machine adjustments in the productions, where the number of setup waste is constant according to quality regulations. The production scheduling policy used in most of the industries is based on a system where monthly demands are divided into short sub-periods in order to increase the flex-

Table 2. Comparison of cash flow analysis of the current system and the Vitaflux alternative

	Current System	Vitaflux Alternative
Quantity of dross (kg/month)	12,299	8,609
Cost of raw material loss ($/month)	14,605	10,224
Labor cost associated to the collection of dross ($/month)	16.25	32.5
NPV of Vitaflux for 3 months purchasing period	-	19,465*
Net Present Value ($/year)	**158,492**	**130,648**

* Calculated due to data of NA Graphics (n.d., n.p.)

ibility of the production. However this may cause production of abundant numbers of setup waste as a result of inverse proportionality between the length of the sub-period of scheduling plan and the number of machine adjustments. If longer scheduling sub-periods are chosen, then the production of setup wastes and the inventory holding costs will be decreased but the flexibility of the scheduling will be lost. On the other hand, if the scheduling sub-period is shortened, then the scheduling will be more flexible but the number of setup waste will increase. For this reason, there is a need to find out an optimum scheduling plan taking into account the production of setup wastes.

When adjusting the production schedule with the aim of minimizing setup wastes, the primary concern of the car battery manufacturing company is the demand level of products. Products with low demands (products whose monthly demands are approximately equal to the production capacity of one shift) are produced in one or two shifts. Products with high demands (products whose monthly demand highly exceeds the production capacity of one shift) are produced on a weekly basis and are sent to customers each week. Namely, the monthly demand is divided to weekly demands. Since these highly demanded products are not produced continuously, a setup adjustment on the closing machine is needed each time the production of this product starts (each week). The number of setup adjustment will be high, as well as the setup waste generated. An alternative waste management solution is to schedule products so that high-demanded products are produced continuously like the low-demanded products. By this one-month-scheduling method, the monthly demand of high-demanded products will not be divided by four; the monthly demand will be produced in one batch. Namely, the production of these products will continue until the monthly demand is reached.

It is necessary to produce one setup waste while making machine adjustments in the battery closing operation. This setup waste is considered as a refurbished battery and can not be sold to customers. Therefore, the production cost of the battery is considered as the on-site waste management cost of the refurbished battery. One way to establish a pollution prevention approach may be to change the production scheduling policy to decrease the number of refurbished batteries. The relation between the length of the scheduling sub-period and setup waste amount is established to find out the existence of an option to obtain minimum waste. The scheduling sub-period (one week, two week, or four week) in a month affects the number of setup waste generated. Therefore, one of the ways of reducing the setup waste is to determine the sub-period with minimum inventory holding and waste removal cost between different scheduling sub-periods. For this reason, different scheduling sub-periods are analysed, such as one week, two week and four week. The company is currently using a production scheduling based on one-week sub-period. A binary integer programming model is developed to determine the sub-period giving the minimum total cost comprising inventory holding and waste management costs. Inventory carrying within the considered sub-period is ignored. The model is demonstrated below.

$$\sum_{i=1}^{m}\left(W_1R_iX_1+W_2R_iX_2+W_4R_iX_4+\frac{3}{2}h_iX_1D_i+h_iX_2D_i\right)$$

Minimize

subject to

$$X_1+X_2+X_4=1$$

$$X_k\in\{0,1\}\qquad ,\ \mathrm{k}=1,2,4$$

Where, D_i is the demand of product *i*, $W_{i,k}$ is setup waste of product *i* derived with alternative *k*, R_i is the waste management cost of product *i*, and h_i is weekly inventory holding cost of product *I* The model is solved for the given data. Different types of products with varying demands (5 of them are low-demanded and 12 of them are high-demanded) are taken into basis and the forecasts of year 2006 are considered as the monthly demands of each product. The battery production cost associated to the refurbished batteries is considered as the waste management cost of the refurbished battery. The weekly inventory cost of a product is considered as the selling price of the product multiplied by the weekly interest rate which is taken as 0.4%. The number of setup wastes changes according to the sub-period chosen. The one-week sub-period produces 4 setup wastes, the two-week sub-period produces 2 setup wastes and the four-week sub-period produces 1 setup waste per month. The model is solved in Excel Solver for the demands of each month. The option giving the minimum cost is found as the four-week sub-period for each run (In the optimal solution, X_4 is 1 while X_1 and X_2 are 0). The cash flow analysis of the optimal solution of the mathematical model and the current system are compared in Table 3.

Table 3. Comparison of cash flow analysis of the current system and the mathematical model

Costs (YTL/month)	**Current Case**	**Optimal Solution of the Mathematical Model**
January	18.41	0.97
February	18.41	0.97
March	19.30	0.91
April	19.30	0.91
May	15.84	0.89
June	15.56	0.89
July	15.20	0.84
August	14.55	0.84
September	23.15	0.97
October	23.42	0.97
November	24.01	0.97
December	23.42	0.97
Net Present Value ($/year)	**207,240**	**10**

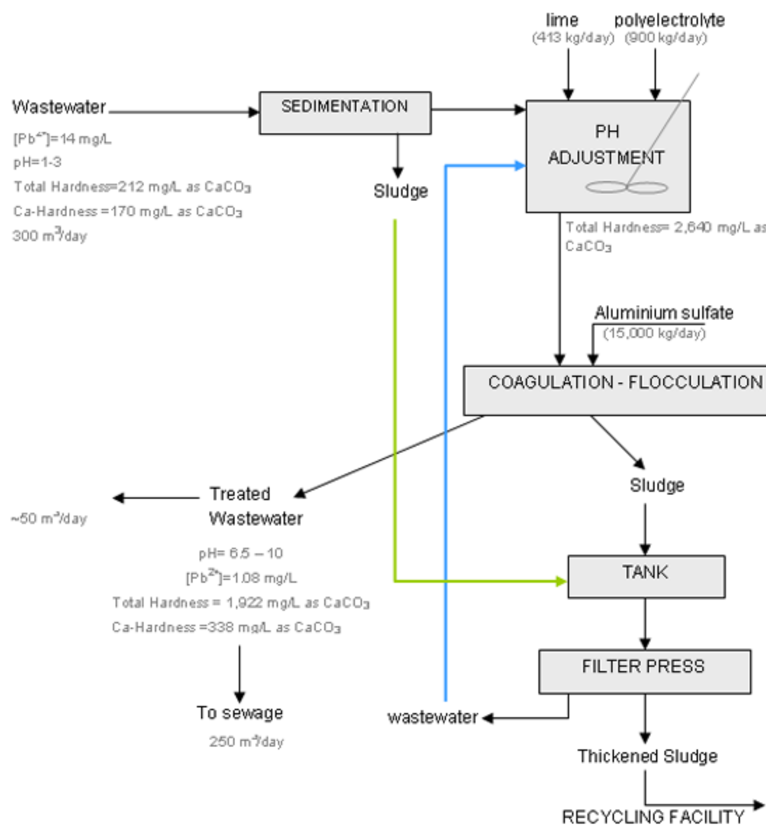
As shown in Table 3, the optimal solution of the mathematical model for each month corresponds to the cost associated to the sub-period giving the optimal solution, the four-week sub-period. When comparing net present values, it can be seen that the four-week sub-period decreases costs by 95% compared to the current system. The wastage of the semi-finished products and the according waste management costs can be significantly decreased with the four-week sub-period. This alternative is an important example showing how the operational decisions can improve environmental problems in a company. However, the production of a high-demanded product in one batch may not be possible in certain cases because of the lead-time of the demands. The operation time of a product may have a long duration, especially when all of the monthly demand is to be produced in one batch. Therefore, the lead time of the other products waiting on the queue will be an important constraint. In addition, production plans must be flexible enough to meet the unexpected demands coming from the competitive environment. The scheduling of this type of environmentally integrated production plan may be difficult and sometimes infeasible for companies that have to deliver products every week.

Modification of the Wastewater Treatment Facility to Reduce the Amounts of Chemicals Used and to Decrease Water Consumption in Production

The cooling and washing water coming from wet-charging process, the charging water of plates and the water used in cleaning equipments are collected and then treated in the wastewater treatment facility operated by the company. Figure 2 shows the unit operations and processes in the wastewater treatment facility of the company.

As shown in Figure 2, the collected wastewater from the resources mentioned above, with a

Figure 2. Operations in the wastewater treatment facility



discharge of 300 m^3/day, is first transferred to sedimentation tank to remove particles, which have high amount of Pb. The sludge formed in this process is sent to the tank used for the collection of sludge. The cleared wastewater (supernatant) is then transferred to pH adjustment unit in which lime (CaO) is added (413 kg/day) to raise pH value of the wastewater from 1.3 to 8.5-9.0. The addition of polyelectrolyte, which is a polymer used to stabilize the sludge, is also accomplished in this unit (900 kg/day). Following up the pH adjustment, aluminum sulfate ($Al_2(SO_4)_3$) is added as precipitant for the removal of Pb dissolved in wastewater in coagulation and flocculation unit. The sludge formed in this reactor is sent to sludge collection tank and then to filter press to become thicker. The wastewater from the filter press unit is recycled back to mixing process. The sludge is sent to the recycling facility since it contains considerable amount of lead. The wastewater from flocculation unit is discharged to sewage while about 1/6th of the volumetric flow is reused as lead suppressant and in negative drying purposes. Since the hardness of the treated wastewater is high enough to stain the containers, it is not possible using it as cooling water or cleaning water for equipments. In cases it is used in wet-charging, white traces will be left on the surface of containers. Hard water is not preferred for cleaning the equipments since it reduces the performance of detergents used. Therefore, using another chemical to adjust pH instead of CaO, for example NaOH, may decrease the water consumption.

The hardness of water is mainly caused by divalent or trivalent ions, Mg^{2+} and Ca^{2+}, and water can be softened by chemical precipitation technique (Patterson, 1985, 220-226). If the chemical (CaO) used for pH adjustment is replaced by another chemical containing an ion, which does not cause any additional hardness, then the treated wastewater can be recycled back to the production system to be used in wet-charging, cleaning, etc. This change is expected to decrease the water consumption of the company significantly. To be able to compare the benefits of using NaOH instead of CaO, there is a need to find out the amount of NaOH required to neutralize the wastewater containing H_2SO_4 and to raise its pH to 8.5.

Calculation of CaO and NaOH Amounts: The theoretical calculation of the amounts of CaO and NaOH to be added to neutralize the wastewater containing 496 mg SO_4^{2-}/L (5.2 x 10^{-3} mol SO_4^{2-}) and to adjust the pH to 8.5 requires the following assumptions:

1. The ionic strength of the wastewater is very low, so that the influence of other ions in concentration estimations can be ignored.
2. The temperature of the wastewater is 25°C.
3. Dissociation of $Ca(OH)_2$, which is the product of a reaction between CaO and H_2O is complete.

$CaO\ (s) + H_2O \rightarrow Ca(OH)_2\ (aq)$ (Reaction 1)

$Ca(OH)_2 \rightarrow Ca^{2+} + 2OH^-$ (Reaction 2)

4. The dissociation of NaOH in H_2O is complete.

$NaOH \rightarrow Na^+ + OH^-$ (Equation 1)

5. The CaO and NaOH used are 100% pure.

Dissociation of H_2O:

$K_w = [H^+]\,[OH^-] = 10^{-14}$

$$\left[OH^-\right] = \frac{10^{-14}}{[H^+]}$$

Mass balance on Ca^{2+} and SO_4^{2-}:

$$C_{T,Ca^{2+}} = [Ca^{2+}] = \frac{\text{number of moles}}{\text{total volume}}$$

$$C_{T,SO_4^{2-}} = [SO_4^{2-}] = \frac{\text{number of moles}}{\text{total volume}}$$

Charge Balance:

$$2[Ca^{2+}] + [H^+] = 2[SO_4^{2-}] + [OH^-]$$

$$2[Ca^{2+}] + [H^+] = 2[SO_4^{2-}] + \frac{10^{-14}}{[H^+]}$$

$$\text{pH} = 8.5 = -\log[H^+]$$

$$[H^+] = 10^{-8.5}\ \text{M}$$

$$[Ca^{2+}] = 5.20 \times 10^{-3}\ \text{M}$$

Therefore, Ca^{2+} to be added:

$$= 5.20 \times 10^{-3}\ \frac{\text{mol}}{L} \times 300\,\frac{\text{m}^3}{\text{day}} \times 1000\,\frac{\text{L}}{\text{m}^3} \times \frac{1\ \text{mol CaO}}{1\ \text{mol Ca}^{2+}} \times \frac{(40+16)\ \text{gr}}{1\ \text{mol CaO}} \times \frac{1\ \text{kg}}{1000\ \text{gr}} = 87.36\ \text{kg}/day$$

The calculated amount of CaO is much lower than the amount added into the pH adjustment tank in the wastewater treatment plant, which is 413 kg/day. The difference is huge, but it could be due to the assumptions made in theoretical calculations especially the grade of the CaO used in the plant, which may be very low. Moreover, the dissociation of CaO and $Ca(OH)_2$ may not be completed in the pH adjustment unit as a result of poor mixing conditions.

Mass Balance on Na^+ and SO_4^{2-}:

$$C_{T,Na^+} = [Na^+] \frac{\text{number of moles}}{\text{total volume}}$$

$$C_{T,SO_4^{2-}} = [SO_4^{2-}] = \frac{\text{number of moles}}{\text{total volume}}$$

Charge Balance:

$$[Na^+]+[H^+]=2[SO_4^{2-}]+[OH^-]$$

The equation was similarly solved and the amount of $[Na^+]$ was found to be 0.01037 M which corresponds to 124.46 kg/day. The reason for adding more NaOH than CaO is the number of hydroxyl ions in the compositions of the chemicals. It should be noted here that there is a significant difference in the solubility of NaOH (1,080 gr/L) and CaO (1.39 gr/L) (Dean, 1992). The NaOH can be dissolved in the water in almost instantly requiring mixing enough to sustain the homogeneity of the wastewater. On the other hand, the solubility of CaO is lower than NaOH.

In the experiments made in the wet-charging operation, it is seen that caustic does not leave white traces in the surface of containers. Therefore it is feasible to use caustic instead of lime. In addition, with the use of lime, it will be possible to treat and reuse the same water for several days. The wet-charging operation uses 150 tones of water every day; so the reuse of the treated water in wet-charging will remarkably reduce the water consumption. The remaining 150 m^3 of refined water may be used in the cleaning of equipments, in the negative drying of plates and as lead suppressant. Table 4 shows the comparison of lime and caustic. Since 100 tones of treated wastewater will be used in equipment cleaning once a day, this amount of wastewater can not be recycled back to production system. Otherwise, there would be a need for tank with capacity of at least 100 tones. Since the water needed in the facility is 300 tones/day, the company will have to use tap water of 100 m^3 to clean the equipments each day. In the calculations, it is assumed that 300 m^3 of tap water is captured in the first day of the week and 100 m^3 of water in each of the remaining 5 working days of the week. Therefore, the weekly water consumption is:

Water consumption = 300 + 5 x 100 = 800 m^3/week.

In addition, as calculated previously, it is also known that 124.46 kg/day of caustic will be used instead of 87.35 kg/day CaO. Since no experiment could have been performed using real wastewater to find out the amount of NaOH for adjusting the pH to about 8.5, the comparison of costs of lime and caustic was made based on theoretical calculation of the amounts of chemicals with the assumptions made. The prices of the pure CaO and NaOH are

Table 4. Comparison of cash flow analysis of the current system and lime alternative

	Current System	**Lime Alternative**
Water Usage (m^3 /month)	7,200	3,200
Total Cost of Water ($/ month)	15,930	7,080
Chemical Usage (tone/month)	2.1 (0.08735 x 6 x 4)	2.9 (0.124460 x 6 x 4)
Unit Cost of Chemical ($/tone)	76.25	562.5
Total Cost of Chemical ($/month)	160	1,680
Net Present Value ($/year)	**174,413**	**94,957**

76.25 $/tone and 562.5 $/tone, respectively. The unit cost of water is 2.21 $/tone. The cash flow analysis of the using caustic instead of lime is compared with the current system in Table 4. As it is seen from Table 4, even though the unit cost of caustic is greatly higher than lime, this alternative gives lower costs because it significantly reduces the water consumption by allowing the reuse of the refined wastewater. A high cost saving is obtained with the use of this alternative. The net present values of the current system and the suggested alternative are calculated for one year, as seen in Table 4. The costs are assumed to derive at the end of each month and the monthly interest rate is taken as 1.6%. When comparing net present values, it can be seen that the suggested alternative decreases costs by 45% compared to the current system.

Comparison of Alternative Waste Management Solutions

Table 5 shows the suggested alternative waste management solutions and the environmental and economical benefits that can be obtained by using them in the company. As seen in Table 5, it was demonstrated that the formation of dross which is the biggest waste problem of the company could be decreased by 30% by using a flux during dross collection. Since the waste was reduced at the source, the waste and recycling costs could be significantly decreased, and most importantly, a very big quantity of lead (Pb) raw material could be recovered consequently. The reuse of the treated wastewater was also a good alternative for the company since a very high quantity of water is used and wasted every day due to production requirements. By using caustic instead of lime, the company could reduce its weekly water usage up to 44%, which would make a considerable decrease in environmental impacts and operating costs.

Table 6 shows the difference in waste management costs when quantity of wastes are decreased according to the suggested alternative waste management solutions. It can be seen in Table 6 that a cost improvement of 63% is achieved by implementing all the alternative waste management solutions suggested. The calculation of the waste management cost of the suggested alternative for the dross obtained in grid casting operation is based on the alternative waste management solution covering the addition of excess parts and rejected grids in batch mode.

FUTURE RESEARCH DIRECTIONS

It is believed that several new approaches and techniques can be added to improve this methodology in the future. A decision support tool can be

Table 5. Suggested solution alternatives and advantages

Wastes	Alternative	Environmental Advantages	Economic Advantages
Dross, excess parts and rejected grids from grid casting	Addition of Excess Parts and Rejected Grids in Batch Mode	Waste reduction at source	Cost Reduction: 94,631 $/year.
		Recovery of 70,848 kg Pb/year.	
	Separate Pure Lead From Dross With Vitaflux	Waste reduction at source. Recovery of raw material from the waste at source.	Cost Reduction: 27,812 $/year.
		Recovery of 44,280 kg Pb/year.	
		Recovery of 1,934 kg Pb/year.	
Refurbished battery from battery closing	Change the Production Schedule	Waste reduction at source.	Cost Reduction: 197,231 $/year
Treated wastewater from the wastewater treatment facility	Use Caustic Instead of Lime	Usage of water decreased by 52,000 m3/year.	Cost Reduction: 79,456 $/year.

Table 6. Comparison of waste management costs

Waste	Current Waste Management Cost ($/year)	Waste Management Cost of Suggested Alternative ($/year)	Cost Improvement
ON-SITE RECYCLED WASTES			
Refurbished Battery	207,240	10	96%
OFF-SITE RECYCLED WASTES			
Dross of grid casting	203,552	108,920	47%
WASTEWATER			
Wastewater	174,413	*94,957	46%
TOTAL COSTS	**585,205**	**108,930**	**82%**

* The addition of excess parts and rejected grids in batch mode is taken into basis

designed for calculating and comparing costs and benefits of solution alternatives. By using such a decision support tool, the unit costs and unit profits can be saved in the system and costs of solution alternatives can be easily calculated. It will be also possible to define criteria and give weights to them in order to compare the operational, technical, economical and environmental characteristics of solution alternatives. Implementation of this environmentally integrated manufacturing system analysis in a different sector or company will also provide important inputs for improving the system and understanding its capabilities.

CONCLUSION

This study has introduced an environmentally integrated manufacturing system analysis methodology for companies willing to be a part of the sustainable development by efficiently using the principles of "cleaner" production techniques in obtaining high productivity levels. The wastes derived from the manufacturing process should be minimized in order to reduce the amount of raw materials used and decrease the need for wastes' recycling. The problem considered is the investigation of a systematic methodology decreasing the waste obtained from the manufacturing process while simultaneously improving the overall performance of the company. This methodology is important in being a roadmap for the evaluation of environmentally friendly and economically favorable alternative waste management solutions. By using this methodology, the manufacturing and waste management system of a company can be analyzed, alternative waste management solutions for decreasing wastes can be investigated, evaluated and compared.

KEY TERMS AND DEFINITIONS

Cleaner Production (CP): The continuous application of an integrated preventative environmental strategy to processes, products and services to increase efficiency and reduce risks to humans and the environment.

Eco-Efficiency: A management philosophy that encourages business to search for environmental improvements which yield parallel economic benefits.

Environmental Operations Management (EOM): The integration of environmental management principles with the operations management process for the conversion of resources into usable products.

Pollution Control Methods: Methods covering the elimination of pollution after the waste is generated.

Pollution Prevention Technologies: The modification or redesign of the production process and the introduction of new technologies throughout the product life-cycle, which contributes to the development of new internal routines and know-how's.

Sustainable Development: Meeting the needs of the current generation without compromising the ability of future generations to meet their own needs.

Chapter 51
Ghabbour Group ERP Deployment:
Learning From Past Technology Failures

M. S. Akabawi
American University in Cairo, Egypt

EXECUTIVE SUMMARY

Ghabbour group "GB Auto," an Egyptian auto trading and manufacturing establishment, has gone through two ERP successive implementations within the past 12 years. The newer implementation has experienced several impediments. The executives and the Board of Directors at the group have thoroughly and aggressively examined the status of the IS services provided by this ERP system and assessed their impact on the quality of decision making at all levels of management. The driver for this was to secure all the necessary platforms and management tools for enabling growth and improving efficiency and effectiveness of the company's business operation and resources. The extent of lack of control and effective utilization of the use of resources in the group has been cited by the top management in many interviews. Following its public offering and registration in the CASE and CMA, GB Auto was legally demanded to provide annual and quarterly audit reports of its varied LOBs' performance. The existing information management infrastructure was not providing such agile services. The trajectory of implementations of integrated Enterprise Information Systems at the group was reviewed in this case study and was duly investigated to assess the effectiveness and appropriateness in servicing those purposes and increasing the company's competitive advantage.

ORGANIZATION BACKGROUND

Ghabbour Group (GB) name has become closely linked to the automotive industry in the Egyptian market – from distribution and manufacturing to after sale services – spanning the full spectrum of the transportation arena. This led the group to adopt the motto "GB Auto - everything on wheels." By the 1990's, privately owned GB group became widely associated with Hyundai passenger cars as a distributor and car assembly manufacturing.

DOI: 10.4018/978-1-4666-1945-6.ch051

The group's role and history in the Egyptian economic field dates back to the 1940's. During this era, the two brothers, Kamal and Sadek Ghabbour established their private auto trading company. The firm was officially incorporated in 1956 as "Ghabbour Brothers." The business area of the firm included trading in automotive products, construction materials, home appliances and electronics.

During the 1960's, the Ghabbours' legacy was firmly maintained despite the economic constraints and hardships in this period, when Egypt embraced the Socialist economic doctrine. By the early 1970's and as a result of the Egyptian government's initiative to adopt the economic open door policy, the group's vision to become serious establishment in the automotive industry not only as a trader, but as a manufacturer, took shape. To that effect, the company started focusing on acquiring licenses and agencies for passenger cars, buses, trucks and automotive parts.

The first manufacturing operation of the group started in 1985 by assembling bus bodies under technical agreement with Scania AB. During this era, Egypt's sole automotive manufacturer was the state-owned El Nasr company for automotive which failed to establish the robust infrastructure for sustainable automotive manufacturing base [removed phrase]. The initial industrial base of GB group started near Cairo-Alexandria Agricultural Road in Qalyubia governorate, which was quite a convenient site due its proximity to major markets and easy access.

With the transfer of management to the younger Ghabbour generations in the early 1990's, the GB group witnessed phenomenal growth and expansion. Horizontal expansion was manifested by the addition of new lines of business (LOB) and diversification of product mixes. While vertical expansion was manifested by increasing the manufacturing base capacities, trade partners and brand names licensing. Hyundai car manufacturer of Korea granted GB group the exclusive agency for the distribution of its passenger cars in Egypt since 1992.

In 1995, GB group was also granted by Hyundai the technical license to assemble passenger cars - Completely Knocked-Down (CKD) units in addition to trading in the Completely Built Units (CBU). Since then, GB group acquired additional agencies for Mazda passenger cars, two and three wheelers products of Bajaj of India; assembly licenses for Mitsubishi trucks and buses; and Volvo trucks and buses. In 2006, GB group entered the transportation services area, for both passengers and cargo, by establishing the new subsidiary - Haram Company.

In 2003, Chairman of the GB Group, Dr. Raouf Ghabbour, established the Raouf Ghabbour Investment Company (RGI) as the holding company of the group's subsidiaries operating in varied LOB portfolio. A list of these subsidiaries is shown in Table 1 together with the business activities pertaining to each subsidiary. In Table 2, we list the various corporate business organizational units in the group and the associated business activities each performs. Those corporate business units provide services across the entire functional activities of the group's subsidiaries.

Before year 2006, RGI (S.A.E) operated as the holding company for GB group's affiliated companies which were wholly owned by RGI. However, one of the groups' affiliated companies – GB Capital was subsequently named as the holding company for the group and RGI became in effect a wholly owned subsidiary. In April 2007, GB capital name was changed to GB Auto.

In July 2007, GB Auto made its Initial Public Offering (IPO) and applied to the Cairo and Alexandria Stock Exchange (CASE) and the Capital Market Authority (CMA) to become a share-holder company with the name of GB Auto (S.A.E). The Ghabbour family maintained ownership of majority of the shares (71 percent). However the offering attracted many foreign and local share holders. A board of directors was formed soon

Table 1. GB holding company and subsidiaries

Ser.	Company Name	Business Activities	Number of Employee
1	RG Investment S.A.E (RGI)	Holding Company for Consolidated Subsidiaries (prior 2006)	101
2	International Trade Agencies Marketing Corp. S.A.E (ITAMCO)	Sales & Dist. Of CBU & CKD PC unites. Spare Parts Dist. Operation of PC after Sales Service Network.	1444
3	Interland Motors S.A.E.	Sales & Dist. Of Volvo heavy range trucks.	33
4	Egyptian Vehicles Manufacturing Company (Ghabbour Misr) S.A.E	Assembly of mini-bus and large coaches, operation of Commercial Vehicles after sales service network and spare parts. Distribution of Volvo Construction equipment	1779
5	Haram Transport Company S.A.E.	Operation of passenger and Cargo Transportation Service	904
6	Cairo Individual Transport Industry CITI S.A.E	Operation of motorcycle and scooter (2 & 3 wheelers) LOB.	64
7	Prima Engineering Industries S.A.E. (PRIMA)	Assembly of Hyundai CKD PC and Mitsubishi light Commercial vehicles, Manufacturing Semi-Trucks	45
8	Vehicles Components Industries S.A.E (VCI)	Manufacturing Semi-Trucks and super-structure, as well as PC Components	45
9	Ghabbour Continental Trading Company free Zones (Alex) S.A.E	Distribution of PCs, mini-buses, spare parts and tires from Alex FZ	17
10	Engineering Company for Marketing and Trading S.A.E	Distribution of tires	33
11	GB Buses, S.A.E (GE)	Manufacturing of bus and Coach bodies	134
12	GB Auto	Holding Company after 2006	1

Source: http://www.ghabbourauto.com

after, and Dr. Ghabbour assumed the position of the Chief Executive Officer of the group.

In September 2007, the group applied to the CMA and the Ministry of Investment for possible merge of its eleven subsidiaries into two major subsidiaries keeping the smaller free zone companies out of this merge. This merge was legally effective by January 2008.

Business Growth Outlook for the GB Group during the Past 5 Years

The historical business growth trajectory and performance of the GB group before the public offering is one of the few business success stories by the Egyptian standards. The group's workforce has also witness substantial growth during the

Table 2. Corporate cross-functional business unites in the group

Unit	Activities
Finance & Accounting	Manages & administer all the group's subsidiaries and the holding company's accounting and finance
Supply Chain	Control all the group warehouses, purchasing and logistics
Internal Auditing	Performs the audit function for all the group's activities in all subsidiaries
Legal Affaires Information Technology	Administers all legal affairs for the group Provides and Manages IT/IS Services to the groups' companies
Administrative Services & HR	Human Resources administration for the group

Table 3. GB auto results for the full-year 2008

(LE million)	FY2008	FY2007
Passenger Cars Revenues	3,675.5	3,314.4
Commercial Vehicles Revenues	740.9	590.0
Motorcycles & Three-Wheelers	571.3	528.2
Other Revenues	204.7	197.5
Total Sales Revenue	5,192.4	4,630.1
Gross Profit	872.3	670.2
Gross Profit Margin	16.8	14.5
Selling & Administration	-277	-218.8
Others – Income / (Expenses)	32.2	18.3
Operating Profit	627.5	469.7
Net Provisions	19.0	112.4
EBIT	646.5	582.1
Foreign Exchange Gains (Losses)	-18.3	2.8
Net Finance Cost	-116.2	-98.4
Earnings Before Tax	512.0	486.5
Taxes	-94.1	-50.7
Net Profit Before Minority Interest	417.9	435.8
Minority Interest	-2.0	-2.3
Net Income	415.9	433.5
Net Profit Margin	8.0	9.4

last four years. This growth is manifested by the nearly tripled human resources tally employed by the group in the period from 2004 to 2008. Table 3 exhibits GB Auto Corporate financial results for the year 2008, while Table 4 shows the increase trend of the employed workforce according to the various broad areas of business activities.

The revenues breakdown of the group from the various broad lines of business as identified above is shown in Figure 1 for FY07.

The last graph identified several lines of business which comprised the following products.

1. Passenger Cars (Hyundai-Built CKD and CBU).
2. Commercial vehicles including (Mitsubishi buses and trucks, Hyundai buses, Volvo trucks and other super structures).
3. Two and three-wheelers of Bajaj brand/ models.
4. Others, including material handling equipments for Linde brand of Germany, tires for Lassa brand of Turkey and Double Coin brand of China, Volvo brand construction equipment as well as Monroe brand shock absorbers.

Management Structure of the Case Firm

GB group's management structure has seen constant changes in response to the changes that occurred during its trajectory of business evolution. We will not indulge in presenting these evolutionary developments. Rather will highlight the major organizational and structural changes before and after the IPO milestone which represented major phase change in the GB group's business practices.

Prior the public offering, GB group has been managed through a hierarchical structure typical

Table 4. GB workforce growth within 2004 - 2007

Business Activity	2004	2005	2006	2007

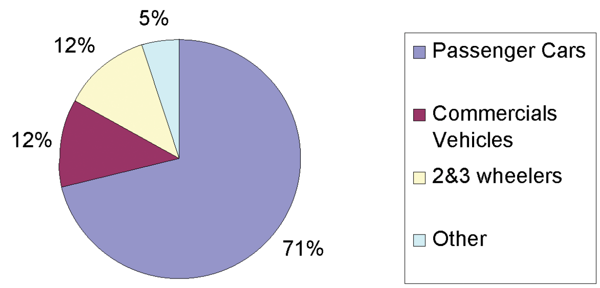
Total	2392	3512	5210	6140
Annual % increase	-	46.82%	48.83%	19.3%

Source: http://www.ghabbourauto.com

Figure 1. Revenues breakdown by LOB (Source: http://www.ghabbourauto.com)



of a privately owned company. Dr. Ghabbour, the chairman, was the ultimate decision maker in any major group–wide decisions. The group was run by a number of senior administrators – reporting directly to the chairman. Senior administrators' organizations were identified according to the particular LOB in which their organizations operate. For example, passenger cars sales organization was led by a vice-president who has control over all the related activities of passenger cars, such as sales, marketing, after sale services and warehouses in addition to the company's showrooms.

Likewise, commercial vehicles which by nature spanned several products, was divided among several organizations; each concerned with a particular product line, for example bus sales, marketing and after sale services were headed by a sector director. While heavy trucks sector was assumed as a different organizational unit with a different sector head.

The functional sector divisions are provided with corporate services that cut across the whole group's functional units and subsidiaries. These services are provided by the following divisions:

- Finance and Accounting
- Information Technology
- Legal Affairs
- Logistics and Supply chain
- Human Resources and administration
- Internal Audit

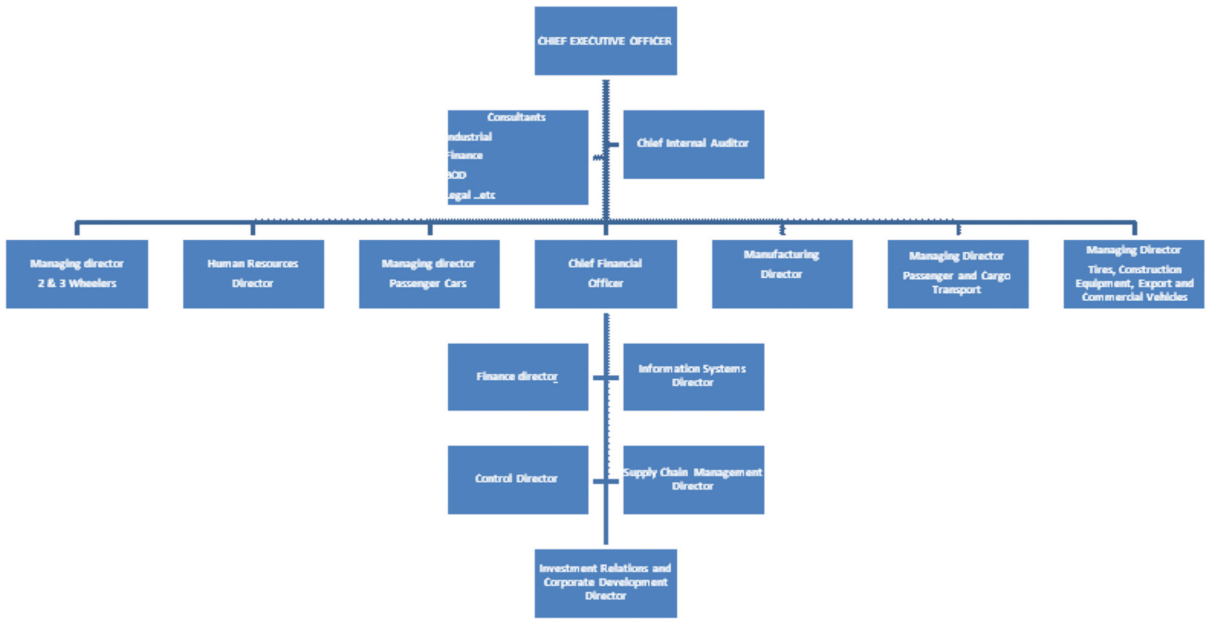
In addition, industrial and construction projects were treated as corporate projects under the direct administration of the group's chairman. Upon the incorporation of the group subsidiaries and the holding company as a joint stock company with the name GB Auto S.A.E, the group has witnessed major organizational restructuring. This resulted in promotions of division heads and the recruitment of key corporate positions such as a Chief Financial Officer (CFO) and investors relations corporate development director. Further Dr. Raouf Ghabbour was named the CEO of the incorporated company. A board of directors (BOD) was formed composed of share holders representatives and industry and finance experts. The GB Auto's organization chart by mid 2007 is exhibited in Figure 2. The management of such a wide range of activities performed by the group cannot be easily described according to the classical organizational theory. However one can postulate that the group is organized according to business sectors as well as product divisions with centralized support service sectors providing cross-functional services to other business sectors and product divisions.

SETTING THE STAGE

Research Method

In this case study, we examine the use of enterprise resources planning (ERP) system in a longitudi-

Figure 2. GB auto organization chart in 2007



nal case study to assess the factors impacting the success and failure of adopting those systems within the context of a developing country's business, legal and political environment. ERP systems are often regarded as an organizational "*administrative framework for planning, conducting and monitoring a large array of functionally segmented operations in a way that both accommodate, in real time, the intrinsic cross-functional interdependencies underlying these operations.*" This postulate implies that '- [ERP systems] *are packages particularly germane in influencing human agency at work*", Kallinikos, (2004, p9). The use of those systems will require making changes in the workflow of the business processes, either through redesigning the old ones to fit the ERP's embedded "best practice" or the re-alignment of the existing workflow. Moreover, ERP systems cut across all levels of management. They are used as the transaction processing workhorse, populating the ERP database with transactions initiated from various business units. The intent is to have one unified enterprise view of the organization's business operations. The prerequisite of such condition is to ensure the timeliness and integrity of the resulting database. To that end synergy among the operational units in organizations has to be provisioned to all stakeholders through a real-time procedural platform. Some members of the user community act as creators/initiators of data items, others as consumers, with each alternating role according to the business model ensued. Such a network of use role-playing will put the ERP operation at the center of the organization's information management model.

The information systems (IS) research on the use of ERP systems in organizations followed two approaches: variance- and process-based approaches (Mohr, 1982). The variance approach included two streams. The first focused on identifying the critical success factors (CSF) that facilitate implementation and "going live" of ERP systems (Bancroft et al, 1996; O'Leary, 2002; Ptak, et al, 2000). The other focuses on development of constructs that assess impacts of ERP systems on work practice (DeLone, et al, 2003; Seddon, 1997; Sedera, et al, 2004; Ifinedo, et al, 2007; Ross, et al, 1999). Conversely, a process based approach focuses on understanding the dynamics of change "how change emerges, develops, and diminishes over time" (Markus, et al, 1988).

We examine the dynamics and success of adoption of the ERP's "administrative framework" during the deployment of two successive implementations at GB Auto, the firm studied in this case. A longitudinal multi-year research project is thus conducted using variance research approach. The study was conducted in two phases, the first, taking almost three years, included the analysis of the dynamics of an operational ERP system, in production for nearly nine years. Phase two of the research began after the "go live" of the second implementation and took one year.

Longitudinal case study approaches are well established in social research. Qualitative panel or cohort studies are commonly used when measuring change over time, whether in attitudes, behaviors or experiences and when looking at causal links. Moreover, the dynamism of the techno-social world points to the need for dynamic methods of enquiry. People's perspectives on technology artifacts use are not fixed and are liable to change for a multitude of reasons. Consequently, research methods with potential to capture this fluidity may be more illuminating than other approaches. These circumstances create a unique role for longitudinal qualitative research which can provide rich information on people's perspectives and how and why these are perceived to have changed over time. The contemporary longitudinal study involves repeat follow-ups of a single sample, panel or cohort and is the approach followed in this research.

To that end, focus group forums from GB Auto, the case firm, were formed to gain understanding of the implemented ERP's operational dynamics during the post implementation period. This is not to be confused with "action research" methodology since no attempt was made by the researcher to make changes in the operation during the study. Those forums enabled direct observations of the working of the system and conducting interviews with all stakeholders. Thirty focus group sessions for different business units were conducted. Each session lasted three to four hours with average participation of 10 to15 persons comprising representatives from business unit management, system users and IT specialists. The researcher acted as session mediator with selected business area specialists as subject-matter process references. Session note-taking and minutes were administered by an MBA student who worked as an intern with the firm.

Theoretical Perspective

Many researchers examined the impacts of the success/failure factors on the accrued value of the ERP systems use to the adopting firms (e.g. Sedera et la (2002), Gable et al (2003), Sedera et al (2004), Ifinedo (2006a), (2007)), and the extent of success in adopting those systems at multiple organizational levels. In this research we pose the following question: "*how relevant those success factors are for the adoption of ERP services in the evolving business organizations within developing countries (DC) business culture"?* The work of Sedera and Ifinedo stands particularly relevant to this scope. To that end, this research is divergent from their works on two aspects: a) cultural context, and b) methodology and analysis tool. On the one hand, the work of Sedera (2002) focused on assessing ERP post-implementation success factors across the organizations' stakeholders (employment cohorts) within Australian Public sector Organizations, and used "*a dual survey approach*". The statistical sample used comprised of 27 Queensland Government agencies, running live SAP systems. While Ifinedo and Nahar (2007), on the other hand, addressed, more or less, the same research domain within the Baltic-Nordic region in Europe. Their sample survey focused on private sector organizations, again using survey measurement instrument which targeted around 500 firms in the Baltic-Nordic region. Conversely, this research is conducted within the

Egyptian business domain and targeting the same research questions addressed previously, using longitudinal Case study approach, as opposed to survey methodology. Qualitative analysis was used for the study of the complex dynamics of the techno-social interaction during the ERP post-implementation phase. The use of longitudinal Case approach was chosen due to several reasons. First, comprehensive and precise information on the rate of penetration of the ERP use in the Egyptian business market proved hard to compile. Second, ERP vendors' statistics on their respective ERP product deployment in the Egyptian firms were extremely misleading. During our study, we noticed there was no differentiation between use of limited number of modules and the use of the full ERP suite modules. Such shortage of information defies the objectives of analyzing success factors for the category of Enterprise-wide IS. Third, the extremely low survey responses, the method that is commonly used for IS variance studies in more advanced and developed countries, discouraged conducting survey data collection within the less matured DCs environment. Instead, as contended earlier, the focus group approach in a longitudinal case setting was used involving all stakeholders in the Case study.

Review of Literature

The two successive ERP implementations in this case falls in the class of commercial off-the shelve software. Those configurable packages are perceived as embedding "best practice" of business processes and the ensued workflows. Often, the objectives of companies in adopting this strategy in managing their information processing needs are to seek cost reduction, increasing productivity, improve customer satisfaction and relations with their suppliers, and ultimately improve their competitiveness in the global networked market space (Davenport, 1988). Due to the far reaching impact of such implementations, many researchers have focused on the identification of the critical success factors (CSF) which facilitate successful implementation and "go live" of the system.

Further, successful adoption of ERP systems is often viewed from the perspective of IS success measurement model developed by Delone and McLean (1992, 2003). This model postulated six independent dimensions. Each dimension provided a measurement construct for the assessment of the extent of success of the IS use. Those six constructs were viewed from the perspective of IS use at large. Many researchers argued that, due to the specific nature of the ERP systems, D&M's model would have to be modified to encompass these peculiarities (Seddon, (1997), Sedera et la (2002), Gable et al (2003), Sedera et al (2004), Ifinedo (2006a), (2007)). For example, Gable, et al (2002), projecting those measurement constructs on ERP, argued for limiting the dimensions to four: a) Information Quality, b) System Quality, c) Individual Impact, and d) Organizational Impact; eliminating the User Satisfaction and Use dimensions in the original D&M model. Ifinedo (2007) then extended those four dimensions by adding the two constructs: Vendor/consultant Quality and Workgroup Impact. Fryling, (2005), in attempting to accommodate the special character of ERP project implementation, advocated "*user acceptance and IS success are highly influenced by the user community for which the ERP system is intended. The earlier a user is involved in the process the more likely they will ultimately be satisfied with the ERP and the more likely they will actually use the system*". This assertion considered the original D&M IS success model as relevant only during the implementation project execution. The novelty of the extensions made by those researchers for the ERP systems success lies in the recognition that ERP implementation and deployment is multi faceted encompassing technological, operational, managerial, strategic, and organizational related components. In particular, the inclusion of the workgroup factor by Ifinedo (2007) as an additional dimension is striking, since successful implementations in large firms depend largely on availing reliable communication infrastructure to empower collaborative work among the user community.

Other critical factors that were researched also in relation to ERP implementation and deployment are the information quality dimension and system configuration. For example, Xu et al (2002) and Madapusi et al (2007) alluded to factors such as top management support, training, communication, employee relations, project team, quality controls, and change management, being crucial in achieving high ERP information quality. The impact of ERP system configuration and/or setup revisions and enhancements of the ERP on the deployment success were also studied by Fryling (2005), Nicolaou (2007), Light (2001), Mensching (2004) and Nah (2001a). Those studies asserted that both the nature and timing of system changes are significant factors to be considered in this respect. As noted in the case, those factors have not received much attention. However, most ERP practitioners considered these factors having profound impacts in the post implementation phase. They assert the importance of the Vendor/Consultant quality factor postulated by Ifinedo (2007). As Fryling (2005) asserts and from our experience, ERP products are continuously subject to software maintenance in the form of patch fixes, version upgrades, add-ons and licensing policies changes by the ERP vendors. The likely disruptions in the operations in such mission-critical applications due to such incidents will undoubtedly send mixed signals to all stakeholders involved. Management will be forced to consider what measures should be taken to secure business continuity, for example through investing in operational redundancy to achieve 24x7x365 operation mode. End-users will have to be alerted and retrained because of the implications of the fixes and/or upgrades on the look and operational changes upon applying these upgrades. IT organizations will alternate between working in project operation mode that these upgrades require, constrained by money, people and time; and at the same time guarantee the "business as usual" systemic use mode of the ERP system by the organizations.

Moreover, it is observed that implementation and utilization of ERP systems in organizations represent a radical change from the operation of legacy systems as noted by Brazel and Dang (2008). ERP workflow crosses functional boundaries that exist in large organizations. The changes Ifinedo (2007) proposed to include the workgroup parameter to D and MIS success model are recalled here to manifest this. In the context of ERP adoptions, operational (rather than technical) factors were also addressed by many researchers. For example, factors such as: business operations coverage of the package and the number of licensed users (Francalanci, 2001; Kumar, et al., 2001; Markus, et al., 2000b; Parr and Schanks, 2000), the implementation process details (Sawyer and Southwick, 2002). The impacts of organizational and national cultures (Krumbholtz et al., 2000; Soh, et al. 2000), users and organizational learning (Fleck, 1994; Parr and Schanks, 2000), knowledge transfer from suppliers to the host organization (Lee and Lee, 2000), the configuration and setup of the package's parameter tables and their overall impact on the architecture and flexibility of the ERP packages for rapid adaptation (Fan et al., 2000; Spott, 2000). Some articles also addressed the impacts of ERP process standardization and the restructuring of organization tasks or business processes reengineering (Kumar and Van Hillgersberg, 2000). The entanglement of the ERP technology with other technological artifacts, such as networks, servers, workstations, etc., as well as commercial interests and external social practices have been addressed by Ciborra et al., (2000), Ciborra and Hanseth, (1998), Fleck, (1994), and how the interdependencies of those components impact the implementation and adaptation in organizations.

CASE DESCRIPTION

Information Systems Services and IT Deployment in GB Group

The deployment of IS/IT services in GB group has seen evolutionary developments since the early 1990's. This evolutionary process can, roughly speaking, be divided into three overlapping phases:

Phase 1: Early adoption phase, which spans the period from year 1990 to1997.
Phase 2: First ERP implementation period, covers the years 1997-2006.
Phase 3: Second ERP deployment phase, which covers the period from 2004 to today.

It is worth noting here that documented records on the details and nature of the IS/IT utilization in phase 1 are missing. This is due to the disappearance of the technical staff for the support of these services and/or the non-existence of physical archives that one can reference to enable the analysis of the usage nature during this phase. In order to shed light on the nature of the use of IT/IS in the group during this era, we have turned our attention to collect data from IT service providers of the group. Also, we asked old timer employees in the finance, accounting and IT divisions to help in identifying the nature of use of IS/IT in the group during this period.

Based on those sources and the remnants of the old systems that were found in the various affiliated companies, the next section provides the foundation of the IT/IS service map in the group during phase 1.

Phase 1: Early IT/IS Deployment

We can assert here that the first serious IT/IS services deployment in Ghabbour group dates back to 1994. Two of its manufacturing subsidiaries, namely PRIMA and VCI companies contracted ORASCOM firm, an Egyptian technology firm, for the deployment of the MFG PRO package of USA-based QUAD Company. MFG PRO runs the following application modules in both factories:

- Inventory management;
- Purchasing;
- Manufacturing, which included
  - Bill of Materials (BOM)
  - Routing
  - WIP
  - Quality Control
- Financials, which included
  - General Ledger
  - Accounts Payable
  - Accounts Receivables
  - Fixed Assets
- Invoicing.

The package was in operation for the period from 1994 to 2003, running on HP 9000 server using HPUX, the HP UNIX variant operating system platform. In an interview with Engineer Albair Shafik, IT specialist in the Ghabbour group IT department, who prior working for the group, was the resident consultant of ORASCOM responsible for the implementation of the MFG PRO package. The following account on the implementation process of the package in the two targeted sites is given next:

"Soon after the contract between ORASCOM and GB group was signed, I was assigned the task of the lead implementation consultant in 1994. We started the first implementation with PRIMA site which lasted for 12 months. We followed this with the VCI site, which lasted for another 6 months. The two factories were new and there were no old IT systems to match. The team started a kind of "clean slate", applying the standard MFG PRO processes and procedures. This made our task much easier and controllable. We have to upload all the master data for the items, suppliers and customers from manual documents. We developed coding system for the master databases, which

was arbitrarily coined without regard to any particular standard. There was even no coordination between the coding systems adopted by the other subsidiaries. The main feature in those two implementations is that we did not do any major customizations and when we needed such customizations, the task was wholly outsourced to the implementer, ORASCOM. Since the implementation and operation of those two factories, they operated satisfactorily until they were migrated to the BaaN system in December, 2003. In my view, this implementation was very successful because it fit properly the user requirements on the one hand. The user did not contest the new system operation and adopted the package's inherent "best practice" processes without much resistance".

In his opinion, this system survived for nearly nine years and gained acceptance and stability due to several factors, among these are:

- Extensive user training was carried out in the early stages of the implementation;
- GB group's MFG PRO implementation was among the first "customers" using the package in Egypt. This has prompted ORASCOM to fully support it in order to make a success story and identify it as its flag-ship in the course of marketing this package;
- The implementer has gone through a thorough and detailed business requirements analysis which helped in properly configuring the package to suit these requirements;
- The system support was totally outsourced after the "go live" for some period, and with the eagerness to make a success story, the vendor exerted every effort to operate the system efficiently and effectively.

Concurrent with the implementation of MFG PRO, ITAMCO and Ghabbour Egypt subsidiaries implemented a sales and distribution package called LEADER, which run on Windows server platform. A third package called El Mokhtar was also implemented for the notes receivables (NR) application for the finance and accounting department. These two implementations were run and operated by separate IT units in each beneficiary division.

This phase of IS/IT deployment can be truly characterized as initiation stage and the implementation of technologies can only be described as fragmented and as such, has caused a great deal of headache for the company when senior management decided at last to streamline all systems under one company-wide unit.

It is an interesting observation to note that even though there was a great deal of common data between the different subsidiaries, each division created their own master databases and respective coding system. This, of course, resulted in duplication of databases among the subsidiaries, thus creating inefficiency within the divisions and increased difficulties when the decision was made to integrate all systems. Also, a great deal of time and money was wasted on the company's behalf. If all relevant information had been shared from the beginning, it would have saved the GB Group a large sum of money and a great deal of time.

The separation of the master databases (customers, suppliers and items) led to the adoption of non-standard and non-coordinated code. The non-standardization of both data structures and processes was deeply rooted in the group's culture. This impeded the subsequent enterprise-wide IS/IT adoption and created mounting problems to the IT organization in trying to fulfill the integration among the group's subsidiaries.

The fledgling islands of computing in the group's companies have taken the IS/IT adoption curve to the second stage of Nolan's (1979) stage model, deepening the non-standardization ailment and strengthening the "silos" mentality in the group's IT management. This particular issue had the gravest impact on the implementation of the first ERP system across the entire group. It dictated an architectural design of this implementation that led to its failure and eventual abandonment as will be seen later.

The senior management of the group realized the imminent increased dependency on the use of IS/IT services all over the group's companies. A decision to centralize those services under one single group-wide unit was thus made. A large enough system to service not only the existing companies but any further expansions in the group's lines of business was to be acquired.

Phase 2: From Expansion to Control, the First ERP Implementation Era

By the year 1997, GB group top management invited prospective systems providers to bid for the procurement, installation and implementation of integrated information systems to serve the needs for the entire group's affiliated companies. Several proposals were presented. Afterwards, the group accepted an offer submitted by a Saudi company named Integrated Systems International (ISI). ISI, the sole agent for BaaN ERP in the Middle East, was chosen to provide the full spectrum of the BaaN application modules. These modules included: manufacturing for discrete and process industries, distribution, finance, service and maintenance, project, transportation, Business Organization Dynamics, Enterprise Modelling and Orgware.

A central IT unit was established as a corporate unit serving the entire group's affiliates. The unit was mandated to install the necessary infrastructure needed for the implementation and operation of the BaaN ERP system. The IT division subsequently contracted IBM branch in Egypt for the acquisition of the hardware, system software and database management system in preparation for the BaaN implementation. The initial configuration installed as the platform for the ERP system operation consisted of the following:

- Three RS/6000 IBM servers, one model H70 to be located in Kalyoubia site and two machines, H70 and H50 models to be located in ITAMCO company at Abo-Rawash site;
- AIX OS, IBM's Unix operating system variant was used for all servers;
- Initially, the T-Base database management system (DBMS) engine was installed, which was replaced in 2001 by the DB2 DBMS

In 1998, BaaN release IV was successfully installed. A fascinating point of interest in this case is that even though BaaN release IV provided an option for group configuration, GB Auto decided to forgo that opportunity in favour of speeding up the implementation process.

The implementation project was executed in 3 stages; the first started with the trading companies and took three years to complete. Thus, in 2001, implementation had taken place in the following companies: RGI, Pre-custom Company, GCT (free zone), GIT (free zone), EMT, ITAMCO, and INTERLAND. Stage two took place during the period of 2001-2003, and resulted in five companies' implementation of BaaN: Ghabbour Egypt, GE Manufacturing, PRIMA, PRIMA Inventory, and VCI.

What is important to consider in those implementations is that from the start, integration was never deliberated. Each company was to be configured as a separate instance with all its master data- even though there was great amount of common data (customers, suppliers and items) among those instances. For example, the customer master database was separately compiled for each individual company regardless the repetition. Another issue that is evident in this case is that the analysis of requirements done prior to the implementation was never thoroughly documented. Also, there was a great deal of customizations taking place in the implementation process in order to fit in the non-standard business processes of each individual company. These customizations have provided nothing more than problems in the long run. In essence, they only encouraged non-integration between the subsidiaries and led to multiple fundamental operational difficulties. The vendor's support was greatly lacking and the group's relationship with them became strained. Due to these problems, as well as others, the IT division had to rely solely on in-house experts who were unable to keep up with the frequent errors due to their limited knowledge on this system.

These problems, as well as the difficulties inherent in the system usage practices led to a fundamental distrust in the system. Data manipulation became commonplace, bringing about the issue of data integrity and validity. This is how the "Excel" culture of Ghabbour Auto came about. As the program aged, costs rose and it became evident that the BaaN operation had come to a dismal conclusion. As Engineer Adel Nassem, the then newly appointed IT and Business Director in 2002 recalls:

"In 2002, when I took charge, the level of business relationship with the BaaN system vendor representative in Dubai was so strained that I had to call BaaN headquarters in Europe asking for help and their interference".

Help was indeed received, BaaN HQ diverted Mr. Nassem's support request to India subsidiary. As a result, GB group contracted two Indian specialists to be on board for fixing the problems of BaaN system which was falling in a vortex spin.

The situation gone from bad to worse by deepening the extent of customizations, forging the non-integration and prohibited scalability and/or upgradeability of the system. Basic functionalities such as consolidating financial reporting were never achieved. Period closing (quarters and/or yearly) was never achieved and data fixing was common practice without regard to audit rules and/or accounting best-practice. In short, what the group ended up with by 2004, a disparate database repository that is totally open for manipulation with no audit trails and no confidence in the validity of the data values.

By 2003, stage three of the implementation project started and the MFG PRO package's operation at both PRIMA and VCI manufacturing installations were stopped. Their databases were migrated to BaaN system, still as separate companies. What is intriguing is that no attempt was made, during this migration process, to perform any form of data cleansing, standardization of the coding systems and/or the processes. This has furthered the "silo" IT operation feature, albeit using the same BaaN "ERP" infrastructure.

As a result of this data chaos, the professional staff in the various functional areas (finance, accounting, logistics, manufacturing, etc) developed the "evil" habit of extracting the data from the BaaN database to their Excel sheets. They performed whatever manipulation they need on this data without regard to audit rules and/or validation and verification controls. To respond to the management demands for performance reporting and to enable fast reply to ad hoc queries whenever decisions are imminent, the "Excel" culture proliferated. Data from BaaN was continuously uploaded to individuals' PCs. This led to creating multiple pictures for the same fact violating issues of data integrity, security and increasing the risk of loss of resources. As engineer Nassem contends:

"The BaaN system has become totally open to the extent that any one from any department could make changes that may be reverted next day just to cover up some mistakes or fix some figures"

The operation of the BaaN, besides its functional flaws, has come to a disastrous and risky juncture when the cost of operating the hardware platform reached prohibitive limits. At the start of the BaaN operation, in order to secure safe and reliable operation of the system, service contracts were signed with IBM for the maintenance of the hardware, systems software and the DB2 DBMS. With the aging of the hardware, the support contract bill rose to extremely high values with no evident ROI. The IT division decided to sever this contract and opted for another hardware support contract other than IBM with the implications of lower performance. The same policy was also extended to the BaaN support contract with the risk of not having support at all for this package, this led to the division becoming under siege and dependent on the foreign (Indian) hired specialists

To worsen the situation even further, with no in-house know-how of database house-keeping, the database sizes for some instances (companies) reached critical levels (85percent to 90 percent limits) requiring major re-configuration process. A situation when referred to the BaaN vendor was unprofessionally exploited by the vendor to recover lost revenues.

Technology Concerns

At this point in time, Dr. Aram Youssef was recruited as the new Vice-Chairman of the group. Dr. Aram felt that it was time to seek the services of external consultants in order to establish where the group went wrong. As a result, a team from the American University in Cairo was consulted. The consultants were requested to evaluate the current IT/IS infrastructure effectiveness and the services provided by the applications. And to propose solutions and recommendations to help the group establish a responsive information systems services. The team met with the group's Chairman, Dr. Raouf Ghabbour; the Vice-chairman for support functions, Dr. Aram Youssef and the IT and Business development Director, Mr. Adel Nassem in February 2004 and were requested to investigate the current IT/IS infrastructure and applications problems and propose recommendations and solutions for the group to establish a robust and responsive information systems services. The team spent eight weeks in activities related to fact finding and data gathering, analysis of the existing IS utilization and other issues related to the operation of the BaaN system effectiveness. The team also surveyed the supporting IT infrastructure and the IT organization unit. At the end of this period, a report was presented to the group's senior management with a proposed action plan to establish a robust and responsive information systems infrastructure. The proposal called for the rejuvenation of the three building blocks of IS building blocks in the group: the systems platform (hardware and system software), the network and communications infrastructure and the business application software platform. The chairman of the group, Dr Raouf Ghabbour, approved the recommendations and the plan was carried out accordingly as will be discussed later.

The consulting team's diagnostic report made several observations explaining the reasons and factors that made the process of BaaN implementation reach a dead end and finally abandonment. These observations were in complete congruence with most of the classical failure factors of ERP implementations found in academic references, text books and research articles (Binji, P. et al.; 1999; Davenport, T., 1998; Lycett, M. et al. 1999; Schwalbe, L, et al., 2000; Akkerman, H. et al., 2002; Turban, E et al., 2006). Among those identified factors are:

1. **Lack of top management support**

In almost all cases of major ERP implementations, the top management involvement and support is considered a tipping point between potential success and failure. At some point of the BaaN ERP implementation project at GB group, management was not fully involved as they should be. At first, the management looked to the project as externally provisioned services by the contracted firm. This has impeded making radical changes (re-engineering) of the business processes and standards within the group's business practice. Such re-engineering endeavors are the norm for successful ERP solution implementations. It was a surprise, for example, to see the requirements document defining separate non-standard business rules among the group's companies. This is by no means what the top management would have required had they been involved in the requirements definition phase of the implementation. This particular issue has led to the fragmentation of the project to a separate company implementation route, impeding any future integration between the instances within the ERP system. Enforcing the integration at the requirements definition phase would have needed the authority and clout of the top management.

2. **Lack of Project team competence**

In reviewing the project team composition, it was striking to see that the implementer is a start-up firm with no or little prior experiences and/or showcases of similar size projects. Further, although the BaaN contract was signed with a regional software firm affiliated to BaaN, the number of implementations provisioned through this firm was also meager to guarantee the success of such a huge undertaking. The counterpart team of the GB group was relatively small and with little or no previous BaaN or integrated information systems experience. Their training was shortened in favor of early start of the implementation process.

The introduction of BaaN ERP system in the region was also so sparse, implicating the scarcity of experienced professionals in both project management and functional know-how using the BaaN ERP system. This explains why GB group ended up with one single qualified trained staff with no redundancy or back up personnel who can effectively operate and maintain the system. This kind of organizational deficiency placed the group in a liability situation impeded any efforts for professional development plans for the existing scarce professionals, who were denied the opportunity to leaving the operation for extended periods for training.

3. **Lack of project ownership**

Like any project, if there is no champion of the project acting as the owner of it, the chances that the project would succeed are usually slim. The pre-requisite qualification of this owner in the group would be one who is not affiliated to one particular subsidiary – but has the group-wide responsibilities. There was no such candidate in the group with such credentials except the Chairman or the group's CFO (back in 1998); both candidates were not acting as the BaaN project champion. Instead, each company's top manager acted as the champion of his individual company's implementation project, furthering the "silo" approach which was reflected in the architecture the BaaN ended up with.

4. **Lack of Standardization**

The lack of standardization on both levels of data structures and processes among the group's subsidiaries, as postulated earlier entrenched the fragmentation and increased the level of customization of the BaaN system. As Engineer Adel Nassim contends, highlighting the gravity of this customization;

"To show how the extent of customization impeded the success of BaaN, the Indian expert who was on board since 2002 was not able to upgrade the BaaN version from IV to V. The effort to do that would have amounted to man-days equivalent to a fresh BaaN implementation in order to incorporate the number of customizations put in version IV. He was barely able to upgrade the operating system AIX version from 4.1 to 4.3 which did not add much functionality to the system."

Engineer Nabil Naguib, the then database administrator for the currently operating Oracle system provides the following account on the magnitude of the inconsistencies in the databases

Table 5. BaaN master database per each company

Company	Customers	Vendors	Items
GE	29087	2517	121102
EMT	29212	2518	1680
ITAMCO	12857	3069	50278
PRIMA	12317	4421	17736
VCI	41	4385	5144
Interland	2808	4421	48283
Total BAAN	86322	21331	244223
Oracle	21366	2154	41451
Repeated	64956	19177	202772

as a result of the non-standardization of the group's data structures;

"The biggest task we encountered when we started the migration of the master databases from the BaaN. The amount of inconsistencies found in these disparate databases was humungous. The code duplications and the inconsistencies were of such a magnitude that it took us months to perform data cleansing. As you can see from Table 5, the repeated records in the source data were nearly triple the number of the actual unique codes for the customer data, nearly 9 times for the suppliers and 5 times for the items data. The effort we expended for the cleansing of this data is humongous. This by no means resulted in 100% clean master database, some items in the master files were still need to be cleansed and were left to be individually dealt with as we come across them in the current Oracle operation".

5. Vendor support and partnership

Although at the time of selecting BaaN as the application software for the information systems infrastructure for the group, this ERP package was considered one of the top 3 ERP systems world-wide. However, the selection criteria did not take into consideration other critical factors in the selection such as:

- Vendor support capabilities in the region;
- Availability of professional skilled staff in the local market;
- The size of the customer base of the vendor in the region;
- Proximity of the support location.

In this case implementation, it was clear that the above critical factors were not readily fulfilled in a satisfactory way to warrant embracing such a complex undertaking. Time has proved that those factors were detrimental to the success of the group's implementation project.

6. Architecture choice

The high level design for the BaaN implementation, in acknowledging the legal requirements for the separation of the group's companies, developed an architecture based on separate instances. This compromised the fact that these separate entities have common back office business processes. For example, the finance and accounting division operates within the framework of corporate resources allocation which proved impossible to implement in this separate instances architecture. This has led to dividing the finance and accounting function to logically disjoint units - each responsible for an instance (company) without regard to the integration nature of those companies. Had the implementation considered the alternate approach in using the BaaN "group" facility coupled with some re-engineering of the integration requirements to cater for the legal considerations, the project may have had a different fate.

Despite the good intentions of the implementation of the BaaN system during the period from 1998 to 2004, the objectives to gain better control over the disparate databases and their integrity were never accomplished. To the contrary, the openness of the BaaN system resulted in the proliferation of the "Excel" culture, fostering the non-integrity of the group's data resources. Based on the findings of the diagnostic study a recommendation document outlining the strategy for implementing new responsive and integrated information systems infrastructure was presented to the management. The strategy addressed the following six major actions:

1. Phasing out the current BaaN ERP system in favor of implementing a new one that avoids the pitfalls of the previous experiences.
2. Development of a blue print for the communications and network infrastructure to serve the current and future connectivity needs for the operation of the integrated business information systems model. Such a blue print must satisfy the following operational requirements:
   - Redundancy;
   - Reliability;
   - Diversified providers;
   - Ample and extendible capacity;
   - Provides good and solid security and safe communications environment;
   - Use of tie lines, MPLS, WiFi and RF technologies for the connectivity of the geographically dispersed locations;
   - Use of the VPN technologies to facilitate virtual presence and mobile access in a secure manner.
3. Establish modern, versatile and high availability datacenter with back up facilities. Acquire and install new server farm infrastructure that will enable serving both the needs for the new information systems infrastructure and the network and communications infrastructure.
4. Establish highly responsive IT team with in-house capacities for operating and maintaining the trilogy building blocks: the information systems, the network and the server farm;
5. Enforce centralized IT service delivery, centralized IT planning process and standardized data structures, databases and processes.
6. Develop the Standard Operating Procedures and Policies (SOP&P) that govern and ensure adequate IT service level delivery to the group's divisions and units.

It has become apparent that there is a need for something more when it comes to the information system at GB group. On the issue of the appropriate selection of the new ERP system, the Oracle e-Business Suite (EBS) was selected. The rationale for this decision was based on several key factors, many of these mentioned previously in the case analysis as problems during the BaaN implementation. There is a local support base for Oracle in Egypt. There is evidence of sustainability and commitment of Oracle to the Egyptian Market. At the time, the business outlook of Oracle is clearly on the rise. EBS functionalities cover almost every line of the business that GB Group is or will be involved in. Also, there is an availability of knowledge workers trained on the full spectrum of the needed professional activities in support of this project.

Phase 3: Technology Components: The New Oracle ERP Implementation

By April, 2004, RGI – the then holding company of the GB group, signed a contract with Oracle Egypt for the licensing of its EBS software which included the following 18 modules:

- Finance which included the five modules – GL,AR, AP, FA and CM
- Distribution which included the three modules – OM, PO and INV
- Human Resources which included the modules – HR foundation and Payroll
- Systems utilities which included – Web Discoverer and Alert manager

- Manufacturing modules which included the six modules – BOM, QC, WIP, MRP, CRP and MPS

Concurrently, RGI invited prospective local Oracle implementation firms to bid for the implementation of the EBS in the group. Two finalists were identified by April, 2004. The implementation contract was finally awarded to the Egyptian implementer CITE company. Their presented technical solution acknowledged the architecture of one implementation instance and not separate instances for the group's companies. This particular concept was the tipping factor in the evaluation of the offered proposals and the selection process of the implementer. Such a solution was thought to guarantee the enforcement of standardization of data structures, database design and the business processes across the entire group's companies.

The implementation plan called for phasing the process into two stages. The first would include the finance, distribution, human resources and the utilities modules; while the second stage will complete the implementation of the manufacturing modules.

In deciding on the operating system platform, use of UNIX operating system as the system layer for the Oracle application was first recommended. This decision was in-line with the best-practice adopted by many organizations for operating Oracle system. However, this recommendation was contested by the management. Among the reasons for this, the not-very satisfactory experience with IBM's AIX support during the BaaN operation. It was subsequently agreed to adopt the option of using Windows 2000 server operating system platform with the caveat of mitigating security vulnerabilities of the Windows platform by deploying adequate security infrastructure. At that time, the 64-bit Windows server architecture was not yet released by Microsoft. This particular issue will be shown to negatively impact the sustainability of the Oracle ERP operation using this platform.

On the organizational level, the consultant team, together with the senior management opted for recruiting an Oracle Project team. The proposed composition of this team is shown in Figure 3. Within few months of setting up the project, the project team positions were duly filled with appropriate professional staff, some were drawn from the existing IT organization, others hired from the market.

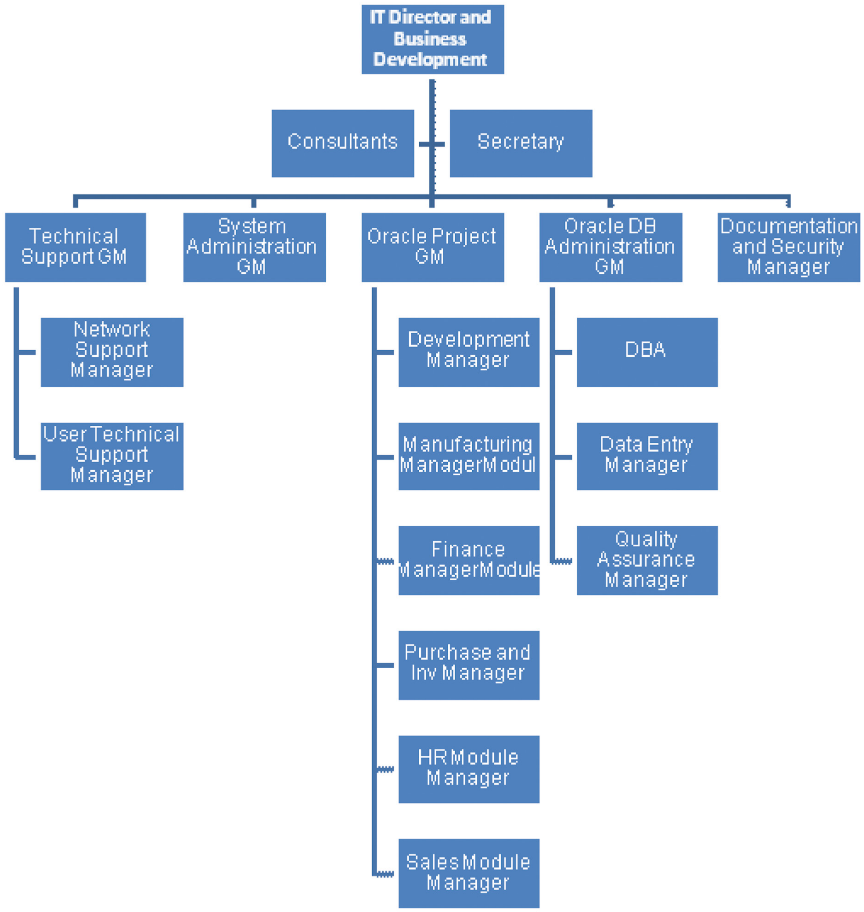
An Oracle Steering Committee (OSC) was also formed. The OSC was to meet on a regular basis to set the project execution strategies and policies, and review the progress presented by the Oracle PM and recommend the necessary actions to deal with any problems or delays in the project time line. The committee composition is as follows:

- The Vice-Chairman for support functions
- Chair of the OSC
- Representatives from the implementation firm CITE
- Representatives from Oracle Egypt
- The IT and Business Development director
- Oracle Project manager from GB
- Oracle DBA from GB
- An external IT Consultant (the author)

Management and Organizational Concerns

The original Oracle project implementation plan stipulated, with the consent of the project steering committee, the conclusion of stage-1 in nine months starting by May 1st, 2004. However, with the unfortunate event of fire breaking in one of the major buildings of the Prima manufacturing company in Abu-Rawash site in December 2004. This resulted in the relocation of the finance and accounting division from this site to the GE company site, some 40 kilometers away from the group's headquarters in Abu-Rawash. Besides the relocation, it was impossible to keep the senior management focused on the project schedules and

Figure 3. The IT organization chart for the GB group during the implementation phase



commitment to the Oracle project in such disaster and damage-control period. The "Go Live" milestone date was subsequently moved to June 2005.

Meanwhile, the project team successfully configured the hardware and the system software infrastructure and readied the platform for the operation of the Oracle application in early 2005.

Soon after, the BaaN databases conversion activities stage started. In this stage, activities such as data cleansing and standardization of data structures, were completed and the databases were uploaded into the readied platform thereafter. Testing, end-user training and go-live for stage one of Oracle project started in early November 2005.

During the live operation of the EBS on the Windows platform, the project team encountered many difficulties and obstacles. The most serious of those was related to the in-adequacy of the WINTEL platform to withstand both the database size and the number of concurrent users using the Oracle application. Although the sizing of the platform was performed collaboratively by both Oracle and HP, the vendors for both the application and the hardware respectively, this glitch persisted. The issue was raised to the top severity level at Oracle's Technical Assistance Request group (TAR) who recommended many solutions and fixes with no avail. It was finally affirmed by both Oracle and Microsoft that the problems encountered were primarily due to the 32 bit addressing limitations inherent in the 32-bit Windows server operating system. The implications of this issue were debated in the project steering committee and a decision was reached to replace the HP/Windows 2000 platform by IBM/UNIX platform. As a consequence, two IBM 570 pSeries machines were procured running AIX operating system. The platform was operationally ready by October 2006. Subsequently, the EBS system was successfully migrated to the new platform and operated by October 2006.

Due to the impending IPO date, the BaaN operation was extended to the end of 2006 and Oracle was placed on the backburner until then. The "Go Live" date was set for December 3,1 2006. This of course had a negative impact on the process of institution and adoption of the new Oracle EBS system. It only meant that user training sessions would have to be repeated and online transaction data entry would cease in favour of BaaN entry.

The go live plan called for populating the balances in all data structures by the 31st of December, 2006. With concerted efforts between the various stakeholders, the system operation started as planned on January 1st, 2007, marking the real start of the third phase of IT/IS deployment trajectory for the GB group.

CURRENT CHALLENGES FACING THE ORGANIZATION

January 1st, 2007 brought about the date that the BaaN system operation was plugged off, and Oracle EBS was put into gear. The IT division at RGI offices was overwhelmingly busy with maintaining smooth and painless transition from the old BaaN culture to the new environment. This was not at all their first encounter with the Oracle EBS live operation. As described before, for a short period of time during 2006, the system operation was in full force – which represented excellent rehearsal of what to be expected after the "Big Bang" of day one in the live of Oracle at GB group. During this period, the team tackled most of the technical glitches related to either the hardware, operating system or the application. It was not therefore a surprise to observe no panic or "fire fighting" reactions in the early weeks after the second EBS "go live" kick off. Nevertheless, change management procedures were noticed to be overly overseen. The after effects of the "cultural changes" started to pile up. The old "Excel" model began to slowly creep back into the company's business process operations. This was manifested by the overwhelming requests made by the users from the business area coordinators for the development of "Excel-like" discoverer reports (reports that are tailor made using the Discoverer tool of Oracle). By midyear 2007, there were over 400 discoverer reports, 90 percent of them mimicked the Excel tabulation. In their pursuit to appease and entice the end-user, the Oracle team submitted to these requests without questioning their effectiveness and /or use that may be accomplished through otherwise standard Oracle built-in reports.

As we mentioned in the beginning of this Case, year 2007 witnessed the start of the preparation for IPO offering under the group's holding company GB Auto. This has created a heavy load on the finance and accounting division, which demanded responsive and agile information system infrastructure. With the limited experienced professional staff in the IT division, handling of those excessive user requests was less than satisfactory from the user's point of view. Coupled with the natural resistance to use the new system in timely manner – the Oracle implementation was perceived by the user as yet another IT failure. At the transaction processing level (TPS), populating the database was in some business areas not performed in on-line, real-time mode. In other instances, entry to the TPS was in error and/or incomplete due to use of untrained employees. The result of such inaccuracies yielded database that does not reflect the real world and a user community without confidence in the Oracle system outputs.

On the management control level, with little or no training in using the Oracle standard reporting system; managers, whether in the middle or top levels, depended on their subordinates' reporting. Those subordinates were compelled to respond through the only way they seem familiar with, downloading data from Oracle and use "Excel" to formulate the required reports. This behavior has proliferated right from the first level management to the most senior level, fostering the perception of the inability of Oracle system to respond to their information needs.

The Oracle post-implementation review conducted by the author and the technical staff suggested that the newly introduced ERP system is passing through critical stage in its adoption path. From an IT planning and control perspectives, it appeared that all the technical ingredients necessary for successful delivery were in place – providing the illusion to the IT management and staff that they have a successful implementation. Blaming the business units/personnel and management of not being receptive to the needed changes. Claiming resisting control and fighting the cause of adopting Oracle within the fabric of the GB group information flow and decision making pattern. On the other hand, focus interviews and direct observations of the various levels of user groups, we found a general perception that the current provisioned Oracle services are not in-line with their needs, neither on the transactional nor on the management reporting levels.

SOLUTIONS AND RECOMMENDATIONS

Following the GB Auto IPO, the CEO together with the BOD members realized that the group's successful growth resulted in the expansion of the organization with a mixture of decentralized management functions at the Business Unit level, while other management functions remaining centralized. Furthermore, the current organization structure showed a relatively high level of vertical layers within each major function, with no clear and effective horizontal communications. This structure led to delays in decision making and impeded progress of work flow, as well as creating conflicts that require top management involvement.

An organizational review has been contemplated to address these issues. Several potential management consulting firms were solicited to bid for this task in early October 2007. The request for proposal objectives included:

1. Working with the GB group's management team to develop the most effective responsive (and lean while capable of continued growth) type of organizational structure, with clear definitions of:
    - Centralized functions versus functions at the Business Unit level
    - Structure of each major areas or function, including definitions on the scope of responsibilities and attributions for each key position
2. Optimization of the operational and administrative processes under the new organization, and incorporating the use of the IT systems to the extent possible.
3. An evaluation of the existing human talent, and a needs assessment in view of the current and future needs of management and professional talent

GB Group intended that the review will focus on those areas that will ensure the effective management of the group and its varied lines of businesses. In January 2008, GB contracted the selected management consulting firm from the three bidders and work on the project started soon after. Among the objectives of the consultant's tasks are the following:

1. **Optimizing processes across the organization**

For a growing organization being able to scale processes and systems is essential to avoid constant reengineering. Also leveraging benefits of scale of similar activities across business units makes managing a growing business simpler. Comparison with standard processes and review of the current processes against a set of best practice industry standard processes will help assess where the biggest gaps are and the advantages of moving towards standardized processes and if needed redesign those non-standardized ones.

2. **Developing effective organization structures and role accountabilities**

All employees who work with a process should be clear on what their accountabilities and responsibilities are. By making this clear and structuring the organization effectively it is possible to reduce the conflicts and confusion between different parts of the organization.

Meanwhile, with the arrival of a newly appointed Chief Finance Officer (CFO) in the senior management level for the group in early 2008, he soon observed that the IT team from one side was accusing the user community of not being receptive to the change. On the other side, users grew more and more resistant to Oracle system adoption, perceiving that Oracle will have to work in the way they are accustomed to and finally consider the Oracle application as a failure since it cannot be customized to their liking.

With ample knowledge of the central role of ERP systems and the implications of its adoption in business organizations, the CFO established an independent task "Oracle Facilitation and Coordination" (OFC) division. The objectives and scope of work of this division were set as follows:

- Review the effectiveness and current use of the current Oracle processes, modules and reports, inform users of all that is available and assist on any alterations or additions needed to the existing Oracle set up in order to operate effectively
- Analyze the current business processes in the various business areas, assess their correctness, validity and appropriateness always keeping in mind operational controls and if needed, redesign those processes to be streamlined with the Oracle configuration
- Document and understand those reports required at the business units and not currently available in Oracle and arrange for them to be included in Oracle by the Oracle system maintainers
- Document reference policies and procedures (P&P) for all business processes in the business functions that have been analyzed as defined in the above points and then monitor the operation on an ongoing basis
- Assess for development any additional KPIs for all management levels in addition to those already existing as well as those in the Oracle DBI module. Coordinate with the IT division for any implementation of business intelligence tools to secure rational approach in managing the group's business resources and operations
- Participate in the implementation of new Oracle modules and assisting in communicating and training end-users
- Conduct on-going training on existing modules to all personnel involved in the use of the developed tools and redesigned operations
- Advise IT division on user requirements and security issues

The scope of work for the new task force would span the entire group's business activities. Work to be done includes:

- Analyze, design and /or redesign the business processes in all the group's line of business
- Analyze, document and evaluate the current configuration of business process operations within the Oracle system and establish gaps between the business needs and the services provided by the Oracle system
- Develop the necessary framework needed for the institution of the Oracle in all business units
- In collaboration with the IT teams and the business unit representatives, develop, institute and operate the business intelligence facilities, either within Oracle or otherwise to maximize the benefits from using the centralized, integrated databases. In collaboration with the group's management, establish the mostly needed KPIs to manage the vast resources of the group
- Provision of on-going monitoring mechanism, overseeing the utilization of, and adherence to Oracle's P&Ps
- Ensure smooth integration of the various activities of the group and institution of any new activities as a result of expansion in new line of business, within Oracle system operation

To that end, efforts of the OFC division team would be aligned with the organization-wide process reengineering initiative to be executed by the management consulting firm, in a concerted effort to pave the way for the institution of the Oracle EBS.

KEY TERMS AND DEFINITIONS

Action Research: Is a process of progressive problem solving led by individuals working with others in teams or as part of a “community of practice” to improve the way they address issues and solve problems. Action research can also be undertaken by larger organizations or institutions, assisted or guided by professional researchers, with the aim of improving their strategies, practices, and knowledge of the environments within which they practice.

Business Process Management: Is a management approach focusing on aligning all aspects of an organization with the wants and needs of the stakeholders. It is a holistic management approach that promotes business effectiveness and efficiency while striving for innovation, flexibility, and integration with technology. If business process management attempts to improve processes continuously, the approach is then described as continuous process improvement (CPI). While, if the approach attempts to revamp the process, then it is often called business process re-engineering (BPR).

Enterprise Resources Planning (ERP): Is an integrated computer-based software system used to manage organizational internal and external resources. It is an architecture which facilitates the flow of information between all business functions within the boundaries of the organization and manages the interfaces with outside stakeholders.

ERP Implementation: To implement ERP systems, companies often seek the help of an ERP vendor or of third-party consulting companies. These firms typically provide three areas of professional services: consulting; customization; and support. The client organization often employs a change program management, business process analysis, and deployment management specialists to align their business requirements with the embedded ERP business processes during implementation

IS Critical Success Factors: Is the term for an element that is necessary for IS project to achieve its mission. They are the critical factors or activities required for ensuring the success of deploying and adopting the IS in the organization. They represent those managerial or enterprise area that must be given special and continual attention to bring about high performance of implemented IS.

IS Success Model: Is a framework and model for measuring the complex dependent variable in IS research. IS Success Model is attributed to DeLone and McLean who originally developed and published the model in 1993 with an update in 2003, which discussed the utility for measuring IS system success within the framework of e-commerce systems.

Longitudinal Case Study: Is a research study methodology that involves repeated observations of the same items over long periods of time. Longitudinal studies are often used in social science research context. The reason for this is that unlike cross-sectional studies, longitudinal studies track the same people, and therefore the differences observed in those people are less likely to be the result of cultural differences across generations. Because of this benefit, longitudinal studies make observing changes more.

Nolan Stage Model: The stages-of-growth model is a theoretical model for the growth of information technology (IT) in a business organization. It was developed by Richard L. Nolan during the 1970s, and published by him in the *Harvard Business Review*

WINTEL Platform: WINTEL is a portmanteau of Windows and Intel. It usually refers to a computer system or the related ecosystem based on an Intel compatible processor and running the Microsoft Windows operating system.

This work was previously published in Cases on Business and Management in the MENA Region: New Trends and Opportunities, edited by El-Khazindar Business Research and Case Center, pp. 177-203, copyright 2011 by Business Science Reference (an imprint of IGI Global).

Chapter 52
Matching Manufacturing and Retailing Models in Fashion

Simone Guercini
University of Florence, Italy

ABSTRACT

The aim of this chapter is to examine the interdependencies that have been established with reference to the manufacturer-retailer interaction in textile and apparel (TA). Retailers' strategies seek to reduce the risk of losses from unsold stock, mark-down policies, and stock-outs. These strategies call for manufacturing suppliers to adopt new practices for fulfilling orders flexibility, rapidly, and efficiently. The practices of "lean retailing" imply new manufacturers' strategies, mainly in term of "lean manufacturing." We examine the implications of these processes on the evolution of the relationships between industry and distribution. The chapter addresses the repercussions of the development of lean methods on the development of other formulas having a significant impact on the relationships between industry and distribution, specifically in TA. We then discuss further developments that may be proposed in TA and its channel relationships by shifting from a perspective of supply to one of demand.

INTRODUCTION

This chapter examines the evolution of the relationships between manufacturers and retailers in the fashion system and its implications over time. More precisely, we focus on the manufacturer-retailer interdependencies (Ailawadi et al., 2010) in the textile and apparel (TA) supply chain and distribution channel, which are analyzed as a retail-apparel-textile system (Abernathy et al., 1995). The aim is to provide a picture of these changes and possible future developments[1].

The chapter is divided into two sections followed by conclusions. In the following section we address the repercussions of the development of lean methods on the development of other 'formulas' having a significant impact on the relationships between industry and distribution, specifically in TA. The ability of retail actors to reduce risk and achieve low response times from

DOI: 10.4018/978-1-4666-1945-6.ch052

their manufacturing suppliers has been a powerful driver of change in manufacturer-retailer relationships. In TA the retail strategies of seeking to reduce the risk of unsold stock and losses from breakage call for manufacturing suppliers to adopt new practices for fulfilling orders flexibly, rapidly and efficiently. It is in this context that the concept of 'lean retail' emerged, and hence the practices of 'lean retailing'. Lean retailing is a process that calls for adopting a whole interrelated series of channel practices, beginning at the retail level, with the goal of matching supply and demand, and minimizing the inherent forecasting errors associated with the management of product mixes (Hammond, 1990; Forza & Vinelli, 2000). The introduction of lean retailing began in TA where lead-times were dictated by the two seasonal change-overs (*a-w* autumn winter; *s-s* spring summer), whose importance lay essentially in operational aspects, that is, the lag times between the forwarding of an order and response-delivery (Hunter, 1990). Subsequently, the spread of lean retailing was to place significant stress on all aspects of company programming, including research, production and marketing of the chain-channel. This had effects on decision-making regarding not only product assortments, but also fashion trend offerings and the presentation of collections even at the level of manufacturers, including those in textiles (Agins, 1999). In fact, the adoption of lean retailing operations puts immediate pressure on manufacturers, who find themselves faced with the choice of either holding greater amounts of finished merchandise in reserve in order to meet potential customer demand, with the risk however of winding up with large surplus stock, or innovating production processes to meet the new demands of retailers and thereby reduce their own exposure to the risk of surpluses at the same time.

In the second section we then discuss the implications of adopting lean manufacturing strategies not only in clothing supplier production processes but also at other levels. The requirements of lean retailing process concern not only apparel producers, but textiles manufactures as well. At the same time, lean retailing put pressure on fashion-oriented businesses to adjust the organization of their creative cycle itself in order to satisfy the final demand.

Overall, the chapter highlights the ways in which retailers are able to reduce risk and propose more attractive offerings to consumers. Advances in IT have brought about significant reductions in the cost of information collection, processing and distribution. Already during the 1980s and 1990s, such innovations set the stage for the implementation of distribution strategies aimed at reducing retailers' exposure to the risks associated to the disparate, constantly changing nature of market demands. The ability to use real-time information from points of sales allowed for adjusting product offerings on a daily basis to best meet the level and profile of the effective demand (Stabell & Fjeldstad, 1998). Such strategies aim to reduce inventory levels as a whole. Trends in this direction were already cited in the literature of the 1980s and were destined to increase considerably over the following decade (Tyler, 2008).

It should however be noted that the information gap remains the weak point in both retailers and manufacturers' relationships with the market. Given the current state of affairs, struggling manufacturing companies need to take a more active role in dealing with their demand-chain, especially by anticipating demand, while retail companies has been able to take an active role in the supply chain. A number of success stories may serve as examples: some manufacturers have managed to thrive by establishing tight relationships with retailers who have developed the capacity to give them a competitive edge in this rapidly evolving sector.

An outline of this evolution and some conjectures about future trends are presented in the concluding section. The relevant issues are addressed through a review of the literature and discussion of the author's own research.

Evolution of the Channel and 'Lean' vs. 'Outlet' Formulas

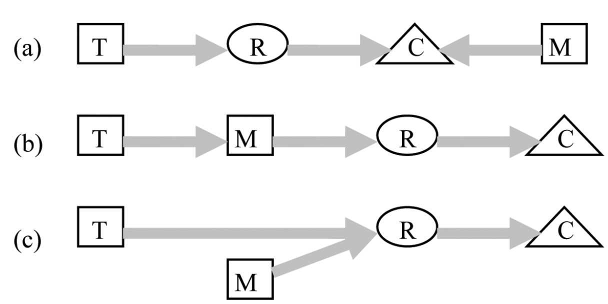
The spread of lean retailing processes over the last twenty years or so serves to highlight a return to the centrality of retail, in which the actors upstream from the chain-channel are in more direct contact with the distribution level. The sequence of traditionally recognized relationships between (1) textile enterprises and clothing enterprises, (2) apparel enterprises and retailers, (3) retailers and consumers has been interrupted, at least in part, by the new centrality of retail. This has translated into the emergence of relationships unaccounted for in traditional models, as retailers may be directly linked as clients to textile firms, and textile firms, in turn, may be direct customers of companies furnishing manufacturing services (Figure 1).

In the model illustrated in Figure 1(c), firms operating at the industry level put their production capacity at the disposal of third parties, and thereby essentially act as contractors. Such enterprises may develop and promote a process of upstream integration of distribution firms, given that that these latter carry out roles typical of industry (sourcing raw materials and semi-finished products, product design, quality control, etc.), which are not carried out by contractors (Weiss, 1958).

In apparel channels characterized by predominately 'independent' relationships, clothing manufacturers interface with the suppliers of semi-finished textile products and retailers essentially through transactions between autonomous agents. Apparel producers operating in channels with largely '*interdependent*' relationships have closer ties with subcontractors and retailers. This results in greater flexibility and a constant exchange of information (Uzzi, 1995). In this case, distribution can furnish information to the manufacturer, with whom it then coordinates actions to carry out merchandising and other marketing activities in their common interests (Sheridan et al., 2006). Such information exchange with the retailer can enable the manufacturing firm to better direct its short-term production, as well as its own design activities. The distribution firm may however decide to take over these critical functions (production planning, design…), provided of course it has the means and resources to do so. Thus, it would not need to develop 'interdependent' channel relationships, but could maintain 'independent' relationships, by which it can make use solely of the manufacturer's production capacity, whose role thus tends towards that of a contractor.

Regarding the last type of distribution channel mentioned, that is, one characterized by '*integrated*' relationships, the roles of both apparel

Figure 1. Supplier-buyer links in the three models considered [Source: our elaboration]



T = textile firm; M = apparel manufacturer; R = apparel retailer; C = consumer:
(a) 'tailoring dominated' model: T(0,1), R(1,1), C(2,0), M(0,1)
(b) 'ready-made clothing' model: T(0,1), M(1,1), R(1,1), C(1,0)
(c) 'retail' dominated model: T(0,1), M(0,1), R(2,1), C(1,0)

producer and retailer are taken on by a single agent, who carries out almost all management functions regarding both manufacturing and distribution operations. Such agents may be firms originating historically in the distribution sector, but who have taken on typically industrial functions, or conversely, they may originally have been involved solely in the manufacturing end and expanded downstream into retailing.

In TA industry-distribution relationships a role of increasing importance is being played by new out-of-town commercial sites called '*outlet centers*'. For manufacturers whose client retailers have adopted lean retailing, such centers can offer an alternative to adopting lean processes to satisfy such clients' needs. Implementing lean retail calls for quick response times on the part of the distribution network. Suppliers that adopt lean manufacturing to satisfy such demands are also able to reduce the negative effects of (1) unsold merchandise, (2) discount sales at cost, and (3) lost sales due to stock breakage, for both themselves and their client distributers. In contrast to this solution, outlet stores, and outlet centers in general, offer a direct sales channel that acts as a 'relief valve' for producers, that is, a means to dispose of excess production, generally through the formula of 'every day low price'. In this sense, the outlet channel can be viewed as an alternative solution to lean manufacturing, in the manufacturer's perspective, though (as we will see) it is potentially complementary to lean retailing in fashion apparel distribution. Despite the higher risk of surplus associated with the higher inventory necessary to ensure rapid service, suppliers of 'lean' distribution firms can maintain their traditional planning because they can later dispose of any such surplus inventory through the direct channel represented by the outlets.

The 'outlet' distribution channel, however, presents at least one disadvantage with respect to the option of responding to lean retailing by implementing lean manufacturing. This is that lean manufacturing allows for the possibility of limiting lost revenues from stock breakage, while this cannot be counted, per se, among the benefits of an outlet channel.

Naturally, we can also envisage types of channels in which sales through outlet stores are combined with lean manufacturing practices, thus regarding the two processes as complementary. In such a scenario, manufacturing enterprises would also undertake a form of integration of the distribution process, albeit through a direct approach, which allows it to dispose of surplus inventory through a dedicated channel. In light of such considerations, it should be no surprise that the outlet channel developed rapidly, in parallel with the spread of lean retailing in the fashion apparel industry – in the United States up until the late 1990s and over the following decade in Europe.

The outlet channel represents a type of 'direct' distribution channel, which is essentially characterized by the presence of an agent, the promoter of the center, whose role is to carry out some of the functions typical of retail. In fact, the promoter may take on certain management functions characteristic of retail activities (hiring personnel, marketing, display management and merchandising), together with other roles that are instead typical of a site promoter, starting with determining tenant-mix strategies and generating traffic by promoting the outlet (Burresi & Guercini, 2003).

The outlet form of direct channel is therefore particularly attractive for operators who are not committed to implementing lean manufacturing in response to the lean retailing adopted downstream by their clients in distribution. The agents that integrate processes of lean manufacturing and lean retailing are therefore by definition those less oriented towards the outlet channel, even though their positioning may in some cases be higher (Figure 2).

The results attainable through integration in channel relationships underlines how tight coordination, prompt information exchange, and risk sharing between industry and distribution are

Figure 2. The relationships between unsold stock management and positioning [Source: our elaboration]

fundamental to providing a timely response to the changes of the final market (Richardson, 1996, p. 410). It seems that such integration need not necessarily be combined with forms of proprietary control. Besides such forms there are others in which integration between distribution and industry may be the result of a bias towards servicing the latter, which is amenable to the development of agreements and alliances with retail firms through channels dominated by 'independent' relationships.

The proliferation of items references (i.e., number of Stock Keeping Units to manage) is a long-term trend in TA, and suggests a series of implications for both producers and retailers, the first amongst which is the greater uncertainty over what product(s) will sell best (Abernathy et al., 1995, p. 192). After all, companies produce a variety of merchandise in order to gain a greater market share (competitive logic), as well as to fulfill the wishes the final consumer (demand logic).

The greater the variety of merchandise, the greater the uncertainty for each single product. In order to furnish more service to clients without winding up with more surplus, retailers must be able to acquire needed goods without delay. Accordingly, this requires that manufacturers be able to fill orders promptly and efficiently. If manufacturers respond simply by increasing their own inventories, they will incur rising costs (especially from unsold stock) and they will, in the middle-to-long term, be less competitive. Sooner or later, at some point client distributors will be driven to seek a more efficient supplier (Blackwell, 1997). Thus, lean retailing inevitably appears to favor the development of lean manufacturing. Adopting lean retailing practices offers retailers a way to capitalize on advances in information technology and to minimize exposure to uncertainties in demand. The demands of clients with such preferences will bring pressure to bear on manufacturing suppliers, engendering substantial changes in the practices of the supply chain, and moreover with consequences on the entire business process (Milgrom & Roberts, 1988). Thus, at one extreme, manufacturers could simply opt to not innovate their internal routines and hold the necessary inventory to service lean retailers, thereby increasing their inventory costs. On the other extreme, manufacturers could upgrade their operations of internal planning and design, provisioning, supply and production, to be able to rapidly respond to changes in demand, and thereby minimize the risks associated with surplus inventory, as much for themselves as for their clients. In an even more developed form, it could be the manufacturers themselves to impel retailers unwilling to follow such an approach to adopt lean forms of retailing, thereby leveraging their own quick response capacity as lean manufacturer to gain a competitive advantage over competitors (Guercini, 2001).

PERSPECTIVES IN THE NEW MANUFACTURER-RETAILER RELATIONSHIPS

As we have seen, the introduction of lean retailing leads to significant transformation in both the standards of service expected and the interactions between industry and distribution, with a shift of manufacturers' investments in distribution centers and service systems towards the retail segment. The development of lean retailing entails the increasing dominance of retailers within channel relationships. The need for suppliers to adapt their behaviors to meet the demands of retailers does not necessarily imply symmetry in the flow, or even sharing, of information, given that retailers simply impose compliance to their standards and are not obliged to share data on demand beyond that information implicit in supply specifications (Hunt & Nevin, 1974).

Distribution practice has also undergone substantial progressive changes in terms of logistics. Traditionally, goods have always been transported from manufacturing plants to warehouses also owned by the manufacturer, whence they would then be transferred to retailers' storehouses. In lean retailing systems, the warehouse has been replaced by automated distribution centers, which interface directly with both industry and distributors (Hoover et al., 2001). Clothing suppliers can set up their distribution operations so as to increase the information links between manufacturing enterprises and retailers, thereby enabling labeling or informing retailers of upcoming deliveries, for example. Thus manufacturers can provide retailers with new services, which may even involve advance price labeling, as well as general merchandising services (Park, 2004).

Innovations in the apparel channel also have effects upstream on the textile market. At times change arrives suddenly, at others it comes more gradually, but it looks a general trend, and it is always the retailers who represent the essential agents of change (Doyle et al., 2006). Retailers call for clothing suppliers to invest in the first, emergence stage of "lean retailing" strategies – a whole series of basic information technologies whose purpose is to meet the requirements of ever-more demanding retail service in terms of short lead-times and rapid fulfilling of orders (Palmer & Markus, 2000; Forza & Vinelli, 2000). Retailers do not care much about how suppliers satisfy such requirements, as long as they do (Geysken et al., 1999). We are now witnessing the ever-increasing emergence of practices that address the problems of interfacing retailers and manufacturers, rather than the purely manufacturing concerns of clothing enterprises. If clothing producers adapt their operations to face the new and rising demands of the channel, their suppliers must also become more prepared to respond with new offerings of finished and semi-finished fabrics, as well as other new products and services (Jones, 2002). Although purchase price has traditionally represented the basic reference element for assessing supply alternatives in the TA industry, the spread of lean retailing strategies has brought other criteria into play, in particular, supply lead time. Lead times are traditionally longer for the delivery of fashion fabrics than for basic ones. In particular, in the formulation of the early 1990's, lean retailing focused mainly on "*basic*" or "*fashion-basic*" goods, rather than "*fashion oriented products*" (Abernathy et al., 1995). The spread of lean retail strategies in the field of fashion becomes evident in the second formulation of such strategies, widely adopted especially in the late 1990's, though their inception had come somewhat earlier [2].

Lean retailing processes, in fact, underwent a second stage, whose peculiar features with respect to the preceding stage include: (1) greater involvement of textile suppliers in the adoption of lean retailing; (2) the spread of lean retailing also to the field of fashion-oriented products, which imposed a reorganization of the stages of planning and designing apparel. A number of other aspects are also interesting in this regard: (a) the retail-apparel-textile channel appears increasing driven by actors who take on the role of lean retailers or, when originating in the manufacturing sector, producers who take on the functions typical of retailers and assist their retail clientele in implementing lean practices; (b) increasing interdependencies arise within the channel, and are linked to the processes of organizational integration, which also promote processes of vertical integration in response to the increasing need for coordination; (c) there is an increasing service orientation in the exchanges within the channel; (d) although the prime movers of change come clearly from the retail level, other actors may also address the problems of interfacing with distribution and consumers; (e) since lean retail requires a "quick response" from the supplier, when dealing with fashion and fashion-basic products, local suppliers may enjoy a relative advantage due to their shorter reaction times (Christopher et al., 2004).

New information technologies, new production process management, the evolution of production costs abroad and new organizational solutions are all aspects that have contributed to transforming the relationships between distribution and industry in TA (Palmer & Markus, 2000). It seems that the close communication within such relationships have come to substitute for inventory reserves (Milgrom & Roberts, 1988). The emergence of lean retailing processes has progressively revolutionized the relationships between distribution and industry in TA. Within the broader context of modern clothing distribution, such revolution may be invoked to partly explain the central importance attained by retailing among the various roles in the TA supply channel. Lean retailers differ from traditional clothing businesses in their greater exploitation of information technologies, an aspect that especially characterizes the first stage of lean retailing's development, and which has brought about a change in the demands on manufacturing suppliers for speed and reliability, thereby driving them to adopt lean manufacturing practices. The second stage of development of lean retailing therefore led to the involvement of other components of the value chain, generally within the manufacturing sector, and particularly affecting the areas of planning and design (Jackson, 2001; Sheridan et al., 2006). The consequent initial increase in the number of seasonal collections (from two up to four or even six) was quickly followed by a veritable explosion, even as far as the creation of weekly collections in fast fashion enterprises. Various critical factors account for the success of seasonal fashion-oriented products (Mattila et al., 2002), all linked to sourcing: *forecast accuracy*; *process lead-time*; *offshore-local sourcing mix*; and *up-front/replenishment buying mix*. In lean retailing forecast accuracy is less critical, because what is produced is tightly linked to the demands of direct customers (Mattila et al., 2002, p. 343).

Brand manufacturers who work with lean distribution clients may find themselves having to manage potentially unsold stock, if they themselves do not "go lean" in their own manufacturing processes, that is to say, adopt *lean manufacturing.* In the event that they do not, then the organization of the supply chain / distribution channel will see to it that that any surplus stock is essentially left with manufacturers. Another way that this can happen is when the industry is integrated at the retail level, which however does not practice lean retailing. Thus, the reserve stock is functional – it is necessary in order to fully serve the sales sector and avoid stock-outs. These two situations are illustrated by "c" and "d2" in Figure 3. In both cases industrial producers can manage these reserves through a direct outlet channel, offering "out of season" and/or "out of standard" products. It is interesting to note how lean manufacturers who interface closely with lean retailers, by limiting the amount of products released into the retail channel, should not need a presence in such outlet channels.

The relationships between industry and distribution in TA can be analyzed by comparing manufacturer management of the "*supply chain*" and retailer management of the "*demand chain*"[3]. As already seen, from the 1980's until the 1990's

Figure 3. Lean strategies in TA manufacturing and retail [Source: authors' processing]

		Retailing: lean	Retailing: non-lean

	non-lean	(c) manufacturer holds reserves	(d1) retailers hold reserves, or (d2) retail-integrated manufacturers hold reserves

new technologies and new strategies and organizational models were progressively adopted to reduce lead times and limit surpluses due to market forecasting errors. This process has produced *quick response* times for lean retailer clients, but should per se be distinguished from the processes involved in *quick fashion* (Guercini, 2001, p. 70). This latter development represents a formula aiming not only to reduce leads times, but also to adjust organization of the creative cycle itself as a function of the requirements of final demand. In traditional "programmed" production management systems, the fashion chain leading up to a new season calls for an 18-month cycle (Irpet-Textrends, 1991). For instance, during the 1980's the average lead time in the clothing industry, from raw material to final consumer, has been estimated at about 65-70 weeks, of which only 11 were for manufacturing, while nearly 40 were taken up by the processes of wholesaling and logistics. In recent years a rather general rule appears to have defined a 12-month cycle (thus 15-20 weeks less than in the 1980's). The main benefit of this reduction in lead times has been to minimize forecasting errors and their effects. It has been estimated that, while traditional times can lead to forecasting errors of about 40% of overall production, reducing lead times from 12 to 9 months can cut this margin of error by half (Jacobs, 2006, p. 85). Further reductions in lead-times can bring about progressive reductions in forecast errors, with consequent improvements in the overall balance sheets of channel enterprises. It has been estimated that the pre-season forecasts currently suffer from an error of about 10% (Lowson et al., 1999, p. 44, p. 93 ff.).

In this regard, fashion designers conceive of new trends about one year before the target season. However, the decisions regarding semifinished textiles, beginning with the fabrics to employ, are made months before (Jackson, 2001, p. 127 ff). Nowadays, many successful firms have reduced lead times so drastically that they are no longer tied in the same way to the seasonal production management model. Vertically integrated firms such as Inditex-Zara and H&M can complete the entire cycle from design to distribution in only three to eight weeks, thereby effecting substantial changes in operating relationships within the channel.

The development of lean retailing aims to limit lead times and thereby avoid errors in forecasting and, consequently, the associated higher costs / lower profits. Two parts of the TA value chain can be distinguished: the "*supply oriented*" and the "*demand oriented*", as per the well-known scheme proposed by Porter (1985, p. 35). This chain is normally represented with horizontal left-to-right arrows, which indicate the flow from raw materials to final consumers. Thus, we speak of "*demand and supply chain management*", in which the flow of products are oriented in one direction (supply), and the information relevant to decision-making in the other (demand). According to Jacobs (2006, pp. 86-87), some components of the value chain can be represented as flowing from right to left in the "demand" perspective, in which the position of end consumers on the right-most side emphasizes their determining role in orienting and driving enterprise activities in the chain-channel. Because suppliers are clearly crucial to important segments of clothing firms' value system, reducing lead times in the supply chain requires a concerted effort with these partners. Suppliers' orientation or stance with respect to their specific "*demand chain*" is clearly important in this process. In fact, there are two ways suppliers may define such stance. The first way for suppliers to take such a demand stance is to assume that the requisites expressed by retailers is the true expression of demand. In this case, the directly relevant agents of demand for the manufacturing firms are their immediate retail clients. The second approach instead takes the demand stance in perhaps the strictest sense of the term, by equating it directly with end consumption. Consequently, cooperation with retail occurs through different means. In fact, in this case manufacturers may seek to integrate vertically, taking on distribution functions in an effort to bring themselves closer to end consumers.

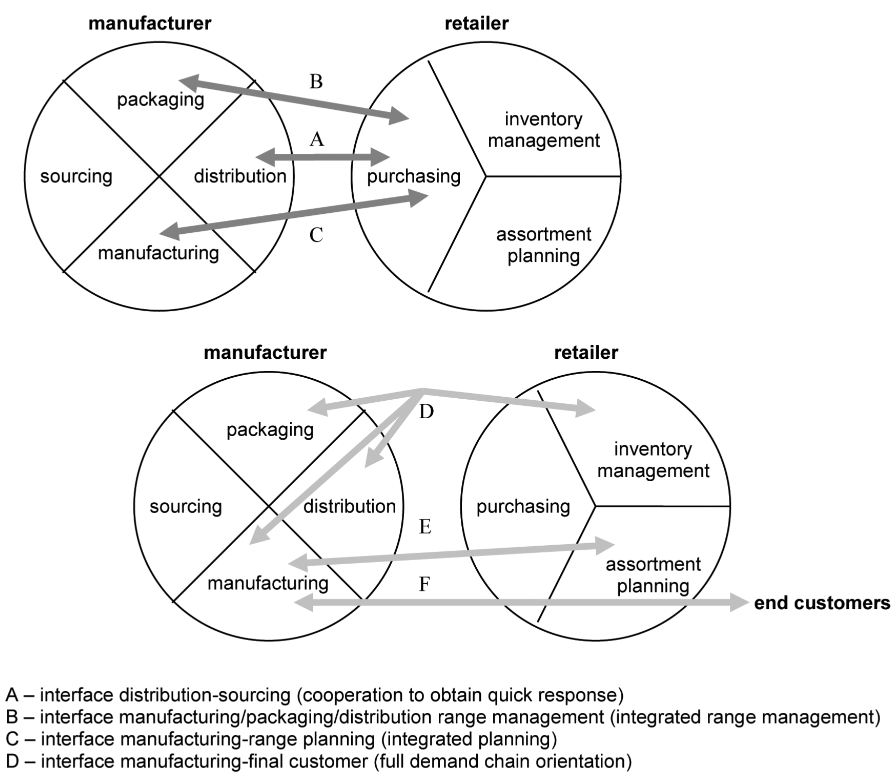
Nowadays, the fact is that for manufacturers the demand side of industry-distribution relationships is still generally represented by retailers, who must plan their own product mix ("what" to sell), manage their inventory ("how much" of each article and SKUs) and consequently decide on purchases ("where" and "who from"). Retailers make such decisions based on their knowledge and assessments of the needs and desires of consumers. Such assessments may however suffer from significant shortcomings, especially considering, as highlighted by some recent studies, that more than half of European fashion consumers fail to find what they are looking for at sales points (Stockert, 2004). The logical conclusion, already drawn by various authors, is that the state of information on consumption remains the "Achilles' heel" of TA chain-channel management. The supply side of industry-distribution relationships is clearly of relevance to retailers, given that they must interface with manufacturers who combine or collect the inputs for production (sourcing), and must organize its various stages, including packaging and delivery of products to the distribution channel.

Analyzing the supply chain and the demand chain is also of considerable importance to the organization of integrated enterprises, as they do not necessarily require distinct, recognizable agents. When such vertical integration has not been implemented, it falls to the manufacturer to study the demand chain, just as it is up to the retailer to examine the supply chain, thereby giving rise to a distinction based on which the links between the two perspectives can be discussed with greater precision.

On the *demand side* the supply chain can be managed through purchasing policy, by seeking different types of links through which to interface with different areas in the typical supply chain of manufacturers (Hoover et al., 2001, pp. 74-76). These are represented by "distribution" (A), "packaging" (B) and production in its narrowest sense, i.e., "manufacturing" (C). Retailers can in fact look for contacts with manufacturers' distribution divisions, with the aim of ensuring rapid delivery, as the supplier has probably invested in substantial amounts of inventory (scheme "A" in Figure 4). In the second approach mentioned, retailers look for contacts with packagers and request assembled products from clothing suppliers in response to precise consumer demands. Such requests may include logistics management, dedicated packaging, adjustments to product specifications and/or private labeling ("B" in Figure 4). Lastly, in the third approach, retailers interface with suppliers' manufacturing processes, from whom they can order custom production (*manufacture-to-order*), though this comes at the cost of lower efficiency and longer delivery times. Such solutions moreover generally involve accepting higher supply prices ("C" in Figure 4). Retailers therefore come to manage these alternative sourcing methods by operating on the demand side and carrying out "*supply chain management*". On the industry side, manufacturers must cope with the requisites and constraints of production technologies. Moreover, they are often responsible for managing the more well-established, if not traditional, requirements of inter-organizational relationships along the TA chain / channel. Often producers who avoid such role, do so by taking on a more demand side approach, that is, they manage process so as to achieve high levels of distribution sell-out by favoring retail activities over direct relationships with final consumption.

On the *supply side*, industry can implement various different policies for managing the demand chain, thereby adopting so-called "*demand chain management*" (Baker, 2004). Four different forms can be distinguished (Hoover et al., 2001, pp. 76-80). The first form, interfacing producers' distribution functions, essentially involves retailer purchasing. Such an approach to demand chain management is a mirror image of the first of the three types of supply chain management cited with regard to retailers ("A" in Figure 4). This first case therefore represents a form of cooperation that can provide suppliers with a quick response strategy to satisfy the requirements of lean retailers (Iyer & Bergen, 1997). A second form of demand chain management by manufacturers calls for joint effort in the operations of manufacturing, packaging and distribution, which may need to interface administratively with purchasing, but which, in any event, seeks to coordinate with retailer clients' inventory management,

Figure 4. Alternative relationships between manufacturer (supply perspective) and retailer (demand perspective) in TA [Source: authors' processing]



thereby providing savings in inventory costs ("D" in Figure 4).

A third type of demand chain management involves establishing relationships between producers' manufacturing divisions and retailer clients' inventory management. In order to collaborate in defining retailers' inventories (including merchandise assortments), manufacturers must, together with their direct clients, try to understand the consumer demand categories that both are seeking to satisfy ("E" in Figure 4). The fourth and last type of demand chain management presents some particular features. Here, manufacturers organize their demand chain management based not on their retail clients, but rather directly on indications from final consumers ("F" in Figure 4).

This last form of demand chain management appears particularly interesting. It has been likened to the strategies used to overcome retailing and achieve mass customization in other sectors, such as the case of Dell in the personal computer industry (Kerin et al., 2009). Such approach to the demand chain may be of as much interest to *manufacturer-retailers* (producer integrated in distribution) as to *retailer-manufacturers* (distributor integrated in production). This latter presumes an inverted perspective of the path: retailers try to achieve a more direct link between manufacturing and final consumers through their own distribution network. In both cases, the relationship between industry and distribution in TA merges the various resources in an integrated fashion to guarantee more direct contact between manufacturing processes and the downstream activities of the demand chain [4].

In such a scenario, industry may also seek to set up new services of interest mainly to the retailer, so as to build up dynamic cooperation through which to improve economic results of equal benefit to both. In the event retailers press excessively for price cuts, the manufacturer may try to establish direct relationships with consumers, following the approach outlined in the fourth and last form of demand management described above. Alternatively, it is sometimes retailers themselves, who by their close participation in typically manufacturing functions, take on the distinctive features of retailer-manufacturers (or industrial retailers), and adopt the fourth approach to demand chain management described, in order to respond more fully to the consumer demands they manage to perceive. In any event, both retailer-manufacturers and manufacturer-retailers come to address the logic of both the supply chain and the demand chain in an at least partly integrated fashion within their enterprises. The understanding of consumer demand that can be gained solely from the information collected by conducting retail activities cannot however account for the so-called "unrealized sales" consequent to consumer dissatisfaction with the assortment offered. The traditional functions of the middleman do not include the developing of close contacts between manufacturers' offerings and final demand. Managing the demand chain does not simply represent the mirror image of supply chain management by the retailer, given the important role that this latter's orientation to final demand may have. This is an aspect that still requires further development, despite the meaningful impetus towards the vertical integration of fashion enterprises. Integration must go beyond the simple, partial forms that developed in the early stages of lean retailing, and broaden vertically to the include interfacing with consumers downstream and with the design processes upstream.

With more complete vertical integration the drive to cooperation among actors within the same channel gives way to a greater impact of competition between channels involving vertically integrated enterprises. Even at the retail level, there seems to be little understanding of the causes of unrealized sales to actual customers (not to mention prospective clients), and to this end information technologies are of little use without the ability to relate to customers, draw nearer to them, gain greater understanding and learn through a relationship with them. The fourth type of supply chain management ("D" in Figure 4) therefore has the potential to bring about more radical innovation – not only in end consumer products and services, but also in the relationships between industry and distribution – than the two stages of development of lean retailing (Jacobs, 2006, p. 92). At the same time, there has been a shift from greater *vertical cooperation* toward one marked essentially by *horizontal competition.* This suggests that the evolution of industry-distribution relationships in TA is potentially destined to devote greater attention to the acquisition of knowledge on the prospective behaviors of the final customers of all businesses, that is, consumers. This comes about in the face of the continued standardization of service centers, as highlighted by the excessive uniformity in the various types of shopping centers, which in turn has stemmed from the pursuit of economy by the large fashion chains and the management and control systems of the promoters that have created them.

One important related aspect concerns the considerable difficulties involved with actually using the data produced by distribution information systems (micro-marketing applied to apparel distribution). Such difficulties stem from the currently limited number of case studies on market segmentation based on the data collected by POS systems. Faced with such limitations in retail information technologies, fashion demand seems ever more difficult to predict, especially in light of the long-term increase in its diversity that began in the 1950's and 60's (Abernathy et al., 1995) and which has accelerated considerably in recent years. Cooperation between retailer and manufacturer does not appear enough to face such rapid development, either with regard to inventory and selection management alone, or at the level of planning product ranges and manufacturing. Moreover, the potential benefits of cooperation in terms of understanding prospective consumption do not seem extend beyond that which has been defined a generic advantage of two partners may possibly know more that one (Jacobs, 2006, p. 89).

CONCLUSION

This paper has discussed how the evolution of the relationships between industry and distribution in TA seems to follow particular paths that are quite distinct from those developing in other fields of distribution. Such paths are shaped by the peculiarities of the manufacturing and distribution processes in the fashion industry and the TA production cycle. More specifically, what emerges from the analysis are at least three possible evolutionary patterns, which in historical terms define the last three decades, at least. However, such paths of evolution also take on a conceptual quality and therefore may be abstracted from any specific time period.

In a first stage of evolution the relationships between industry and distribution are characterized by the early success of lean retail formulas, which shape the operational processes of industry. This upsets the established order, in which both industry and distribution organize their product offerings (textiles and apparel) based on two seasons (spring-summer and autumn-winter). Thus, with the rise of lean retailing, this first evolutionary stage allows for going beyond the traditional patterns of production cycle times, and brings about profound changes in retail enterprises' operations and their relationships to industry. In this stage, enterprises seek to minimize lead times through the collaboration between industry and distribution made possible by the introduction of technological innovations in information management. This stage reached its peak in the 1980's and was characterized by the development of business enterprises, such as Benetton, which represent models for analysis and emulation at the international level.

During the second stage of evolution of industry-distribution relationships the consequences of the adoption of lean formulas spread to involve industry, particularly in their interior functions upstream of logistic and commercial aspects. Once again, such trends are triggered at the level of retail functions and processes and, unlike the preceding stage, they not only tend to shape the operational activities of supply process management, but come to involve and profoundly modify the very creative processes of industry. Within this framework, some manufacturing processes can be integrated directly into enterprises whose prime concern is distribution. The spread of fast (or quick) fashion processes is symbolic of this stage. Not only are operative lead times reduced to a minimum, but conception and design times come to be defined by ever more frequent offerings as determined by the need to bring to market merchandise in a continuous "state of becoming" and hence able to stimulate demand. In this stage the lead times dictated by two fashion seasons have been definitively superseded by a large number of new offerings brought out at an ever more rapid pace. Firms such as Zara are emblematic of this stage of evolution of the relationships between industry and distribution in TA. Cooperation through vertical relationships gives way to processes of true strategic and operational integration, accompanied by the heightening of horizontal competition. There is a full-blown trend toward market- and service-orientation, with a consequent shift from a supply chain in which the guiding principles for buyers-suppliers are defined by technology (upstream), to one in which the (downstream) processes of distribution and consumption play the central role.

This model seems to have reached full maturity in recent years. Enterprises that have adopted such practices have even achieved better performance than those gained through other strategic groups. Such market orientation has led to improvements in industry response times to customers' actual purchasing behaviors and moreover stimulates consumer interest by intensifying the pace of new, and therefore 'fresher', fashion offerings. Such model seeks to minimize the lag times between conception and production, on the one hand, and better respond to consumer purchasing behavior, on the other. However, it does not address the need for knowledge, for instance, on unrealized sales due to a consumer's failure to find the sought for product in stock. In other words, in both the evolutionary stages described, attention is devoted more to purchasing behavior than to actual consumption. This represents the "Achilles' heel" in the market orientation of TA firms. Both industry and distribution enterprises remain largely committed to marketing offers at an ever accelerating pace, with the aims of stimulating the market and reacting rapidly to its manifestations of interest. Even more so than in other fields, TA is still lacking the market research tools necessary to acquire direct knowledge of consumption. A greater understanding, for instance, of unrealized sales and their relations to what customers look for, could have significant implications for the strategy decisions of enterprises, which over the last years have often focused on points of sales and customer-experience aspects. Such an approach marks the third and last stage of evolution of the relationships between industry and distribution, one which could lead to, or at least offer, alternative prospects to the trends that dominated the earlier stages.

For future research, it will be interesting to find analytical evidence to theoretically verify some critical insights revealed in this paper. For example, for channel coordination issues in different stages, the respective operational benefits and coordination mechanisms can be explored (see Eppen and Iyer 1997, Chen et al. 2006 for more details).

ENDNOTES

1 The study of the retail-apparel-textile system seems amenable to a functionalist approach: given its internal links to the supply channel, it can be analyzed as a whole (Bucklin, 1970). The sole fact that a number of different manufacturing agents are involved (in both textiles and apparel) does not by itself seem sufficient to compromise the application of some facets of functionalist analysis (after all, the distribution channel begins with manufacturers).

2 Good examples in this regard are the fashion-oriented product lines offered by Zara and H&M, or those of the Italian Liu Jo, Patrizia Pepe and Pinko.

3 The offer chain / distribution channel can be interpreted in both a "supply" and a "demand" perspective (Jacobs, 2006), as it presents aspects of both (Gipsrud, 2004, p. 202).

4 This may also represent an alternative response to the appeals of many retailers for ever lower prices for the manufacturing supplier's products (Guercini, 2008).

Chapter 53
Production Information Systems Usability in Jordan

Emad Abu-Shanab
Yarmouk University, Jordan

Heyam Al-Tarawneh
Ministry of Education, Jordan

ABSTRACT

Enterprise systems are becoming more important as they support the efficiency and effectiveness of operations and reduce cost. In this chapter we explored the literature related to production information systems (PIS), enterprise systems, and other applications and their influence in an industrial zone in Jordan. Constructs from the Innovation Diffusion Theory were used, where results indicated that the adoption rate is acceptable and all variables have high means with respect to their evaluation by managers, but only two variable significantly predicted intention to use. In a second study that explored the status of IT usage in manufacturing firms using a different sample, results indicated that accounting information systems were widely used and distribution systems and manufacturing aiding systems were the least used. Other findings, conclusions and future work are stated at the end of the chapter.

INTRODUCTION

The industrial sector in Jordan is one of the main dimensions in the economic life of the country and is a major contributor in local production figures. Statistics indicate a contribution of 21.5% of the local production in the year 2006, which concluded 90% of the national size of exportation (Jordan Industrial Chamber Website, 2008).

DOI: 10.4018/978-1-4666-1945-6.ch053

Thus, the attention paid to this sector is one of the factors that lead to improving this sector's efficiency and productivity. Statistics also indicated that this sector employs 15% of The Jordanian workforce, which is a high percentage compared to other sectors (same source).

Research defined innovation as an intellectual performance that leads individuals to problem solving, or the intellectual effort that leads to non-repetitive or ordinary results (Trairy, 2008). Gnaim (2005) used another definition of innovation but in the higher education quality area, where he claimed that innovation is doing something good and not bad. Finally, Smadi (2001) stated that employee innovation in the manufacturing area in Jordan was more prevalent in small-size businesses than in larger ones, where he explored 870 employees and studied their inclination to adopt the Kaizen model in improving work environment.

One of the most important tools that help in improving this sector is information technology (IT), where its role in this sector ranges from supporting operations to a major role in automation and control of operations. The important role of information technology in manufacturing especially in reducing cost and pushing operations forward, and adding value to the manufacturing process, which satisfies firms' objectives. The importance of production information systems (PIS) is becoming vital to all manufacturing firms to gain and sustain competitive advantage. The adoption of PIS is becoming a priority to firms in this sector especially those who work in alliance with foreign (global) firms.

The word adoption is not a secret one, firms need to convince their employees and managers to effectively use and utilize information systems in a way that achieves firms' objectives. What makes this adoption more important, is that when we deal with complex systems (like EIS or PIS) users need more attention and involvement to guarantee their acceptance and thus the full benefit from such systems (Wang, Hsieh, Butler & Hsu, 2008). Research indicates the importance of users' adoption when dealing with new technology. Users are cautious to use new technology unless they believe it will bring to them some advantage, and would be easy to use. Also, they need to make sure it is compatible with systems they used before and many other factors that influence their perception of technology. This study reviewed the literature related to the technology acceptance area and adopted the innovation diffusion theory (IDT) proposed by Rogers in early 1983 (Rogers, 1995; Moore and Benbasat, 1991). This study reviewed also the literature in the area of production systems explored the factors predicting the rate of adoption of such systems through the reported opinions of managers in this sector. Finally, conclusions and future work are stated at the end.

BACKGROUND

Many theories tackled the adoption of new technology concepts and proposed a variety of theories and models that exceeded hundreds of propositions and variables. The argument in this domain emphasizes finding the suitable set of "factors" that can predict users' behavior with respect to using new technology. Most theories and research utilized the users' "intention to use" the technology as a surrogate to actual usage of the technology. Thus, many theories used "Intention to Use" (ITU) as the dependent variable, and proposed many predictors ranging from two variables to more than ten in some cases. The following section will explore the literature related to the IDT and other theories in the technology acceptance domain, then literature related to production information systems and enterprise resources planning systems usage.

Production Information Systems

Enterprise Information Systems (EIS) control all major business processes with a single software architecture in real time (Turban, Leidner, McLean & Wetherbe, 2008). Under the EIS category, the same authors list production information systems (PIS), Supply Chain Management Systems (SCM systems), Customer relationship Management Systems (CRM systems), Product lifecycle management systems (PLM systems), and Enterprise Resource Planning systems (ERP Systems). EIS account for 54% of licensing revenues, and expected to have the highest growth rates (expected to be \$55 billion in 2012) (McCrea, 2008). Our focus in this study is more towards PIS and ERP as they relate to manufacturing and industrial applications.

Production Information Systems (PIS) are defined as systems that work with production and operations information. PIS collect information from end terminals (like point of sale terminals - POS, shop floor machines, and operation and factory sensors) and store in transaction processing machines and then feed some management information systems (MIS) or other types of functional systems like: decision support systems (DSS), and enterprise resource planning systems (ERP) (Turban, Leidner, McLean & Wetherbe, 2008). The output of PIS is used to support managers in the process of decision making and to improve the managerial functions in the firm. The described architecture is not a unique one, as many disputes are related to the difference between functional systems and management information systems, as an example, PIS can get input data from transaction processing systems (TPS) and generate reports and output that can be used in the managerial decision making process. Some academicians describe all these systems as MIS, even enterprise resource planning systems (ERP).

Many definitions were reported in the literature for PIS like the definition used by Ciurana, Garcia-Romeu, Ferrer and Casadesus (2008) which indicates that PIS are systems that are related to transferring raw material into products with special specifications.

PIS are defined as data processing network systems (Hssain, Djeraba & Descotes-Genon, 1993, pp. 1). It seems that it is a simple definition but, the authors add further that it includes other components like the input data from process devices (sensors and terminals). On the other hand, the output is meaningful information used in decision-making. The authors report three methodological requirements related to design of PIS: managing the large volume of data and knowledge compounding the core of the network, coping with high complexity of operations, and providing reliable and available data and knowledge inputs to the PIS. Hsu and Rattner (1990) conclude that to meet these requirements, design of PIS should be a part of a global design approach within total-system architecture.

PIS aim at planning and scheduling and organizing for operations with related issue of work orders to shop floors and production (Ciurana, Garcia-Romeu, Ferrer & Casadesus, 2008). The importance of PIS comes from the role that it plays in facilitating the process of design and production of products, and forwarding it to customers (the distribution function). Research related to PIS focused on the applications related to the theory of planning and production control, where the main objective is reducing costs and risks, this is applied in more than one industry and type (Wang & Hu, 2008). On the other hand, research stressed the importance of providing the correct and timely information through the installation of sensors on the production line, or the use of web-based systems. Research emphasized the importance of synchronization of information systems to guarantee the required reduction of cost and the needed customer satisfaction (Mourtiz et al., 2008).

PIS can aid in the reduction of cost and facilitation (smoothing) of the flow of material in the manufacturing process. Also, the flow of information and material is becoming more vital to the production process when considering the global perspective or the supply chain management concept (SCM). A study that explored mobile communication technology importance in the integration process when transferring information and material between suppliers and customers, concluded that it is very important to utilize the benefits of PIS to reduce cost and gain integration between partners (Ende, Jaspers & Gerwin, 2008). In another study that explored the application of fuzzy logic concepts within a smart agent, solutions were provided for production problems utilizing previous solutions to previous problems (Lu & Sy, 2008). Authors concluded that it is useful in the industrial environment to provide decision makers with information residing in PIS to make accurate and timely decisions.

Finally, a group of Greek researchers studied the manufacturing strategies and the influence of IT on financial performance, where cluster analysis method with VACOR algorithm was used. Results indicated that the usage of information technology in industrial sector would have a significant effect on financial measures especially in organizations utilizing flexible manufacturing and with medium cost. The influence of using IT was higher in organizations that concentrate less on innovation and quality (Theodorou & Florou, 2008).

ERP Systems Research

The American Production and Inventory Control Society (APICS, 1998) defines ERP as *"an accounting-oriented computer information system that assists enterprises to define and plan on the resources required during the operation process of purchase, production, distribution and strategic planning to satisfy customers' orders"* (Lo, Tsai & Li, 2005, pp. 13). Deloitte Consulting (1999) refers to ERP systems as a packaged business solution that is designed to automate and integrate business processes, share common data and practices across the enterprise and provide access to information in a real time environment.

The previous definitions present a link between PIS and ERP systems, where the operation and production are closely linked through both types of systems. Thus, this study will visit literature related to ERP systems that might built a better picture of users' adoption of these systems.

ERP developers claim that their systems are claimed to increase firms' productivity, improve operational efficiency, improve communication and collaboration, grant better control on processes, enhance scalability and performance, leverage IT infrastructure, and reduce cost (SSA Report, 2006). ERP systems expand the processes of operations to reach external partners as well as internal firm constituents (Microsoft, 2003) and increase the level of automation and the value of business (SAP, 2006). Oracle proposed an enterprise manufacturing intelligence (EMI) tool that adds contextual dimension to shop floor data then synchronizes with ERP systems. Such addition provides real time intelligence to operations and move manufacturing and resource planning to another level (Smith, 2008).

When looking at research work, Carton and Adam (2008) concluded that ERP systems improved management decision making process. The authors did a case study in the pharmaceutical sector and concluded to the fact that implementing and utilizing ERP systems faces many barriers that prevent firms from benefiting from the rich information like: the lack of skills needed and the lack of access to data. Also they emphasized the incompatibility of transaction data with aggregate management queries.

Research work related to the perceptions of users towards ERP systems implementation explored different factors that make ERP systems more acceptable. Fan and Fang (2006) tested empirically the DeLone and McLean model. Their main findings were the significant relationship between system quality and system use; system quality and perceived usefulness; information quality and user satisfaction; perceived usefulness and system use; perceived usefulness and user satisfaction; system use and individual impact; user satisfaction and individual impact; and finally, individual impact and organizational impact. The major conclusion of the study was that user perceptions of IS success plays a critical role in ERP implementation. Similar to their study, Singla (2005) explored ERP performance and found that adopters consistently outperformed non-adopters across a wide variety of measures. The study used tangible and intangible benefits of ERP and a set of business performance measures.

Some research explored the resistance to change when applying and ERP systems. The study utilized an empirical test using a sample of Dunlop C&F employees (30 responses). Results indicated that firms need to work towards improving the user's attitude towards the ERP system. Again attitude is affected by users' self-efficacy and perceived usefulness. Other issues that can inflect failure into the implementation process might be employee education and vendors' support (Tsai & Hung, 2008). ERP systems integrate resources to enhance the overall performance and reduce costs (Lo, Tsai & Li, 2005). In a try to differentiate between ERP adopters' performance and non-adopters' performance, Hunton, Lippincout and Reck (2003) reported a decline in performance over time for non-adopters, while adopters enjoyed a steady performance.

We conclude that it is crucial to benefit from the capabilities of PIS, ERP and other IS in the industrial sector to gain competitive advantage in the market through the reduction of cost and the smoothing of material and information flow, and better utilization of resources.

Innovation Diffusion Theory

Rogers's diffusion of innovation (DOI) model appeared to be one of the most widely accepted models by researchers in identifying the "perceived" critical characteristics for innovation in information systems research and technology adoption research.

Rogers (1995) defines the "innovation diffusion process" as the spread of new ideas from its source of invention or creators to its ultimate users or adopters. Innovation is 'an idea, practice or object that is perceived as new by an individual or other unit of adoption (Rogers 1995, p.11). Diffusion is the 'process by which an innovation is communicated through certain channels over time among the members of a social system (Rogers 1995, p. 5).

Rogers classified people into categories according to their innovativeness; where individuals who are relatively earlier in adopting new ideas than other members of their social system are considered to be more innovative. The categories are the following arranged from adopters to non-adopters: innovators, early adopters, early majority, late majority, and laggards.

According to Rogers' theory, people start to adopt innovations slowly, and then the increased number of adoptions will continue until it reaches a peak, after that it diminishes leaving few individuals as non-adopters (laggards). Innovators are willing to try new ideas and venturesome. Early adopters are the opinion leaders in their community and carefully adopt new ideas. Individuals in the "early majority" category adopt new ideas before the average person and rarely seen as a leaders. On the other hand, individuals in the "late majority" category adopt an innovation only after a majority of people have tried it. At the end come the laggards who adopt the innovation only when it is a common and traditional aspect of their life or work. People in this category are suspicious of change, and resist such initiatives.

The Innovation Diffusion Theory (IDT) is a well accepted model in social sciences as it investigates the environment of adopting new innovations (the technology or information systems in this case) in organizations. The IDT was first proposed by Rogers (1983) and then modified by many researchers who modified the model and proposed different set of variables (Moore & Benbasat, 1991). Rogers (1983) proposed his theory as a model that includes the factors influencing the usage and adoption of innovation.

Rogers proposes five important factors that influence the adoption decision: the first is *relative advantage*: the degree to which the innovation perceived as being better than its precursor/supersedes. Second, *compatibility*: the degree to which an innovation is perceived as being consistent with existing system of values, past experiences and needs. The third is *complexity*: the degree to which an innovation perceived as being difficult to understand and use. Fourth, is *triability*: the degree to which an innovation can be tried and experimented with a limited basis. Finally, *observability*: the degree to which the beneficial results of use are observable and visible to users. Rogers addressed that innovation was more likely to succeed and be more readily adopted if the relative advantage as a consequence of its introduction was evident; if it was compatible with the adopter, its operations and its view of the world; if it was not 'too' complex; and if it was trialable and results can be observed prior to adoption.

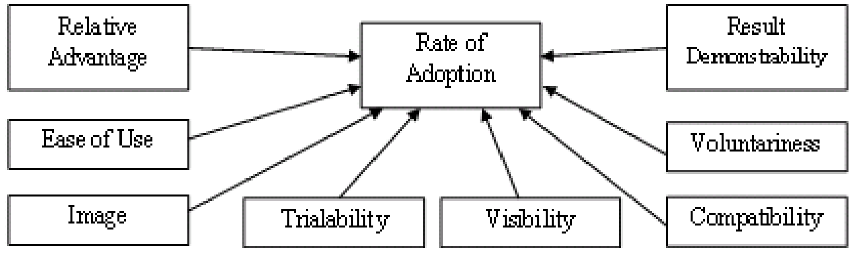
The theory measures three major areas: the adoption rate of technology related to time, where the theory is a suitable tool for measuring the diffusion of innovation in organizations (Brancheau & Wetherbe, 1990). Later, some researchers utilized this theory in studying the gap in technology accommodation (Fichman & Kemerer, 1999). Second, the work of Brancheau and Wetherbe (1990) included demographic factors related to the innovator characteristics that were explored in addition to the original factors proposed in the original theory. Brancheau and Wetherbe concluded that younger individuals were more receptive to technology adoption earlier in the process. Also, better educated individuals (subjects with higher degrees of education) were more open to interacting with the technology and thus were the ones with initiatives and opinion. Finally, the same authors explored the adoption of technology, where they anticipated that adopting a technology would go through four stages: awareness, persuasion, decision and implementation. The work of Brancheau & Wetherbe, coincides with the work of Agarwal (2000) with respect to the four adoption stages reported. Agarwal proclaimed that the IDT provides a better explanation of the adoption process and its interaction with time.

The work done by Moore and Benbasat (1991) is considered one of the important milestones in the life of this theory, where they used Rogers' work to develop a well validated instrument to measure the factors involved in predicting the rate of adoption. Moore and Benbasat built an instrument that explains the rate of adoption with reliable level of measurement. They added at the first stage of their study two major constructs and found them to be distinctive from the five proposed ones in Rogers' work. The first was *Image*; defined as "the degree to which use of an innovation is perceived to enhance one's image or status in one's social system". The second is *voluntariness of use*; defined as "the degree to which use of the innovation is perceived as being voluntary or of free will" (Moore & Benbasat, 1991, pp. 195).

The constructs' formulation took a multi-stage process and resulted in an eight construct model predicting the rate of adoption. Researchers focused their efforts on the time extension of the adoption process, where they used a longitudinal perspective instead of the snapshot view (cross-sectional snapshot of the data). The model utilized in their work is depicted in Figure 1.

Moore and Benbasat built their results on the responses of 540 employees from more than one organization, where the personal work-station was the technology under consideration. The major objective of the study was to build a highly reliable instrument to measure the set of

Figure 1. The IDT model proposed by Moore and Benbasat (1991)



factors used in the IDT. The study included four stages; the first was to review all the literature and the instruments available and used at that time. The second stage, researchers reviewed the items used for each variable in the instrument using a panel of experts. The third stage performed a pilot test on 20 subjects, followed by a test on 66 subjects to improve the instrument and increase its validity and reliability. Finally, the instrument was used on a large scale, where 34 items were the results of this study that measured the variables of the study.

In later studies, Agarwal and Parasad (1998) used part of the variables of the IDT like relative advantage, ease of use and compatibility, to study personal innovativeness influence on the rate of adoption of new technology. The results of the study indicated that personal innovativeness will be a significant moderator in the relationships influencing the rate of adoption of new technology. On the other hand, other studies that depicted the set of factors used in the IDT showed that this theory is stronger in predicting the rate of adoption than one of the widely used models in the area; the technology acceptance model-TAM (Davis, 1989). Results indicated that the IDT explained 45% of the variability in the rate of adoption, where the TAM explained only 32.7% of the variability of the same construct (Plouffe, Hulland & Vandenbosch, 2001).

Other studies that adopted some of the variables listed in the IDT and proposed by Moore and Benbasat (1991) went and tested the tendency to purchase on the Internet (Fitzgerald & Kiel, 2002). Using a snowball sampling method, 128 respondents were recruited to complete a survey that included measures from three domains: perceived attributes of use (included six constructs from the IDT and perceived risk), traditional normative beliefs (partner, family, friends, and near peers), and Internet normative beliefs (e-mail, discussion groups, virtual communities, and chat rooms). The mediators in the model were attitude, and motivation to comply with normative beliefs, and the dependent variable was future use intent. The results indicated that attitude was a strong factor explaining the intent to use for both adopters and non-adopters. Also, the major constructs explaining attitude were result demonstrability and risk for adopters, and risk for non adopters.

Mirchandani and Motwani (2001) performed a study related to the usage of e-commerce activities and focused on the relative advantage and compatibility, but added few constructs like: enthusiasm of top manger, compatibility with the company, relative advantage, and knowledge within the firm. Speier and Venkatesh (2002) proposed a comprehensive model to explore the perceptions of salespeople that affected their decision to reject a technology. The study analyzed the responses at two points of time utilizing 454 salespeople across two firms that implemented sales force automation tools. The model tested the interactions between individual characteristics, role perceptions, organization's characteristics, individual perceptions of the technology, professional state, person-fit technology, objective outcomes, and subjective outcomes. Relative advantage was the only significant factor from the set of individual perceptions of the technology that affected job-fit (at both time measures). Voluntariness had a low effect on the individual perception factors. Finally, the study reported a failure of the sales force automation technology based on the rejection of the salespeople as a result of negative job-related perceptions.

In an integration of multiple models in the technology acceptance area, Hardgrave, Davis, and Riemenschneider (2003) integrated the TAM/TAM2, IDT, and TPB/TRA to come up with a model that consisted of perceived usefulness, complexity, compatibility, social pressure and organizational mandate (voluntariness) as predictors of intention to follow a methodology. The results confirmed the effect of all factors except complexity (ease of use). The authors redefined the model to account for the indirect effects and proposed another model that linked complexity to usefulness, which yielded a significant result. Also, social influence and compatibility kept their significant relations with intention and usefulness.

Finally, in Saudi Arabia, Al-Gahtani (2003) tested a subset of the IDT constructs in a study aimed at computer technology adoption by Saudi workers in 136 organizations. The usable responses were 1190, and the dependent variable was adoption of computer technology. The results confirmed the five proposed constructs adapted from the IDT (relative advantage, complexity, compatibility, trialability, and observability).

JORDANIAN MANUFACTURING FIRMS ADOPTION OF PIS

This paper investigated the extent that manufacturing firms in Jordan are adopting IT as one of the innovation tools that help in the production and operation processes. PIS are considered, for the purpose of this research, the innovation under consideration. This research consists of two tests, where a group of surveys were distributed on factories mainly in the Northern region of the country (mainly in Al-Hasan Industrial Zone). The total collected surveys were 74 surveys that included a number of questions related to the information technology and applications content of the firm and some information about the organization itself and their information systems usability. On the other hand, another survey was distributed in Al-Hasan Industrial Zone and only to general managers, information managers and heads of departments. The second survey focused on managers' perceptions about adopting this type of systems and how well they accepted such technology. Total number of surveys collected was 91 usable surveys. The two studies were not addressing the same sample, and results of both studies are not closely related.

Jordanian PIS Usability

Table 1 shows the demographic details of the sample distributed, where 100 surveys were distributed and 74 were collected (response rate 74%). The survey aimed at collecting data related to managers' opinions on the usage and availability of PIS and other related systems. The main objective was to measure the adoption of PIS in the manufacturing sector in Jordan. When asking managers about using IT in their operations, 66 factories out of 74 reported that they used one or more of the systems listed in Table 2. Also, 8 factories only reported that they did not use any type of IT or systems in their operations. Table 2 lists different types of systems and the users among Jordanian factories.

Managers were asked about the relationship between supply chain management systems (SCM) and the employment of PIS, and how these systems are related to suppliers' capabilities also. Results indicated that 39 factories employ central

Table 1. Information related to the factories studied

Number of factories according to number of employees		Number of factories according to sales size (in 1000JD)		Number of factories according to number of computers

11	Do you use manufacturing aiding systems	25

systems, 13 factories employ distributed systems, but integrated together. Also, results indicated that 20 factories employed enterprise systems that are utilized in many functions and tasks. Finally, only 8 factories have extended systems that reach suppliers, distributors and customers (SCMS or ERP).

The second part of the survey included items related to the systems used in these factories. 47 managers indicated that they are interested in extending and using part or all of the systems listed in Table 2. Also, the distribution of the source and type of these systems were as follows: 32 factories used locally designed systems, and 33 factories used ready-made exported systems (off-shelf systems).

One of the objectives of this study was to see the relationships between variables like computer diffusion, sales and employee size. This was done through the correlations between those variables to test if any relationship exists between those. Also, to relate demographics with the main objective of this work, we estimated a new construct based on the count of the number of systems employed by the firm (example: manager of firm XYZ checked yes for using three systems (accounting information systems, HR systems and sales systems), so the total number of systems employed were three). This number (or set of data) was correlated against each of the variables mentioned. The correlations matrix is depicted in Table 3.

The results indicated significant correlations between the three variables and the total number of systems deployed. Also, it is shown that significant correlations existed between all three variables.

The Intentions of Managers to Adopt PIS

The second major objective of this study was to explore managers' intentions to adopt or continue using PIS systems utilizing Rogers' IDT model. In a separate study, the researcher employed a

Table 3. Correlations matrix of the demographics against the number of systems employed

	Number of employees	Sales size	Number of computers
Number of employees	1		
Sales size	0.551**	1	
Number of computers	0.636**	0.810**	1
Total number of systems	0.437**	0.394**	0.398**

** Correlation is significant at the 0.001 level survey that introduced a description of PIS and asked questions related to the different constructs of the model. The main source for the items used in the study was Moore and Benbasat (1991) work. The items were translated to Arabic language and tested using 10 experts for language. The nature of this exploratory study makes it convenient to use such method and the size of data allows for such test. Data used a seven point Likert scale, where 1 indicates a high disagreement to the statement and 7 indicates a high approval to the statement. The total number of surveys collected was 91 surveys from factories in Al-Hasan Industrial Zone (total number distributed = 100).

The survey included 3 items for measuring rate of adopting, 5 items for measuring relative advantage, 3 items for measuring compatibility, 3 items for measuring image, 2 items for measuring voluntariness, 2 items for measuring trialability, 2 items for measuring visibility, 4 items for measuring results demonstrability, and 4 items for measuring ease of use. Table 4 shows some descriptive statistics related to constructs.

On the other hand, correlations between all variable depicted in the IDT model were calculated and they are shown in Table 5. All correlations were significant except two and as shown in the matrix (with different levels of significance). Also, all variables were entered to calculate the regression coefficients between the rate of adoption and all variables. Results indicated that a significant correlation exists between the variables and the rate of adoption, where the coefficient of determination R^2 = 27.6%, with a p value less than 0.001 ($F_{8,82}$ = 5.285, p < 0,001). Results are shown in Table 6.

DISCUSSION OF RESULTS

This exploratory work tried to answer two major questions using multiple studies and methods. The first objective was to explore the extent to which PIS are used and adopted in manufacturing companies in Jordan. Through a descriptive survey, opinions were collected from managers of 74 factories in an industrial zone in Jordan. Results indicated that 66 factories (89%) used at least one system related to production and operations. The most popular systems used in Jordan were accounting information systems (60 factories, 81%), and the least used systems were computer aided design systems (23 factories, 31%). Results indicated also that PIS were used in 45 factories (61%), and inventory and warehousing systems were used in 47 factories (63.5%). The results indicated a fair adoption rate for such systems. Part of the reason for that is the influence of partnership with global firms and international organizations that outsource part of their production within Al-Hasan

Table 4. Descriptive statistics related to constructs in the IDT model

Variable	Number of Surveys	Min	Max	Mean	Standard Deviation
Rate of adoption	91	1	7	4.762	1.775

Industrial Zone. It also seems that accounting and human resources systems were more popular as it is a major function for any firm regardless of their size of operations. This conclusion might be as a result of another test we did on the size of firms with respect to their sales and number of employees.

Using supply chain management systems (SCMS) was not that popular as only 8 firms used an extended system (11%), and the reason for that are the distinctiveness of the sample, as the sample in the first study came from an industrial zone, where international contracts are more common and a closed system from the local market is forced in this free zone. Such situation might be in a lesser need to an extended integrated system (SCMS). Finally, enterprise systems were not that popular as only 20 factories indicated using such integrated type of systems (27%)

When trying to explain the results of the correlations between the total number of systems (a measure of usability in this study) and the number of computers and employees and the total sales, it seems obvious that the size of the firm is a

Table 6. Coefficients table for the multiple regression test

Variable	Beta	Std Error	Std Beta	t	Sig
Constant	1.334	1.026		1.301	0.197
Relative advantage	0.246	0.158	0.156	1.556	0.124

Trialability	0.210	0.164	0.154	1.283	0.203
Voluntariness	0.041	0.125	0.037	0.329	0.743

Dependent variable: Rate of adoption, method: enter direct influencer (predictor) of the usability of IT. The larger firms will have higher numbers of employees and larger sales and thus they tend to utilize technology to improve operations and gain competitive advantage in the market. Also, it is logical to conclude that the firm size is directly correlated to complexity of operations and thus firms adopt IT to better control operations and improve flow of material and information. Finally, we can conclude that firms with higher sales will have larger tendency to invest in IT and thus buy more computers and adopt more types of systems.

The second objective was to explore managers' intention to adopt such systems. Results indicated a high intention to adopt PIS because of two main reasons: The first was the high mean values of predictors, which indicates the high perceptions of managers towards the adoption process. All means were above 4.5 out of 7, which indicate a high acceptance rates with respect to all variables used. The second reason for this conclusion is the high significant bivariate correlations with the rate of adoption, and this indicates that the method used and the large number of predictors was a limitation. The only variable with none significant correlation is ease of use and this supports the limitation of the method used. The highest correlation was between rate of adoption and results demonstrability (0.440**).

On the other hand, when summed together, the set of variables competed on the variance and only two variables showed significant prediction of rate of adoption. The two variables are: results demonstrability; the ability to see tangible results out of the system, and ease of use; where the complexity of the system is a huge obstacle to using it. The IDT model explained 27.6% of the variance in the rate of adoption. Results might have some limitations as the IDT have 8 predictors competing on the variance in the rate of adoption and this might limit the ability to explain the dependent variable well. The regression method used was to enter all variables forcefully and this might be the reason behind this surprising result. As this study is an exploratory one, we can conclude that a larger sample size and a thorough conceptual analysis of the predictors will lead to better utilization of variables and better and accurate results.

CONCLUSION

This paper aimed at exploring the status of using IT and specifically PIS in the area of production and manufacturing in Jordan. The study utilized two samples for two separate studies; the first was a sample of managers mainly related to IT in a group of factories in Al-Hasan Industrial Zone and other areas mainly in the Northern part of Jordan to explore the usage of PIS and other types of systems in the industrial area. The second study utilized another sample (after four months and from a different set of factories), from the same area and from the Northern part of the country to test the IDT using an instrument translated from Moore and Benbasat work (1991). Results indicated that systems like accounting information systems and HR and payroll systems were the mostly used among firms and distribution and manufacturing aiding systems were the least used among the sample used. The role of IS in production area was highly appreciated and a major conclusion is that the size of firm indicates the high computer usage and the diversity of systems used.

The second study resulted in high and significant indicators in predicting the adoption rate, and most of the constructs used in the IDT were significantly correlated to rate of adoption. But when regressing all indicators on rate of adoption, only two competed on the variance and yielded significant explanation of the variability of the dependent variable and they were results demonstrability and ease of use.

One of the limitations of this research, which makes its generalizability limited, is the usage of two separate samples. This research utilized two different samples, and to relate the real usage of PIS to the adoption rate, the same sample would have been used. Still the inferred results of this work are valid, but researchers are encouraged to use one sample and extend the size to improve the statistical generalizability. The second limitation of this study is the instrument used; this study used a translated instrument from the original one used in Moore and Benbasat (1991) in English, and thus researchers are encouraged to use the instrument in Arabic to improve the language and improve content and face validity of the instrument. Finally, research related to PIS and the factors influencing the adoption of such systems is not highly popular, which resulted in high competition between variables. The IDT needs a larger sample or dropping some of the variables based on conceptual bases. When exploring systems like ERP or PIS systems, as they are considered complicated and comprehensive systems, one needs to keep relative advantage and ease of use for sure, but further exploration needs to be done to try to deduct the scale size and improve predictability of the model.

FUTURE RESEARCH DIRECTIONS

This research is needed in this area and considered a first step in validating the instrument and testing factors influencing the rate of adoption. It is highly important to continue such research using longitudinal settings to explore the adoption and check the validity of results.

Future research is needed to validate the instrument and apply it to more settings and environments. Another direction that is needed is the multi-stage process applied by Moore and Benbasat (1991), where the adoption rate is investigated with time and also, a better conceptual perspective is reached through the reduction of variable. One idea is to compare other models predictability with the IDT like the Technology Acceptance Model (TAM), the theory of Reasoned Action (TRA), the Theory of Planned Behavior (TPB) and its extension the Decomposed Theory of Planned Behavior (DTPB).

As we now know the situation of PIS usability in industrial zones, would that knowledge facilitate better research in other environments like local industrial areas and other major factories in Jordan? Also, would it result in a different conclusion if we explored other types of systems? Finally, results indicated a weakness in utilizing computer aided design systems, future research can explore the reasons behind such phenomenon and would that be related to the industrial development of the sector in general or because of this global partnership with local factories specifically in the industrial zone.

ABSTRACT

Manufacturing transition is an important part of industrial upgrading. At present, Chinese scholars study the problem of manufacturing chiefly from two perspectives: The first is to discuss the status quo of Chinese manufacturing from the perspective of industrial competitiveness, with countermeasures put forward against manufacturing upgrading. The second is to directly discuss the upgrading of manufacturing from the perspective of global value chain, with the following proposal put forward: Chinese manufacturing upgrading should stretch from the low end to both ends of value chain. In addition, a discussion is also made to the role of producer services in promoting manufacturing, and the role of governmental regulations in upgrading manufacturing. Although these two perspectives are rational, they have some defects: Both of them are based on the hypothesis that the institutional environment in which manufacturing lies is stationary, and manufacturing is considered and measured with systems as exogenous variables; so the impact of institutional environment on manufacturing upgrading is overlooked. Based on reviewing previous literature, this chapter analyzes and discusses the path evolution of manufacturing in the transitional period in mainland China.

DOI: 10.4018/978-1-4666-1945-6.ch054

1 INTRODUCTION

Industry, especially manufacturing, is the foundation and pillar of national economy. To most developed and developing countries, the leading role and fundamental function of manufacturing cannot be replaced by those of any other industrial sector. Since reform and opening-up began over 30 years ago, especially since China joined WTO in 2001, Chinese economy has been developing very rapidly, along with the continuous rise of its economic aggregate. This is closely linked with the swift development of manufacturing. So to speak, the development of manufacturing supports the "ridge" of Chinese economy. The same trend has also occurred to other countries. The governments of many Western countries have again brought forward their plan of "reindustrialization", i.e. paying attention to the important contribution of manufacturing to economic growth. Therefore, China cannot develop its economy without the development of manufacturing. Instead, we must pay attention to the role and function of manufacturing.

At present, Chinese manufacturing develops very rapidly. In the past ten years, both the volume and value of production of Chinese industry have always been growing rapidly. If calculated as per a constant price, the annual average growth of the total production value of Chinese manufacturing from 1995 to 2003 was 14.53%. By 2003, the total production value of manufacturing had reached about 12.27 trillion yuan. According to the calculation of UN Statistics Division and Industrial Development Organization, the annual average growth rate of Chinese manufacturing from 1998 to 2003 reached as high as 9.4%, while the same figure for developing countries in the same period was only 4.4.%. The value of the total export volume of Chinese manufactured goods divided by the number of employees in manufacturing rose from 1763.92 US dollars in 1995 to 9570.09 US dollars in 2004; the annual average growth rate from 1998 to 2001 was 18.30%. Since China joined WTO, the growth rate of export has been increasing more rapidly. The annual average growth rate from 2002 to 2004 reached 22.50% (Jin,et al., 2007). In 2008, the number of manufacturing enterprises in China was 396950, with an added value of 44135.836 billion yuan, total assets of 32340.308 billion yuan, and 77315.7 thousand employees. The number of manufacturing enterprises, total production value, total assets and number of employees in 2008 grew by 174.90%, 497.13%, 243.69% and 67.37% respectively over 2000. Among them, the total production value had the biggest growth rate: nearly 500% (Lin, 2010).

However, behind the rapid development of Chinese manufacturing exists a series of problems yet to be solved in an effective way.

First, the per capita added value of Chinese manufacturing is far lower than the world average. If calculated as per the constant price in 2000, the per capita added value of Chinese manufacturing in 2006 was 610 US dollars, lower than that of the developing regions in West Asia and Europe, Latin America and the Caribbean, merely equivalent to 13.5% of that of industrialized countries (Please refer to Table 1) (Li, et al., 2009).

Second, the regional distribution and industrial structure of Chinese manufacturing are seriously imbalanced. From the perspective of regional distribution, a huge gap exists in the distribution of manufacturing among eastern, central and western China. The total production value, added value, the total assets and number of employees of the manufacturing in eastern China are 73.68%, 68.85%, 70.14% and 72.50% respectively; the same figures in central China are 16.23%, 18.86%, 16.91% and 16.75% respectively; the same figures in western China are 10.10%, 12.29%, 12.95% and 10.75% respectively. From the perspective of industrial structure, the distribution of manufacturing is also imbalanced. Nearly 66% of the added value of manufacturing in 2008 was distributed in ten industrial sectors including ferrous metal smeltering, communication equipment and computer (Lin,

Table 1. International comparison of the per capital added value of manufacturing (the constant price of 2000)

Year Country group	1991	1994	1995	1998	2000	2006
Industrialized countries other than CIS	3573	3614	3730	3996	4291	4509
African countries located to the south of the Sahara	29	26	26	27	27	30
East Asia and South Asia	128	151	164	166	199	267
Latin America and the Caribbean	664	694	680	736	739	792
West Asia and Europe	431	448	460	518	535	664
CIS countries	422	227	216	198	239	369
North Africa	164	162	167	183	195	207
China	167	233	254	313	366	610

Note: The data of China include those of Taiwan Province and Hong Kong Special Administrative Region, but exclude those of Macao Special Administrative Region.

Data source: UN Industrial Development Organization (UNIDO)

2010). This imbalance will lead to the huge waste of human, material and financial resources in eastern, central and western China, especially in central and western China, and the ineffective utilization of resources, thus setting back industrial development and economic progress.

Third, the added value of Chinese manufacturing makes up a relatively high proportion in China's GDP. From 2003 to 2007, the proportion of the added value of Chinese manufacturing in China's GDP did not change a lot, always remaining between 34% and 40%. This proportion was not only far higher than that of such developed countries as USA, Japan, Germany, UK and France, but also far higher than such developing countries as Brazil, India and Mexico. Although some research indicates that China is now in the mature period of new industrialization (Li Gang et al, 2009), but this relatively high index not only reflects the characteristics of industrial structure of China in the middle stage of industrialization, but also indicates that there possibly exists a problem of disproportion to some extent in Chinese economic structure (Jin, et al., 2007).

We should not only develop our economy, but also upgrade our manufacturing. We can solve the problems existing now in Chinese manufacturing only by transforming manufacturing from a low end to a high end and from resource wastage and environmental pollution to resource conservation and environmental protection by applying a series of practical measures. Therefore, so to speak, the sustainable, rapid and healthy development of Chinese economy in the future will be closely linked with the upgrading of manufacturing.

2 THE INTERNATIONAL COMPETITIVENESS OF CHINESE MANUFACTURING

Of all the fundamental theories of industrial international competitiveness having been so far put forward, the most influential are the theory of comparable advantage (Ricardo,1817) and the theory of competitive advantage (Porter,1990; Liu, et al., 2006). In Paul Krugman's International Economics (the most extensively-distributed and authoritative textbook in this field in the world), "comparative advantage" is defined as: "If the opportunity cost for producing a certain product in a country is lower than in other countries, then this country has relative advantage in producing this product". Therefore, the fundamental principle concerning comparative advantage and international trade is: "If a country exports commodities in which it has comparative advantage to another country, then both these two countries can benefit from the trade between them". In contrast, according to the theory of the competitive advantage of nations put forward by Professor Porter, the competition among countries in market economy in fact goes on among enterprises, and enterprises with international competitive advantage are concentrated in only a limited number of industrial sectors. Therefore, industrial sectors should be used as the basic units for studying national competitive advantage. The competitive advantage of enterprises not only comes from themselves, but also originates from the microeconomic foundations on which their development relies---a diamond system consisting of factor conditions, demand conditions, the competitive background of corporate strategy and structure and relevant supporting industrial sectors. Therefore, the attention to national competitive advantage should be focused on the cultivation of these microeconomic foundations (Liu, et al., 2006).

As regards to the index-based appraisal of industrial competitiveness, the industrial competitiveness of a country can be appraised by using more than one index. As indicated by relevant researches, we can derive somewhat different judgments if we appraise the competitiveness of Chinese manufacturing and its subsidiaries by using different indexes. Some indexes reveal that the international competitiveness of a certain industrial sector of China is elevated, while some other indexes reveal that the international competitiveness of this industrial sector of China is declining. As a matter of fact, this phenomenon often occurs when we observe a complicated thing from different perspectives, or the same complicated thing manifests itself in different ways in different aspects. Jin,et al.(2007) combine many indexes into one to express the trend of the change of the industrial competitiveness of China in a comprehensive way. Through due research, they worked out the composite index of the international competitiveness of Chinese manufacturing (Please refer to Table 2).

By comparing Chinese manufacturing with American and Japanese manufacturing, they formed such an opinion: The competitiveness of Chinese manufacturing has always been rising continuously. From the perspective of its subsidiaries, the competitiveness of Chinese manufacturing in "other products" in the above table is the strongest. Office products and telecommunication equipment, whose competitiveness has exceeded

Table 2. The composite index of the international competitiveness of Chinese manufacturing

	The index of comparative advantage	The index of competitive advantage	The composite index of the international competitiveness
Manufacturing	102.8	132.1	117.5
1.Iron and steel	210.0	172.5	191.3
2. Chemical finished products and relevant products	88.2	115.7	102.0
3. Other semi-finished products	98.1	130.5	114.3
4. Mechanical and transportation equipment	119.8	164.1	142.0
Including: Office products and electronic products	134.9	190.9	162.9
5.Textiles	93.5	132.8	113.2
6. Apparel	83.2	113.5	98.4
7.Other products	89.2	108.1	98.7

that of textiles, are called "the second most competitive industrial sector of manufacturing". Transportation equipment (especially automobile), chemical products, integrated circuits and components and power machinery and equipment have the weakest competitiveness in China, with their competitiveness still shrinking continuously. Compared with EU, China has the most obvious disadvantage in chemical products (especially medicines), transportation equipment (especially automobiles) and power machinery and equipment. In contrast, office and telecommunication equipment, other products (especially personal and household goods), apparels and textiles, enjoy a relatively high competitiveness advantage. At last they derived such a conclusion: The present elevation of the international competition of Chinese industrial enterprises is not determined by industrial enterprises to a very large extent; instead, this elevation depends on the development of Chinese finance and mass media. In our opinion, there are two important conditions for guaranteeing the enhancement of the international competitiveness of Chinese manufacturing: One is that Chinese manufacturing enterprises must secure a financial support from Chinese financial enterprises all over the world; the second is that China must have some media (including newspaper, TV and radio) influential in the mainstream crowds in foreign countries (especially European countries and the USA). Therefore, while assisting Chinese industrial enterprises in "going abroad", Chinese government must consider how to assist Chinese financial institutions (especially banks) and media (especially newspaper) in "going abroad".

In addition, Chen et al. (2009) studied the international competitiveness of Chinese and American manufacturing through empirical analysis on the basis of the hierarchy-based opinion of industrial competitiveness. In their opinion, industrial competitiveness consists of four hierarchies, which are in turn (from bottom to top): the source of competitiveness—industrial environment; the essence of competitiveness—productivity; the performance of competitiveness—market share; the result of competitiveness—industrial profitability. These four hierarchies are interlinked and cycled logically. The ultimate goal of industrial competitiveness is to generate profit; to generate profit, we should first prove that we have a stronger industrial competitiveness than other countries in trade; the foundation for enhancing trade competitiveness is to enhance the productivity of this manufacturing sector; to enhance the productivity, we should invest in the construction of soft and hard environments including technical innovation, advanced equipment and education & training; the capital resources for investment in environments rely on industrial profit in turn. Only by investing in environments (the first hierarchy) with profits (the highest hierarchy of competitiveness), can we enter the new-round cycle of productivity and market share, and can we acquire continuously-reinforced market competitiveness. On this basis, they analyzed the international competitiveness level of 30 types of manufacturing in China, and derived an inconsistent conclusion: Measuring industrial competitiveness with the index of profitability and the index of productivity has a very high goodness of fit, which proves that the industries with a higher productivity will also have a higher profitability in Chinese domestic market. However, the result of sequencing based on the index of profitability and the index of productivity is quite different from the result of sequencing based on the index of market share: Gamma coefficient is negative, which proves that the industrial sectors with a higher profitability and a higher productivity do not necessarily have a bigger global market share, or things may happen the other way round. This proves that the first hierarchy and explanatory variable of industrial competitiveness---the factor of industrial environments, exerts a very great influence upon the status of competitiveness; industrial structure, industrial policy, trade policy, system environment, etc. can bring about some difference among the three competitiveness indexes. Compared with Chinese manufacturing, not only are the indexes of the hierarchy of profitability and the hierarchy of productivity in American manufacturing interrelated, but also the competitiveness indexes of the hierarchy of market share and the hierarchy of productivity are somewhat interrelated; namely, the sequencing results of these three competitiveness indexes are not quite different. This proves that American manufacturing has a more mature development environment than Chinese manufacturing, so production efficiency can be smoothly transformed into market share and profit in the USA. From this we can see the importance of environments, namely, the important influence of such factors as systems upon the upgrading of manufacturing.

3 THE UPGRADING OF MANUFACTURING FROM THE PERSPECTIVE OF GLOBAL VALUE CHAIN

To discuss the upgrading of manufacturing from the perspective of global value chain is the mainstream of the contemporary research into industrial upgrading. As the internationalization of contemporary economy becomes more and more intensified, features that are different from those of the previous tide of globalization have occurred to production, trade, investment, turnover, means of organization, etc. As known to all, division of labor is the source of economic growth, while industrial transfer is an important means to realize spatial division of labor. As international division of labor is intensified from among industries to among different products in each industrial sector, and then to different working procedures of each product, international industrial transfer is also evolved from spatial transition among different industries to that among different products, and then to that among different working procedures of each product. The intensification of division of labor and industrial transfer are the key contemporary features of this globalization different from those of the previous rounds of globalization. On the other hand, global value chain is the leading force for boosting the intensification of division of labor and coordinating industrial transfer. This leading force has not only changed the microscopic foundation of globalization, but also produced a revolutionary effect upon competition models and development strategies.

As regards to the theory of global value chain, an American scholar (Michael E Porter,1985) put forward the theory of Value Chain from the perspective of the theory of enterprise competition strategies. This theory is a theoretical framework for analyzing enterprise activities under the condition of international competition. Its core opinion is: The value created by enterprises in fact originates from some specific value activities on a relevant value chain. Grasping “strategic link” is a key factor for controlling the entire value chain and relevant industrial sector. In 1990s, a scholar(Gereffi, Korzeniewicz,1994,1999)put forward the theoretical framework of Global Commodity Chain. This theory directly related the value-added chain with global industrial organizations, and therefrom made a comparative research into the commodity chain driven by producers and purchasers. To eliminate the limitation of the word “commodity”, and highlight the importance of the creation of the relative value of enterprises and the acquisition of value on the chain, Gereffi and numerous researchers in this field reached an agreement at the beginning of the 21st Century to replace global commodity chain with a term “Global Value Chain (GVC)”. The classification of global value chains is basically based on the dichotomy under the framework of global commodity chain, namely, the producer-driven value chain and purchaser-driven value chain put forward by Gereffi. The producer-driven value chain means boosting market demand through producers’ investment, thus forming a system of vertical division of labor of local production supply chain. Under this value chain, investors include not only transnational companies blessed with technical advantages and seeking for market expansion, but also national governments trying hard to boost local economic development and set up an independent industrial system. The purchaser-driven value chain means that large purchaser organizations blessed with strong brand advantages or sales channels coordinate and control production, design and marketing activities that aim at the target market. This value chain is featured by labor intensiveness and represented by consumer goods (e.g. apparel, shoe, toy, consumer electronics, etc.).

Another important content of the theory of global value chain is about the governance model of value chain. So far, no uniform conclusion has been reached in the academic circle on the classification of the governance models of global value chain. As regards to the governance models of global value chain, Humphrey, Schmitz(2002) made a distinction among the following four governance models on the basis of the difference of organization coordination and power distribution: market-based model; model based on equilibrium network; capture-based model; hierarchy-based model. The enterprises in developing countries generally enter the assembly and manufacturing link of capture-based GVC as subcontractors by relying on cheap labor force. The high competition and low income brought by low-entry barriers make subcontracting enterprises face a huge pressure of upgrading. Through an empirical analysis into the textile and apparel sector of industry in the world, Gereffi(1999)worked out the sequential upgrading model under GVC, namely technical upgrading—product upgrading---functional upgrading—chain's upgrading, and optimistically held the opinion that the subcontracting enterprises in developing counties can smoothly realize this kind of sequential upgrading by joining GVC and accepting the supports from leading enterprises in developed countries in such aspects as technical diffusion, employee training and equipment introduction. With this sequential upgrading, the performance of subcontracting enterprises, namely the quantity of value created and acquired by them, also increases gradually. Gereffi's analysis has two problems: First, as indicated by a lot of practice of developing countries, the above-mentioned model of sequential upgrading cannot be realized automatically (Humphrcy,Schmitz,2002). In addition, upgrading will change the contrast of powers and the structure of income distribution in GVC. Therefore, the upgrading of subcontracting enterprises is subject to suppression from leading enterprises. The size of upgrading barrier depends on the governance model of GVC. Next, upgrading does not necessarily mean the enhancement of the performance of subcontracting enterprises. In the capture-based GVC, the upgrading of subcontracting enterprises is a kind of passive upgrading aiming to obey the global strategies of leading enterprises. By continuously searching for and supporting new subcontractors and intensifying competition, leading enterprises capture the newly-added value created by the upgrading of subcontracting enterprises. In contrast, in the market-based and network-based governance with more equivalent powers, enterprise upgrading is a kind of active upgrading adapting to competition and seeking for profit, and can accordingly acquire the benefits brought by upgrading. According to the research of Liu (2007), and in connection with the practice of developing countries, Zhuo(2009) worked out four matching models of management, upgrading and enterprise performance: (1) Market-based management—(independent and slow sequential upgrading)—(slow enhancement of performance). Under this governance model, the transaction target is mature standardized products; the division of labor and transaction among enterprises are based on market contracts marked by "at arm's length"; therefore, enterprise upgrading is a kind of endogenous and independent upgrading based on competency. This upgrading is free from the control and hindrance of other enterprises, but it is relatively slow, so the enhancement of enterprise performance is also progressive. (2) Governance based on equilibrium network ---(independent and fast sequential upgrading)—(fast enhancement of performance). Governance based on equilibrium network is a coordination method of division of labor and transaction based on the mutual supplementation of competency, the sharing of knowledge and technology and relative equality; it does not involve a relationship between controlling and being controlled; therefore, enterprises can independently carry out upgrading in various forms. In this kind of network, the partial innovation required by high-degree division of labor greatly reduces the investment required by upgrading and mitigates investment risks, while the sharing of competency, technology and knowledge accelerates the realization of upgrading and the enhancement of performance. (3) Capture-based management---(rapid but passive technical upgrading and product upgrading)—(it is difficult to enhance the performance, or even the performance declines). In capture-based GVC, in order to guarantee the diversity of products, the timeliness of supply and the reliability of product quality, transnational companies of developed countries have to assist subcontracting enterprises in accelerating technical upgrading and product upgrading. In addition, by such means as patent pool, strategic isolation, brand reinforcement and retail market merger, they endeavor to raise the entry barriers for links with a high additional value including design, R & D and marketing, and slow down the process of the functional upgrading and chain's upgrading of subcontracting enterprises, so as to prevent their core competency and income from being eroded. Under such circumstances, it is generally difficult to realize the sequential upgrading of subcontracting enterprises, and the income created by the rapid technical and product upgrading is also captured by transnational companies as a result of the intensification of the competition in the assembly manufacturing link. (4) Hierarchy-based management--- (rapid but passive technical upgrading, slow product upgrading)—(it is difficult to enhance the performance greatly). Hierarchy-based governance model is a method of production organization and coordination. Under this model, in order to reduce their cost and occupy the market, transnational companies of developed countries establish joint ventures through FDI in other countries, and control and operate enterprises by relying on such core competencies as ownership and R & D design. In the hierarchy-based GVC, as joint ventures can directly obtain the technology, brands, capitals and equipment of transnational companies, they can realize technical upgrading rapidly, and make their products meet the uniform global quality standards of transnational companies. Under this model, product upgrading is relatively slow because of its dependence on the market development and competition status of the countries to which the investment is oriented. Moreover, functional upgrading and chain's upgrading are strictly controlled by transnational companies. On the other hand, it is difficult to greatly enhance the performance of joint ventures, because transnational companies try to squeeze the profit margin of joint ventures by collecting a high fee of technical transfer, key parts and components, and brand licensing.

With the Yangtze River Delta as its research subject, Liu, et al.(2009) analyzed the disadvantages of Chinese manufacturing upgrading under GVC. In their opinion, merging into GVC has weakened the relationship among industrial departments in different regions in China, and exerted an unfavorable influence upon the integrated development of regional substantial economy. The technology transfer and technology spillover embedded in outsourcing and subcontracting activities have an obvious "breakpoint" and "isolation" effect upon the industrial development of developing countries. The imbalance and asymmetry of GVC income distribution lead to the difficulty in fund accumulation. In the "captured" value chain, owing to the change of the global competition environment, the continuous entry of suppliers and the competition effect of cheap commodities, the foundation for the existence of some previous obvious advantages that can be acquired by relying on international big purchasers has already been seriously eroded, and has been replaced with more and more obvious defects and shortcomings, which constitutes a serious threat and hazard to the industrial upgrading process of developing countries. Under GVC, as international subcontractors, enterprises of developing countries will, while molding their global brands and independently building sales terminal channels at home and abroad, meet with "the positional block" of transnational companies that control core technical patents and product standard systems and international big purchasers that control the sales terminal passages and brands of international demand market. Therefore, through the so-called "Learning by exporting", the skills of product and technical upgrading can be learned at most, and the real core technology and functional upgrading skills cannot be learned at all. For this, they held the opinion that the export-oriented development strategy based on GVC has made a huge contribution to economic takeoff during the early stage of economic development of Yangtze River Delta. However, in order to make Yangtze River Delta really become a base of advanced manufacturing and transfer from manufacturing to creation, we cannot merely rely on this development strategy. On the basis of attaching equal importance to international and domestic market, we should try to integrate the industrial relevancy and cycle system on which Chinese enterprises rely for survival and development, mold the governance structure of domestic value chain, and adjust the relationship structure among Chinese industries located in different regions, so as to lay a solid development platform for the manufacturing upgrading of the Yangtze River Delta and the integrated development of regional economy.

4 THE UPGRADING OF MANUFACTURING FROM OTHER PERSPECTIVES

Promoting the upgrading of manufacturing by developing producer services is an indirect upgrading method. Modern Producer Services is an industrial sector offering direct services to productive or commercial activities as intermediaries, including finance, insurance, accounting, R & D design, law, technical and management consultancy, transportation, telecommunication, modern logistics, advertising, marketing, brand, personnel, administration and property management. Obviously featured by high knowledge, intelligence, growth, employment and influence, it is derived from the matrix of manufacturing. Therefore, it has a natural and intrinsic industrial relevancy or interaction with manufacturing. As indicated by the research of Park and Chan (1989), the development of manufacturing can bring about that of producer services, which can, in turn, promote the upgrading of manufacturing. There is an obvious positive relevancy between them. In contrast, by arguing from an opposite perspective, Farrell and Hitchens (1990) pointed out that the lack of producer services or the inadequate price and competitiveness of producer services in a region will set back the efficiency, competitiveness and operation of local manufacturing, thus destroying the development process of this region. Some other scholars, including Zhi (2001) and Zhou(2003) analyzed this from the perspective of industrial amalgamation. As pointed out by them, with the continuous advancement of information technology revolution, the traditional boundary between services and manufacturing becomes vaguer and vaguer, and they tend to develop in an interactive and amalgamated way. Liu(2008) also held the opinion that the development of producer services can reduce the installation cost of manufacturing enterprises, thus assisting enterprises in forming their core competitiveness and forming their interaction in industrial relevancy.

5 CONCLUSION

There are a lot of research literatures of experts and scholars on the upgrading of manufacturing. All the researches into the upgrading of manufacturing, from such perspectives as industrial competitiveness, global value chain and "the indirect method of upgrading", have their respective theoretical bases and realistic significances for existence. All of them have made their respective due contribution in this regard. However, all the existing literatures neglect to study the upgrading of manufacturing from the perspective of the entire national systems, which is a macroscopic perspective that is difficult to grasp. From the emergence of institutional economics in the field of economics to the gradual perfection of new institutional economics, we should abandon those things regarded as hypothetical exogenous variables in the past, and turn these exogenous variables into endogenous ones, and study some practical problems from this perspective. We can discover some useful things from both transaction costs and institutional history, and from both the national theory of new institutional economics and its enterprise theory, so that we can study and practice the upgrading of manufacturing in a better way.

Economic development cannot do without systems, because economic development needs to be promoted by people, and people promote economic development by working out some systems. Such an objective fact as economic development is promoted by people subjectively. Therefore, it is very important to study this kind of subjective representation and some things hidden behind it. For example, in Chinese industrial upgrading, the promotion of government plays a very great role. However, in the process of decision making, the government does not always have a very thorough understanding of industrial upgrading. A very big misunderstanding has occurred in the present industrial upgrading, namely: as understood by many of us, the industrial upgrading can be realized through a transition from the low-level facet of one industrial sector to the low-level facet of another. As a result, we always provide processing sites to large transnational companies of developed countries under economic globalization. Many people understand this simple transfer from the low end of one industrial sector to the low end of another as industrial upgrading, which is, as a matter of fact, very unreasonable. Therefore, how to standardize this kind of understanding and the behaviors of the government from the perspective of systems, and how to measure the opportunity cost of this kind of upgrading from the perspective of transaction cost, will be an indispensible part of our future research.

ACKNOWLEDGMENT

I would like to express my sincere gratitude to the financial aid of Natural Science Foundation of China (grant number:70971031, 71031003), Sanjiang University (project number: K08010),and the innovation project for the graduate students of the Business School of Nanjing Normal University(project number:10CX_003G).

ABSTRACT

This chapter presents a double complementary international collaboration approach between the University of Bordeaux 1 (UB1) and Harbin Institute of Technology (HIT). Within this framework, the higher education collaboration (dual Master's degree programme) is supported by research collaboration that has existed for more than 15 years. Furthermore this collaboration is based on the complementarities of competencies of the two sides: production system engineering (UB1) and software system engineering (HIT). After a brief introduction on the background and overview, the complementarities between UB1 and HIT are assessed. Then a formal model of the curriculum of the dual UB1-HIT Master's programme is shown in detail. A unified case study on manufacturing resource planning (MRPII) learning is presented. Preliminary results of the Master's programme are discussed on the basis of an investigation carried out on the first two cohorts of students.

BACKGROUND AND OVERVIEW

Research relationships between the University of Bordeaux 1 (UB1, France) and Harbin Institute of Technology (HIT, China) exist for several years and both parties have established strong and long-term relationships with their industries over some 30 years. In the research domain on computer integrated manufacturing and production system engineering and integration, the cooperation between the University of Bordeaux 1 (IMS-LAPS: Laboratory for the Integration of Materials into Systems-Automation and Produc-

DOI: 10.4018/978-1-4666-1945-6.ch055

tion Science Department) and China started in 1993. Several Europe-China projects coordinated by UB1 have been carried out (1993-1995; 1996-1997; 1998-2002) in this domain, involving more than 7 major Chinese universities such as Tsinghua University, Xi'an Jiaotong University, Harbin Institute of Technology, Huazhong University of Sciences and Technologies, and others. More recently, the cooperation between the University of Bordeaux 1 and Harbin Institute of Technology has been strengthened to develop enterprise interoperability research activities in the Interop Network of Excellence (2004-2007) programme under the auspices of the European 6th Framework Programme for Research & Development (FP6) (European Commission, 2003b).

There is a long and strong cooperation between UB1 and HIT in research on other topics as well, including enterprise system modelling, engineering and integration. However co-operation in higher hducation was not so well-developed in the past. Consequently, it was logical to extend the existing co-operation from the research base to incorporate higher education.

Therefore, in September 2006 UB1 and HIT launched a dual master's degree programme on enterprise software and production systems. This programme relies on the know-how of HIT in computer sciences and enterprise software applications, and of UB1 in enterprise modelling, integration and interoperability research.

This joint international programme aims to train future *system architects* of production systems, with the ability to model, analyze, design and implement solutions covering organization, management, and computer science in order to improve performance of both manufacturing and service enterprises. It also aims to develop the capabilities of students to develop and grow in an international working environment particularly in China or France but also in most other countries where the themes covered by the programme are now and will continue to be vital.

The programme is organized over two years. The first year's courses are given in HIT and are concerned with industrial oriented computer sciences. The second year's courses are given in UB1 and dedicated to production management and engineering. The first two cohorts of the master's programme have successfully completed their studies and their industry internships in China and France and have obtained the Master's Degree of the University of Bordeaux 1 and the Master's Degree of Harbin Institute of Technology in September 2008 and 2009.

Table 1 gives an overview on the organization of the two year programme. All courses are presented in English, including examinations and internship defense. One characteristic is that the industry internship can be carried out in China, or in France or in any third country in the world.

• Option (45h / 3 ECTS),
• Training in enterprise (450h / 30 ECTS).</td></tr>
</table>

The internship placements are mainly in companies, large as well as small/medium enterprises (SMEs), which have industrial co-operation projects with China, but not necessarily limited to that. Besides IT-oriented work, the internships are situated in the manufacturing industry sector as well as that of the services, typically as a responsible person in charge of industrial management (production, quality, and maintenance), a person in charge of design, development and implementation of software applications, a consultant, or a project leader.

COMPLEMENTARITIES UNDERPINNING THE COLLABORATION

Software Engineering and Production System Engineering

As mentioned above, this collaboration is based on the complementary strengths of UB1 (production system engineering) and HIT (software system engineering).

Considering an enterprise from the general point of view as a system providing goods and services or, from the narrower point of view of its information system, it is clear that both of these approaches relate to the fundamental philosophy of engineering. In both cases the purpose is to design an overall architecture for the system, consistent and relevant to a predefined mission. Models and simulations have a central role in both approaches.

Production system engineers view the enterprise as a system having a purpose related to a strategy. Within this purpose and strategy, performances are defined and enable the evaluation of how well the enterprise runs.

The necessity for communication and co-operation between sections within a company or between companies within a network has led to the important concept of integration. Today, the numerous forms of co-operation and the versatility they require brings into prominence the concept of interoperability that can be broadly understood as a loose integration.

Because of the complexity of the enterprise, it is always considered to relate to a *reference* (a conceptual model or reference architecture). With respect to this reference, the engineering methodologies used are supported by modelling languages and frameworks (enterprise modelling), the role of which is to enable the understanding of the structure and behavior of the enterprise. The existing diversity of languages and software supports leads to the need to analyze them in detail, in order to compare them and potentially use them together. In this perspective, a pure syntactical approach is not enough, and therefore current scientific developments in this field are related to semantics and deal with meta-models and ontology.

Furthermore, the consideration of the human-being as a component of the enterprise must always be remembered. For this reason the relation of the models with decision-making (of design and/or of management) is an important issue, whatever the approach used.

From a software engineering point of view, the need for integration can be matched through the provision and the implementation of software tools, mainly enterprise resource planning (ERP) tools. This domain then focuses on IT solutions analysis, implementation projects, IT solution performance analysis, and the identification of the usability domain and the limitation of classical methods. The ways in which the functions of the information system are integrated using such IT tools is globally understood today. Organizational challenges are also quite well known. The main outstanding issues relate to supporting the processes of the enterprise by consistently integrating the several IT solutions that have functionalities that generally cover more than is required. In this context, the capability to match the models of the enterprise (the requirements) with the models emerging from the IT solutions (the so-called space of solutions) becomes crucial. Finally, a continuing core problem is ensuring a permanent alignment of the information system and its various implemented IT solutions with the strategy of the company. Because the economic environment is dynamic, this leads, of necessity, to a policy of continuous engineering.

In summary, the two domains relate both to the design, integration and control of systems under performance conditions. In order to match the dynamic requirements and take changing constraints into account, it is necessary to continually improve the understanding of the interactions between the various models and to gather and integrate the various points of view such as organization, software, etc. In this drive to keep on improving performances, the exploitation of the complementarities between software engineering and production systems engineering is a thoroughly necessary requirement.

Enterprise Interoperability as an Emerging Topic Related To These Complementarities

Enterprise interoperability is a topic currently emerging at the confluence of software engineering and production systems engineering. It is a topic of considerable and growing scientific and technical research, fundamentally because of the considerations presented above.

Worldwide, the competitiveness of enterprises, including SMEs, will strongly depend in the future, on their ability to develop and implement massively and rapidly networked dynamic organisations. New technologies for interoperability within and between enterprises will have to emerge to radically solve the recurrent difficulties encountered - largely due to the lack of conceptual approaches - to structure and interlink enterprises' systems (information, production, decision) (European Commission, 2003b).

Today, research on interoperability of enterprise applications does not exist as such. As a result of the IST Thematic Network IDEAS (Baan, 2003), the roadmap for interoperability research emphasises the need for integrating three key thematic components, shown in Figure 1:

- software architectures and enabling technologies to provide implementation solutions
- enterprise modelling to define interoperability requirements and support solution implementation
- ontology, to identify interoperability semantics in the enterprise.

Interoperability is seen as the ability of a system or product to work with other systems or products without special effort on the part of the user/customer (Baan, 2003).

The ISO 16100 standard (2002) defines manufacturing software interoperability as the ability to share and exchange information using common syntax and semantics to meet an application-specific functional relationship through the use of a common interface. The interoperability in enterprise applications can more simply be defined as the ability of enterprise software and applications to interact usefully. The interoperability is considered to be achieved if the interaction can, at least, take place at the three levels: data, application and business enterprise through the architecture

Figure 1. Three key thematic components and their integration (Baan, 2003; European Commission, 2003b)

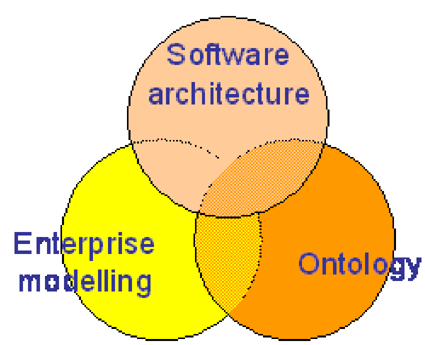

Figure 2. The three levels of interoperability (European Commission, 2003a)

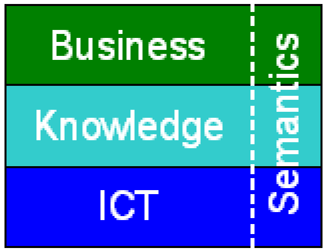


of the enterprise model and taking semantics into account, as shown in Figure 2.

At the beginning of the 2000s, research in the interoperability domain in Europe was badly structured, fragmented, and sometimes overlapping unnecessarily. There was no unified consistent vision and no co-ordination between various European research centres, university laboratories and other bodies. Not only was this the case with the pure research, but it was true in the training and education areas as well. To improve this situation, two important initiatives were launched by the European Commission: Interop Network of Excellence and Athena Integrated Project (European Commission, 2003a; 2003b).

The Interop Network of Excellence and the Athena Integrated Project

Interop NoE was a Network of Excellence (47 organizations, 15 countries) supported by the European Commission for a three-year period (2003-2006) (European Commission, 2003b). This Network of Excellence aimed to extract value from the sustainable integration of these thematic components and to develop new industrially significant knowledge. Interop's role was to create the conditions of a technological breakthrough to avoid enterprise investment being simply pulled by the incremental evolution of the IT becoming commercially available.

Consequently, Interop's joint programme of activities aimed to:

- integrate the knowledge in ontology, enterprise modelling, and architectures to give sustainable sense to interoperability
- structure the European research community and influence organisations' programmes to achieve critical research mass
- animate the community and spread industrially significant research knowledge outside the network.

In more detail, the joint research activities were composed of the following work packages:

- enterprise modelling and unified enterprise modelling language (UEML): unifying for interoperability and integration
- ontologies for interoperability
- domain architecture and platforms
- domain interoperabiliy
- synchronization of models for interoperability
- model driven interoperability
- model morphisms
- semantic enrichment of enterprise modelling, architectures and platforms
- business/IT alignment
- methods, requirements and method engineering for interoperability
- interoperability challenges of trust, confidence/ security
- services/take-up towards SMEs.

Athena (Advanced Technologies for Interoperability of Heterogeneous Enterprise Networks and their Applications) was also an Integrated Project supported by the European Commission for the three-year period (2003-2006) (European Commission, 2003a).

Its objective was to be the most comprehensive and systematic European research initiative in the field of enterprise application interoperability, removing barriers to the exchange of information within and between organizations. It would perform research and apply results in numerous industrial sectors, cultivating and promoting the *networked* business culture. Research and development work was carried out hand in hand with activities conceived to give sustainability and community relevance to the work done. Research was guided by business requirements defined by a broad range of industrial sectors and integrated into piloting and training. Athena would be a source of technical innovations leading to prototypes, technical specifications, guidelines and best practices, trailblazing new knowledge in this field. It would mobilize a critical mass of interoperability stakeholders and lay the foundation for a permanent, world-class hub for interoperability.

Projects running within Athena were organized in three action lines in which the activities would take place. The research and development activities were carried out in action line A. Action line B would take care of the community building while action line C would host all management activities (European Commission, 2003a).

Concerning the R&D action line, six projects were initially defined as follows:

- enterprise modelling in the context of collaborative enterprises (A1)
- cross-organisational business processes (A2)
- knowledge support and semantic mediation solutions (A3)
- interoperability framework and services for networked enterprises (A4)
- planned and customisable service-oriented architectures (A5)
- model-driven and adaptive interoperability architectures (A6).

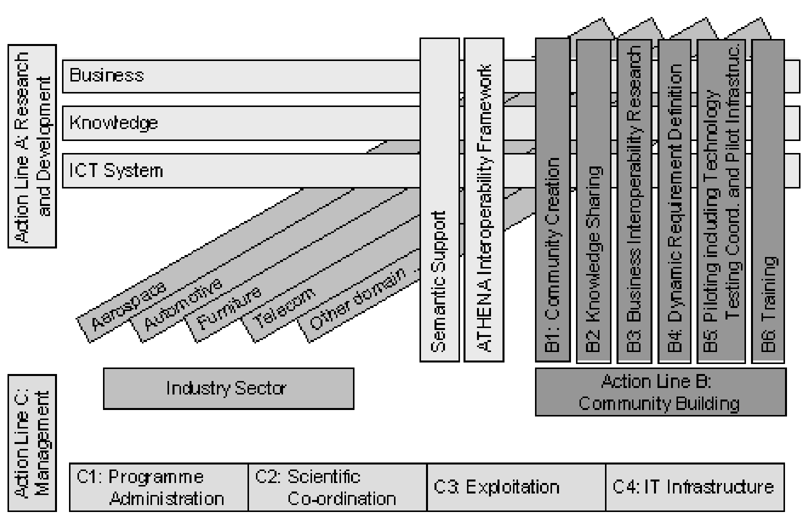
Relations between the three action lines are shown Figure 3.

Interop NoE and Athena IP have strongly influenced and contributed to research and development on enterprise interoperability in Europe and beyond. Harbin Institute of Technology was also been invited to participate in Interop NoE meetings and in the creation of the Interop Virtual Laboratory which is considered one of the important achievements of this Network of Excellence.

The Interop Virtual Laboratory (Interop-VLab)

Interop-VLab, a sustainable European scientific organization, is the continuation of the Interop

Figure 3. Interaction of Athena action lines



Network of Excellence. It aims at federating and integrating current and future research laboratories, both academic and industrial, in order to fulfil objectives that a participating organization would not be able to achieve alone. It is supported by local institutions to promote interoperability in local industry and public administration. Interop-VLab's mission includes the following:

- **Promoting the enterprise interoperability domain and acting as a reference**: establishing a sustainable organization, at European level, to facilitate and integrate high level research in the domain of enterprise interoperability and be a reference for scientific and industrial, private and public organisations
- **Contributing to the European Research Area**: contributing to solving one of the main issues of the European Research Area - the high fragmentation of scientific initiatives - by synergistically mobilizing European research capacities, enabling the achievement of critical mass by aggregating resources to match major future research challenges that would not be possible by individual organisations
- **Developing education and professional training**: promoting and supporting initiatives of European higher education institutions in the domain
- **Promoting innovation in industry and public services**: facing the industrial challenge of creating networks and synergies, Interop-VLab aims to promote and support applied research initiatives addressing innovation and the reinforcement of interoperability between enterprises, at European, national and local levels; this approach will also help to create synergy between European, national and local research programmes.

Harbin Institute of Technology is the leading partner of the China Pole of Interop-VLab. The China Pole is constituted of ten important Chinese universities spread across China. Besides research related projects, an Interop master's degree programme involving Interop-VLab members including HIT and UB1 was also planned.

FORMAL MODEL OF THE UB1-HIT DUAL MASTER'S DEGREE CURRICULUM

This section presents the details of the dual UB1-HIT master's degree curriculum. Because this programme is built on two separate disciplines and carried out in two locations in two different countries, the main challenge to its success would be the development of a deep mutual understanding of the curriculum implemented in each location and a close collaboration between the two teams, to avoid unnecessary redundancies and emphasizes synergistic complementarities. To meet this objective, a detailed and explicit representation of the curricula was necessary.

Usually university training curricula are presented in a textual form, often using tables. In general, inter-relationships between various courses and lectures tend not to be identified and/or explicitly described and considered. Sometimes this can create difficulties for students in fully understanding the relationships between component courses and their logic, and consequently in mastering the overall knowledge that they need to acquire (Alix et al., 2009).

Based on the feedback from the students after three years running on an experimental basis, it is necessary to present the master's degree programme overall curriculum in a more formal and explicit way so that both students and teachers on both sides can have a clear and unambiguous understanding of the contents of the programme and of their roles within it. Therefore, the purpose of this section is to present the formal model of the

UB1-HIT dual master's programme curriculum. Unified Modelling Language (UML) was chosen to model the lectures delivered in the two years and the possible relationships between the series of lectures in the two years. Complementarities and potential future improvements are also discussed below.

Model of Year 1 Curriculum in HIT

This section describes and model of the Year 1 curriculum carried out at Harbin Institute of Technology School of Software in China. The objective of the Year 1 training is focused on software engineering, information systems analysis and design, programming techniques and IT project management.

This curriculum is mainly organized in three modules as shown in Figure 4: Language; Science and Methodology; IT Technique.

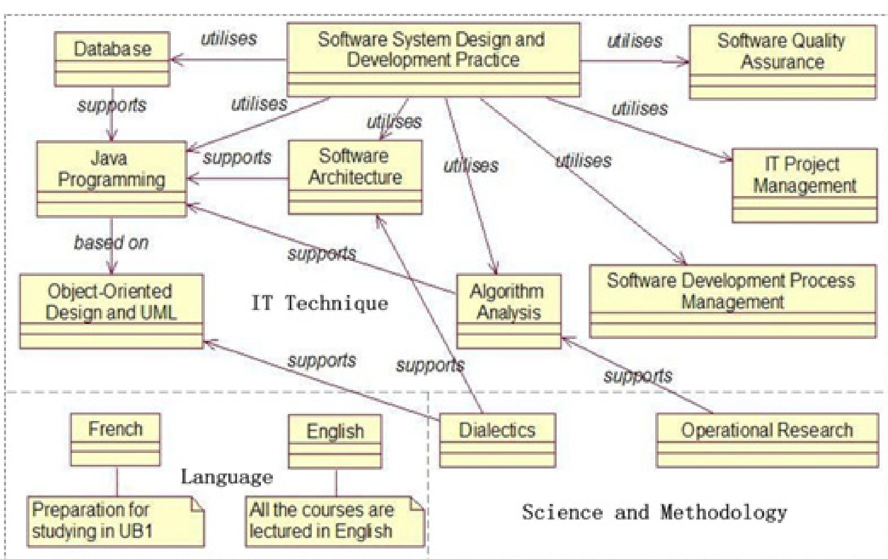
In the Language module, there are two courses, English and French.

- **English:** Because of all the courses of this joint master's programme are in English, a command of English is very important. The objective is to give the students the ability to read and write reports/papers in English, and to communicate with professors fluently, orally and aurally, in English.
- **French:** This course aims to teach the Chinese students daily French, which can help them to adapt to French daily life when they arrive in France.

The Science and Methodology module aims to teach students how to carry out scientific research, how to analyse the objects in the universe and the relationships among them. This module contains two courses, dialectics and operational research.

- **dialectics:** This course is to teach students the resolution of disagreement through rational discussion and ultimately the search for truth.
- **operational research:** This shows how to use mathematical modelling, statistics, and algorithms to develop optimal solutions to solve complex problems, improve decision-making, and make process efficiencies, to finally achieve a management goal.

Figure 4. UML model of year 1 curriculum at HIT



The IT Technique module is the main part of the first year study. This centres on software engineering. It offers a series of IT technique courses, such as databases, Java programming, etc., as well as a series of software management courses, such as software quality assurance, IT project management, etc.. In addition, there is a practical course in this module, in order to put both IT and project management knowledge into practice.

- **IT:** this set of modules aims to teach students the skills of design and implementation of IT solutions for different kinds of firm. The modules are as follows.
    - **databases:** this module focuses on how to use a relational database, including, designing a proper entity relationship model (ERM), creating correct data view based on ERM, querying data by structured query language (SQL), defining store procedure for a database, etc.
    - **algorithm analysis:** this module is an important part of broader computational complexity theory, providing theoretical estimates for the resources needed by any algorithm to solve a given computational problem: it shows how to analyze an algorithm, how to determine the amount of resources (such as time and storage) necessary to execute it, and finally achieve the goal of optimising the program.
    - **software architecture:** this module shows how to analyze, design and simulate the structure or structures of the system - the software components, the externally visible properties of those components, and the relationships between them.
    - **Java programming:** this module introduces one of the most popular programming languages: after completing this module, students should have the ability to implement an executable application and learn other programming languages by themselves.
    - **object-oriented design and UML:** unified modelling language (UML) is a standardized general-purpose modelling language in the field of software engineering: it includes a set of graphical notation techniques to create visual models of software-intensive systems; after this course, students should have the ability to use UML to design a proper software system model.
- **Management:** This set of modules contains lectures on the methodology of IT project management. The courses involve the following modules.
    - **software quality assurance (SQA):** this topic covers the software engineering processes and methods used to monitor and ensure quality: it encompasses the entire software development process - software design, coding, source code control, code reviews, change management, configuration management, and release management.
    - **IT project management:** this topic shows how to lay out the plan for an IT project, and how to realize, and anticipate and avoid the risks of failure of the IT project development: after this course, students should be able to use the methodology learned to reduce the cost of the IT project and to make the project efficient and as successful as possible.
    - **software development process management:** this module gives more details about SQA and IT project management in the development phase of a project.

- **Practical work:** This module gives students a chance to put their knowledge into practice. Students are required to manage a full IT project by themselves, from requirement analysis, system model design to software implementation, test, and then software deployment: after completing this module, students will have an overall understanding of software engineering.

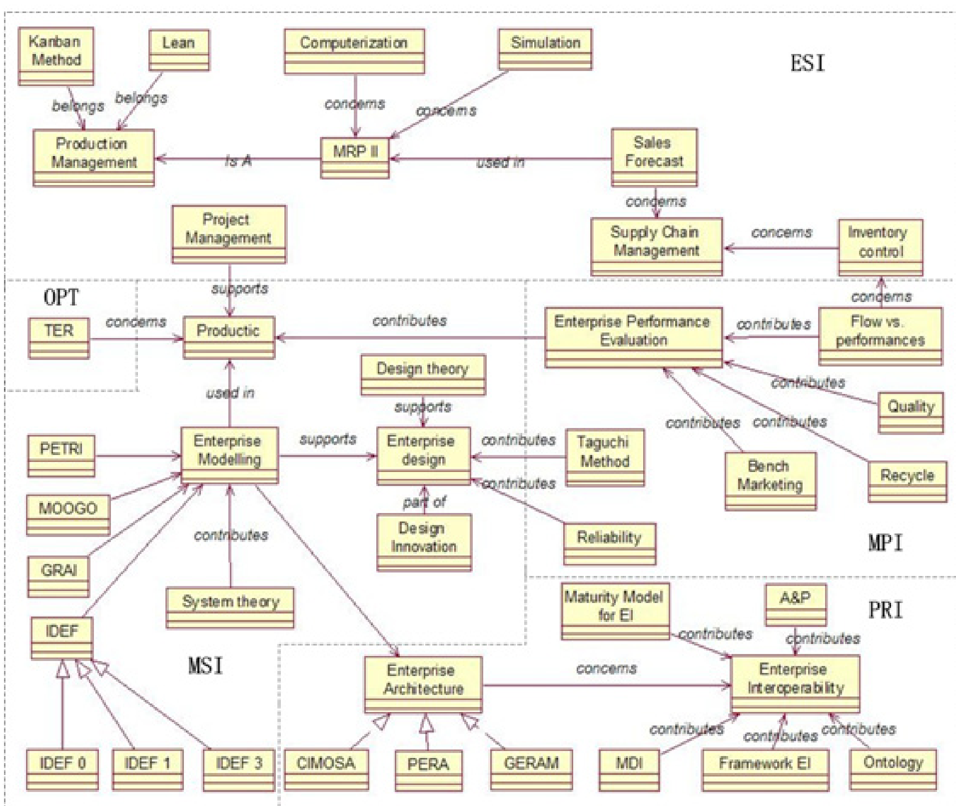
Model of Year 2 Curriculum in UB1

This section presents the model of the Year 2 curriculum at the University of Bordeaux 1 in France. The objective of this training is focused on enterprise system engineering, and in particular, enterprise modelling, production management, enterprise integration and interoperability.

The curriculum of year 2 is organised in five modules, as shown in Figure 5: MSI (industrial system modelling); ESI (industrial system management); MPI (industrial system performance); PRI (industrial system integration); OPT (option - bibliographical research work).

The MSI module is mainly concerned with enterprise modelling and design. It starts with a lecture on system theory, laying down the fundamental concepts of the systemic view of the enterprise. Then enterprise modelling focuses on GRAI (graphs of interlinked results and activities) and IDEF (integration definition) methodologies (IDEF0 function modelling, IDEF1 information modelling and IDEF3 process modelling). The MOOGO (method for object-oriented business process optimization) process modelling tool developed by the Fraunhofer Institute for Produc-

Figure 5. UML model of year 2 curriculum at University of Bordeaux



tion Systems and Design Technology (IPK) of Berlin and Petri net formal modelling are complementary to GRAI and IDEF. Productic (production science) is a lecture presenting the general problems and state-of-the-art of enterprise engineering. In parallel, design theory and innovation are presented to allow understanding of the basic concepts and principles of enterprise system design.

The ESI module focuses on production planning and control techniques with the emphasis on the MRPII method. MRPII teaching is mainly organised around an extended case study (details are given below), including (a) paper exercises, (b) game based simulation, (c) computerisation using *Prélude* software (Chen & Vallespir, 2009). Sales forecasting and inventory management methods (for example, the order point method) support both manufacturing resource planning (MRPII) implementation and supply chain management which is also another important lecture in this module. In addition, other recent methods, such as KANBAN based on JIT (just in time) and lean manufacturing, allow complementing MRPII. In parallel, project management techniques such as the PERT (programme evaluation and review technique) method are also presented.

The MPI module covers enterprise performance evaluation. Besides the Taguchi method and the reliability approach which can be related to design issues in the earlier MSI module (as shown Figure 5), a large part of the teaching is focused on quality concepts and methods. Benchmarking is also considered an important approach to improving the performance and quality of the enterprise systems and products. Another lecture is concerned with problems and solutions for recycling which is becoming more important in modern industrialised societies. Finally a game based on simulation shows how to link the flow (physical, information) in an enterprise to the performance (quality, delay), and how to act on the flow to improve the performance.

The PRI module is about enterprise integration and interoperability. Here, enterprise integration is approached principally through the use of enterprise architecture and framework modelling approaches, such as CIMOSA (computer integrated manufacturing open system architecture), PERA (Purdue enterprise reference architecture) and GERAM (generalised enterprise reference architecture and methodology). In parallel, basic concepts, framework and metrics for enterprise interoperability are also presented, because these are becoming significant new trends replacing traditional integration oriented projects. It is also noteworthy that teaching in this module is largely based on e-learning on the one hand and on the other, on seminars presented by well-known European experts in MDI (model driven interoperability), A&P (architecture & platform) for interoperability, and ontology for interoperability.

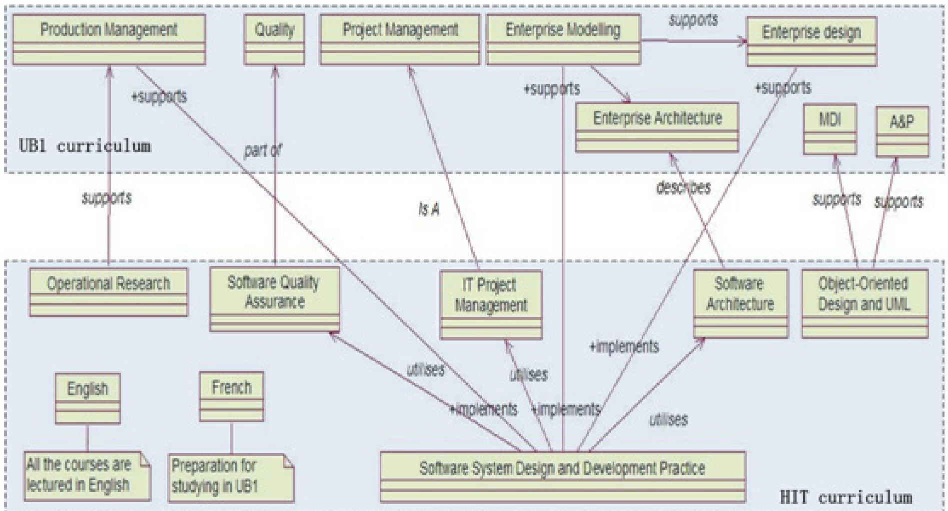
Finally the OPT module was originally designed to be a slot for optional courses. For the time being it has only one option (bibliographical research work). The students are asked to choose a subject proposed by professors and perform a bibliographical research on this. This work is done by groups of two students. Each group must write a report, present the work and answer questions in front of a jury. This work is an initiation to research work and aims at developing the capability of students to carry out bibliographical research.

Complementarities and Possible Improvements

Relationships between the courses in years 1 and 2 are tentatively identified as indicated in Figure 6. Several types of relationships are defined as follows:

- *is a* relationship: for example the IT project management lecture given in year 1 is a particular type of project management (general) studied in year 2
- *part of* relationship: the software quality assurance lecture in year 1 is part of more general quality course in year 2

Figure 6. Links between the courses of the two years



- *support* relationship: this means that one course is used as a preparation or a means for another one, such as for example software oriented design and UML that are used to develop MDI and implement A&P in year 2. Enterprise modelling techniques can also be used to model user's requirements at higher level abstraction in software system design, for example, control and information management (CIM) level in the model drive architecture (MDA) framework.

Several complementarities can be identified.

- At the global level, courses on computer science are complemented by training on enterprise and production systems. This allows HIT students to acquire supplementary knowledge to be better able to develop production system oriented software such as enterprise resource planning (ERP), customer relationship management (CRM), supply chain management (SCM) and others. On the other hand, UB1 students who are more familiar with industrial systems are empowered with software development skills.
- At a more detailed level and from the modelling point of view, enterprise modelling (mainly at conceptual level focusing on global system modelling) is complementary to IT oriented modelling. This is also true from the architecture perspective where enterprise architecture needs to be detailed in IT architecture and IT architecture must also be consistent with enterprise architecture.
- Both Years 1 and 2 deal with design issues. Design related lectures in year 2 (design innovation, design theory, Taguchi, reliability, etc.) provide generic design concepts and principles complementary to software design techniques learned in year 1.

At the course level, several potential improvements are envisaged as follows:

- Better coordination on the project management courses of the two years is needed. A consistent framework is necessary to position each lecture to show links and complementarities.
- More explicit relations between IT architecture and enterprise architecture must be

defined, and, in particular, the alignment between business/IT, and the consistent elaboration of IT architectures in relation to enterprise architecture.

A UNIFIED MRPII TRAINING CASE STUDY

Professional training in universities on MRPII-based production planning and control techniques as well as its implementation is one of the key issues in most of the production related master's degree programmes in France. Quite often, MRPII-based education and training do not reach a satisfactory level in university curricula. There are several reasons for this. One is the lack of production and industry concepts and experience among most master's degree level students. Another reason relates to the high conceptual character of production planning and management methods, requiring mastery of many abstract ideas, definitions and terms. The third reason is that the lectures, exercises and practical work on computers usually deal with different discrete examples, case studies and illustrations. A unified common case study allowing students to learn, understand, analyse and practise MRPII-based production planning techniques is still elusive.

In this section, an innovative and experimental MRPII training project is presented. This project was first implemented in the master's degree programme (in engineering, direction and performance of industrial systems (IPPSI)) at the University of Bordeaux 1 during academic year 2008-2009, and has been partly used on an experimental basis in the dual UB1-HIT master's programme. The characteristic of this project is to combine an MRPII game, enterprise modelling (the GRAI methodology) and software implementation within a single common case study. The objective of the project is to provide the students with a unified and consistent case study to learn MRPII-based production planning, from the fundamental concepts, through paper exercises and manual game simulation to the implementation of an MRPII-based software system. After the presentation of the principles and broad organisation of the project, we will show the various phases the students follow to learn MRPII-based production planning and control in a gradual and systematic manner. The experiences of the students obtained through formal feedback and possible improvements in the approach will also be discussed.

Description of the Case

Turbix (Centre International de la Pédagogie d'Entreprise (CIPE), 2008b) is a small company that manufactures reduction gears referenced from R1 to R8 (8 finished products). The reduction gears are composed of two types of parts, E1-E8 manufactured in the company, and P1-P5 purchased externally. The E1-E8 parts are manufactured using two types of raw materials, M1 and M2. Figure 7 shows the structure of R3.

Turbix is organised in two workshops, the machine shop to manufacture the E parts and the assembly shop to manufacture the finished products (R). Masteel and Fournix are two suppliers providing raw materials M and purchased parts P, respectively. The overall organisation and physical flow is shown in Figure 8.

Figure 7. Example: R3 product structure (Centre International de la Pédagogie d'Entreprise (CIPE), 2008a)

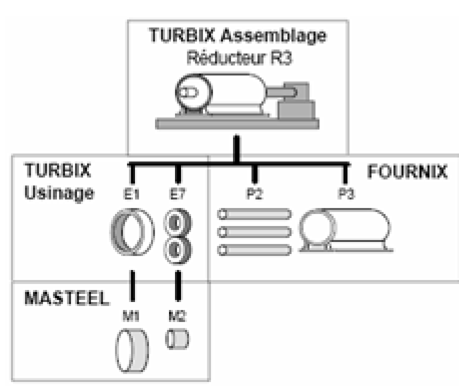


Figure 8. Organisation and physical flow of Turbix (Centre International de la Pédagogie d'Entreprise (CIPE), 2008a)

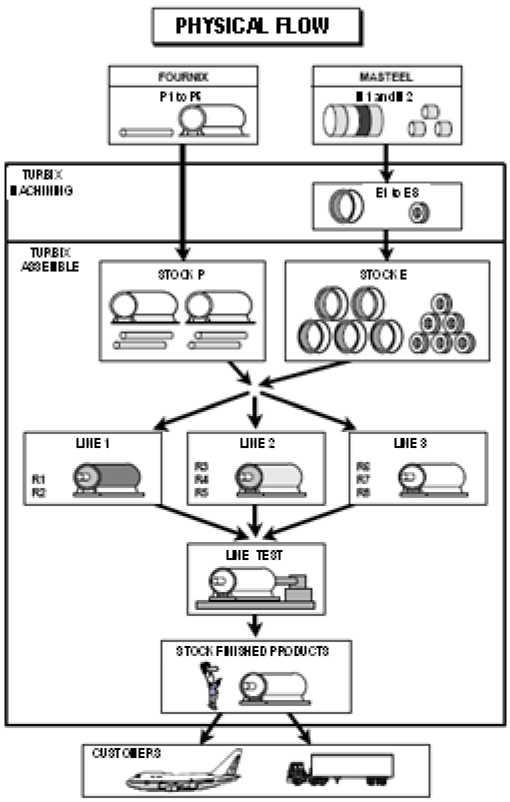


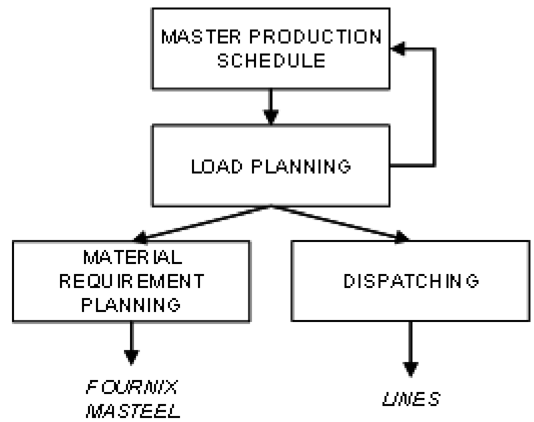
Because of different customer lead times, R1 and R2 are produced according to sales forecasts established beforehand. R3-R8 are manufactured upon firm customer orders. E1-E8 and P1-P5 are manufactured and purchased according to the needs for R1-R8 production. M1 and M2 are purchased according to the needs for E1-E8 production.

On the basis of this physical organisation, the architecture of the production management implemented in Turbix is presented Figure 9.

First Component: The Manufacturing Resource Planning (MRPII) Game

The objective of the MRPII game (Centre International de la Pédagogie d'Entreprise (CIPE), 2008b) is to allow a group of participants to discover for

Figure 9. Turbix management architecture



themselves how the MRPII method works and what are the steps one must follow to implement MRPII software in a company. Participants using this game can plan the production and purchasing orders using the MRPII technique, and simulate the execution of planned orders through various functions of the company - commercial service, manufacturing service, inventory/stocks, purchasing service. etc. During the simulation, each participant takes a precisely defined role/responsibility.

In detail, the game allows students

- to understand the structure and functioning of the existing production system
- to plan the master production schedule (MPS) for the finished products and draw up the material requirement planning (MRP) for parts E and P
- to calculate load and perform load levelling
- and finally to simulate the functioning of the production system over a period of two months, all consistent with the management architecture in Figure 9.

Second Component: The GRAI Methodology

The GRAI methodology (Vallespir & Doumeingts, 2006) was developed at the Department for

Automation and Production Science/Graphs of Interlinked Results and Activities (LAPS/GRAI) of the Laboratory for the Integration of Materials in Systems (IMS) at the University of Bordeaux 1. This methodology sets out to model, analyse and design the decision-making sub-systems of a production management system. The method consists of

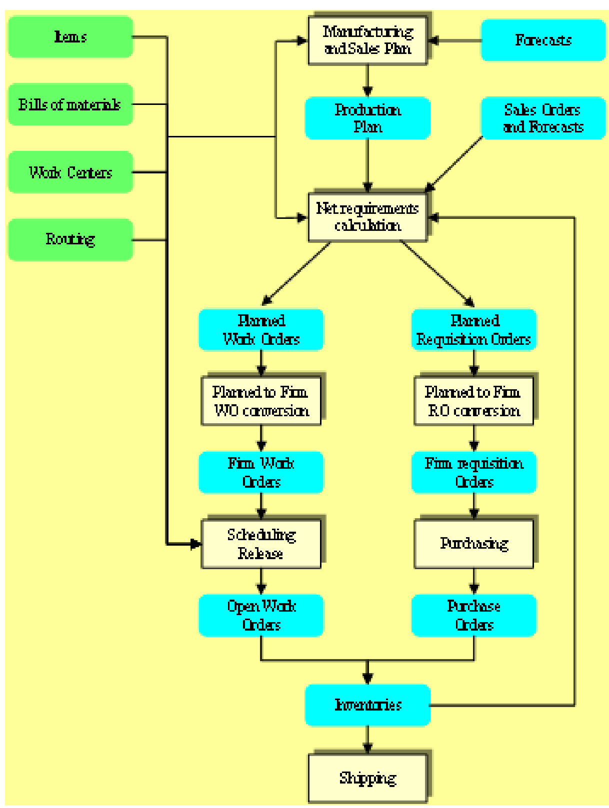
- a conceptual reference model defining the set of fundamental concepts
- modelling formalisms, and
- a structured approach.

The GRAI methodology is used in the project to model and analyse the existing production system of Turbix, to detect its potential inconsistencies and to design a new improved system.

Third Component: The Prélude Production MRPII Software

Prélude Production is an MRPII compliant software developed for professional training and teaching purpose (Centre International de la Pédagogie d'Entreprise (CIPE), 2008a). Its user-friendly interface allows students to learn how to manipulate MRPII software in a gradual way. This software is used in the project to computerise the production planning and management activities in Turbix Company. After the implementation of Prélude Production in the company, it is used to plan and control the daily production activities. It is also used together with the game to perform a simulation. Figure 10 shows the main functions of the Prélude Production software.

Figure 10. Main functions of Prélude Production software (Centre International de la Pédagogie d'Entreprise (CIPE), 2008a)



The Programme and the Implementation of the Project

In this section, we present the programme for the project and its organisation and implementation. The project is carried out by the students over several months. Two groups of students are formed, each group of about 10 students. Figure 11 gives the overall logic of the project.

Initialisation Phase

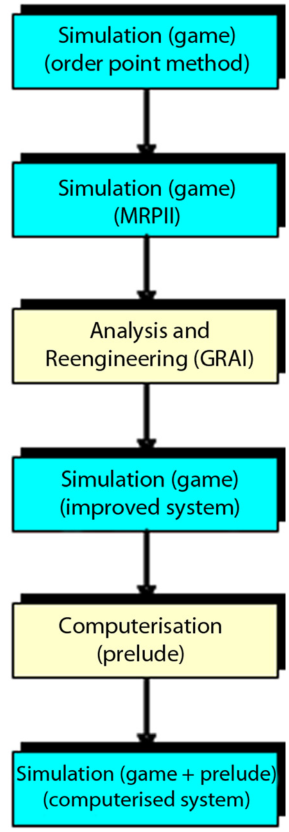
To start the project, the objective, the organisation and time table, as well as the expected results at the end of each phase are presented to the two groups of students.

Playing the Game

The next phase aims to show the students how to carry out the planning and simulation without the MRPII software tool. The objective is to allow students to develop a better understanding the basic concepts and techniques of the MRPII calculation, and, at the same time, a thorough understanding of the existing Turbix system.

The game is played over one day and a half. At the beginning the students use the traditional inventory management technique (order point method) to manage the Turbix system for a one month (January) period. Then they are asked to migrate to the MRPII technique. Manual MRPII calculation is done to plan all the orders needed for the finished products (R1-R8), and parts (E1-E8) and (P1-P5). Load calculations on the four lines in the assembly workshop (the L1-L3 assembly lines, and the L4 test line) are carried out in order to validate the master production schedule (MPS). The MRPII simulation is launched on a day-by-day basis for the duration of the next month (February), for managing the production activities (purchasing, manufacturing and assembly) and the management activities (order release, production follow-up, inventory, orders close-up, etc.).

Figure 11. Overall logic of the project



Existing System Analysis

After the MRPII game, the students are asked to analyze the functioning of the existing production system based on their knowledge and experience gained during the game. The GRAI method, using GRAI grid and nets, is used to model the decision-making structure of the existing project management (PM) system. Based on the model of the existing system, GRAI rules can be applied to detect possible inconsistencies. If inconsistencies are found (for example, a bad decision horizon or faulty period values), the students will propose necessary corrections to the existing system in order to improve its functioning.

Simulation of Improved System

After the analysis and possible redesign of the production system in Turbix, the students then play the game again. The game simulation is done on the new system, having implemented the set of suggested corrections and modifications to the existing system. For example, one of the possible suggestions that might be proposed by the students is to adjust the value of the planning horizon in the MPS and the MRP levels to allow an improved co-ordination between them.

Implementation of Prélude Production Software

During this phase, the students are asked to computerise the production planning and control activities in Turbix using Prélude Production software. For this task, the students are divided into small groups (2 students per group per computer). Firstly, the students need to make a compilation of all the relevant technical data (bill of materials, routings, items and workstations) and put them in an appropriate form to be entered in the computer. Then a small scenario (using a number of sales forecasts and firm orders) is given to students to allow them to test the Prélude Production implemented for Turbix. This tends to be a very interesting task because the students need to find errors they may have made during the data collection.

MRPII Software Based Simulation

After the validation of these test results, the simulation can begin. During the simulation, the students are asked to perform the same activities they did during the game but this time using the MRPII software.

This phase allows students to compare the two simulations, the game simulation without computer aid and the simulation with the MRPII software (Prélude Production).

DISCUSSION AND REMARKS

The experimentation carried out among students of the master's class in 2008 showed strongly the student interest and feasibility of the project. The main added values of the project were found to be the following:

- The project allowed the students not only to learn MRPII concepts and techniques, but also to practise the MRPII-based production control in a concrete and unique case study. The students could evaluate and compare the problems, difficulties and benefits at the different stages of the project using the same case.
- The game played before the computerisation stage allowed the students to take an active part in the activities of the enterprise as if they were actors in the company, thus putting them in a situation similar to that in the real enterprise
- The use of the GRAI method before computerisation allowed the detection of possible inconsistencies in the system. The benefits are to show the usefulness of enterprise modelling to improve company performance, and to computerise a re-engineered system after the correction of inconsistencies.
- The project showed that computerisation of production management is not only a matter of software. Before introducing an MRPII package in a company, it is necessary to analyse and re-engineer the existing system to make it consistent, to have the appropriate technical data, to define the most suitable parameters for the software, etc..

This project has contributed to improving MRPII-based production management training courses in French universities by providing a unified case study framework which covers the various types of exercises (understanding fundamental concepts, paper-based MRPII planning and manual simulation, enterprise modelling/analysis and re-engineering, computerisation, MRPII software-based simulation). One of the improvements planned for the near future is the reinforcement of the use of the GRAI methodology in the second phase of the project. It will also be necessary to investigate ways of increasing the time horizon of the simulation (from two months, possibly to 6 months or preferably one year). The extension of the time horizon will allow simulation of a long term production plan and the incorporation of some strategic production management decisions.

PRELIMINARY ACHIEVEMENTS AND ASSESSMENT

This section describes the results of the two first cohorts of students on the master's programme, and the feedback received from them. The students are asked to give a personal overview and overall appreciation on the content of the programme as well as the difficulties encountered in studying and comprehending each year and the benefits expected at the end of the programme. Finally the students who have earned all the European Credit Transfer System (ECTS) credits at the end of the second year of the programme and are eligible for the dual master's degrees, are asked for a professional perspective/discussion on the advantages of the programme and degree.

The first cohort of students, class 2008, had thirteen students, twelve Chinese and one French. The second cohort, class 2009, had fourteen students in year 2, ten Chinese and four French. The third cohort, class 2010, has fifteen students in its year 1, ten Chinese and five French. The relatively low number of French students, although growing, is probably because the predisposition to go abroad for study is weak in France and the students who go aboard tend to be pioneers.

The employment opportunities for the graduates are in both manufacturing and service companies. Graduates can become managers and more specifically production, quality, or maintenance managers, R&D engineers and managers, consultants, project coordinators and managers in the general domain of implementing enterprise software applications (such as ERP, SCM, PLM and many others) in large companies and in SMEs. If, as would seem likely, the internship is a springboard to employment, another employment opportunity is in research teams and projects in academic institutions. Indeed, in 2008 eight students did their final internship in an academic or research laboratory, three in France and five in other European countries. In 2009, ten students have chosen research internships, five in French laboratories and five in other European ones.

Survey of the Opinions of the Students

In December 2008, a questionnaire was sent to all the students of class 2008 and class 2009. The objective was to obtain an evaluation of the programme, taking into account the student's difficulties, the facilities and their expectations before, during and after the programme, and to obtain feedback on the professional experience gained after the two periods of internship by the two cohorts. A simplified view of the questionnaire used is presented below.

Questionnaire Used

1. Position, name and address of the company or university?
2. Position of the internship activity (daily job) in the company?
3. Competencies before year 1, before year 2 and at the end of year 2
4. Difficulties met and facilities provided during the first and the second year of the programme?
5. Advantages and disadvantages offered/encountered in relation to the double com-

petency, EM (enterprise modelling) and IT (information technology), of the programme ?
6. Thoughts about the continuity between Harbin and Bordeaux
7. In your daily job do you use the double competency (if not, which one do you use), advantages offered by IT / EM knowledge in your job?
8. Differences and similarities between the form and operation of the internship in Harbin and in Bordeaux?
9. Is the double competency an advantage in finding a job or PhD position?

Seven students of class 2008 replied, two of them employed in private companies, three PhD students, and two looking for a job or further training opportunities. Twelve students of class 2009 replied.

Results from Class 2008

- **Competencies**: Most students (5) had low or only a fundamental level of software programming skills, and some students (2) had no software domain knowledge but principally mathematics or control theory and engineering respectively before the programme year 1. At the end of the first year, almost all the students (6) had achieved competency in software engineering, especially software architecture, software development, Java and databases. At the end of two years, most students believed they had acquired (i) knowledge about enterprise modelling and production management, (ii) knowledge about enterprise modelling methods like GRAI and IDEF, (iii) deep understanding of SCM, quality assurance and performance measurement, and (iv) knowledge through the bibliographic research work in academic fields like ontology and interoperability. After the full programme, most of the students agreed that they had made progress in the English and French languages.
- **Difficulties and facilities**: During the first year of the programme, most problems came from language misunderstanding which made some courses difficult to assimilate. Three students thought that the courses were heavy even though they had a good studying environment (2 of them lacked knowledge and experience in software engineering). In the second year of the programme, 4 out of the 7 students who responded thought that topics such as interoperability and service oriented architecture were too conceptual and difficult to comprehend. With insufficient background knowledge of practical enterprise cases, models that are abstract and connections between these models are hard to understand.
- **Double competency statement**: Students have acquired knowledge of software development and enterprise modelling by the end of the two years. They have good knowledge of how IT works in the enterprise and also a good understanding of business processes which can help them to find the right technology when they design an enterprise management system. In their daily jobs five students out of the seven use this double competency. IT knowledge is used directly and regularly by persons in employment in companies while the PhD students use IT to implement programs to prove, analyze and show their research results. For those in employment, enterprise management knowledge supports their understanding of the framework and architecture of the issues they work on and supports the design of solutions in their daily work.
- **Teaching specificities**: The teaching in the IT domain tends to be considered more theoretical while the teaching in the EM domain is considered more practical because

of the game-based simulations and exercises that can be seen as playing realistic roles. The enterprise games are also considered a useful tool to explore a particular context and have special values because most these games tend to be team-oriented. In Harbin the internship takes place at the same time as the course. Consequently, students have a complete project in which they use IT technology to carry it out. An advantage, according to the students, is that they can go deeper into detail through asking for information from the teachers but that sometime this becomes too closely detailed to form a proper overall view. In Bordeaux, the internship has a specific period and the subject in question is sometimes disconnected from the course even if that subject deals with management. This requires more individual initiative and creativity because the students can feel alone in confronting their problems even if they can ask their teacher. But it is considered a strong advantage that the students are totally immersed in the company.

Results from Class 2009

- **Competencies**: At the beginning of year 1, 9 of these students had competencies in software engineering: operating system, data structure, databases, IT project management, software quality assurance and some popular development languages such as Java, C++ and.NET. One student had specialized in automatic control and another had knowledge linked to mechanical engineering and production management. Thus the competencies were much more diverse than in the previous cohort. Before year 2, most of the students (9) had improved their programming skills as software engineers. By then they had more experience in programming and project management, and knowledge of advanced databases, algorithm, software architecture and so on. They had also improved communication skills, with a good level of French and fluent English. The other two students had acquired knowledge of programming using Java, database design, and IT project management. At the end of semester 4, all the students had gained knowledge in enterprise computing and engineering, including production management, enterprise modelling, and quality management.
- **Difficulties, facilities**: Like the previous cohort, the first difficulty cited is language. The second arises from the fact that students are not au fait with the production environment and so concepts relative to an enterprise are difficult to comprehend, the concept of interoperability for example is understood, but the finer details are not, and while the model-driven architecture and enterprise modelling methods are readily learned, the lack of experience makes their use far from obvious. All the students complained about the schedule of the course, with too many courses planned in too short a period and too many different types of knowledge to be learned in different areas/domains.
- **Double competency statement**: Despite difficulties, students agreed that they had acquired a double competency. Not only did they know how to do programming but also understood how an enterprise works using IT technologies. The background of one domain was felt to be a great help when working in the other. The dual competency provides more choices for a future career. Even if it is not easy to re-orient one's mind from the software view to the enterprise view, they were confident that they would be able to bring these views together in the future.

- **Teaching specificities**: In Bordeaux, there are more games-based training exercises as opposed to the programming practicals in Harbin. As regards the internship, they did not find major differences between Harbin and Bordeaux. In the first year, the goal was to develop software systems, and students worked directly from the analysis, and then designed the system and wrote the code. In the second year, students needed to read the materials about the production system to gain a holistic understanding of the subject.

Remarks

The dual master's degee programme represents a good challenge for all the responding students because of the challenging multidisciplinary and cross-domain training during the two years. The students also became very aware of the interests and needs of companies which are very close to the topics and subjects dealt with in the programme.

Needs Expressed During the Internship (So-Called, M2)

This section provides the analysis of the internship of year 2 of class 2008, because internships of class 2009 are only in progress. As mentioned earlier, in 2008 five students did their internship in private companies. One internship topic concerned pure management issues, while all the others combined IT problems and the use of enterprise modelling methods to analyze and model enterprise systems.

Topic Relative to Management Only

A well known large company in the domain of material construction had proposed a study on pricing strategy because the market is becoming more and more competitive, and the pricing strategy must be adjusted to take into account product turnover, life cycle phase and other dynamic variables. This study focused on the analysis and comparison of the commonly used pricing strategies: premium pricing, value pricing, cost/plus pricing, competitive pricing and penetration pricing. The internship project led to the proof that the value strategy was the best strategy for new products and high-end products, but that for all other products, the competitive strategy was shown to be the best one. This conclusion has enabled the company to improve customer loyalty, keep market share and make expected profit (Jia, 2008).

Internship Studies Involving Combined Topics

One study led to the analysis of the possibilities of applying data mining techniques in cross-selling to increase the overall sales of a company specialising in material construction. The study elaborated a process methodology based on data mining software, and described the way to build mining models to do cross-selling analysis. The student described how to write associative prediction queries, integrate these queries into a Web cross-selling application and then discussed the architecture of a web application with data mining predictions (Li, 2008).

Another subject proposed by the same company concerned the exchange of data between servers of 120 commercial agencies which constitute the company. The objectives of the company were to (i) find a solution which could monitor the servers, (ii) analyse their performance, and (iii) predict potential problems and inform the system administrator in advance. Furthermore the company needed software to help the administrator do his daily work, in verifying the backup machine and the working situation of the servers, and other tasks. The mission of the student was to choose a correct solution to satisfy the company's needs and then design and implement the architecture on the existing system (Yang, 2008).

A third combined topics study related to a small company specializing in internet search engines. The main challenge of the company was to offer to internet users the relevant information about an enterprise, a product or a service. For this task the search engine limits the referencing to the web site of the enterprise in order to have consistent and precise information. Blog, personal page and forum pages are avoided. The student participated fully in the whole project, from the requirement analysis phase to the development phase, including learning and using specific languages, technologies, etc. The student acted as an actor in the project but also as project manager during the development phase (Wang, 2008).

The fourth internship was carried out in a large French worldwide company, in the Oracle project pole. The student worked on the ERP technology taking into account the requirements of a specific customer that is a public sector administration. The company maintains the Oracle IT system for the administration. The student worked on the purchase order process from the demand, to the invoice payments, including the orders and receipts. This allowed him to study the complete acquisition workflow, and introduce some new concepts of finance and accounting, and new concepts and ontology in the financial area (Fausser, 2008).

Analysis of the Topics by the Private Companies Involved

Information on projects carried out by the students during their internships in private companies was collected through the report they gave at the end of year 2 of their programme. Three subjects out of the five were proposed by one enterprise. This indicates the difficulty of finding industrial internship in France, mainly due to the language barrier. French companies find the double competency of the student very interesting but most are not prepared to integrate students who do not speak French into their company. A second important conclusion is that most of the topics (4 out of 5) required a double competency, and in those cases the students successfully applied IT techniques to improve the performance of those companies.

CONCLUSION

This chapter presents an international collaboration between the University of Bordeaux 1 and Harbin Institute of Technology. This collaboration is characterised by the fact that it is based on:

- a long-term strategy of both institutions (UB1 and HIT) to develop sustainable co-operation in the domain of interoperability which is considered a priority subject on both sides
- the two competencies, in UB1, enterprise modelling and interoperability, and production system sciences, and in HIT, computer sciences and software engineering, are complementary in the development of R&D and in this education programme
- the combination of research activities and education/training allow benefits to flow from the latest advances in research in enterprise software application interoperability (such as the European Union R&D projects, Athena, Interop, and others).

This collaboration model has considerable potential to be duplicated and extended to other universities and other countries.

The formal UML model to represent the joint master's programme curriculum allows explicit identification of all elementary lectures and the possible relationships between the lectures and modules. We believe that this formal modelling approach can help students to better understand the training curriculum and lead to an improved quality of education. Furthermore it also allows the teachers involved to check the overall consistency of the curriculum, to better coordinate and organise their lectures, to avoid unnecessary redundancies and overlapping coverage, introduce possible contractions and bring out synergies and complementarities.

The feedback on the students' experience of the dual master's degree programme shows that it responds to real business needs and concerns. Even with the language barrier, more companies are becoming interested in students with the double competency. For the students, even though the programme is difficult to assimilate during the two years because of its breadth and density, they are satisfied at the end because they have come to understand the crucial impact of IT on enterprise performance.

ACKNOWLEDGMENT

The authors thank Zhiying Tu and Zhenzhen Jia (University of Bordeaux 1) for their contribution to this chapter.

KEY TERMS AND DEFINITIONS

Dual Master's Degree: A master's degree programme involving at least two different universities / institutions from two different countries, and allowing students to obtain two degrees from the two institutions.

Enterprise Modelling: Representing the enterprise in terms of its structure, organisation and operations according various points of views (technical, economic, social and human).

Interoperability: A property referring to the ability of diverse systems and organizations to work together (inter-operate). The term is often used in a technical systems engineering sense, or alternatively in a broad sense, taking into account social, political and organizational factors that impact system performance.

Production Management: A set of techniques for planning, implementing and controlling industrial production processes to ensure smooth and efficient operation. Production management techniques are used in both manufacturing and service industries.

Software Engineering: A profession dedicated to designing, implementing, and modifying software so that it is of higher quality, more affordable, maintainable and rapid to build.

This work was previously published in Software Industry-Oriented Education Practices and Curriculum Development: Experiences and Lessons, edited by Matthew Hussey, Bing Wu and Xiaofei Xu, pp. 57-81, copyright 2011 by Engineering Science Reference (an imprint of IGI Global).

Section 5
Organizational and Social Implications

This section includes a wide range of research pertaining to the social and behavioral impact of Industrial Engineering around the world. Chapters introducing this section critically analyze and discuss trends in Industrial Engineering, such as participation, attitudes, and organizational change. Additional chapters included in this section look at process innovation and group decision making. Also investigating a concern within the field of Industrial Engineering is research which discusses the effect of customer power on Industrial Engineering. With 13 chapters, the discussions presented in this section offer research into the integration of global Industrial Engineering as well as implementation of ethical and workflow considerations for all organizations.

Chapter 56
Process Innovation with Ambient Intelligence (AmI) Technologies in Manufacturing SMEs:
Absorptive Capacity Limitations

Kathryn J. Hayes
University of Western Sydney, Australia

Ross Chapman
Deakin University Melbourne, Australia

ABSTRACT

This chapter considers the potential for absorptive capacity limitations to prevent SME manufacturers benefiting from the implementation of Ambient Intelligence (AmI) technologies. The chapter also examines the role of intermediary organisations in alleviating these absorptive capacity constraints. In order to understand the context of the research, a review of the role of SMEs in the Australian manufacturing industry, plus the impacts of government innovation policy and absorptive capacity constraints in SMEs in Australia is provided. Advances in the development of ICT industry standards, and the proliferation of software and support for the Windows/Intel platform have brought technology to SMEs without the need for bespoke development. The results from the joint European and Australian AmI-4-SME projects suggest that SMEs can successfully use "external research sub-units" in the form of industry networks, research organisations and technology providers to offset internal absorptive capacity limitations.

DOI: 10.4018/978-1-4666-1945-6.ch056

INTRODUCTION

Through case study research, this chapter discusses some of the challenges Small and Medium Enterprises (SMEs) in the manufacturing sector face in identifying and adopting Ambient Intelligence (AmI) technologies to improve their operations. Ambient Intelligence technologies are also known as Pervasive computing or Ubiquitous computing, and we include the descriptions of these terms when we refer to AmI technologies. Our study includes case studies of three Australian SMEs and a comparison with similar application requirements in a German SME manufacturer. The outcomes of the study are likely to be applicable to small firms in many nations.

The 1980s and 90s saw the operations of many large manufacturers revolutionized by the introduction of process and technological innovations (Gunasekaran & Yusuf, 2002). While there have been uneven adoption rates in smaller businesses and across different nations (Chong & Pervan, 2007; Oyelaran-Oyeyinka & Lal, 2006) it is clear that technological innovations such as Electronic Data Interchange, Business Process Re-engineering, Enterprise Resource Planning and robotic automation, amongst others, have played key roles in increasing manufacturing productivity. At the beginning of the twenty first century this transformation continues. Ambient Intelligence (AmI) technologies are being positioned as the next performance and productivity enhancing purchase for manufacturers, and a potential means for manufacturers in developed nations to counter perceived threats from lower labour cost countries (Kuehnle, 2007).

Thus, the key objectives of this chapter are to consider potential applications of AmI technologies in Australian SME manufacturers, and discuss the opportunities and shared challenges faced by such firms in adopting these technologies. In doing this we will compare different levels of absorptive capacity and technological readiness in Australian firms, seeking possible reasons for similarities and differences in their comparative technology adoption processes. The chapter also examines the role of intermediary organisations in alleviating these absorptive capacity constraints.

Our overarching research question is: "Can external intermediaries overcome absorptive capacity limitations in SMEs seeking process innovation through the application of AmI technologies?" In order to understand the issues surrounding this problem, a brief overview of ICT (Information and Communication Technologies) adoption in manufacturing and an explanation of Ambient Intelligence (AmI) technologies are provided in the following section. Following that we examine the role of SMEs in the Australian manufacturing industry plus the impacts of government innovation policy and absorptive capacity constraints in SMEs in Australia.

BACKGROUND

ICT Adoption for Business Performance Improvement

Brown and Bessant (2003) described the global manufacturing environment developing in this new century as an increasingly competitive landscape, characterised by on-going demands for improved flexibility, delivery speed and innovation. A frequently occurring element in manufacturers' responses to these pressures is the implementation of increasingly sophisticated ICTs. The benefits of incorporating ICTs on business responsiveness have been identified as: more effective and more efficient information flows; assisting in value-adding improvements for current processes; greater access to efficiency enhancing innovations throughout the value chain (Australian Productivity Commission, 2004); and the ability to access world markets through e-commerce (Kinder, 2002).

ICT adoption has been considered worth the risk, given the competitive pressures placed on business to keep pace with technology. For example, in Australia, the uptake of ICTs has increased dramatically towards the later part of the 90's and into the 21st Century. Reports show that in 1993-94, 50 per cent of firms used computers with 30 per cent having internet access; by 2000-01 these figures had increased to 85 per cent and 70 per cent respectively (Australian Productivity Commission, 2004). Recent figures (Australian Bureau of Statistics, 2009) reveal that almost all Australian SMEs use ICTs, and 96% of them access the internet through a broadband connection. One of the latest developments in the application of ICTs to business improvement is that of Ambient Intelligence (AmI) technologies. The objective of AmI is to broaden and improve the interaction between human beings and digital technology through the use of ubiquitous computing devices. By using a wider range of simplified interaction devices, ensuring more effective communication between devices (particularly via wireless networks) and embedding technology into the work environment, AmI provides increased efficiency, more intuitive interaction with technology (Campos, Pina, & Neves-Silva, 2006) and improved value and productivity (Maurtua, Perez, Susperregi, Tubio, & Ibarguren, 2006).

Ambient Intelligence (AmI) Technologies

Existing literature (Kopacsi, Kovacs, Anufriev, & Michelini, 2007; Li, Feng, Zhou, & Shi, 2009; Maurtua et al., 2006; Vasilakos, 2008; Weber, 2003) points to the co-existence of three features in any AmI technology: ubiquitous computing power, ubiquitous communication and adaptive, human-centric interfaces. Regardless of arguments about terminology and definitions (the terms "pervasive computing" and "ubiquitous computing" are in common use in the US, while "ambient intelligence" is favoured in the EU), these technologies are already commonplace. The beep signalling the automatic deduction of a road toll from your account as your car passes under a toll gate is one aspect of an AmI technology known as Radio-Frequency Identification (RFID). RFID technology is having an impact in many industries, some of which are not normally associated with high levels of ICT adoption. For example, during 2006, in NSW alone (one of the 7 states and territories within mainland Australia), more than 1.2 million head of cattle were automatically tracked from farm to saleyard to abattoir as their RFID ear tags passed through RFID sensor gates (NSW Farmers Association, 2007).

In addition to increasing process speed and efficiency, AmI technologies have the potential to provide tracking of employee and customer activity. While concerns about the impact of technology upon power relations in the workplace are not new (Zuboff, 1988), the characteristics of AmI technologies present new challenges to worker privacy, informed consent and dignity. AmI technologies may, intentionally or not, dramatically increase employee surveillance and monitor consumer activity over the entire product life cycle. This potential and the very nature of 'ubiquitous computing' raises important ethical issues. Proposals to use RFID tags to track sufferers of Alzheimer's disease (Caprio, 2005) and children provide examples of the ethical dilemmas AmI technologies can present. While these issues are beyond the scope of this chapter, we suggest Cochran et al (2007) for a review of ethical challenges associated with RFID.

Social factors associated with the introduction and implementation of AmI technologies may be exacerbated in small and medium businesses. In addition to concerns shared with corporate workers, such as disquiet about their personal data potentially being sold to marketing groups and anxiety about the security of the information gathered, members of small businesses are particularly prone to AmI's ability to 'break the boundaries of work and home through their pervasiveness and 'always on' nature' (Ellis, 2004, p.8). While some profit-maximising small business owners welcomed this blurring of work and home boundaries, others did not, preferring to keep work and family spheres separate. Ellis cautions that in order to overcome existing negative preconceptions of AmI technologies, users must feel they control the devices and the data they produce, and be able to override them and cope with systems failure. In particular, AmI needs to be presented as "smarter" than existing ICTs and able to correct some of the problems associated with traditional forms of ICT support. In short, Ellis (2004, p. 9) asserts, "AmI needs to be associated with undoing some of the more problematic aspects of existing ICTs, to be accepted and not resisted as a more invasive, insidious and controlling form of what already exists."

Much of the promise of Ambient Intelligence (AmI) technologies rests upon connecting increasingly sophisticated and powerful sensors with existing computing facilities. McCullough (2001) identified the need to expand our thinking beyond the notion of filling environments with physical objects when considering Ambient Intelligence technologies. There is no longer such a thing as "empty space" when sensors and processing power combine to produce an environment that is "aware" of the locations, actions and information needs of humans. Clearly, the extent of existing Information and Communications Technology (ICT) infrastructure in an organisation will impact AmI technology implementations, providing either a "clean slate" from which to start or the opportunity to integrate new AmI capabilities with existing ICT systems and processes. In much the same way as the advent of mobile phones in China and India provided an opportunity for people unable to afford a landline, to access telephonic services, AmI technologies may prove a way for SME organisations to "leap frog" a stage of ICT implementation, and move directly to wireless and similar AmI technologies.

Many other applications of AmI technologies are appearing as technologists extend the concept into areas such as "wearable technology" (clothing that incorporates sensors and interface devices), more intuitive home space designs, shopping assistance and the creation of seamless interfaces between work, home and leisure activities. While many of these applications currently seem unrelated to improving business productivity, it is clear that the applications for business can only grow as the technologies become more sophisticated and less expensive. As Rao and Zimmerman (2005, p.3) state "there is a gap in the scholarly discussion addressing the business issues related to it, and the role of pervasive computing in driving business innovation". It is in this context that the following case studies of four small-to-medium (SME) manufacturers - three Australian and one German firm – have been undertaken. In each firm, critical process analysis was carried out to examine possible process weaknesses and existing ICT systems, and recommendations were made concerning a selection of AmI technologies with the potential to boost business performance.

AMBIENT INTELLIGENCE TECHNOLOGY IN MANUFACTURING

This section considers the applicability of several emerging AmI technologies to three SME manufacturers in New South Wales, Australia and compares the situation within these SMEs with one German SME manufacturer undertaking a similar technological adoption. In doing this the section also addresses questions about the preparedness of SMEs, particularly concerning their absorptive capacity limitations and how these may be overcome. Later sections also consider the potential impact of Ambient Technologies on the employees of the organisations studied.

AmI technology is much more than RFID inventory control systems. Wireless, multi-modal services and speech recognition systems have the potential to increase manufacturing flexibility by supporting dynamic reconfiguration of process and assembly lines, and improving human-machine interfaces to reduce process times (Maurtua et al., 2006). Also, maintenance and distribution processes may be improved by linking common mobile wireless devices, such as mobile phones, Personal Digital Assistants (PDAs) or even pagers to production alert systems (Stokic, Kirchhoff, & Sundmaeker, 2006).

Small and Medium Manufacturers in Australia

Organisations with between 20 and 199 workers employ 56% of Australia's workforce (Wiesner, McDonald, & Banham, 2007). The Australian Bureau of Statistics (ABS) defines a small business as employing less than 20 people, and a medium enterprise as employing between 20 and 200 employees (ABS, 2001). The most recent ABS figures available (2007) for Australia indicate that there are around 47,000 manufacturing firms employing between 1 and 20 people, around 10,000 employing between 20 and 200 people, and only 873 employing over 200 people. In turnover terms, around 29,000 manufacturing firms reported annual turnover between $500,000 and $10 million, while only 3,300 firms reported turnover of $10 million or above. It is clear that the bulk of manufacturing in Australia occurs in small-to medium firms. While SME firms employ the majority of manufacturing workers their expenditure on R&D notably lags behind that of large manufacturers. Within the manufacturing industry companies with more than 200 employees were responsible for 73% of total industry R&D expenditure, with only 27% being contributed by the SME sector (ABS, 2007).

However, in their exploration of the cost and impact of logistics technologies in US manufacturing firms Germain, Droge & Daugherty (1994) found that for manufacturing managers wanting to innovate with logistics technology, organisational size provides an advantage that transcends both the cost and nature of the technology. These authors confirmed the established view in 1994; that organisational size was positively correlated with technology adoption, as found in many previous studies. This link between manufacturing organisation size and increased ability to extract benefit from technological innovations may provide some explanation for the fact that while Australia's manufacturing output has quadrupled since the mid 1950s, the Australian Government Productivity Commission (2003) states that overall, it has not grown at the same rate as the service sector. The Productivity Commission also describes Australia's manufacturing sector as having "missed out on the productivity surge" of the mid 1990s while noting signs of improved manufacturing productivity in 2002 and 2003. The widespread availability of off-the-shelf ICT systems has probably meant that a great many more SMEs are adopting ICTs today than in 1994, however the limited resources of many such firms (both financial and human) almost certainly mean reduced awareness and limited capacity to exploit newer technologies commonly appearing in larger manufacturers. Given the significance of SMEs in Australian employment and the perceived need to increase manufacturing productivity, examination of the potential improvements available through the systemic application of AmI technology to SME manufacturers forms an important topic for research and government policy.

Absorptive Capacity

This chapter applies the concept of *absorptive capacity* to manufacturing SMEs. We argue that SMEs can benefit from AmI technologies, using specialised intermediary organisations to overcome the "absorptive capacity" limitations evident in many SME organisations. Cohen and Levinthal (1990) proposed that internal Research & Development activities serve two purposes: to generate innovations, and to provide the ability to absorb relevant knowledge appearing in the external environment. The absorptive capacity of a firm is comprised of these two categories of activity. Their foundational paper conceptualised absorptive capacity in the context of large U.S. manufacturers, as evidenced by their survey of identifiable "R&D lab managers" (Cohen & Levinthal, 1990, p. 142) and their discussion of "communication inefficiencies" between business units. But what of small- and medium-sized manufacturers? Does the notion of absorptive capacity have relevance to SMEs outside narrow, industry-segment specific technologies? If so, can external intermediaries assist SMEs to overcome absorptive capacity limitations regarding ambient technological innovations? The preparedness of SMEs to adopt and benefit from the mobile capabilities of AmI technologies is likely to be linked to their ability to overcome the limited absorptive capabilities associated with their small size.

However, it is possible for SMEs to successfully deploy AmI technologies. Clear evidence of the benefits produced by a range of AmI technologies have been observed by the researchers at Costa Logistics' distribution centre in Western Sydney. Costa Logistics specializes in the distribution of fresh fruit and vegetables, and achieves astounding levels of accuracy and throughput: staff average zero to three errors per million cartons picked in the warehouse, the daily inventory turn ratio is 100% and over A$2 billion of product is handled annually on behalf of their clients (Game-Lopata, 2008). The company was a SME when it started to use wrist-mounted bar-code scanners coupled with wireless communications. These successfully implemented AmI technologies are key factor that have enabled Costa Logistics rapid expansion to well over 200 employees in late 2009.

Innovation, Manufacturers, SMEs and Government Policy

Several previous studies (Cutler, 2008; Philips, 1997) have concluded that innovative Australian firms of all sizes (both manufacturing and service-based) tend to be more successful in terms of sales growth and market share than non-innovating firms. In addition, the impact of innovation is considered to be cumulative (Chapman, Toner, Sloan, Caddy, & Turpin, 2008) with some level of innovative behaviour or research and development being required to equip a firm to identify, assess and adopt technologies. The innovativeness and absorptive capacity of SMEs is a matter of concern for other nations besides Australia. For example, in its 2008 budget, the UK government signalled its intention to set a goal for innovative SMEs to win 30% of its £150 billion public procurement spending (Kable's Government Computing, 2008), equating to $98 billion (AUD) of incentives to encourage UK SMEs to innovate. While similar incentives are yet to appear in Australia, there are clear signs of government interest in the ability of SMEs to innovate (Department of Innovation Industry Science and Research, 2008).

There is a growing body of work in the innovation literature on the limited absorptive capacity of SMEs to identify relevant innovations, understand and appreciate possible applications, and finally adapt and implement innovation in their organisations (Beckett, 2008; Liao, Welsch, & Stoica, 2003; Muscio, 2008). Many points concerning "constraining factors" and "implementation challenges" support the notion that SMEs can experience organisational absorptive capacity limitations. Beckett (2008) identifies knowledge and resource constraints that impede the ability of SMEs to develop absorptive capacity, but also provides an example of how absorptive capacity is built when the outlays of time and money required match the SME's available resources.

While the benefits of AmI technologies are already accruing in large organisations (Angeles, 2005) if manufacturing SMEs are to benefit from AmI technologies, one challenge requiring attention will be that of their limited absorptive capacity for technological innovations. Our research considered the possibility of external intermediaries being used to facilitate SME manufacturers' assessment of the application of AmI technologies for process innovation, thus overcoming, at least partially, the problems of limited absorptive capacity within the partner SMEs.

METHODOLOGY AND DATA COLLECTION

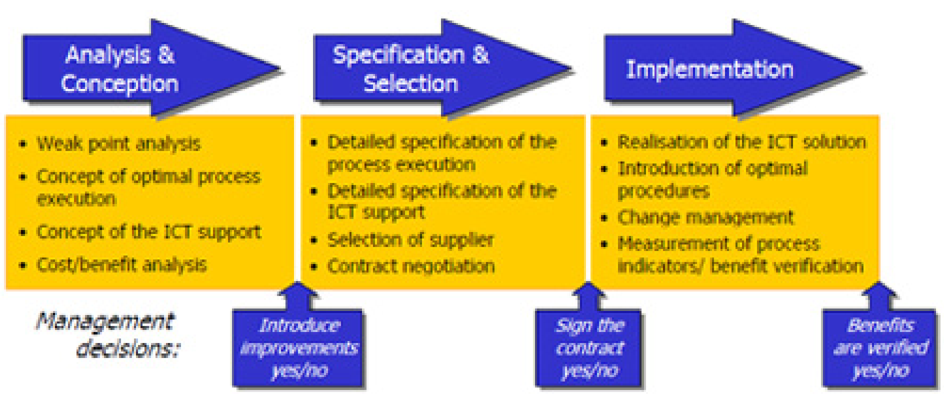
Case research has been used to review and compare the operations of the three NSW manufacturing SMEs, identify process weak points (in partnership with the SME executive managers) and suggest potential Ambient Intelligence Technologies to assist each organisation. The data has been gathered as part of an Australian government funded International Science Linkages Project, which in turn was part of a larger European-Australian project on Ambient Intelligence in manufacturing - Ambient Intelligence Technology for Systemic Innovation in Manufacturing SMEs (AmI-4-SMEs). The European component of the AmI-4-SMEs project involved six SMEs, three research partners and three Information and Communications Technology (ICT) providers located in Germany, Ireland, Spain and Poland. The Australian AmI-4-SMEs project consists of six SMEs, two research partners (University of Melbourne and University of Western Sydney) and two ICT providers. Six SMEs were selected from those responding to a request for expressions of interest in participating in the study. Using the Australian Bureau of Statistics metrics (2001), all are classified as small-to-medium sized manufacturers and all are privately owned.

The EU AmI-4-SMEs project aimed to design and develop a coordinated approach for process innovation using, ICT "building blocks" and a software platform to support the improvement of manufacturing processes in SMEs. These improvements were achieved by re-engineering processes and introducing appropriate ICT tools. The method used to analyse and re-engineer business processes is an extension of the COST-WORTH methodology (ATB Institute for Applied Systems Technology Bremen GmbH, 2004) and has three main phases: Analysis and Conception, Selection and Specification, and finally Implementation. Due to lower levels of government funding support, the Australian Ami-4-SMEs project performed only the Analysis and Conception, and the initial aspects of the Specification and Design phase but not the Implementation phase. The links between these phases are shown in Figure 1.

The Analysis and Conception phase produces an implementation plan for the proposed AmI solution. Analyses of each SME's business processes and bottlenecks form the majority of this phase which concludes with presentation of a business re-engineering recommendation and a Return on Investment Analysis (Kirchhoff, Stokic, & Sundmaeker, 2006).

One challenge of working with SMEs is to gather sufficient information without intruding to the extent that the organisation is adversely affected. On-site interviews and observation, questionnaires (these were developed as a part of the precursor

Figure 1. Representation of the Three Phase AmI-4-SME Methodology (*Source (Kirchhoff et al., 2006)*)



COSTWORTH project, see Nousala, Ifandoudas, Terziovski and Chapman, 2008), video recordings, a visit to a company (Costa Logistics) already using wireless, wearable and voice (Chang & Heng, 2006) technologies in its warehouse, and joint creation of process maps where they did not previously exist were used to collect data and minimise disruption to the SMEs. Interview and questionnaire data were used to select important, problematic processes for each SME. On-site observations and video recordings were analysed to create "as-is" maps of the process selected for improvement, and identify key limitations of each process. AmI technologies with potential to improve the selected business process were selected and the likely costs and benefits reviewed with the SME executive managers.

A strength (and simultaneous limitation) of this approach, is that the time spent at each SME site is not extended or intensive. However, given the objectives of the analysis and conception phase of the AmI-4-SMEs project, and the need to minimise disruption to the operation of the manufacturing businesses, the methods are appropriate.

RESULTS

Overview of the Three Australian SMEs

The three Sydney-based SMEs represent a wide range of existing ICT complexity and skill, from "craft-work" factories to highly sophisticated manufacturers of technology. Although the organisations were not intentionally recruited to represent a typology of low, moderate and highly integrated ICT installations and skill sets, they do display these characteristics and it is useful to consider how AmI technology capabilities may be added to each of these settings. Pseudonyms have been used for the SME companies. Ranked in order from low to higher technological capability they were: SwivelMould – a plastics manufacturer specialising in rotational moulding work; BottleTop – manufacturer of plastic packaging closures; and TechMakers – a contract electronics component manufacturer.

As described in the methodology section, due to lower funding levels, the Australian AmI-4-SMEs project did not fully incorporate the latter two phases of the project (see Figure 1), instead leaving it to the individual companies to complete these steps. The European project funding also included direct funding support for the SME partners, which was not provided under the Australian government support funds. However, the Analysis and Conception phase, and the initial aspects of the Specification & Selection phase, included a detailed initial assessment of each SME, identified possible AmI solutions and produced a rough implementation plan for the proposed AmI solution. Analyses of each SME's business processes and bottlenecks formed the majority of this phase, and these were conducted on-site at the three NSW SMEs.

Tables 1 and 2 present summary information and key issues related to technology adoption for each of the three SMEs from New South Wales, Australia.

Similarities and Differences between the Three Australian SME Manufacturers

Scalability issues related to specialised equipment appeared as a limitation shared by the three Australian SMEs. Production could not rapidly increase without the purchase of more machinery, and in the case of TechMakers, difficulty in arranging for the rapid importation of components also limited their growth.

Key differences observed in the three Australian SMEs relate to the proportion of standardised production and organisational culture. Eighty per cent of BottleTop's product volume results from standing contracts with its top twenty customers. Beyond the top twenty customers is what the Operations Manager refers to as a "long tail" of hundreds of small customers. In contrast, TechMakers survives

Table 1. Company summary

BottleTop	TechMakers	SwivelMould
Turnover: $30M **Employees** 97 **Profit**: moving from break-even to profitable trading in 2008/09. **Industry**: Manufacturing of packaging closures **Outlook**: Growing in a shrinking market by taking market share from competitors. BottleTop has set an aggressive revenue growth target of $50M by 2011/12.	**Turnover**: $7 M **Employees** 70 **Profit**: Trading profitably **Industry**: Contract Electronic Manufacturers. **Outlook**: Industry is shrinking, work is increasingly being sent off shore, TechMakers are diversifying by creating and selling the devices they created to assist in their contract electronic manufacturing activities.	**Turnover**: $20M **Employees**: 80 **Profit**: trading profitably, but recently burdened by a major bad debt. **Industry**: Rotational Moulding **Outlook**: Rapid growth during drought through manufacture of water tanks,

Table 2. Key issues related to technology adoption

BottleTop	TechMakers	SwivelMould
Staff The company managers view their employees as loyal, and based on a long association, almost like family. Some staff members resent the profits they believe the company owners are making and draw unfavourable comparisons to their hourly wage rate. A profit sharing scheme based upon reducing the scrap rate has been enthusiastically embraced by staff. BottleTop's labour efficiency has increased from 76 to 92% in the last year primarily attributable to their process focus as they implement Six Sigma Manufacturing techniques	No staff-related comments or concerns appeared in interviews or observations.	SwivelMould have a high employee turnover as the work is repetitive, takes place in a hot and noisy environment and does not pay high hourly rates. SwivelMould had difficulty recruiting and retaining employees while unemployment rates were low. New employees are only given formal training after they have completed a probationary period and if they appear likely to work at SwivelMould for some time.
Tracking of Products Product tracking is highly automated, integrated links between moulding machines and software packages running on PCs provide a real time view of activity.	The Quality Manager describes product tracking as "the black hole" because once a job commences no job status information is available until the end of the manufacturing run. This issue can be addressed by the organisation as TechMakers employ a full time in-house programmer. When time permits the programmer will interface product tracking with the MRP system.	Orders are received by fax and transcribed onto job sheets by hand. As jobs are completed on the shop floor the quantity, colour etc details are confirmed by the foreman writing on the same sheet. Any variations in process are also hand written on the sheet.
Process Improvements BottleTop is using six sigma methods to improve quality, reduce product variability and reduce waste. The company is focussing on improving each process prior to automating it. As the Operations Manager states "We want to have strong processes, we don't want rubbish processes just being done more quickly." When quality processes are in place BottleTop's focus will shift to automation and then to monitoring.	TechMakers processes are well developed and highly automated and with one exception, their work in progress system, discussed in the "Tracking of Products" column. A more difficult process to address concerns the performance of the distributor that acts as the exclusive Australian agent for the US manufacturer of components used by TechMakers.	SwivelMould has not mapped its processes. The process map built for one process as part of the AmI-4-SME process was the first time the company had used process mapping. Tradition and the knowledge of gang foremen are used to guide manufacturing processes.
Training Courses A mix of in-house and external training is used at BottleTop. External training is used to provide Six Sigma training.	No comments made in relation to training.	SwivelMould has developed a competency based training program in conjunction with an external training consultant. The objectives of the training are to increase productivity, quality and produce a change in the organisational culture.

Table 2. Continued

BottleTop	TechMakers	SwivelMould
Growth BottleTop managers are optimistic about their ability to grow revenue in a shrinking market. However, growing acceptance of closure systems make in countries with low labour rates may limits their growth.	TechMakers is and is the oldest and fourth largest contract electronic manufacturer (CEM) in Australia. The CEO is content to remain the fourth largest firm and claims there are advantages in not being the biggest player in the Australian market. The market for CEMs in Australia is shrinking as work moves off-shore. While the Quality Assurance Manager believes the company is committed to increasing revenue, the CEO (who is the owner of the company) stated privately that his objective is to improve the profitability of operations.	SwivelMould's ambitious expansion plans are on track to deliver the anticipated growth in revenue. However as rain water tanks provide 55-60% of annual revenue SwivelMould's plans are dependent to some extent upon the maintenance of government rebate policies, and continuation of Australia's ten year drought. During the course of the study the drought broke on the eastern seaboard, reducing demand for rainwater tanks. While newer entrants to the market have been unable to cope with the downturn in the tank business, SwivelMould's Managing Director is confident of its ability to continue its expansion due to investments made in new products and its pursuit of new markets.
Overseas Operations Sixty per cent of the company's revenue is derived from importation and distribution activities. Logistics is important and problematic for the company as products imported as finished goods create significant supply chain challenges. BottleTop is considering employing a logistics outsourcing firm to manage these challenges	TechMakers are pursuing export opportunities for the technologies they have invented in house. They do not intend to attempt to compete with CEMs located overseas.	A reduction in demand for water tanks has occurred with the breaking of the drought in two cities (Sydney and Brisbane). To some extent this has been offset by increases in exports; the quantity of goods exported to the USA and China has trebled in the last year.
Documentation & Processes Highly integrated with and automated by ICT systems.	Highly integrated with and automated by ICT systems.	Rudimentary documentation, handwritten and physically carried between office and factory floor. Little integration with ICT systems.

in a shrinking market due to its flexibility, rapid prototyping turn-around and high quality output. The CEO and Quality Assurance manager concur that "every day is different." SwivelMould's operations sit between the other two SMEs. SwivelMould offers a full service from product concept through design to manufacture. As each type of product requires a specialised mould, batch runs are used in production. While safety equipment is in use at TechMakers and BottleTop, SwivelMould employees resist using standard safety equipment such as hard hats and hearing protection. Only foremen wear high visibility vests. The Managing Director describes these actions as symptomatic of the "70s culture" that he is trying to change.

AmI Technology Recommendations

The Australian SMEs

The wide range of technical skill levels in the three Australian SME manufacturers results in very few similarities in their technological capacities. The staff in two of the SMEs are happy with the opportunity to enhance their skills and comfortable with process change. In all the SMEs the arrival of technology that is industry-specific is seen as a form of "natural progression" from previous machines. In one SME (SwivelMould) the CEO is experienced difficulty in moving staff away from established skills and procedures.

The recommendations for the SMEs were tailored to the existing environment of each organisation in terms of industry segment and their legacy ICT systems. In the case of SwivelMould, recommendations were made for AmI technologies that either link together existing "islands" of ICT equipment or provide quickly implemented, stand-alone solutions to environmental issues. For example, a recommendation to implement an integrated manufacturing system, taking advantage of the flexibility of wireless communications was made. As Kirchoff, Stockic and Sundmaeker (2006) assert, if insufficient or poorly integrated ICT infrastructure exists the first step towards obtaining the benefits of AmI technologies is to introduce ICT systems to support general manufacturing processes. Given the size of SwivelMould's operations, it is likely that a standardised manufacturing package working on a PC/Windows, Unix or Linux operating environment will address this need. To provide a small example of the benefits available, using a secure on-line order entry system will avoid the need to manually transfer order details faxed to SwivelMould by their distributors onto worksheets.

The second organisation, TechMakers presents a challenge as their business is manufacturing electronic devices and sub-assemblies, effectively acting as an outsourced technology design and manufacture facility for their clients. TechMakers are well aware of AmI technologies and would have already incorporated them into their operations if they had identified potential applications. Furthermore, their key business issues concern their contracting market and their dependency upon an intermediary distributor to order components from the USA. For TechMakers, the benefits available from AmI technology may exist in opportunities to design, manufacture or modify AmI systems for other companies.

At BottleTop an alert system based on AmI technologies in the form of wireless communications has the potential to improve productivity by decreasing the number and duration of production stoppages caused by machine parameters moving out of set tolerances, and release personnel from repetitive inspection tasks for higher value, and more rewarding and interesting work. The following section compares the detailed findings from one Australian SME (BottleTop) with those from a German SME participating in the European AmI-4-SMEs project. Despite differences in industry and location, both these SMEs have very similar opportunities to address production issues using AmI Technologies, pointing to the potential for standardised AmI based solutions to improve SME manufacturing operations.

Comparison between European and Australian SME Manufacturers

German SME (Truckbody GmbH)

Truckbody GmbH claims market leadership for EU manufacture of truck swap bodies (steel framed transport containers, and the legs on which they stand while waiting transfer from truck to truck, or truck to rail) primarily intended for the EU domestic market. A key competence is the manufacture and powder coating of large structures, up to 15m long, such as bus frames. The company employs 330 people, which places it in the EU classification of SME organisations, in contrast to Australia where a SME is classified as an organisation with between 20 and 200 employees. Truckbody's production system is characterized by strong interdependencies between different task groups; a delay in one step impacts many other groups further down the production line.

To reduce production delays the EU Ami-4-SMEs project research and technology partners identified a need for automatic production alerts that interfaced to the company's planning system. The ATB Institute for Applied Systems Technology, based in Bremen, Germany is the project leader of the EU AmI-4-SMEs project, and is currently finalising the implementation of a rule engine and user interfaces on mobile devices. When problems occur in Truckbody's production, employees who need to know about the disruption, such as the shift supervisor and the person with the skill to solve the problem, receive an automatically generated alert message. The alerts are based on user profiles (e.g. manager, foreman), the current location of the user (e.g. meeting, office, home) and the severity of the situation (e.g. deviation threshold, breakdown, loss). Use of a multi-modal user interface, (specifically a wireless message sent to a mobile phone or PDA) leverages the capability of AmI technologies to provide timely alerts that are "pushed" to relevant employees regardless of their location. In this manner, the AmI technology provides immediate and mobile access to production information, warns of delays to the production line, and so supports reallocation of work and staff. Prototypes have been developed as part of the Selection and Specification phase of the study.

Australian SME (BottleTop Pty Ltd)

BottleTop produces a very different product from that of Truckbody GmbH. BottleTop manufactures specialty packaging, with particular strengths in the personal care, pharmaceutical, health foods, chemical, cleaning, food, beverage and cosmetics markets. Operating for sixty years from its single Sydney manufacturing site, it has built a strong sense of loyalty among its 97 employees, and has extensive links to international fastening manufacturers.

Although plastic manufacturing accounts for around 7% of all Australian manufacturing activity, the industry is quite mature (McCaffrey, 2006), and is shrinking at around 4% per year, mainly due to increased purchases from foreign injection moulding companies. BottleTop is growing in this shrinking market, winning market share from its competitors by focussing on quality, service, technology and relationships within and outside the organisation. The company plans to more than double its revenue by 2011/12. While the revenue goal is ambitious, BottleTop's revenue grew by 12% in 2006 even after allowing for a 5% reduction in revenue from its existing customer base due to some customers moving their business to off-shore suppliers.

Discussions with BottleTop's Production Management team identified the following AmI technology scenario as an attractive business concept: BottleTop's moulding and assembly machines have in-built Programmable Logic Controllers (PLCs) which can monitor the six key variables that control the formation of the plastic closure. If a software program collects and monitors the PLC data, when any of these six parameters move outside pre-set limits an SMS alert to a mobile phone, or pager message could be automatically generated and sent to on-site maintenance personnel. This provides several potential business benefits, including minimization of machine downtime, reduction of defective, scrapped product and reduced need for visual inspection. Currently all the plastic fasteners are inspected by a human operator as they leave the machine.

Previous attempts to use computers coupled to cameras to replace human visual inspection of parts leaving the injection moulding machines were not successful due to the camera's inability to cope with reflective foil routinely used in BottleTop's products. It is important to note that the company's HR practices are likely to support the introduction of the proposed AmI solution. A bonus scheme rewarding operators for reducing the amount of defective caps produced from each machine has been enthusiastically embraced; operators have been heard to comment, "That's my money on the floor" when the speed of the machine is set too fast and fasteners overshoot the hopper.

The preceding comparison demonstrates that despite operating in unrelated industries in different countries, some SME manufacturing processes have sufficient commonality to permit the development of generic AmI solutions. Furthermore, the appearance of the same requirement in different manufacturing contexts shows that AmI technologies have the potential to be "general purpose" production enablers in diverse SME manufacturing settings. This in turn suggests the possibility that affordable "turn-key" AmI solutions may become available from technology providers. The next section considers the possibility of third party technology providers tailoring generic AmI solutions to the specific requirements of each SME, thus overcoming the absorptive capacity limitations inherent in SMEs.

DISCUSSION AND DIRECTIONS FOR FUTURE RESEARCH

In Australian manufacturing SMEs, there is a very low likelihood of in-house R&D being used to build absorptive capacity to investigate AmI technologies. SMEs prefer to buy new technology when it is already embedded in an industry specific product rather than master the details of the underlying innovation (Oyelaran-Oyeyinka & Lal, 2006). Instead, we propose that SMEs are more likely to use industry or informal networks to become aware of potentially useful innovations, and then "buy" the innovation embedded in capital equipment or consulting services as a means to 'recognise the value of new information, assimilate it, and apply it to commercial ends' (Cohen & Levinthal, 1990, p.128).

However, Cohen and Levinthal (1990) question the effectiveness of "buying" absorptive capacity in the form of consulting services or through acquisitions when the knowledge is to be integrated with existing business systems. They state "To integrate certain classes of complex and sophisticated technological knowledge successfully into the firm's activities, the firm requires an existing internal staff of technologists and scientists who are both competent in their fields and are familiar with the firm's idiosyncratic needs, organizational procedures, routines, complementary capabilities, and extramural relationships" (Cohen & Levinthal, 1990, p. 135).

Out-sourcing of deep absorptive capacity to equipment and software vendors able to provide "turn-key" solutions that match industry requirements seems to be a way for manufacturing SMEs to gain the commercial benefits of AmI technologies despite the resource and time constraints that prevent them building absorptive capacity in any area other than their core business competence. Similar requirements appear in two very different SMEs on two continents. The potential for the same AmI technology solution components to address these requirements, albeit tailored to the specifics of equipment in use at each site, suggests that SMEs can benefit from AmI technologies by using specialised intermediary organisations to provide the "absorptive capacity" on their behalf. This finding points to potential links between absorptive capacity and "make vs. buy" decision-making, and to "broad" or "deep" versions of absorptive capacity (Henard & McFadyen, 2006) as avenues for future research. In addition, an opportunity exists to track the spread of AmI technologies in SME Australian manufacturers and in doing so contribute to the diffusion of innovation literature.

Additionally, AmI implementation challenges for Australian SME manufacturers extend beyond the boundaries of their own organisations. Large ICT manufacturers use a channel marketing approach to sell their products to the SME market segment. The channels may include retail and direct sales forces, but frequently hardware is "bundled" with service and software offerings from business partners, specialising in a particular industry segment, such as manufacturing. While intermediary business partners may supply specialised knowledge and generic AmI solutions to compensate for limited SME absorptive capacity, the organisations that partner with large ICT providers are often SMEs themselves. The ability and willingness of these business partners to gain AmI skills may in turn be a limiting factor in the adoption of AmI technologies by Australian Manufacturing SMEs. Absorptive capacity limitations of SME organisations can potentially affect uptake of AmI technologies at two points: within the manufacturing SME and within the SME technology partner. Low levels of in-house AmI skills and heavy level reliance on SME Australian technology providers suggest there may be an argument for the provision of government subsidies to encourage the adoption of AmI technologies in Australian manufacturing. A precedent exists in that subsidies have been provided for the purchase of RFID scanners for NSW meat producers (NSW Farmers Association, 2007). Without some form of government encouragement, the task of integrating AmI systems with existing ICT investments and the concomitant diversion from core manufacturing activities, may be enough to prevent the adoption of AmI technologies and, therefore, achievement of the elusive "productivity surge" in Australian manufacturing SMEs.

CONCLUSION

Advances in the development of ICT industry standards, and the proliferation of software and support for the Windows/Intel platform since Cohen and Levinthal's 1990 paper have brought technology to SMEs without the need for bespoke development. Furthermore, Cohen and Levinthal appear to assume that investments in absorptive capacity only exist in the form of R&D spending, rather than networking with other organisations to use "connect and develop" models typical of Open Innovation (Chesbrough, Vanhaverbeke, & West, 2006). In contrast, the results from the EU and Australian AmI-4-SME projects (ATB Institute for Applied Systems Technology Bremen GmbH, 2008) suggest that SMEs can use "external research sub-units" in the form of experiences reported by members of their industry network and trade associations, and solutions proposed by research and technology providers, to offset internal absorptive capacity limitations.

ACKNOWLEDGMENT

The authors would like to thank the SME participants in the Australian AmI-4-SME project for providing access to, and information about their organisations. We would also like to thank our colleagues in Australia, Assoc. Prof. Mile Terziovski and Richard Ferrers at the University of Melbourne, Dr David Low at the University of Western Sydney and our colleagues at the ATB Institute for Applied Systems Technology; Bremen, Germany for their helpful advice and the opportunity to compare Australian and EU based SMEs. The authors would also like to acknowledge the support of an International Science Linkages grant from the Australian Department of DIISR (Project Number CG110181), the University of Western Sydney and the University of Melbourne.

KEY TERMS AND DEFINITIONS

Absorptive Capacity: The absorptive capacity of a firm is comprised of its ability to generate innovations, and absorb relevant knowledge appearing in the external environment.

Ambient Intelligence Technologies (AmI): Technologies that combine to create an environment that is are sensitive and responsive to the presence of people

Open Innovation: Organisations using ideas and capabilities originating outside their boundaries in order to increase the rate with which innovation occurs and decrease innovation costs. Open innovation also includes an organisation selling innovative ideas it has generated but cannot use in its business.

Pervasive and Ubiquitous Computing: Terms in use in the USA to refer to the same technologies as those named Ambient Intelligence Technologies in Europe

Radio Frequency Identification Device (RFID): Data collection devices consisting of electronic tags for storing unique identifying data.

Small Medium Enterprise SME: Small to Medium Enterprise. This measure of a company's size is generally based upon employee numbers, and varies across countries.

Technology Adoption: A process that begins with awareness of a specific type of technology or device, and progresses through stages ending in use or rejection of the technology.

This work was previously published in Handbook of Research on Mobility and Computing: Evolving Technologies and Ubiquitous Impacts, edited by Maria Manuela Cruz-Cunha and Fernando Moreira, pp. 65-82, copyright 2011 by Information Science Reference (an imprint of IGI Global).

Chapter 57
Teaching Technology Computer Aided Design (TCAD) Online

Chinmay K Maiti
Indian Institute of Technology, India

Ananda Maiti
Indian Institute of Technology, India

ABSTRACT

Since Technology Computer Aided Design (TCAD) is an important component of modern semiconductor manufacturing, a new framework is needed for microelectronics education. An integrated measurement-based microelectronics and VLSI engineering laboratory with simulation-based technology CAD laboratory is described. An Internet-based laboratory management system for monitoring and control of a real-time measurement system interfaced via a dedicated local computer is discussed. The management system allows the remote students to conduct remote experiments, perform monitoring and control of the experimental setup, and collect data from the experiment through the network link as if the student is physically in a conventional laboratory. The management system is also capable of evaluating of a student's performance and grading laboratory courses that involve preliminary quiz and viva-voce examinations, checking of experimental data and submitted online laboratory reports. The proposed online TCAD teaching methodology will provide an opportunity for expanding microelectronics education.

INTRODUCTION

The field of microelectronics technology is recognized as a driving force for the Information Age. Micro- and nanoelectronics device and circuit design and fabrication are specialized fields in electrical engineering. The main goal of undergraduate and/or postgraduate level microelectronics teaching is to produce high-quality engineers who are able to make contributions in the context of the rapid change that characterizes integrated circuit (IC) fabrication. For microelectronics courses, laboratory should include a clean room infrastructure, semiconductor equipment operation procedures, process and metrology, device testing, and process integration and manufacturing learning as hands-on fabrication as well as characterization of devices that enhance the educational

DOI: 10.4018/978-1-4666-1945-6.ch057

experience. However, due to the high cost of a microelectronic fabrication laboratory, teaching microelectronic circuit fabrication is very much driven by the availability of resources at the institution providing such courses and is primarily taught at universities where an actual fabrication facility is available and, currently, it is mostly taught via demonstration mode. Microelectronics engineering education is in transition. New thought is being given to topics such as what constitutes microelectronics process design fundamentals, how to shrink the gap between industrial and academic perspectives on process design, and how to help students gain more experience and knowledge.

Currently, in most final year undergraduate and virtually all master's level programs, there are courses on device physics and processing technology (usually as one single course) based on standard text books on MOS and bipolar device physics that often do not include a laboratory component. Integrated circuit fabrication courses are offered as an elective in some Electrical and/or Electronic Engineering programs that cover fabrication theory of integrated circuits and process modeling. The introduction of process and device simulations in undergraduate teaching is also considered a difficult task. This is mainly due to the complicated user interaction with most of the available process and device simulators; usually the input information is prepared in the form of files written in a specific input language for each simulator. In general, professional Technology CAD (TCAD) simulation tools are difficult to use and are considerably more complex. The users need dedicated training sessions to successfully use the tools.

Also, during the last three decades, a new generation of semiconductor processing involving new material systems such as strained-Si and Silicon-Germanium (SiGe) have appeared, and integration of Group III-V compound semiconductors with Si technology is evolving (Maiti, Chattopadhyay, & Bera, 2007). With these advancements in semiconductor manufacturing, it is becoming difficult for the VLSI designers to optimize circuit design without considering the effects of advanced ULSI/GSI integration processes. The International Technology Roadmap for Semiconductors (ITRS, 2007) predicts the use of TCAD may provide as much as 40% reduction in technology development costs. TCAD has grown in both sophistication and maturity and is now an essential engineering tool for new technology development in industrial environments. Recent industry trends have given rise to major development opportunities for TCAD, and the virtual wafer fabrication has now become an integral part of semiconductor fabrication.

THE NEED

Semiconductor device theory and IC processing courses are becoming more important in electrical engineering curricula due to the fast changing semiconductor technologies and the challenges faced by the semiconductor industry. Process/device simulation tools are being introduced to students taking graduate courses in device physics and SPICE for circuit simulation. Semiconductor CAD originated in the early 1960s with efforts to understand and optimize bipolar transistors (Dutton, & Yu, 1993). TCAD is now a proven approach for developing process technologies, and a comprehensive set of TCAD tools is available from universities and from TCAD vendors. Advanced TCAD tools are capable of modeling the entire semiconductor manufacturing process. Also, the most challenging issue in the context of IC design and manufacturing now is product yield because the main causes for yield loss have changed over the years. Technology development in the semiconductor industry is a very complex task and requires a deep understanding of different physical and mathematical techniques. Next generation semiconductor engineers will need to be competent in the use of advanced process and device simulation tools as part of their everyday practice, as TCAD simulation allows a more transparent vision of state-of-the-art IC fabrication. The renewed focus on chip interconnects is moving TCAD modelling beyond active devices and further into the higher levels of the EDA tool hierarchy.

It is imperative that microelectronics education introduce industry-standard computer aided design tools to enhance traditional teaching methods and to provide students with the necessary CAD skills as required for semiconductor industry. TCAD software requires a considerable investment both in development of new capabilities and training in the use. Several attempts have been made to integrate professional TCAD simulation tools in semiconductor device courses (Kenrow, 2004). The students are also encouraged to take an IC fabrication laboratory along with the course. However, available TCAD tools are dispersed in nature and problems are encountered in locating, acquiring, installing, and learning to operate a proper simulation tool. The other difficulty is to provide the students with access to TCAD simulation tools through user-friendly computing platforms, which now tend to be personal computers to support the process/device simulation and modeling activities.

Availability of high-speed internet and advances in Information and Communication Technology (ICT) has allowed the enhancement of traditional learning methods. Advances in computer technology have made it feasible to provide engineering students with computer support for learning, especially in technical education. Nowadays, many universities have developed e-learning materials for theory courses and online laboratory facilities allowing students to perform laboratory experiments by simulation or with remote equipments (Maiti, 2010, Fjeldly, & Shur, 2003). Internet accessible device simulation laboratories for semiconductor education, which is a virtual laboratory accessible via standard World Wide Web (www) browsers, have also been reported and provide students using different computing environments access to a broad range of simulation tools (for example, http://www.ecn.purdue.edu/labs/punch). Users can define simulations, run them, and view the printed and graphical output.

To take full advantage of the predictive power of TCAD to reduce cost and time in semiconductor process development, introduction of "Technology CAD" as a subject in final year undergraduate and graduate level microelectronics courses was introduced in 1998 at IIT Kharagpur. In this chapter, we shall present a summary of our experiences gained in teaching TCAD during the last ten years. Emphasis is given to the critical role of the integrated online TCAD laboratory toward VLSI design along with process and device modelling. The chapter will address the issues and problems related to the intranet and/or internet to be used as the network for TCAD simulation laboratory for the remote users. Technology CAD is a one-semester, three credit (35-40 lecture hours and 30 laboratory hours) course for graduate students enrolled in Microelectronics and VLSI Design at IIT Kharagpur. The curricula are designed in such a way that the students are exposed to design procedures by participating in device and process designs via simulation. The course covers various topics via lectures, homework, laboratory assignments, and design projects that give the students the opportunity to gain extensive knowledge in semiconductor device/circuit design and fabrication. A brief review of the TCAD applications in semiconductor manufacturing is made first. The TCAD course structure and the objectives of the laboratory session are presented next. Use of an integrated measurement-based online Microelectronics and VLSI Engineering Laboratory and simulation-based Technology CAD Laboratory for expanding microelectronics education is described in detail.

What is Technology CAD?

Simulation of the fabrication steps of microelectronic devices and integrated circuits is a technique that is used extensively in silicon IC manufacturing to speed product development and reduce the development costs. Technology computer aided design is the term used to describe a broad range of modeling and analysis activities that consist of detailed simulation of IC fabrication processes, device electrical performance and extraction of device parameters for equivalent circuit models. Semiconductor manufacturing companies use TCAD for monitoring, analyzing and optimizing the IC process flows. The demand for engineers with experience in TCAD is increasing. Possessing a working knowledge or proficiency with TCAD is rapidly becoming a highly marketable skill for process engineers. Introduction of TCAD tools in device physics courses is becoming a necessity to provide the students with critical skills in the microelectronics area.

Two major components of TCAD are (a) Process simulation and (b) Device simulation. Process simulation is modeling of semiconductor manufacturing processes. Process simulation allows one to investigate the possible process steps prior to actual fabrication. Process simulation includes basic unit steps such as oxidation, implantation, diffusion, etching, growth, and deposition. Process simulation can also highlight issues that could potentially lead to circuit failure. Simulations allow verification of process design rules with the goal of design for manufacturability. Device simulation is for modeling the semiconductor devices. Device simulation produces the dc and ac characteristics of devices and is used to determine transistor models. SPICE model parameters are extracted from the measured electrical characteristics and the model parameters can be used in circuit simulators such as SPICE, which is often used as a key tool in Electronic Computer Aided Design (ECAD) to design VLSI circuits.

As TCAD helps in the design of process technology, it is often used in research and development of new processes and devices using computers as a substitute for the semiconductor processing laboratory. In process modeling, a systematic design of experiments (DoE) run is performed. DoE experiments can be systematically set up with control over process parameters and arbitrary choice of device performance characteristics. Most TCAD simulation tools provide detailed, colorful plots of device profiles and processing steps, giving the student the ability to see what is happening inside the device and to understand how the details of fabrication affect device properties. TCAD also offers greater physical insight into device operation; for example, one can visualize parameters that cannot be measured, such as current or electric field distributions inside a device. A costly fabrication laboratory is not needed for the purpose of demonstrating the fabrication steps as a computer is used as a substitute for a semiconductor processing laboratory. Students can also perform TCAD simulations beyond normal laboratory hours and at their own pace. Currently available professional TCAD tools are a very powerful and economical means for teaching microelectronics technology.

The area of Design for Manufacturing (DFM) is also becoming very important. The idea of DFM is to shorten the design cycle, to reduce manufacturing costs, and to improve yield, resulting in faster time-to-market and increased profitability. TCAD also addresses the issues of process and device variability in manufacturing to mitigate the rising costs of semiconductor process and product development as each technology node is driving towards higher performance and increased complexity. TCAD may be used as a powerful tool to identify root causes for yield loss and are used to study device sensitivities on process variations. Currently a major trend in the industry is to apply TCAD tools far beyond the integration phase into manufacturing and yield optimization. Linking of process parameter variations with the electrical parameters of a device through Process Compact Model (PCM) is in use. Process Compact Models are necessary to enable efficient analysis of complex and multivariate process-device relationships, with applications to enhancing process manufacturability and process control. PCM may be used to capture the nonlinear behavior and multi-parameter interactions of manufacturing processes. This is driven by the fact that product yield loss nowadays is dominated by systematic defects coming from lithography and IC design as well as by random process variations. For an extended TCAD in process modeling, generally a systematic design of experiments run is performed. DoE experiments can be systematically set up to study the control over process parameters and arbitrary choice of device performance characteristics. SPICE process compact models (SPCMs) can be considered as an extension of PCMs applied to SPICE parameters. By combining calibrated TCAD simulations with global SPICE extraction strategy, it is possible to create self consistent process-dependent compact SPICE models with process parameter variations as explicit variables.

The simulation experiments in TCAD have the advantage that every process condition can be accurately controlled and that arbitrary product performance characteristics can be determined. This is opposed to real experiments, where the control of process steps may be difficult and subject to uncontrollable drift or variation in the equipment and where the limitations of metrology can make it difficult, expensive or impossible to make both nondestructive and destructive measurements. Visualization is one of the big advantages of TCAD tools, as during process simulation, evolution of actual cross-sections of the structure can be observed.

SPICE Parameter Extraction

The success of a VLSI circuit design depends on the device models used to describe the device behavior. As semiconductor devices shrink, the need for accurate circuit simulation SPICE model becomes acute. The most important test structures in an IC manufacturing process are the devices themselves. It is thus imperative that these devices are accurately characterized so the most accurate model parameter set for the device under test can be extracted. The device models usually consist of a set of model equations that are either empirical or derived from device physics or a combination of both. Therefore, the design of integrated circuits is heavily dependent on circuit simulation, which needs compact device models. From the measured device characteristics SPICE parameters are extracted.

Parameter extraction is an integral part of compact modeling. The goal of parameter extraction is to determine the values of device model parameters that minimize the total differences between a set of measured characteristics and results obtained by evaluation of the device model. Several programs for parameter extraction are available on a commercial basis. Agilent offers an integrated circuit characterization and analysis program (ICCAP, 2004). ICCAP offers device engineers and designers a state-of-the-art modeling tool that fills numerous modeling needs, including instrument control, data acquisition, parameter extraction, graphical analysis, simulation, optimization, and statistical analysis. ICCAP runs on MS Windows 2000 or XP platforms and is easily accessible via Internet. Microsoft's Remote Desktop Connection, an application that recreates the desktop of a remote machine on the local machine over a network, may be used for parameter extraction from remote locations.

Silvaco's Universal Transistor Modeling Software (UTMOST, 2008) is another data acquisition and parameter extraction tool with applications in the areas of device characterization and modeling. UTMOST generates SPICE models for analog, mixed-signal and digital applications. UTMOST accepts data from direct measurements, measurements stored in a measurement log file, process and device simulation, or from other model parameter sets in order to create a suitable parameter set for a chosen model. UTMOST can control a wide range of commercial measurement equipment and probers so a user has maximum flexibility in the configuration of a measurement system. UTMOST supports the simulation of dc, transient, capacitance and s-parameter characteristics. UTMOST also incorporates commercial device models, user-defined device models and macro models.

THE TECHNOLOGY CAD COURSE

The TCAD course, offered since 1998 at IIT Kharagpur, has four primary objectives, and upon successful completion of the course, the students should be able to demonstrate a high level of proficiency. These objectives are as follows:

1. The use of TCAD tools allows students to learn the fundamentals of device processing in a virtual environment, including the determination of SPICE parameters;
2. The ability to develop skills on semiconductor process design (very similar to the actual experience obtained from a fabrication laboratory);
3. The ability to acquire proficiency with the use of TCAD tools and issues relating to analog and digital circuit design; and
4. For a career in circuit design (both analog and full custom digital) and/or as process engineer.

To support the aims and learning objectives more effectively, the course goes beyond the possibilities offered by traditional lecture type microelectronics courses. The curriculum was developed by researching various universities recognized for microelectronics education. TCAD software tools are introduced to students taking a required course in semiconductor device physics in the electrical engineering program. The course consists of theory (3-credits) in classroom (three hours) and the online TCAD laboratory (http://lod.iitkgp.ernet.in/netlab/). The classroom teaching is used to present and develop specific topics that support theory and the corresponding laboratory work. As part of the course, students are introduced to the TCAD tools during class demonstrations by the instructor. Students are expected to spend time in the classroom learning the theoretical background, objectives, and purposes of the simulation runs to be performed in the laboratory sessions.

Visualization is one of the biggest advantages of TCAD tools. During the process simulation, the evolution of actual cross-sections of the structure can be seen. TCAD visualization can also be brought to the classroom in different ways. Simulation results in a fixed graphics format can be integrated into the lectures, and the evolution of a simulation can be presented as a movie, e.g., embedded in a PowerPoint presentation. Tutorials are critical to the learning environment because they are designed with the purpose of enabling students to learn the material independently in an adaptive learning environment (learning at their own pace and areas of interest). Following the classroom teaching, the students continue with the tutorials, which are assigned as homework. TCAD tools in the laboratory are made available in an open laboratory environment in which students can use the software independently at any time and from anywhere. TCAD softwares (mostly the student versions) run with reasonable speed on any modern laptop under Linux or Windows operating systems, making interactive simulations possible in classroom as well.

The topics covered in lecture classes are the introduction and overview, role of TCAD for semiconductor technology development, TCAD principles, tool integration, process technology for Si, silicon-germanium (SiGe), III-V semiconductors, process simulation, device simulation, bipolar and MOS device models, heterojunction device modeling, simulation of SiGe HBTs, simulation of heterostructure FETs, simulation of AlGaAs/GaAs devices, introduction to virtual wafer fabrication (VWF) automation tools, device characterization and dc and ac SPICE model parameter extraction, TCAD calibration procedure, process compact models (PCM), and design for manufacturability (DFM).

TCAD LABORATORY

With the advancements in semiconductor manufacturing, it is becoming increasingly difficult for the VLSI designers to optimize the design without considering the effects of the VLSI processes. The conventional TCAD laboratory is designed for both undergraduate and graduate students. It takes place in a classroom where a stand-alone sever running the Silvaco suite manages twenty PCs as clients. The Silvaco software used by the students are ATHENA, the process simulator, and ATLAS, the device simulator. Prior to the beginning of the laboratory sessions, an interactive software presentation is conducted that helps the students set up the preliminaries necessary for simulation runs for the tutorials, like doping, diffusion, etc. The tutorial sessions also include several simple example runs for familiarization with the tool. The laboratory class consists of five/six sessions. All sessions are designed for developing two levels of knowledge: the definition/implementation of the simulation script (input file) and the analysis/understanding of the results.

Session 1: The process simulator ATHENA is introduced. The student simulate step-by-step an NMOS transistor. During this session, the doping profiles are investigated after each process step. In this session the effect of boron implantation used for the threshold voltage adjustments is studied. Also in this laboratory session the students observe the evolution of the device structure through all processing steps and are asked to write down their observations.

Session 2: Still with the ATHENA tool, this session continues with the polysilicon deposition and finishes the transistor processing. Like the prior session, the doping profiles are investigated after each step. The students are encouraged to compare the process flows for long channel and short channel devices.

Session 3: The device simulator ATLAS is introduced. In this session the students compute the ID-VD and ID-VG characteristics of the NMOS transistor for several process parameters. The gate sweep covers the operation regions of accumulation, depletion, inversion and deep inversion. The student then compares 1D cross-section of the carrier distributions at the center of the device with the theoretical predictions. With this comparison, the student is able to analyze the short channel effects observed in MOSFETs.

Session 4: In this session the mixed-mode device and circuit simulators are introduced. The electrical characteristics are used to obtain the compact model of the transistor and the students have to build a CMOS inverter.

Session 5: The student uses the Silvaco tools to design a process flow for a bipolar transistor using the graphical process flow editor tool. The students test the process flow by simulating it with the process simulation ATHENA and extracting the doping profiles across the emitter, base and collector regions.

Session 6: With the device simulator ATLAS, the students compute the output and Gummel characteristics of the BJT for several process parameters. The electrical characteristics are used to obtain the compact model of the transistor. The student extracts Gummel-Poon model parameters from TCAD device simulations.

TCAD Tools

During the last forty years, various simulation tools, mostly from the University laboratories have been reported. The principal aim has been to provide semiconductor engineers with computer simulation tools that form a quantitative link between the basic technological parameters and the electrical behavior of semiconductor devices. With the rapid development of the semiconductor industry, movement of individual TCAD tools from predominantly research and development to production environments has taken place (Fasching, Halama, & Selberherr, 1993). This fact has motivated a rapid development of TCAD systems as a uniform framework that supports the effective usage of multiple simulators with simple user interface, convenient and standardized data transfer, and visualization. Commercial TCAD vendors (Silvaco and Synopsys) provide an excellent collection of TCAD systems from different points of view regarding their respective origins, interests and goals. Commercial TCAD tools may be used to show students the link between physical and electrical simulation through the mixed TCAD and electrical simulation abilities of Silvaco and Synopsys tools. Advanced TCAD suites include process simulation, device simulation, compact models parameter extraction and circuit simulation suites, interconnect simulation, and optimization to other technology CAD requirements. However, the use and maintenance of coupled TCAD tools becomes difficult and requires a significant level of user experience.

TCAD Tools: Remote Access Solutions

Historically, all the TCAD tools developed were available on various UNIX-based platforms. Central computer servers often with multiple CPUs and UNIX- or Linux-based operating system and large amounts of RAM are used, as such servers are ideal for large-scale computing tasks such as TCAD. Attempts have also been made for Windows versions of TCAD tools, but the use of Windows versions are very limited, as the software packages are distributed and supported by third-party vendors. Also, as laptops are typically optimized for mobility and long battery life instead of large-scale computation, laptops are generally not used for running TCAD applications. However, the use of commonly available remote access software tools conveniently transforms a Windows-based laptop into a graphic terminal for a central UNIX- or Linux-based computer server. Choosing a remote access tool requires several important considerations, as they are available from various vendors and differ in several respects:

- Bandwidth requirements
- Support for encrypted data exchange
- Support for Open GL graphics
- Possibility to disconnect from and reconnect to a terminal session
- Possibility to use local Windows applications
- Ease-of-use and initial setup
- Cost

ONLINE LABORATORY AT IIT KHARAGPUR

Major steps for remote online laboratory development are (a) the design of the experiment, (b) remote control and operation of the instruments (for example, via LabVIEW, IC/CVlite, EasyExpert, VEE etc), (c) conversion to web applications, and (d) launching the experiments on the internet. A modular online remote laboratory typically consists of 12-15 hardware-based experiments that always need to be made available to students. The Laboratory-on-Demand (available at http://lod.iitkgp.ernet.in/netlab/) is an initiative to develop an online measurement-based novel integrated Microelectronics and VLSI Engineering Laboratory with simulation-based Technology CAD laboratory. The Home page for the laboratory is shown in Figure 1. An online TCAD laboratory gives the student, even at the undergraduate level, a chance to learn about realistic silicon wafer processing via hands-on simulation experiments. Recent advances in computer hardware now make even

Figure 1. The TCAD laboratory

a standard laptop suitable to run TCAD simulations in a matter of minutes. In Microelectronics and VLSI Engineering Laboratory, the students perform real measurements on a wide variety of devices. The measured experimental data are then passed on to the simulation-based TCAD laboratory for the extraction of SPICE parameters and will be discussed later in this chapter.

Microelectronics and VLSI Engineering Laboratory

Measurements are fundamental to an understanding of any semiconductor device. To teach device design and developing concepts at the Indian Institute of Technology, one of the premier engineering educational institutions in India, we use tools from the National Instruments (NI) electronics education platform. With the NI ELVIS integrated design platform combined with LabVIEW (Travis, 2000), we teach microelectronic devices concepts in the EC29004 Semiconductor Devices Laboratory and the EC39004 VLSI Engineering Laboratory classes. The EC29004 and EC39004 courses are required for juniors in the electronics and electrical communication engineering and electrical engineering degree programs at IIT Kharagpur.

The Internet is a powerful tool for engineers both for measurement and automation of the characterization laboratory and process optimization; allowing them to access from distant locations, along with their control. Internet-enabled measurement of devices utilizes the internet to achieve greater flexibility. The laboratory management system should be able to handle both the hardware and the software components. The hardware side includes the design and development of an experiment and controls it from the local computer. The software side covers the design and development of the tools for the physical measurement and administration. There are many factors associated with the network, the internet or the intranet, that have direct influences on the system performance throughout the remote operations. These factors among others need to be addressed for a proper application of online laboratories.

The Laboratory Server developed by the IIT Kharagpur NetLab developer team has several interesting features. Briefly, the IIT Kharagpur NetLab is an online Microelectronics and VLSI

Engineering Laboratory in which several experimental modules are included. In this chapter, we emphasize the device characterization module, which makes use of two distinct pieces of laboratory hardware/software. The heart of the system is the LCR meter and a semiconductor device parameter analyzer (Agilent E4980 and Agilent 4156C). Broadly speaking, the units generate the user-specified inputs to a connected test device, perform the test and collect the measured data. The Laboratory Server, at a high level, consists of three main software layers. The first is the Web Server Layer (WSL). This portion of the system contains all functionality that operates within the web server process space on the Laboratory Server. The second is a system Data Layer, which contains system information such as experiment logs, accounts, system settings, etc. Third, the Experiment Execution Layer interfaces directly with the laboratory hardware and is responsible for performing experiments submitted to the system.

Online Laboratory Development

During development of the Microelectronics and VLSI Engineering Laboratory, the roles of the System Administrator, Laboratory Manager, and students were considered in an integrated manner. For example, System Administrator's role includes (a) Design of online laboratory system specifications, (b) Design of measurement, monitoring and control interface, (c) Administrative interface and database, (d) Web server configuration design, (e) Design architecture for sharing remote laboratories, (f) Adding/removing experiment, (g) Failure detection/recovery, (h) User login, (i) Time scheduling, (j) Managing students accounts, (k) Automation of student performance evaluation, and (l) Student feedback. The Laboratory Manager's role includes (a) Preparing experiment modules, (b) Assisting students to conduct experiment, (c) Maintaining the experiment, (d) Developing new experiments, (e) Student's progress report generation, and (f) Laboratory grade sheet preparation/publishing. The students' role includes (a) Selecting laboratory and the experiment, (b) Studying laboratory manuals, (c) Appearing for preliminary quiz, (d) Booking experiment time, (e) Performing the experiment, (f) Passing the control to partner (collaborative learning), (g) Submitting laboratory report, (h) Appearing for viva-voce examination, and (i) Closing the laboratory session.

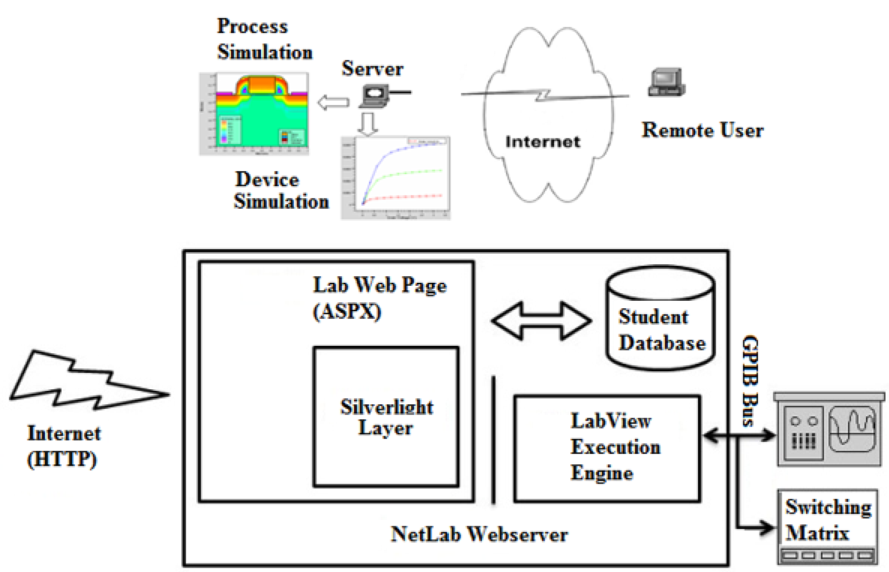
The System Administration Interface (SAI) contains Microsoft Silverlight or equivalent Web Application that captures the administrative functionality necessary to run the Laboratory Server. This includes human interfaces for log/record viewing and resource management. This interface is accessible only to registered Laboratory Server administrators and, as such, also contains authentication and authorization functionality. In the current version of the Microelectronics and VLSI Engineering Laboratory software, the validation of experiment specifications is handled entirely by the Laboratory Server. The experiment validation component contains all the functionality required for implementing any experimental module. After the experiment module is confirmed, the specification is checked for permission for submitting the experiment as well as the software imposed (by LabVIEW) constraints on the device. This confirms that the specified experiment should be allowed to run within the current configuration/session.

The Experiment Execution Layer (EEL) is a laboratory module (experiment) specific set of components that interfaces directly with the laboratory hardware and governs the experiment execution process. This layer can be broken into three individual components: the execution engine runs as a separate and independent process and interacts with the other Laboratory Server layers. The execution engine runs in the background at all times while the Laboratory Server is operational. At a given interval, the execution engine checks the experiment execution queue for new jobs. In order to communicate with the laboratory hardware, the Experiment Execution Engine (EEE) uses the methods defined by the set of Hardware-Specific Drivers (e.g., Agilent E4980). This component is made up of a series of custom built drivers specific to the hardware. In particular, each of these driver libraries defines methods that are specific to the piece of hardware they are meant to control using low level GPIB commands. At the lowest level of the Experiment Execution Layer is the library defining the GPIB Interface API. For the Laboratory Server to control the necessary laboratory hardware via a GPIB network, a GPIB Interface card supplied by the manufacturer must be installed. Combination of National Instruments (NI) software and hardware is found to be very effective for development of web-based laboratory such as Microelectronics and VLSI Engineering Laboratory. With the flexibility and power of NI ELVIS and LabVIEW, students can perform automated measurements. The online laboratory organization is shown in Figure 2.

Laboratory Management

As one particular experiment can be performed at a time by an individual student or a group of students (in case of collaborative learning), a careful scheduling of the experiments is required. Thus, for proper implementation and management of online laboratory system, an efficient laboratory management system is essential. As the experiments require 'real-time' control of the equipment, the online laboratory currently uses 'time-slot', during which the students set the measurement conditions and conduct experiments from remote PC. The time-slot (duration) is the time necessary to carry out an experiment and needs to be pre-estimated. The scheduling system for online experiments assumes the student would be able to finish the experiments during this time, just like they would in a conventional laboratory. The students first select a time slot and register (booking) to use the laboratory. At the scheduled time, the student logs in and is able to launch the laboratory client. However, the students can read manuals, watch experimental setups and videos, analyze the measured data without occupying the measuring equipment. Interactive experiments require the control of instruments, during which the users set the parameters and observe the results. As the actual measurement time is usually very

Figure 2. Online laboratory architecture



short, it is not desirable to provide the equipment to students for long periods of time. In fact, for a measurement, most of the time is spent setting up measurement conditions and post experiment data analysis. Thus, for proper utilization of the resources, proper scheduling is necessary in the laboratory management system. In order to choose the laboratory service provider with different kinds of measurement equipment and target devices, an efficient equipment sharing software tool is necessary in case of multiple student requests arriving at the same time.

When a student is prepared to conduct the experiment involving a unique experimental setup (i.e., cannot be used concurrently by others), the student logs in and is able to launch the laboratory client for the time slot already registered. Each experiment is associated with a given time length the administrator thinks is enough for the experiment, keeping in view the speed of the Internet and other network elements. The workflow may be summarized as follows:

- Selection of the experiment
- Opening of the scheduling web page link in the experiment page
- The system displays the scheduling interface for the next 15 days
- The system displays the available time slots for the selected experiment in green color
- The learner selects the date/time for an experiment in the scheduling interface
- The learner selects the desired time slot and submits the request for booking
- The system saves the learner schedule information and updates the scheduling database.

The system displays a confirmation of the schedule to the learner. In due course, the user is given a temporary link to the web page through which the equipment can be accessed and controlled. After the specified amount of time, a JavaScript automatically closes the window with a warning. Some of the advantages of the time-slot scheduling are the user gets full control of the equipment/system and performs the experiment at any time he/she wants and does not have to wait, and it is ideally suited for experiments where several measurements are necessary under different measuring conditions. However, the utilization of the resources is poor and the efficiency of the management system is not high since the equipment is not always in use and is sitting idle for some time and the number of users accessing the resources is low. Existing remote laboratories limit the number of users to the number of actual available resources. By integrating mixed-mode scheduling services in the laboratory management system, it is possible that a diverse set of experiments can easily be deployed online, and resources can be shared, thus optimizing the resource utilization.

MOSFET Characterization and Modeling

In this experiment, the student first measures the MOSFET characteristics, such as output and threshold voltage characteristics. Using these measured data, the student extract the "MOS Level 1" compact model parameters for a long-channel device. For a short channel device, the students use TCAD simulations for parameter extraction.

MOS Capacitor Characterization and Modeling

Maintaining the quality and reliability of gate oxides is one of the most critical and challenging tasks in any semiconductor fabrication. Electrical characterization and monitoring are critical for maintaining gate oxide uniformity. Many electrical characterization techniques have been developed over the years to characterize gate dielectric quality. However, the most commonly used tool for studying gate oxide quality in detail is the Capacitance-Voltage (C-V) technique. C-V test results offer a wealth of device and process information, including bulk and interface charges and many MOS device parameters. The importance of C-V measurement techniques is that a large number of device parameters can be extracted from the high frequency C-V curve. These parameters can provide critical device and process information. In this experiment, 1D MOS capacitor model is used to explain the formation of the inversion layer in an MOSFET device. While such a 1D model is quite appropriate to describe the long channel devices, modern deep sub-micron MOSFETs exhibit strong 2D effects, such as charge sharing between the source and drain depletion regions and the depletion under the gate. With TCAD simulation, these effects can be visualized.

For the TCAD simulation laboratory, a physically based, semi-analytical, charge control model for Silicon-Germanium (SiGe) quantum well MOS capacitor structure has been developed for the purposes of simulation. The program calculates the capacitance, charge distribution in the SiGe quantum well and parasitic surface inversion layer under various gate biases. The SiGe layer should be underneath a thin Si cap layer to assure formation of a high quality gate oxide since oxides formed directly on Silicon-Germanium have high density of interface states. The MOS capacitor structure consists of the following layer sequence: (100) oriented p-type substrate, p^+ doping spike, Si spacer layer, SiGe quantum well, Si cap layer, oxide and gate. It is assumed that the semiconductor region is doped uniformly throughout with N_d donors/cm^3, with the exception of the p^+-doping spike, which is doped with N_a acceptors/cm^3, and thin enough so that it is fully depleted at zero gate bias. Here, we have utilized quantum mechanical descriptions for mobile charge distributions in the Silicon cap layer and SiGe well layer using internal electrostatic potential calculation. In this experiment, the students first measure the MOS capacitor characteristics and then compare the experimental data with TCAD simulation.

Bipolar Transistor Characterization and Modeling

In the following, we discuss in detail the bipolar device characterization module, which makes use of a single instrument (Agilent 4156C) for the characterization of bipolar junction transistors (BJT) involving five experiments sequentially. The Experiment Module for BJT characterization consists of the following experiments:

- Static Collector Characteristics
- Gummel Plot
- Emitter Resistance
- Collector Resistance
- Current gain vs. Collector Current

In this experiment the students are asked to do the following:

- Collect data on output and transfer characteristics for a given device,
- Graph observed characteristics
- Download and analyze data
- Extract device parameters from the data and model the bipolar device

The complete range of semiconductor dc parameters can be quickly and accurately evaluated with 4156C stand-alone instrument. The measured static collector characteristics of an NPN transistor are shown in Figure 3. Results may be used to analyze to obtain early voltage and collector output resistance. One of the most important steps in evaluating bipolar transistor parameters is measuring collector current and base current as a function of base-emitter voltage (Gummel plot). These measurements can be graphically analyzed to obtain saturation current, current gain, and current gain vs. collector current characteristics, along with base resistance and recombination current characteristics. The collector current and base current characteristics are illustrated in Figure 4. The series resistance of the emitter of a bipolar transistor can be determined by stimulating the base with current and measuring the voltage between the collector and emitter. The inverse of the characteristics curve gradient can thus be obtained for emitter resistance determination. The measured characteristics are shown in Figure 5. Figure 6 shows how the 4156C can be used to accurately measure series collector resistances in low voltage regions, making it particularly valuable in parametric analysis of CAD models. The measured transistor's current gain vs. collector current characteristics is shown in Figure 7.

In the integrated online TCAD laboratory described above, simulation program, Tool for Electronic Model Automation (TEMA) is used for the extraction of SPICE parameters (TEMA, 2010). The software is an EDA tool for automated SPICE modeling of advanced semiconductor devices for development of an Analog/RF circuit design kit. The tool is suitable for modeling of dc, ac, RF, 1/f Noise and high-frequency noise for on wafer or packaged semiconductor devices. The parameter extraction for the industry standard compact models, such as, SGP, VBIC, HiCUM, BSIM, PSP and HiSIM can be performed for design of complex analog/RF circuits and to verify analog mixed-signal designs. In the present version used in our laboratory, only the dc simulation is implemented. The extracted SPICE parameters from the measured Gummel plot (see Figure 4), are shown in Figure 8.

STUDENTS' PERFORMANCE EVALUATION

Keeping track of each learner's activities and progress in the laboratory sessions is essential for the instructor. In the Microelectronics and VLSI Engineering Laboratory, the students' performance evaluation (for each experiment) is generally done at several stages: i) pre-laboratory quiz (after which a student is allowed to book time and perform experiment), ii) submission of the laboratory report after the successful completion of the experiment, and iii) appearing in the viva-voce examination for the experiment. Once an experiment is successfully performed, the student needs to save the data for analyses. After the completion

Figure 3. Output characteristics

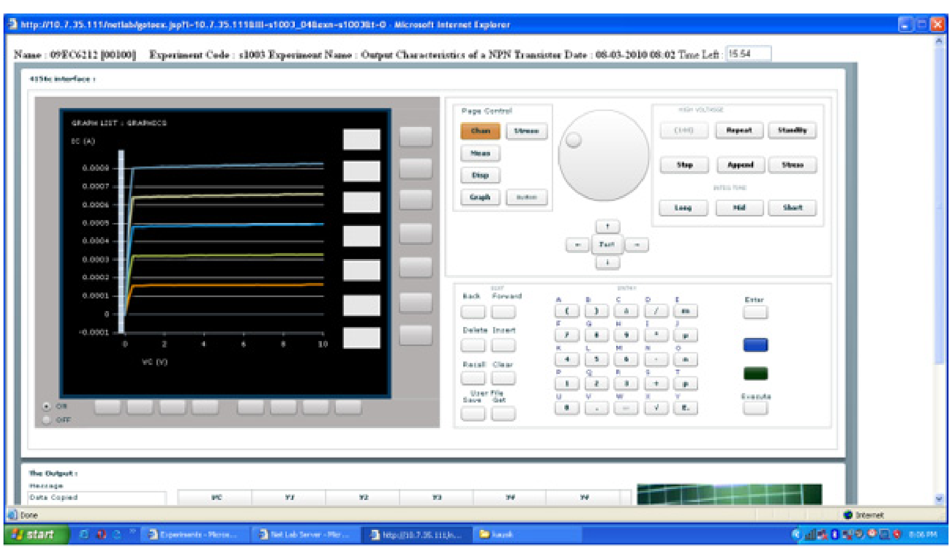


Figure 4. Gummel plot

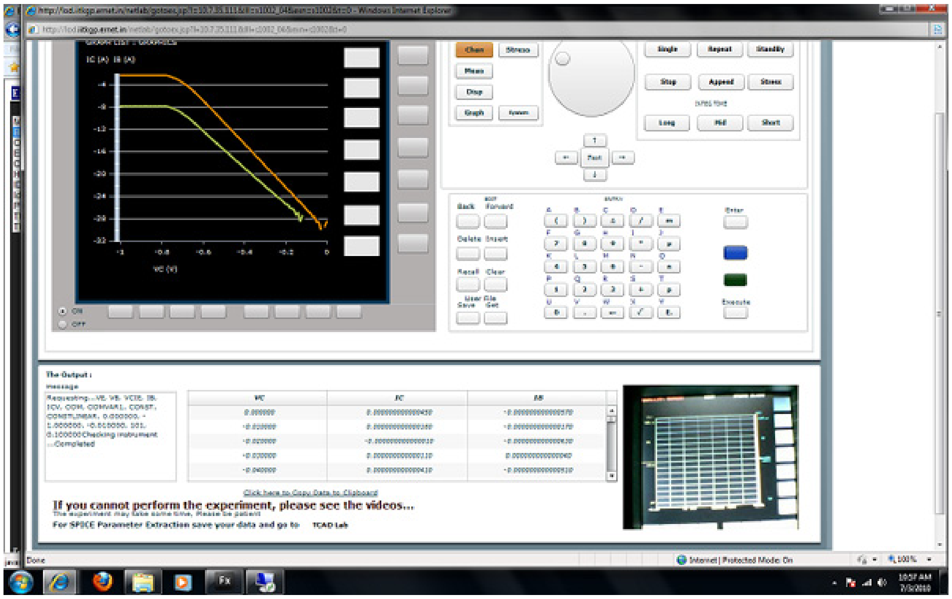

of the data analyses, the student has to prepare a detailed laboratory report for submission. In the developed laboratory management system, an online submission facility is provided. The online report submission format contains the details from the experiment as well as the data obtained and the analyses. The uploaded laboratory report may be edited by the student for some time even after submission. Only the laboratory teacher has access to this report for evaluation and comments. Students are not allowed to have access to reports submitted by other students. Only after successful submission of the laboratory report, can the student take part in the viva-voce examination,

Figure 5. Emitter resistance

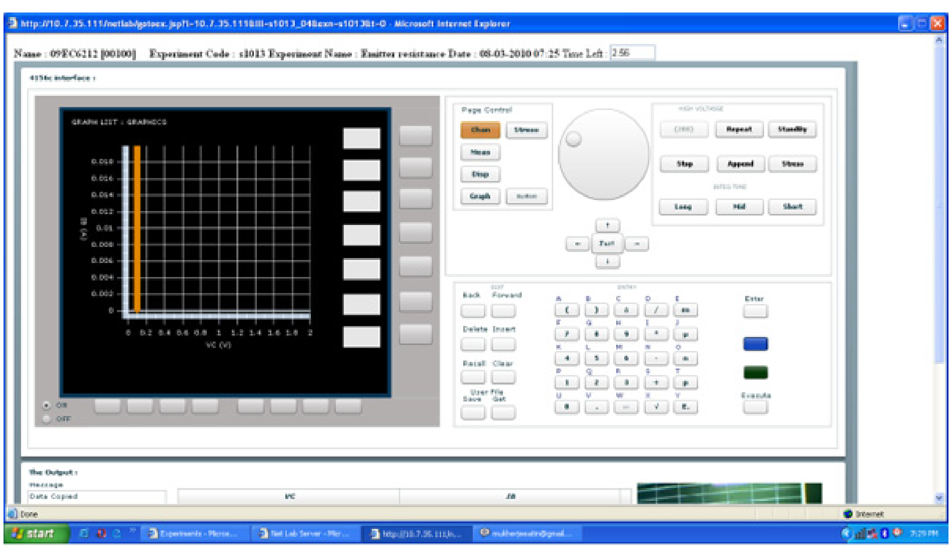

Figure 6. Collector resistance

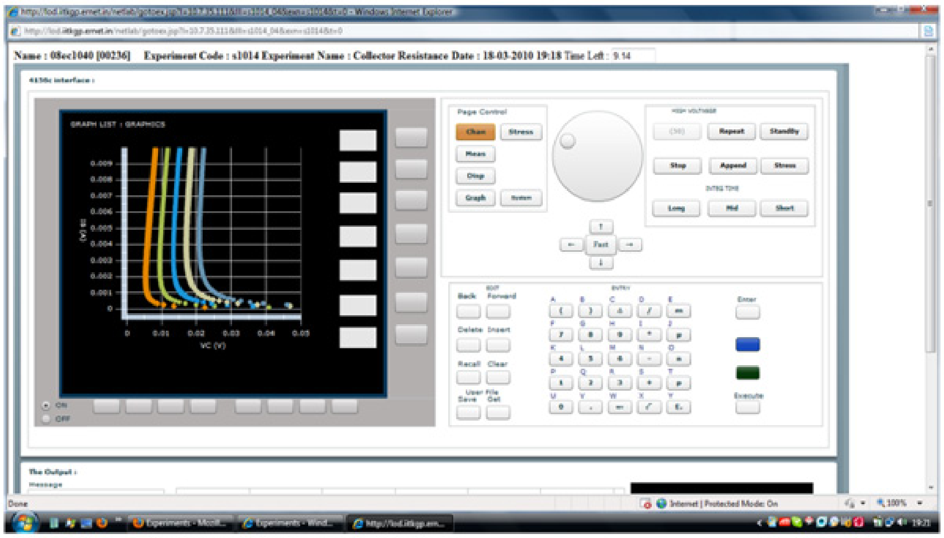

which consists of several online true/false, yes/no or short questions. Both the viva-voce performance and the laboratory report are checked for each experiment performed successfully by a student. Once the student completes the laboratory module (say consisting of 10 or 15 experiments), then the final grade is prepared and displayed. Only the student and teacher can see this grade. Finally, for all the laboratory users, the final grade sheet is prepared and displayed.

Preliminary Quiz

The main motivation of online hardware-based laboratory experiment is to provide the facility to as many students as possible, and thus the number

Figure 7. Current gain vs. collector current

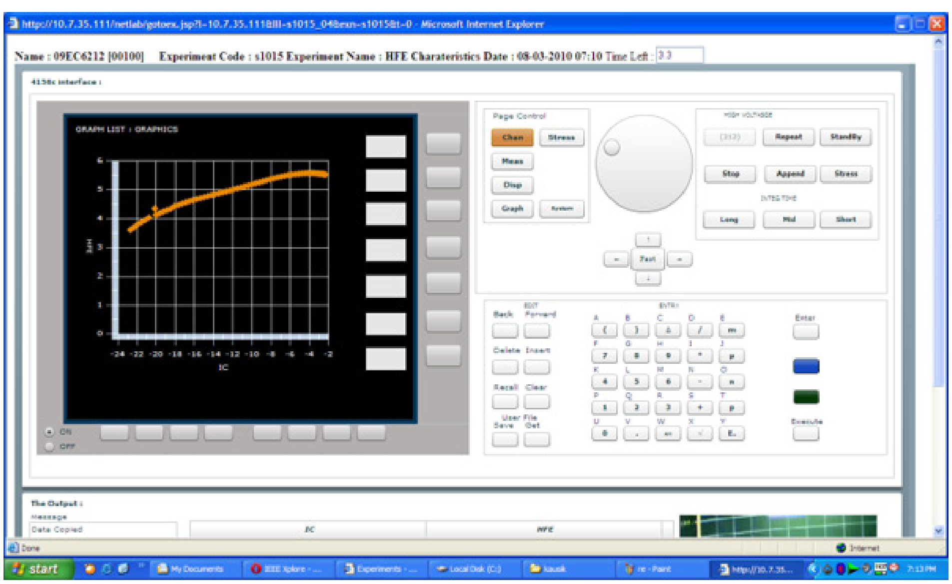

Figure 8. SPICE parameter extraction

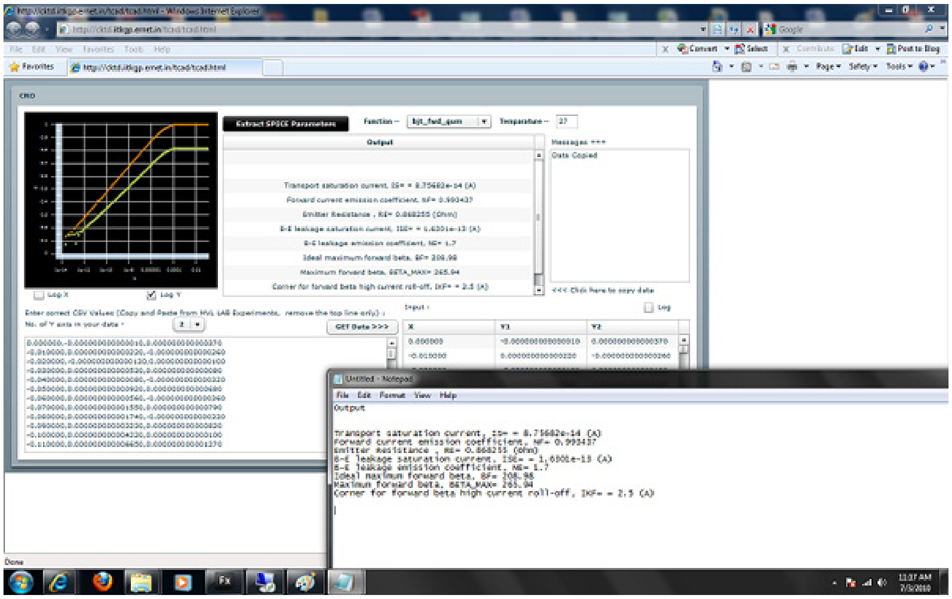

of users per instrument is large. It is thus necessary that a user really engages the equipment only when he performs the experiment. This is why a preliminary quiz is introduced and conducted before the learner can gain access to the actual experiment webpage and the equipment and/or the experimental setup. This is done primarily to optimize the use of the instruments by making sure that the user is familiar with the instruments and has sufficient knowledge about the experiment. The quiz consists of several random true/false questions about the instrument, setup, experiment and fundamentals, etc. The user goes through the learning materials, videos, and details of setup available for each experiment. When the user is ready to use the instrument, he/she appears for the quiz. Only after the learner obtains a certain mark (set by the instructor for each experiment), is the student allowed to book the experiment time slot and gain access to the experimental setup during that time.

Uploading Laboratory Report

After the experiment has been successfully performed by the learner, is the experimental data saved and analyzed by the student for the preparation of the laboratory report. This report should contain detail from the experiment, setup, data, and results for parameter values, etc. The online laboratory report submission is basically filling in a form. After the preliminary section of the laboratory report is submitted, the user needs to enter the final results (parameter values) obtained from the analyses. These parameter values are then compared with the pre-set (default) parameter values generated by the instructor. Depending on the off-set (in percentage), the student is given marks, and grading is done accordingly. The instructor needs to set some tolerance for evaluation purposes and the system compares the student's uploaded value with the default value. For example, for a tolerance of 10%, 1 mark will be deducted from the full marks (FM) for the parameter. The instructor may also specify 3 tolerances levels and the corresponding marks that are to be deducted.

Viva-Voce Examination

Finally, the learner has to take part in the viva-voce. The viva-voce consists of several true/false or multiple choice questions as asked in a conventional oral examination. The students need to answer them in a certain period of time. The data is matched for correctness, and the number of correct answers is determined. The performance is graded accordingly. This value is then added to the laboratory report marks to get the final marks for the experiment.

Final Grading

The final grade for the student is prepared when all the experiments in the laboratory class have been successfully completed. Both the student and teacher can see the grade. The instructors and/or teachers can save this information for future reference. Marks for each experiment are then added to get the final grade report/sheet of the entire group of students for the class.

LABORATORY EVALUATION AND STUDENTS FEEDBACK

In order to learn how the remote laboratories provide useful learning environments, different models of assessment are employed. Our experience with internet learning systems has shown that the greatest benefits come from automating the laboratory assessment, as described in the previous section. To evaluate the utility of the online TCAD laboratory, we offered the students (with 27 students) an option to repeat the experiment in a scheduled laboratory class to improve their learning. Only 16 students operated the equipment for 20 minutes or more in the scheduled laboratory class, while nearly all the students managed to complete the assigned task using the remote laboratory. Our trial with the remote access laboratory showed that students could perform experiments in a lesser time. Using the remote laboratory system, 80% of the students managed to complete the required tasks, remotely operating the equipment, collecting data and running the simulations. These results demonstrate that the remote laboratory has significantly extended the laboratory experience for most of the students in the class.

TCAD tools are critical components of microelectronics engineering education. Over years of extensive development and incorporation of simulations tools in our course have taken place. Our impression is that available TCAD tools have been used extensively by the students and the students have received first-hand experience of using the tools. In the course evaluation and assessment process, the instructors have validated the outputs following the given specifications to assess the technical aspects of the home assignments submitted by the students. The students were asked to answer an online questionnaire and identify themselves by their roll number so that the instructor could relate their responses to logfile records of experiments performed. In a survey among the students on the use of the integrated Microelectronics and VLSI Engineering Laboratory along with simulation-based Technology CAD laboratory tools, several generic and concept-specific questionnaires were asked. Analyses of some of the responses indicate a good balance of available tools in the minds of the students. The assessment results collected from the laboratory class (106 students in two semesters) are analyzed in Table 1.

CONCLUSION

The Virtual Wafer Fabrication (VWF) has become an integral part of the semiconductor industry. The possibility of teaching semiconductor manufacturing in a university environment in a highly cost-effective manner by taking the advantages of high speed internet and available TCAD tools has

Table 1. Statistics of laboratory assessment

Evaluation Questions	Very Useful (%)	Useful (%)	OK (%)	Neutral (%)	Not Useful (%)
Adaptability	67	21	11	01	-

Simplicity and interactivity	89 (high)	-	-	11 (medium)	-

been explored. Technology CAD is shown to be an excellent resource for teaching microelectronics. The objective of a laboratory component of any semiconductor fabrication course is to teach the students the unit processes involved in microelectronic fabrication and to introduce the practice of process development. Technology computer-aided design (CAD) tools for process and device simulation are now widely used in semiconductor process design. Microelectronic courses can be taught efficiently and cost-effectively by using process and device simulation tools without any physical process laboratory setup. When used in conjunction with conventional modes for teaching design and fabrication of semiconductor devices and circuits, the process simulation tools, combined with the device simulation, can be a very powerful tool for greater understanding of electronic devices and their operations. Device modeling and parameter extraction can help students understand the principles of electronic device operations and their applications in electronic circuits. With online the TCAD laboratory, the students are able to perform simulation experiments and explore the impact of process flow modifications at virtually no cost. An online Microelectronics and VLSI Engineering Laboratory integrated with a simulation-based Technology CAD laboratory can offer a new degree of flexibility in microelectronics education. However, the best environment for teaching semiconductor processing courses would be to use both the TCAD simulation tools along with the microelectronics laboratory, which is costly.

The developed online TCAD course with the associated laboratory gives the students, even at the undergraduate level, a chance to learn about real silicon processing via hands-on process/device simulation without the need for IC processing facilities and the opportunity to explore device behavior at a much deeper level. We expect online TCAD laboratories will encourage creativity, as interested student can design, create, and test devices in a matter of minutes to hours without using expensive resources.

KEY TERMS AND DEFINITIONS

Architecture: The architecture defines a framework or structure of an online laboratory.

Client Requirements: The Client requirements describe different conditions (Operating System, Browser, Run-Time engines etc) necessary on a server/machine prior to run an application.

Device Simulation: Semiconductor device simulation is the modeling of semiconductor devices.

Experiment: Experiments are part of different types of Online Laboratories. Experiments may be real measurement-based or virtual (simulation).

Hybrid Laboratory: The Hybrid Laboratory is a mix of remote software simulations and real experiments in one single environment that can be accessed over the Internet.

Laboratory Management System: This represents a software application for the administration, documentation, scheduling experiments, tracking students' activities and performance.

Measurement Experiment: The structure of a measurement-based experiment is generally fixed. Measurement conditions and parameters might be changeable.

Microelectronics Laboratory: Microelectronics is a sub-field of electronics. Microelectronics laboratory is related to the study and manufacture of micrometer-scale electronic components usually made from semiconductors.

Online Laboratory: An Online Laboratory is defined as the hardware and software platform that provides resources over the Internet. Online laboratories may be divided in sub-categories:

Remote Laboratory, Virtual Laboratory and Hybrid Laboratory.

Process Simulation: Semiconductor process simulation is the modeling of fabrication processes of semiconductor devices.

Remote Laboratory: The Remote Laboratory provides real experiments that can be accessed via the Internet. This definition implies the control of real hardware and the realization of real measurements.

SPICE Parameters: SPICE parameters are semiconductor device parameters necessary for circuit simulation.

Technology CAD: Technology CAD is a branch of electronic design automation that models the semiconductor processes and semiconductor devices.

Virtual Laboratory: The Virtual Laboratory provides remote software simulations. The simulation model runs on the server and can be accessed over the Internet.

This work was previously published in Internet Accessible Remote Laboratories: Scalable E-Learning Tools for Engineering and Science Disciplines, edited by Abul K.M. Azad, Michael E. Auer and V. Chapter 58
Implementing Business Intelligence in the Dynamic Beverages Sales and Distribution Environment

Sami Akabawi
American University in Cairo, Egypt

Heba Hodeeb
American University in Cairo, Egypt

EXECUTIVE SUMMARY

To compete successfully in today's retail business arena, senior management are often demanding fast and responsive Information Systems that enable the company not only to manage its operations but to provide on-the-fly performance measurement through a variety of tools. Use of (ERP) systems have been slow in responding to these needs, despite the wealth of the internally generated business databases and reports as a consequence of functional integration. The specific nature and demands by those senior management staff require the congregation of many external data elements and use data mining techniques to provide fast discovery of performance slippages or changes in the business environment. Data Warehousing and Business Intelligence (BI) applications, evolved during the past few decades, have been implemented to respond to these needs. In this case write-up, we present how the ERP system was utilized as the backbone for use by BI tools and systems to provide Sales and Marketing units in a transnational company subsidiary in Egypt to actively respond to the demands for agile information services. The Egypt subsidiary is the HQ of the African region's operations of several franchises and distributers of the company products, in addition to operating a beverage concentrate manufacturing plant in Egypt, which services the entire region's beverage products needs.

DOI: 10.4018/978-1-4666-1945-6.ch058

BACKGROUND

Company Overview

The case firm considered in this chapter is a transnational company subsidiary in Egypt, which is located in the Free Zone in Nasr City district, in the country's capital, Cairo. The company owns and operates a beverage concentrate plant within the domain of its facility for producing the concentrate syrup used in all its beverage products. These concentrates are then delivered to many bottling operators in African countries for the production of the final product mixing, bottling, packaging and trade fleet distribution in their respective territories. The concentrate plant is among the few plants of the transnational company world-wide, where the technical know-how formula of the company is produced, and the plant caters for the supply of concentrate syrup for the entire African, Middle East and Asian bottling territories.

The company is divided into a number of business units (BU). Egypt's subsidiary assumes the function of the head office to the African business unit which constitutes more than 25 franchises and distributers in many African countries. In this case-paper, we consider the analysis and evaluation of the information systems categories used in the head office of the company's subsidiary in Egypt for the Sales and Distribution management in the region. In particular, we detail how the backbone Enterprise Resources Planning (ERP) and business intelligence systems (BI) are integrated and used to leverage the need for agile management of the operations in the Sales and Distribution functions within the highly dynamic competitive beverage market.

Brief Economic Outlook of the Country Where the Case Company Operates

Forecasts put Egypt's food and drink exports growing by 59.4 percent between 2007 and 2012, which is not only a reflection of the free trade agreements ratified by the government of Egypt since late 90's, but also the country's improving food and drink processing industry. Regional trade agreements such as the Greater Arab Free Trade Area (GAFTA) have also given producers access to a far larger market. Having gone into effect in 2005, GAFTA has gradually lowered customs on locally produced food across a broad range of Middle Eastern countries. These agreements opened larger markets for Egyptian producers, given the similarity of diets and lack of language barrier. Meanwhile, Africa is also becoming another key export market, mainly for its proximity and lack of domestic production capacities in the African countries.

Sharply rising food prices have been the cause of growing unrest in Egypt over the past two years.

Though the Egyptian government has taken a number of measures to deal with the mounting public discontent, inflation hit the 20 percent mark and food prices skyrocketed, and a dire situation has evolved in the country.

Egypt is a rather unique market for the region as it benefits from a very large population (over 80mn) and an unsaturated food and drink market. However, the food and drink trade balance is highly dependent on imports. In addition, inflation, in a country with national poverty rate of 22.9 percent according to the World Bank Development Data Group, (2002) and Earth Trend Country profile estimating 20 percent of the population below the poverty line, led to increased levels of political risk and unrest. Against a backdrop of worsening global financial market turmoil and rapidly accelerating inflation, particularly in emerging markets, Egypt has significantly more economic hardship clouds on the horizon. Nonetheless, Egypt receives a pretty high score in the region for its food and drink market due to its per capita food consumption growth. Egypt does not fare well for the country structure indicator, with low GDP per capita, although the size of its population and lack of market maturity help pull up its score.

SETTING THE STAGE

Companies in the beverage industry often operate as producers and distributors of canned and bottled soft drinks, concentrate and other juices and liquid beverage products. They experience rapid changes in the way they have to do business. For one thing, increased commoditization and diversification of beverage products has made it more difficult than ever for beverage manufacturers to differentiate their products and their brands against rivals and competing brands.

In addition, beverage consumers are demanding greater product variety, higher levels of service and more value for their money (Bingham, 1999). The increased global competition, escalating retailer demands and increasingly stringent government regulations have added to the pressure on those companies, making it harder for them to compete globally. With growing concerns with food safety issues, these companies are also finding it necessary to monitor and track every phase of operation – from raw ingredients through finished product, to packaging, storage and distribution – to ensure compliance with the higher safety standards.

Driven by these challenges, beverage producing and distribution companies are looking more and more to their manufacturing processes and supply chain in an effort to increase production efficiency, reduce operational costs and effect better overall management of the enterprise and its assets to sustain desired levels of profitability and growth.

Business Imperatives

Historically, there has been resistance to the introduction of technology in the beverage industry except perhaps to automate certain production processes (e.g. mixing, canning, bottling and packaging). In many large companies, use of information technology (IT) has been limited to off-the-shelf or custom-tailored systems implemented to assist employees with such discrete business processes as accounting, corporate finance, human resources and purchasing. However, in the past few decades, many firms have implemented Electronic Data Interchange (EDI) and host of functional separate systems, often in response to customer and vendors demands or management directives for adopting business-to-customer (B2C) and business-to-business (B2B) e-business functionalities. Despite all of the information flowing through these disparate systems across the enterprise, the information services to operational and top management more often than not lacked integration, timeliness and comprehensiveness.

The lack of timely financial information, integrated with order and production flow would hamper the ability of firms to know where they stand from day to day, both from financial and operations point of views. In most companies, by the time financial information becomes available in a report, it's historical and too late to change course to correct problems. In today's fast-paced global economy and rapidly changing marketplace, the lack of integrated, real-time information to provide business and market analysis, business intelligence and decision support tools negatively impact profitability, growth and ability to act quickly to external marketing forces. Moreover, efficient order entry, materials and inventory control and fast turnover dictate the need for agile and responsive information systems to minimize waste and delivering efficient customer service. In market-driven industries, once the product is made, time is not nearly so critical – but storage, transportation and distribution are.

On the beverage industry side, we see an astonishing level of diversification fragmenting this industry. Where once there were a finite number of carbonated and non-carbonated soft drinks occupying the competitive landscape, today there is an almost infinite explosion of choices – from pure juice and juice blends, to sodas of every kind, waters, and host of beverages. Sales in this area are market-driven, so producers tend to rely on special packaging, competitive pricing, event-driven promotions and other attention-getting techniques to differentiate themselves. For these firms, forecasting and timing of product-to-market are crucial. Market-driven companies thus need to be able to put a product out on the shelves, see how it sells, then turn to adjust production to match demand.

The preceding characteristics illustrate that each segment of the beverage industry has its own challenges to overcome whether it competes in local, national, regional or global markets. However, to retain customer loyalty and grow market share, all beverage manufacturers and distributors need greater flexibility to respond quickly – whether to changing customer expectations, government regulations, or fluctuations in the marketplace resulting from seasonal changes in drinking patterns. In short, beverage producer and distributer companies are finding they have to increase the speed or decrease the lag time between when their products are made and when they are out on the market. To coordinate their production capabilities, manufacturers also need to increase their ability to handle different materials and product lines simultaneously. If they are to improve procurement and inventory control, they must find a way to accurately track both raw materials and finished goods. And, to build their company and product brands among customers and consumers, they must be able to ensure consistency of quality across product lines.

On the business end, optimizing plant operations can be a tremendous source of savings. Companies attaining high visibility and close control of key production elements opt to simplify complexity and better manage cash flows. They need to be able to forecast more closely to customer demands – avoiding either overextending or under-producing – to improve their return on corporate assets. The use of enterprise resources planning (ERP) systems becomes the natural choice for fulfilling such needs (Davenport, 1998). ERP systems operate on enterprise-wide domain to ensure integration among all business functions and result in one large single view of the company's data resources. If those systems are well matched to the business and well implemented, many benefits can be accrued such as: decreased reaction times, better logistics flow, increased responsiveness to market and customer changes and improved supply chain management (SCM).

Information Systems Backbone Implementation in the Case Firm

By early 2000, the case company presented in this chapter planned to acquire an ERP system to replace its aging legacy systems. The company looked for a proven technology platform for its business applications with strong functionalities in areas such as financial applications, procurement, order entry and fulfillment, planning and scheduling, inventory management and optimization, product configuration, flexible product costing, manufacturing, EDI capabilities, and support of multiple plants and/or warehouses and complex distribution system. To that end, a blanket, multilayer deal with highly reputed ERP vendor was selected and configured to run several business application modules to cut costs and share data through multiple distributed systems located in multiple regional datacenters, with secured global access. These applications are built around ERP, customer relationship management (CRM) and SCM modules as well as set of integration middleware tools. The system aimed at helping improve the logistics of store deliveries, sales orders and the back office operations of the networked company's manufacturers, bottlers and distributors around the globe. This distributed approach targeted the improvement of market execution, better service to consumers, in addition to giving a more integrated system platform to serve the information needs at the store level and account level, and more effective management of the business on the street. The implemented distributed ERP systems provided the following application and service tiers:

1. The back office tier which included several modules. The African region implementation provided the following modules:
    a. Marketing Expenses Management
    b. Business Travel Management (BTM)
    c. Human Resources (HR)
    d. Financials and Sales
    e. Logistics
    f. Supply chain and Manufacturing
2. Data warehouse and decision support tier which included the following modules to serve the African business unit:
    a. Value chain modeling, the module manages everything that adds value to a product. Starting from raw material used to produce the product such as sugar, water, vitamins and caramel, to the time employees spend on various functions and the salaries of employees, to the trucks used to distribute the product and the gasoline needed for the trucks. It uses all those individual costs to know how much the product should sell.
    b. Forecasting module, the sales business intelligence module is responsible for everything related to sales. It manipulates three types of data: historical data, which include the actual weekly sales; the business plan data, which constitutes the forecasting for the sales of the year; finally, the rolling estimate data, which is a more accurate prediction of the sales based on the discrepancy between the actual sales and the business plan.
    c. Decision support System, this module helps sales function managers in making decisions based on sales by providing the following services:
        - Sales flash report issued on specific day of the week. Sales reports of the week are sent to employees on company-provided blackberries. The weekly sales updates are given versus business plan predictions or versus prior years. In addition, sales is always directly related and translated into market share. The company used push strategy to alert the employee that he/she has received an email.
        - Telecom reporting is used to control the escalating costs of telecommunications within the African business unit. Managers get periodic data from mobile service operators to determine how much their units pay for mobile services. This particular application used the EDI facility provided by the system through the middleware layer.
        - Margin minder report is used to track sales in every outlet, and provides small outlets with data on how to make more profit. For example if a small café is buying more of a certain Stock Keeping Unit (SKU) but the reports show that the café is not selling much of it, the system then recommends that the outlet buys less of this SKU and buys another one that seems to be selling good at the particular café. In addition, it does the 'Right Execution Daily' (RED) that manages the product display and the picture of success (pos), i.e., to make sure that company logo is put at the entrance of sites, that the tempera-

ture of the product is set at the prescribed temperature, that the company refrigerators given to sites have their products only.

d. Business Intelligence (BI) tools which perform activities such as collecting and transforming data from a variety of systems, consolidates and aggregate these data in readiness for reporting to assist in decision making. A visual reporting component was missing from this battery of tools for presentation of knowledge to assist with decision. At this stage of implementation, as such, this tier did not incorporate dashboard to provide visual summary of the operations key performance indicators (KPIs). This particular shortage is the subject of the additional development addressed in this chapter.

Additionally, there are some applications used in the African region Egypt HQ that the IT manager referred to as 'ko' which literally means 'knock-out', but what it actually meant is that it is site-specific, internally developed by the company, for the network of sites in the African business unit

A middleware tier was deployed by the company to achieve integration among these disparate enterprise applications through using several reporting and communications layer comprising:

- **Mail:** the mail system used by the company is 'lotus notes' platform. This platform provides a collaborative work environment as well as email service.
- Microsoft office: the end-user productivity tool for the client side hardware (PCs, laptops, PDAs, etc.)
- **Share point portal service:** used as the gateway/ portal through which authorized employees can gain access to the various service provided by the host of applications in site or globally.

The architecture of the technology service layers after the implementation of the ERP system in the datacenter accessed by Egypt subsidiary HQ is shown in Figure 1. Some of the modules were implemented in a "vanilla" standard mode while others were customized to adapt to the beverage industry-specific operations. The company gets, through a blanket contract, upgraded versions of the modules on a periodic basis (for the standard application modules only).

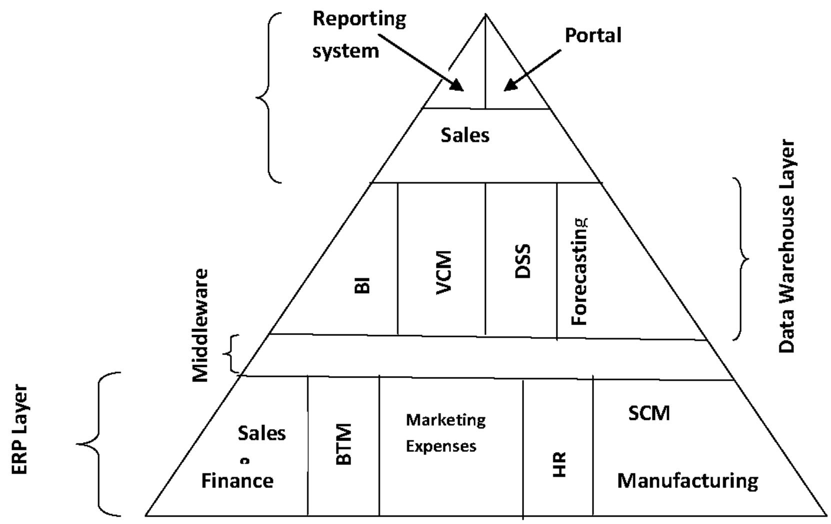
The network and communications infrastructure provided connectivity to the corporate datacenter for all sites in the African BU. Business transactions are entered on real-time basis into the respective ERP module. Each site must thus secure the health status of its internet/private connectivity and monitor its operational effectiveness and availability of its links.

The Sales Reporting System Prior Implementing the New Dashboard Facility

For each regional site, the specific reporting and operational needs (which included manufacturing supply chain, sales force management, marketing, inbound and outbound logistics), are accessible remotely from the regional datacenter of the company in Africa. Several functionalities were considered for the management of the African BU in Egypt's HQ site, which is concerned, among other business functions, with the consolidated sales within its domain. The process with which this objective was initially achieved is described in Figure 2. In this process, sales data exchanged between the franchises/bottlers and the HQ constituted:

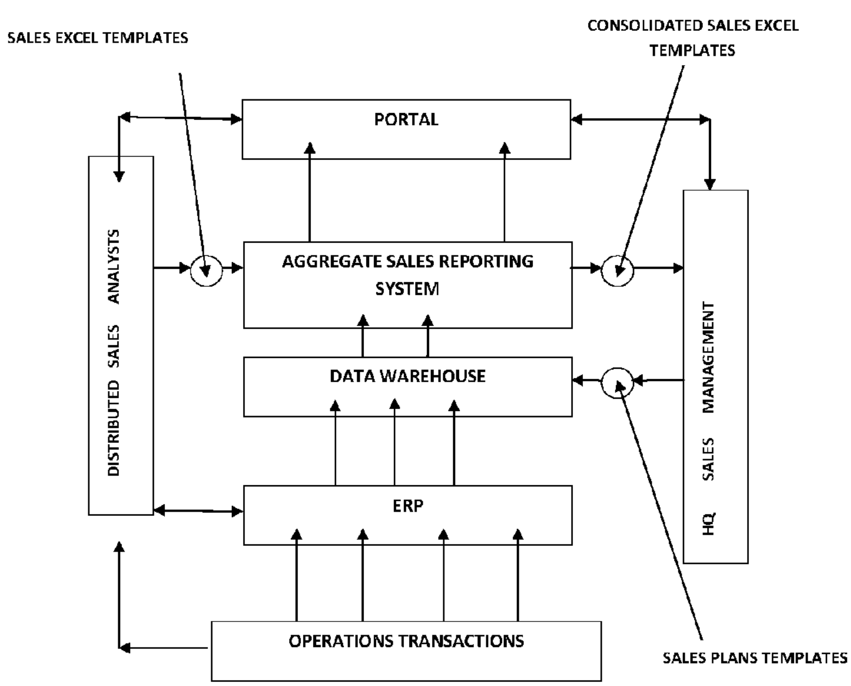
- **Actual sales figures:** These are the actual sales volume reported by the bottlers. Actual sales were communicated on a daily basis through e-mails, via Excel templates, sent to every franchise analyst.

Figure 1. Architecture of the IS layers used in the company before the new BI dashboard implementation



- **Rolling estimates (RE) figures:** which reflect the adjusted sales on a monthly basis to adjust targets during the course of a year, thus reflecting changes in the market and used to predict sales volume for the balance of year. These figures are confirmed after communication between the franchise managers, the business planning manager and the HQ office. Once confirmed, the business planning manager sends the final

Figure 2. Sales reporting process before implementation of the IDB system



confirmed version of the file which contains the actual sales so far and the balance of year figures on a monthly basis for all sites in the domain countries

- **Business Plan (BP) figures:** are set by the BU management at the beginning of the year. They do not change during the course of the year. The BP dictates target sales per brand per pack per month.

Sales Excel sheets Templates which are formatted by the sales analyst of each franchise/bottler liberally, are used by the company for sales reporting. These templates constitute the following reports:

1. Daily Reports

Bottlers of each country send daily sales reports that include the daily actual sales volume in both physical and unit case volumes to the franchise sales analyst. If they send it in physical cases, the franchise analyst converts it into unit cases using the unit case conversion factors. The reports include sales by brand and pack for every day of the week. The drawback of this reporting scheme is that there is no fixed template format for the daily reports sent by bottlers, who communicate the daily sales volume to the HQ.

2. Weekly Reports

The franchise Sales Analyst prepares and sends weekly reports after consolidating the daily sales sent by the bottlers to get total weekly figures. The reports also display the rolling estimates split weekly in addition to the weekly budget split and prior year weekly split. The Business Planning managers use the data communicated through those reports and consolidates data of all franchises to send consolidated weekly reports to HQ.

3. Monthly Reports

Every franchise analyst is requested to submit monthly reports as per deadlines dictated by a quarterly reporting calendar communicated by sales analyst. Those monthly reports include the following:

- Best estimate for current month, draft of upcoming month RE and upcoming month weekly split. This data is usually communicated before the current month is closed.
- RE volume by brand and pack. This report is submitted after the month is closed, it communicates the 'Actuals' of the closed month in addition to the RE figures of the balance of the year data. All 'Actuals' and RE figures are provided with a brand/pack split.

The HQ Sales Analyst then consolidates monthly brand/pack data sent from all franchisees to prepare brand/pack monthly RE updates.

As noted from this process, there are many countries involved in the reporting cycle of the sales results and many reports are communicated back and forth, using email and non-standardized Excel sheet templates between the country sales analysts and their corresponding managers in the HQ site. Many errors and inefficiencies continuously existed due to the use of those sales templates. The oft problems encountered included the following:

- Data inconsistencies due to inconsistency in product coding and Excel template variations led to lateness in reporting;
- Miscommunication due to network problems, variable semantics and other inconsistencies resulted in many duplicate data items (same data repeated in several reports);
- Consolidating non-uniform templates data and variable-semantics led to waste of time and efforts;

- Lack of analysis due to meager analytical competence of sales analysts;
- Lack of standardization led to too many data but no information;
- Redundant processes resulted in data chaos (too many templates causing confusion).

To that end, the focus of this case write up is to determine how the company utilized a new business intelligence dashboard tool, to provide the Sales and Marketing units with the necessary agile and fast decision making platform and to respond to the dynamic market and consumer changes over a wide geographic area; at the same time overcome the critical impediments illustrated in the process described earlier and schematically diagramed in Figure 2.

Literature Review

During the past two decades, many organizations adopted the ERP as their preferred backbone information system for data and information management, since then world ERP market poised to command a little under $65 billion by the end of 2009, according to AMR Research Market Analytix Report (2005). The use of ERP systems by those organizations targeting cost reduction, increase productivity, improve customer satisfaction and suppliers relations in the drive to improve competitiveness in the global networked market space (Davenport, 1998). The cost expended for the acquisition and implementation of ERPs exceed millions of dollars and affect the overall firms' earnings and revenues (Davenport, 1998) and their market values, (Chatterjee et al. 2002). With such huge capital investments, many firms are forced to assess carefully their return of investment (ROI) of such an infrastructure.

The impact of adopting ERP normally goes beyond the immediate control of the business resources, it sets the grounds for organizational changes and the way business processes are performed, (Kallinikos, 2004). As noted by Brazel and Dang (2008), the implementation and use of ERP systems represent a radical change from the operation of legacy systems. Many researchers have therefore studied ERP use and adoption from various perspectives. As a category of information system, several authors approached research on ERP from the perspective of information systems success model (DeLone and McLean, 1992, 2003; Gable, et al. 2001 and 2003; Seddon, 1997; Sedera, et al. 2004; Ifinedo, et al. 2006a and 2007; Robey, et al, 1999).

ERP implementation is a challenging endeavor for many organizations, spanning many functional areas (Yen, et al. 2002), demanding high level of coordination among all stakeholders and adjusting to changes and synergy in the procedural workflow by every business function. Use of such systems implies changes in the workflow of business processes (Kallinikos, 2004). To that end, success of the implementation projects and the critical factors influencing this success was studied by many researchers to investigate ERP implementation success factors, (Bancroft et al, 1996; O'Leary, 2002; Ptak, et al, 2000). Other studies aimed at identifying the critical factors impacting implementing ERP projects (Fryling, 2005). Factors such as those influencing successful implementation, from the operational (rather than technical) point of view were addressed by many researchers, for example, the business operations coverage of the package and the number of licensed users (Francalanci, 2001; Kumar, et al. 2001; Markus, et al. 1988; Parr and Schanks, 2000).

The impact of system configuration and/or setup revisions and enhancements was also studied by Fryling (2005), Nicolaou, et al. (2004 and 2007), Light (2001), Mensching, et al. (2004) and Nah, et al. (2001); impacts of organizational and national cultures (Krumbholtz et al. 2000; Soh, et al. 2000); the configuration and setup of the package's parameters tables and their overall impact on the architecture and flexibility of the ERP packages for rapid adaptation (Fan et al. 2000; Spott, 2000). Some articles also addressed the impact of ERP process standardization and the restructuring of organization tasks or business processes reengineering (Kumar and Van Hillgersberg, 2000). The ability of the system to provide quality and trusted information for operational and executive management decision making has been identified by many researchers (Xu, 2003; Madapusi, et al. 2007).

ERP integrates all functional areas of the organization, acting as the backbone of the information management platform of the organization (Chou, 2005). With its integrated database, ERP systems integrate other functional business components such as Customer Relationship Management (CRM) and SCM systems data resources to support informational needs for decision making. Since ERP system is internally looking, the need to accommodate access to data across the organization boundary is required for decision making at the strategic and organization-wide levels. It is not that ERP systems don't have wealth of information, they do; the challenges lie in the ways of mining them. ERP cannot facilitate real-time decision support function for several operational reasons. Since information is the foundation of every critical business decisions, Decision Support Systems (DSS) are vital for any organization (Drucker, 1998). Report writers can access data from multiple ERP modules and consolidate them with other data elements for decision support. Business Intelligence (BI) is about getting the right information, to the right decision makers, at the right time (Alter, 1980). It is an enterprise-wide platform that supports multi-dimensionality reporting, analytics and decision modeling leading to fact-based decision making and enabling to get a "single version of the truth" (Rasmussen et al., 2001). The common pain points that BI is used to solve are typical examples of what most organizations experience:

- Data everywhere, information no where
- Different users have different needs
- Excel versus PDF
- Pull versus push
- On demand – on schedule
- Your format – my format
- Takes too long – wasted resources/efforts
- Security
- Technical "mumbo jumbo" … Why I just can't get it to you when you want it.

By integrating business intelligence (BI) tools and ERP modules, data flows directly from the ERP database on real-time basis. However, some reliability, availability and scale efficiency may arise as a consequence – particularly due to the excessive access load that may hinder transactional operations. Separating the active ERP database from that of the BI resulted in embracing a second data storage tier, a data warehouse (McDonald et al., 2002). The ERP-BI, On-line Analytics Processing (OLAP) and DSS tools integration framework is based on congregating all needed data from the ERP system and other external data resources, load them into a Data Warehouse or a data Mart, then link to several BI tools, such as OLAP, data mining, analytics tool and reporting systems to create more consistent and knowledge-centric data reporting. BI tools provide such functionalities. More and more organizations extend their ERP beyond the level of back-office to improve sales, customer satisfaction, and decision making (Stedman, 2002).

Integration of the BI and ERP system contributes additional values to businesses (Chou, 2005). According to Holsapple and Whinston (1996), characterization of common DSS features, BI generates different views for available data systems, a scaled data mart or data warehouse providing rich, timely and well structured and cleansed information to the BI. Bolt-on BI systems are also used to view financial, marketing and sales queries by using different tools (CRM2day.com, 2004). Customer Experience Management (CEM) in retailing has also been researched within the framework of BI by score of researchers such as Ding, et al. (2006) and Kamaladevi, B. (2010).

Issues of integration of SCM with customer experience management were dealt with by Chou (2005). Approaches to building and implementing BI systems were investigated by Celena Olszak, et al. (2007) being an important decision to many implementing organizations.

CASE DESCRIPTION

Technology Concerns and Needs

Within the context of the studied case, a new Sales Reporting process was developed to address the inefficiencies and pitfalls of the template based sales reporting system described earlier. Egypt's HQ IT department together with the Sales unit, embarked on the development of a new BI tool which was code-named the IDB (information dashboard). The new IDB tool was designed to provide enhanced method for uploading sales data, address the inconsistencies of the country sales figures and the cumbersome method of obtaining the consolidated reports at the HQ. Analysts were trained to upload data on the new IDB platform using a newly developed product coding system. They get the codes from commonly accessible codes database. The coding system is based on a code consisting of 10 digits. The first four digits represent the brand type and flavor. The last four digits represent the package size and type. The two digits in the middle represent the type of syrup whether liquid for normal packages or powder supplied to machines. This level of breakdown for any product provided an easy and efficient facility for tracking Stock Keeping Unit level since it embedded all the necessary information regarding the product whether in terms of brand type, flavor, package size, type, format……etc.

The implementation of the IDB tool availed single unified interface for users to upload the sales data from the respective country to provide aggregate reporting of sales for the HQ in Egypt. The tool allowed drill-down granularity for users. We will first analyze the structure of this implemented information dashboard tool (IDB) and then describe the new sales reporting process. The IDB acted as the single "database" view for all trade related information used by all franchisees and is used through applying several data mining techniques. It is a customized web based application built to access the warehouse database and allowed access from anywhere through the company's network. Furthermore, the IDB is used as the reporting vehicle to management - globally, retiring the use of once prevalent sales templates and the use of the email for posting these templates. Access to the IDB is achieved via web browser using specific URL or via the Company Portal (based on MS Share Point platform). Users log in through their IDs and passwords. After updating the system with the daily, weekly or quarterly sales, figures, respective users can log in and retrieve any report needed at any granularity level for any specific period.

The sales reporting process constituted several activities. Every franchisee analyst is to prepare the weekly sales data using the relevant codes and upload the data on the IDB. The upload is performed automatically through an Autoloader and scheduled on Mondays every week. The system decodes the uploaded codes and maintains the actual data on the system. Business plan figures and rolling estimates figures are also uploaded in the same format and manner. Whenever any discrepancy in the uploaded data on the IDB of a single country affect the accuracy of the data of the total business unit, control measures are promptly carried out to assure the integrity and accuracy of data on the system. After all franchisees upload their weekly figures on the IDB, the HQ Sales Analyst verifies the data on the system and adjusts/deletes any discrepancies found by detecting the countries responsible for the discrepancies and suggests methods for resolving these conflicts with the concerned analyst. The Sales Analyst can also report any variance detected on the IDB due to any error in the application engine through Business

Applications Call Logging system, used by the IT department as the support tool for any encountered technical problems while using the IDB.

The HQ sales analyst is also responsible for planning and coordinating all IDB activities with all franchisee analysts in terms of training analysts, installing new IDB applications and communicating with IT to resolve encountered problems. The HQ sales analyst is also responsible for issuing new codes for newly launched packs that are not on the system by filling a request form. The HQ Analyst also monitors the status of expired codes and de-activates them.

Developing the IDB Dashboard Layer

The described new sales business process is depicted in Figure 3. Upon upload of the sales data on IDB, users can simply log into the system from anywhere and access the reports menu via the portal or the specially provided URL and pick the type of report required using drop down lists. These lists include all product parameters. The IDB system enabled users to get any type of information by selecting the specific criteria needed in the downloaded report with any degree of granularity. In other words, users can customize the reports retrieved from the system by choosing the appropriate parameters from the displayed scroll down lists. Drill down lists may include, but not limited to, parameters such as:

- Country
- Bottler
- Period (Year/Month/Week)
- Brand
- Flavor
- Package type
- Pack size
- Historical data
- Business plan data
- Rolling Estimate (RE) data
- Analysis of sales performance versus prior years, BP, RE…..etc.

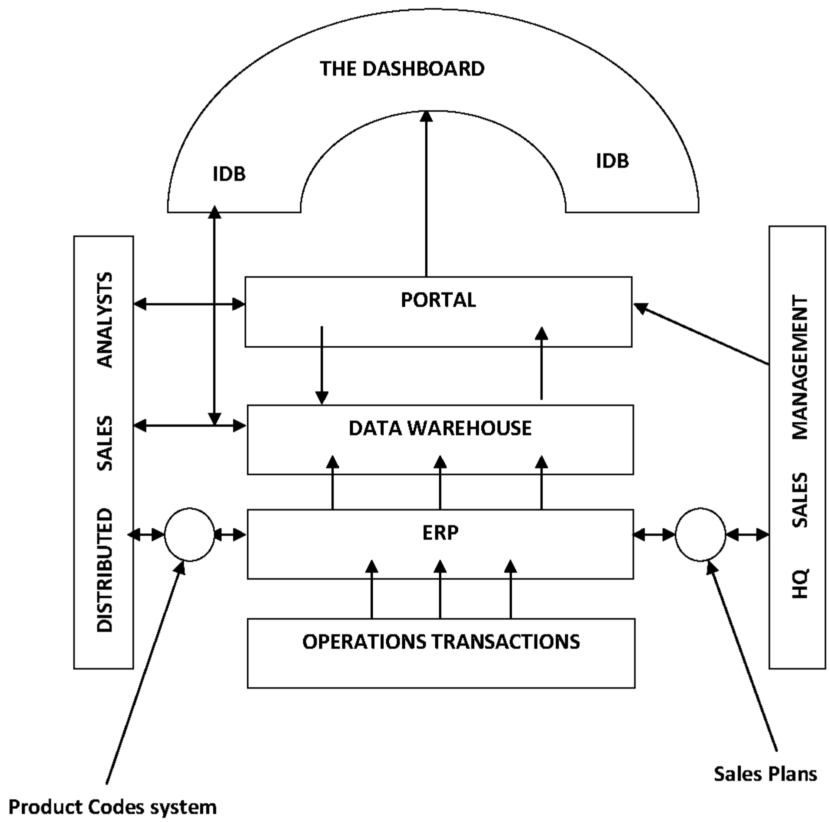
Access to the facilities offered in the IDB system is granted though a robust and premeditated authorization scheme. IT unit provides authorized users with their respective personal user name and password for authentication, however accessing and retrieving information at various data-granularity levels are subject to authorization policies. This authorization scheme is set by the respective country management, and communicated to the IT department, to provide various access privileges for the various organizational hierarchical levels.

The Impact of the IDB System on the Effectiveness of the Sales Reporting Process

The use of the IDB facility as a component of the battery of BI tools of the Company's IS platform enhanced the Sales reporting cycle in many ways and had increased the overall efficiency of the Sales Reporting Process. The major areas of improvement IDB offered are:

- First of all, it has eliminated the redundant process of sending the former sales reports templates that were subject to various interpretations, wasting time and effort and causing inconsistencies and mistrust of data.
- Using IDB as an outer shell of the data warehouse provided a very useful tool as it integrates all types of information required whether historical data, brand information, package information, business plan figures…etc. Before using IDB, managers and analysts had to go through many Excel files and sheets to obtain information which is time consuming and some of the required data were lost or hidden. Besides, the same information was sometimes obtained with different values from different sources causing confusion.

Figure 3. Sales reporting process after implementation of the IDB system



- Provided multi-dimensionality reporting using "slice and dice" operations by the analysts.
- IDB acted as a timely and trustworthy reporting tool with a single source of sales data which is not subject to various interpretations. All analysts are bound by specific deadlines to upload their data, so the managers are confident to find the data on time and to retrieve it in a standard format to facilitate the data integration and the decision making process.
- IDB provided analysis facility. Reports retrieved facilitated comparisons and analytical measures that can be used to help managers in the decision making process.
- IDB helped in determining profitable trading partners through the use of multi-dimensionality data mining
- Augmented and replaced cumbersome previous spreadsheet-based system.
- Enabled driver-based planning to streamline and focus efforts around HR plans, manufacturing requirements, or sales resources.
- Enabled use of rolling forecasts to increase forward visibility.
- Reduced the need for consolidation, close and reporting cycles by days or weeks..
- Facilitated conducting what-if scenarios for different revenue projections or changes in business lines.
- Facilitated tracking key corporate performance indicators from desktop.

Beside these impacts on the performance of the Sales function, it enabled giving brand, marketing, and sales managers the knowledge they need to strongly impact the top line through the use of brand, sales, promotion/marketing and delivering a full range of sales management analyses. With the IDB tool, near-real time measures by account, channel/channel segment, promotion, and campaign - can be used to improve the effectiveness of other business cycles such as the full range of brand, portfolio, and product analyses along with the ability to ask random, ad hoc questions and alert when actual performance varies substantially from plan.

In a nutshell, the IDB tool enabled getting the right information, to the right decision makers, at the right time. It is an enterprise-wide platform that supported multi-dimensionality reporting, analytics and decision modeling leading to fact-based decision making and getting a "single version of the truth."

The integration of the marketing data warehouse with the IDB tool also resulted in many benefits such as:

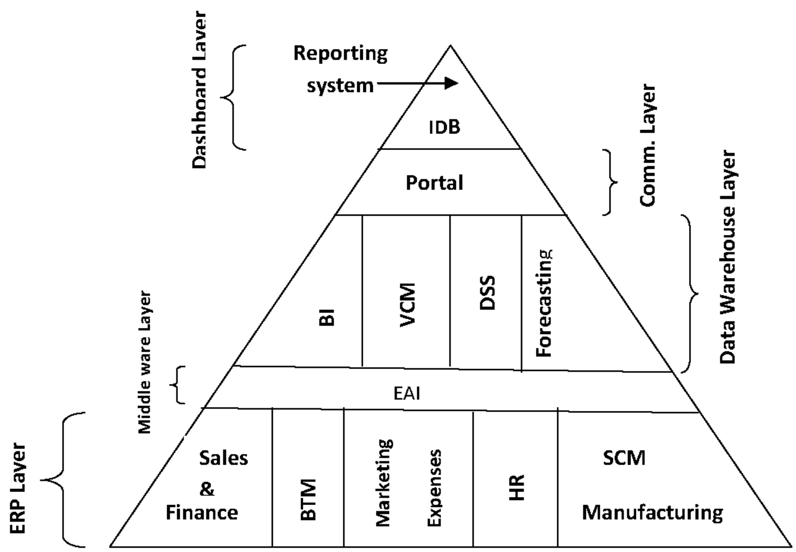
1. Financial process management of annual marketing budgets. Through the marketing Business Warehouse the brand managers gained autonomy in managing this process themselves through accessing this option on the IDB, where they would directly input their budgets online and the embedded workflow would proceed to request granting the necessary approvals. Budget managers were also able to perform internal budget shifts if need be as well as raising new purchase orders where previously it was done manually.
2. Ensuring internal system adherence to corporate financial and procurement procedures, there was no need for manual issuance any more as the ERP system provided the necessary constraints through budget coding, online approval requirements through a hierarchy workflow.
3. Monitoring marketing spend per brand and ensuring correct allocation across the marketing mix. The IDB reports were very malleable in their structure - can be driven by specific periods, campaign types, seasonality, segmentation by below the line marketing activities, or above the line, even by media type which allowed brand managers and marketing managers a better ability to assess the direct impact of a campaign spend over sales in a particular moment in time.
4. Providing budget reporting across franchise functions. Again, this has been a dissolved manual role as the new system allowed for automatic retrieval as explained in the point above.
5. Reporting on brand contribution and profitability per brand, pack, flavor and concentrate. The integration with the company-wide planning system allowed further report segmentation by account, for example, how each cost contributed to the overall profitability of a brand by integrating other operating expenses (OPEX), capital expenses (CAPEX) reports- this type of reports are high level top-line data that were accessed by top managerial staff and also depended on the level of data-breakdown details that were fed in by accountants.

The final Information Systems infrastructure architecture of the company after the IDB implementation is depicted in Figure 4.

CURRENT CHALLENGES FACING THE CASE FIRM

The ERP system has been put in place in the company for many years. Employees did not have an option, they had to use it. Though the company managed to streamline and align some

Figure 4. Architecture of the IS layers used in the company after IDB implementation



of its business processes and operations to the "best practice" processes embedded in the ERP, with minimum changes, to adapt to the specific nature of the beverage industry, customized bolt-in additional tools were inevitably used to cater for those specific characteristics. This was quite evident in the sales and marketing functions. As a result of the deployment of the new IDB system, several problems showed up.

The following obstacles and challenges were observed after installing the IDB

- User reluctance to abandon the use of old Excel templates increased resistance of the use of the new developed data entry facility.
- Training analysts to use IDB was a challenging feat. The dispersed remote locations of analysts made it difficult and costly to provide them with the necessary skills for optimum use of the new tool. Though conference calls and video-conferencing were used to tackle this obstacle, the level of operational excellence in using the tool was less than satisfactory as postulated by the management. Incompetency of use of the facilities of the system was also observed due to the lack of analytical proficiency.
- Unrealistic expectations were anticipated in a relatively short period.
- Lack of in-house technical expertise (The IDB support team is remotely located).
- Real-Time data reporting was accessible once accounting inputs are uploaded into the system in due course. Errors in data entry may thus lead to wrong information and decisions. As one employee contends:

"The initial step when we switched from the legacy system to the new setup involved data migration. This was a very tedious task and involved many months of intricate detailed work where existing data had to be assigned codes similar to the coding on the ERP to allow smooth transition. The challenge was to transition with almost zero error and entailed at certain moment of time to halt transactions entry to ensure all real-time data is

captured. There was a mechanism to double check on validity of data after transition."

- Employees were not receptive to adapt to change and resisted system implementation by initially rejecting the idea for months. Advanced training technology-based methods were adopted to allow for virtual help where global ERP Power Users were able to access local employees' screens to guide them through a step by step process. Adaptability took about one whole year as the users gained more confidence in system maneuver.
- Although the idea of the ERP is to eliminate a lot of paper work, the case was not so in Egypt in some areas as the embedded ERP workflow involved external as well as internal stakeholder's input in the system. For example, marketing assistants raising new purchase orders through the transaction modules were required to attach three different quotations from three different suppliers. The idea is that suppliers were to send those quotations through an interface mechanism that allowed automatic attach to the purchase order. Given that the business climate in Egypt is still underdeveloped in terms of technology maturity, many continued to send their quotations manually by courier messenger, or fax, rarely few at the time were used to the idea of sending through email. This created a bottle neck since the marketing assistant had to then scan those documents and upload them manually to process the purchase order – where a purchase order raising should have taken about an hour for completion ended up consuming a whole day while it has still not been sent to the brand manager for approval. In some situations this produced further time bottlenecks as some suppliers required down payments prior to activation of the required job on the system.
- Brand managers viewed their newly added task of managing the input-output process of budgets themselves and purchase order requisitions as a waste of time as they previously did not do so. They viewed it as a purely transactional administrative task that should be performed by the accounting department or rather assigned to a department secretary for coordination. In the beginning, they did try to perform the processing themselves, but later, decided that this administrative tasks have impeded their focus on managing the brand with consumers from a marketing perspective.
- An operational issue of ERP is currency variations. Although the system allowed for multiple currency input, the final marketing budget to be approved by division heads and headquarters had to be submitted and received in dollars. This created some issues where brand managers initially prepared their budget in Egyptian pounds per the various local quotations and pricing they received. This total amount however did not sometimes equate for the same amount assigned by global HQ on the ERP which was in dollars. The challenge for the finance was to constantly adjust rates according to fluctuations in exchange rates and other market factors such as inflation and so forth which also resulted in some chunks of the budget in Egyptian pounds being eaten away due to these adjustments. It continues to be an ordeal as concentrate pricing is also in US dollars while other transactions are in multiple currencies.
- The deployment of technology into everyday business is still not very mature within people's mindset in Egypt. For example, the lack of trust still persisted in the Egyptian ideology, where the deployment of online signatures through ERP

protocol was still viewed with a suspicious eye. Middle managers especially in the accounting unit still requested a pen-written on paper signature-it made them feel secure. However this required that paper formats of ERP documents were printed and managers were requested put their pen signatures. This did not help in achieving a more lean and streamlined operation which the system was supposed to create.
- End-User Support and Maintenance

A few years ago, for an employee to report an IT problem they had to call the local help desk and technical staff will attend to the call to solve the problem for him or her. However, the company HQ has developed a new process that employees experiencing problems will have to make a call to call center, give their employee ID and describe the technical problem about the software or the hardware. The call center, remotely accessed, will give the employee a ticket number with the problem code and send them an email summarizing the problem. The problem could be simple enough to be solved over the phone (i.e., the center tells the employee on the phone what he or she could do to solve the problem). If it's not then the center directs the problem to the local help desk to solve it. Then the center sends the employee an email asking if the problem has been solved or not to close the ticket. Some employees found this process difficult and time consuming

Future Measures to Enhance the Reporting Cycle and Recommendations

The preceding analysis revealed that key success measures that may help the company to overcome the obstacles cited and leads to turning the IDB system into a success story include the following:

- Executive management involvement and support
- Clear project ownership by including sales analysts in the project management team
- Proper planning
- Hard working and focus by all member countries' analysts
- Clear communication between business and IT by setting meetings, discussing problems and analyzing issues and providing continuous feedback
- Clear role definition for both analysts and IT professionals
- Instituting efficient and effective change management process
- Proper and continuous staff and analysts training

To that end, the company is planning to install new version of the IDB system in the upcoming years. The new system will allow users to create their own queries with specific design and more advanced sales breakdown. Also, the company is planning to use more advanced analytical tools such as the "Instant Visual Analysis" tool which is a simple versatile tool that will make volume analysis and graphic representation faster, easier and more flexible. The Instant Visual Analysis tool uses pivot table reports to help analyze and graph numerical data, answering questions, exhibiting trends, etc. With a few mouse clicks users can see who sold the most where, which brands were the most successful, and which pack sold best.

KEY TERMS AND DEFINITIONS

Business Intelligence (BI): Refers to computer-based techniques used in analyzing business data, such as sales by products and/or departments or associated costs and incomes. In addition, BI technologies avail historical, current, and predictive views of business operations. Common functions of Business Intelligence technologies are reporting, online analytical processing, analytics, data mining, business performance management, benchmarking, text mining, and predictive analytics.

Dashboard: Is the application of visual iconic tools that indicate the status of a particular measurable quantity, event or value. Within the context of business performance measurement, the use of the dashboard may aide decision makers in quickly spotting the status of some KPIs of interest to them.

Data Mining: Is the process of extracting patterns from data. Data mining is becoming an increasingly important tool to transform the data into information. It is commonly used in a wide range of profiling practices, such as marketing, surveillance, fraud detection and scientific discovery. Data mining is often used to uncover patterns in data pertaining to functional or departmental data sets.

Data Warehouse: Is a repository (collection of resources that can be accessed to retrieve information) of an organization's electronically stored data, designed to facilitate reporting and analysis. Data warehousing arises when an organization need reliable, consolidated, unique and integrated analysis and reporting of its data resources, at different levels of aggregation.

Decision Support Systems (DSS): Constitute a class of computer-based information systems including knowledge-based systems that support decision-making activities. DSSs serve the management, operations, and planning levels of an organization and help to make decisions, which may be rapidly changing and not easily specified in advance.

Enterprise Resources Planning (ERP): Is an integrated computer-based software system used to manage organizational internal and external resources. It is an architecture which facilitates the flow of information between all business functions within the boundaries of the organization and manages the interfaces with outside stakeholders.

Key Performance Indicators (KPI): Measures commonly used to help organizations define and evaluate how successful their businesses are, typically in terms of making progress towards long-term organizational goals. KPIs can be specified by answering the question, "What is really important to different organizational stakeholders?"

Chapter 59
Sharing Scientific and Social Knowledge in a Performance Oriented Industry:
An Evaluation Model

Haris Papoutsakis
Technological Education Institute of Crete, Greece

ABSTRACT

The chapter evaluates the contribution of shared knowledge and information technology to manufacturing performance. For this purpose, a theoretical model was built and tested in praxis through a research study among manufacturing, quality and R&D groups. The social character of science is perceived as a matter of the aggregation of individuals, not their interactions, and social knowledge as simply the additive outcome of mostly scientists, members of the three groups, making sound scientific judgments. The study results verify the significant contribution of shared knowledge to the manufacturing group performance. They also demonstrate that information technology influences notably the manufacturing group performance and, in a less significant way, the sharing of knowledge. Study results are useful to researchers and the business community alike as they may be used as a springboard for further empirical studies and can help put together strategies involving knowledge management and information technology.

INTRODUCTION

At the turn of the twentieth century many companies (BP, Canon, GlaxoSmithKline, Honda, Siemens and Xerox, among them) have tried, with varied achievement rates, to leverage knowledge assets by centralizing Knowledge Management (KM) functions or by investing heavily in Information Technology (IT) (Davenport and Prusak, 2000; Hansen and von Oetinger, 2001). In parallel, the number of new knowledge management articles, according to Despres and Chauvel (2000, p. 55) "... has more than doubled each year over

DOI: 10.4018/978-1-4666-1945-6.ch059

the past decade". Among them quite a few have proposed and tested models for the management of knowledge, with or without the support of information technologies (Knight, 1999; Larsen et al, 1999; Liebowitz et al, 2000; Kingsley, 2002). A considerably smaller number of such studies have investigated into how companies can leverage knowledge in order to improve business performance (Nelson and Cooprider, 1996; Chong et al, 2000; Firestone, 2001). Only one (Lee and Choi, 2003), among the articles reviewed for this study is combining all three variables: KM, IT and performance. This is exactly the gap this chapter is coming to fill in. Based on careful analysis of the above mentioned previous empirical studies, it builds and empirically tests a model that simultaneously explores the relationships among these three variables and their antecedents.

The chapter is organized in six sections. In the following section the theoretical framework is defined and a brief presentation of relevant previous empirical studies, focused on the links among knowledge management and information technology to business performance is given. In section three, we situate our own model within the above framework. The variables and the investigation hypotheses are defined. In section four, the research methodology is presented and details are given on the questionnaires –the principal research instruments– and the indicators used for construct measurement. In section five, the investigation hypotheses are tested, using regression analysis, and statistical data are given on questions not analyzed elsewhere. Finally, in section six, conclusions are summarized and recommendations are given for managers of collaborating groups in order to increase shared knowledge and to positively affect manufacturing performance.

THEORETICAL BACKGROUND

In the relevant literature, most attempts to investigate the links among KM and IT that lead to improved business performance, are done within the environment of the knowledge-creating company (Nonaka 1991; Nonaka and Takeuchi 1995). Building upon this pioneer work, Grant, in a series of articles (1995 with Baden-Fuller, 1996a, 1996b, 1997) and Sveiby (1997, 2001) presented in a very clear way the fundamentals of a knowledge-based theory of the firm. According to Grant (1997) –recapitulating on his previous work– the knowledge-based view is founded on a set of basic assumptions. First, knowledge is a vital source for value to be added to business products and services and a key to gaining strategic competitive advantage. Second, explicit and tacit knowledge vary on their transferability, which also depends upon the capacity of the recipient to accumulate knowledge. Third, tacit knowledge rests inside individuals who have a certain learning capacity. The depth of knowledge required for knowledge creation sometimes needs to be sacrificed to the width of knowledge that production applications require. Fourth, most knowledge, and especially explicit knowledge, when developed for a certain application, ought to be made available to additional applications, for reasons of economy of scale.

Theoretically, our research stands upon the 'knowledge-based theory of the firm' (Grant, 1997; Sveiby, 2001). The fundamental problem in traditional management theory is how to align the objectives of workers with those of managers and the stakeholders. In accordance with the knowledge-based view, "… if knowledge is the preeminent productive resource, and most knowledge is created by and stored within individuals, then employees are the primary stakeholders" (Grant 1997, p. 452). Under this perspective, management's principal challenge is to establish the mechanisms for collaborating individuals and groups to coordinate their activities in order to best integrate their knowledge into productive activity. Sveiby (2001) believes that people can use their competence to create value in two directions: by transferring and converting knowledge externally or internally for the organization they belong to. When the managers of a firm direct the efforts of their employees internally, they create tangible goods and intangible structures such as better processes and new designs for products. When they direct their attention outwards, in addition to delivery of goods and money they also create intangible structures, such as customer relationships, brand awareness, reputation and new experiences for the customers.

For Fukayama (1999), the existence of 'social capital' that serves as a glue to hold diverse constituencies together, is a primary cause of success or failure of any organization. The World Bank defines social capital as "norms and social relations imbedded in social structures that enable people to coordinate actions and achieve desired goals", a definition that applies to countries, societies or organizations. It is here where social knowledge has an important role to play. Individuals develop social knowledge through their interactions with the social environment. Stable systems of social knowledge are organized around certain domains; the collaborating groups in our study. According to Turiel (1983) the acquisition of social knowledge can be interpreted in two different ways: (i) it can be knowledge transmitted to the individual by other persons, and in this case the knowledge acquired is dependent on what is transmitted; or (ii) it can be knowledge constructed by individuals specifically about certain social phenomena (p.1). In an effort to capture the dialectic and dynamic relationship between the individual and social knowledge, Jovchelovitch (2007) develops a social-psychological approach in order to investigate knowledge in every day life. In her framework, problems of social knowledge are discussed in relation to individual, social and collective representations. Knowledge represents at the same time subjective, inter-subjective and objective worlds (p. 168).

It is under the above theoretical perspective that we are reviewing the literature, relevant to our investigation, in the following section.

Previous Empirical Studies

Linking knowledge management and information technologies with business performance has never been an easy task. Comparing KM projects to their two prevailing predecessors (total quality management and business process re-engineering) Armistead (1999) notices that authors on KM "… do not use the same hard measures of success consistently" (p. 143). He believes that for a knowledge-based view to be useful, it must help improve some key performance indicators like quality, flexibility and cost. Referring to manufacturing companies he notes that operational processes, which depend more on knowledge, are expected to perform well against measurements of quality in consistency, while at the same time they improve productivity.

Our research focused on two basically diverse areas: The measurement –in terms of both qualitative and quantitative results– of a KM project's impact and, at the same time, the identification of the cause-effect relationship that exists between KM, IT, and the overall business performance. Some previous studies captured KM contribution by focusing on intellectual capital measures (Larsen et al, 1999) or accounts and audits (Liebowitz et al, 2000) but both groups of authors question the generability of their studies. Other studies, criticizing conventional performance measures –such as Return On Investment (used by Anderson, 2002) and Economic Value Added, used by multinationals like The Coca-Cola Company– propose measures based on the Balanced Scorecard (Knight, 1999) or other more abstract and tailored to the company, like the Comprehensive Benefit Estimation (Firestone, 2001) and the Cost of Information (Kingsley, 2002). In a recent work the relevant literature summarized above has been extensively reviewed (Papoutsakis and Salvador Valles, 2006).

In most of the above empirical studies the role of shared knowledge among company departments is not consistent, despite the fact that the knowledge transfer process has been studied extensively. Trust and influence have only been recognized as antecedents of shared knowledge by Nelson and Cooprider (1996), while Lee and Choi (2003) consider trust and information technology as knowledge creation enablers among seven others. What is really missing is an integrative model combining shared knowledge and information technology with performance. Although several studies investigate the relationship between KM and performance (Nelson and Cooprider, 1996; Chong et al, 2000; Firestone, 2001) or IT and KM (Lee and Choi, 2003), they fail to explore the relationships among KM, IT and performance simultaneously.

It is believed that if managers become conscious of the fact that these relationships have interactive features, they can stand a much better chance of improving the performance of their department or company. Measuring the impact of shared knowledge and IT upon manufacturing performance is not an easy task as this will strongly affect the behaviour of managers and employees not only of the manufacturing group, but those of the collaborating groups (in our case the quality and R&D groups). Regarding social knowledge, we have to consider that it exists in the relationships, not in the individuals themselves and thus it requires mutual commitment, since if one party withdraws it disappears. It is under this perspective that we have built and empirically tested the evaluation model proposed in the following section.

PROPOSED MODEL

Aiming to gain insight into the essential factors influencing manufacturing performance, the development and testing of a conceptual model containing the minimum selected theoretical constructs, is considered. Three have been our major concerns, upon building our research model. First, we did not want to propose a model that delineates every possible variable or process that affects manufacturing performance. Second, we wanted to focus on shared knowledge as the leading expression of knowledge management, among the manufacturing, quality and R&D groups of a firm. Third, information technology, in our model, has been perceived to affect both manufacturing performance and shared knowledge.

To assess the type of knowledge to be shared was also an interesting question. Von Krogh, Ichijo & Nonaka (2000) define knowledge as a justified true belief: when somebody creates knowledge, he or she makes sense out of a new situation by holding justified beliefs and committing to them. The emphasis in this definition is on the conscious act of creating meaning. In our study, we focused on collective knowledge that entails notions of collective belief, truth and justification (Corlett, 1996). Our analysis insisted on particular conditions of inter-group, justified true acceptance which is necessary for collective knowledge. According to Corlett, "… what makes belief, acceptance, justification and knowledge collective is that they are the results of human decision-makers related to one another in groups…" (2007, p.245). Obviously, each one represents his or her group interests.

The road to sharing knowledge lies through individuals, mostly scientists in our study, and is based upon building social relationships and trust, deep dialogue and creative abrasion. There is a need of diversity of ideas and an environment where failures and reflection are valued as learning enablers. Science is the process used everyday to logically complete thoughts through inference of facts determined by calculated experiments. As science itself has developed, the so produced scientific knowledge has developed a broader usage within scientists. The development of scientific methods has made a significant contribution to our understanding of scientific knowledge. To be termed scientific, a method of inquiry must be based on the collection of data through observation and experimentation, and the formulation and testing of hypotheses.

The social dimension of scientific knowledge is of significant importance, as well. We perceive the social character of science as a matter of the aggregation of individuals, not their interactions, and social knowledge as simply the additive outcome of mostly scientists, members of the three groups, making sound scientific judgments. Philosophers concerned to defend the social character of knowledge and to explore the social dimension of scientific practice (Laudan, 1984; Brown 1989; Goldman, 1995) have approaches that differ in their details but they agree in stating that scientists are persuaded by what they regard as the best evidence or argument, the evidence most indicative of the truth by their lights, and in maintaining that arguments and evidence are the appropriate focus of attention for understanding the production of scientific knowledge. Opposing them, Jovchelovitch (2007) criticizes the narrow association of knowledge with rationalism in the sense of scientific knowledge. As a result, scientific knowledge is viewed as more valid than everyday knowledge.

Therefore, we have opted for our model to highlight a few key factors that can explain a large proportion of the variation noted in manufacturing performance. We have modified the sharing knowledge model validated and used by Nelson & Cooprider (1996) and we enhanced it with links allowing us to draw conclusions on the role and contribution of information technology as an enabler and facilitator towards both manufacturing performance and shared knowledge. Thus, the proposed evaluation model is built to investigate cause and effect links between sharing knowledge, its components, information technology and manufacturing performance.

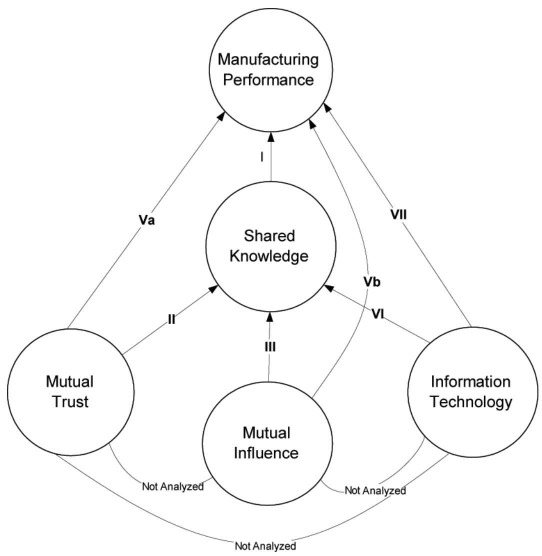
Both general and multiplicative methods are used to measure the indicators, at least two for every construct, and path analysis has been chosen as the analytic technique in this study because it assesses causal relationships (Pedhazur, 1982; Wright, 1971). Pedhazur, building upon Wright, states that "…path analysis is not a method for discovering causes, but a method applied to causal models formulated by the researcher on the basis of knowledge and theoretical considerations." (p. 580). Path diagrams, although not essential for numerical analysis, are useful tools for displaying graphically the pattern of causal relations among the set of variables under consideration. In this respect we consider the model more appropriate than the intellectual capital or the tangible and intangible approach used in other studies.

Despite the fact that in recent years, social and behavioural scientists have been showing a steadily growing interest in studying patterns of causation among variables, the concept of causation has generated a great deal of controversy among both philosophers and scientists. Nonetheless, causal thinking plays a very important role in scientific research. Even in the works of those scientists who strongly deny the use of the term causation, it is very common to encounter the use of terms that indicate or imply causal thinking. Thus, we can conclude that scientists, in general, seem to have a need to resort to causal frameworks, even though on philosophical grounds they may have reservations about the concept of causation.

Schematically, our empirical evaluation model illustrates the relationships among the five variables as shown in Figure 1. Our seven hypotheses correspond to the causal links of Figure 1 and derive from theoretical statements found in the literature related to knowledge management and information systems and technology. In the following section, we shall elaborate upon the variables incorporated in our model and, at the same time, we shall present our investigation hypotheses.

Finally, it is important to bear in mind that path analysis is a method, and as such its valid application is subject to the competency of the researcher using it and the soundness of the theory that is being tested. Finally, it is the explanatory scheme of the researcher that determines the

Figure 1. The shared knowledge and information technology evaluation model



type of analysis to be applied to data, and not the other way around.

VARIABLES AND HYPOTHESES

Shared Knowledge

Sharing of knowledge is a process distinct from managerial communication, which also deserves consideration. Nelson & Cooprider (1996, p. 411) define Shared Knowledge as "an understanding and appreciation among groups and their managers, for the technologies and processes that affect their mutual performance". Appreciation and understanding are the two core elements of shared knowledge. Appreciation among diverse groups must be characterized by sensitivity to the point of view and interpretation of the other group, in order to overcome the barriers caused by the different environments and languages used. A deeper level of knowledge must be shared in order to achieve mutual understanding and this is often characterized as organizational knowledge Badaracco (1991).

Lack of this organizational and cross-functionally shared knowledge may result in loses of Manufacturing group performance, while its presence may lead to better performance. As we do not have *a priori* reasons to expect a different relationship, it is here that we are founding our first hypothesis.

Hypothesis 1: *Shared knowledge among Manufacturing, R&D and Quality groups, as perceived by the manufacturing organization, leads to improved manufacturing group performance.*

In an effort to make more comprehensible the relationship between shared knowledge and the manufacturing group performance, we shall now define the two components or antecedents of shared knowledge: Trust and Influence.

Trust

The significance of trust has been given considerable attention and has even been described as a 'business imperative' (Davidow and Malone, 1992; Drucker, 1993 among others). In rather similar ways, trust has been defined as "a set of expectations shared by all those in an exchange" (Zucker, 1986) or as "the expectation shared by the [involved] groups that they will meet their commitments to each other" (Nelson and Cooprider, 1996, p. 413) or finally as "… maintaining reciprocal faith in each other in terms of intention and behaviors" (Lee and Choi, 2003, p. 190).

Szulanski (1996) empirically found that the lack of trust among employees is one of the key barriers against knowledge sharing and that the increase in knowledge sharing brought on by mutual trust results in knowledge creation. In the model proposed for this study, it is assumed that Manufacturing, R&D and Quality groups work better in an atmosphere of mutual trust based on mutual commitment and a stable long-term relationship, which is the foundation for our conceptualization of trust. We, thus, hypothesize that mutual trust is a determinant of shared knowledge and it is here that we advance our second hypothesis.

Hypothesis 2: *The perception of increased levels of mutual trust among Manufacturing, R&D and Quality groups leads to increased levels of shared knowledge among these groups.*

Influence

As organizational groups engaged in joint work are often dependent upon each other, influence relationships are created. One way influence is developed, is through the law of reciprocity (Cohen and Bradford, 1989). People expect payback for contribution to an exchange. The perception of reciprocal benefits leads to mutual influence and success in future exchanges among the groups. Nelson and Cooprider (1996, p. 414) define mutual influence as "the ability of groups to affect the key policies and decisions of each other." Consequently, we expect the following relationship to hold true and it is here that we are basing our third hypothesis.

Hypothesis 3: *Increased levels of mutual influence among manufacturing, R&D and Quality groups lead to increased levels of shared knowledge among these groups.*

The two important aspects with regard to shared knowledge are demonstrated in the evaluation model used for this research (Figure 1). First, mutual trust and influence are presented as antecedents of shared knowledge, and second, shared knowledge is presented as a mediating variable between mutual trust and influence, leading to manufacturing group performance. Therefore, we can hypothesize:

Hypothesis 4: *Shared knowledge acts as a mediating variable between mutual trust and influence and manufacturing performance.*

As we have no *a priori* reasons to exclude that mutual trust and influence could also possibly affect manufacturing performance directly, we are here introducing our fifth hypothesis.

Hypothesis 5: *There is a positive relationship between mutual trust and manufacturing performance, as well as between mutual influence and manufacturing performance.*

Information Technology

Davenport & Short (1990, p. 11) define Information Technology (IT) as "…the capabilities offered by computers, software applications, and telecommunications" and further explain that "IT should be viewed as more than an automating or mechanizing force; it can fundamentally reshape the way business is done" (p. 12) and that "IT can make it possible for employees scattered around the world to work as a team" (p. 19). Applegate, McFarlan & McKenney (1999; p. vii) identify IT as: "…computing, communications, business solutions and services…" and further down (note in p. 3) they explain that "…IT refers to technologies of computers and telecommunications (including data, voice, graphics, and full motion video)."

In the new economy era, information technology has a very significant role to play in supporting both communication and, in particular, knowledge sharing. IT affects knowledge sharing in a variety of ways. IT facilitates rapid collection, storage, and exchange of knowledge in a scale not possible up to recent times, thus fully supporting the knowledge sharing process (Roberts, 2000). Specially developed IT integrates fragmented flows of knowledge, eliminating, in this way, barriers to communication among departments (Gold et al, 2001). Advanced IT (like electronic whiteboarding and videoconferencing) encourages all forms of knowledge sharing and is not limited to the transfer of explicit knowledge only (Riggins and Rhee, 1999). Thus, we can hypothesize:

Hypothesis 6: *There is a positive relationship between IT support and the knowledge sharing process.*

The use of certain IT infrastructure such as intranets, extranets, groupware, internet, etc has been evaluated, in relationship to sharing knowledge, by means of an ad hoc question. IT, in our model, is perceived to affect manufacturing performance, as well.

Manufacturing Performance

Under an industrial business management approach, manufacturing performance has three main activities: (i) the selection of goals; (ii) the consolidation of measurement information relevant to an organization's progress against these goals, and (iii) the interventions made by managers in light of this information with a view to improving future performance against these goals. Although presented here sequentially, typically all three activities will run concurrently, with the interventions made by managers affecting the choice of goals, the measurement information monitored, and the activities being undertaken within the organization.

For the purpose of our study, organizational stakeholders in every participating company have been questioned in order to assess the manufacturing group performance and, in addition, to compare the manufacturing unit under investigation with other units they have managed. Madnick (1991) points out the major ways in which IT support affects manufacturing group performance. First, IT provides opportunities for increased inter- and intra-organizational connectivity and, thus, increases both efficiency and effectiveness. Second, new IT architectures offer significant cost/performance and capacity advances. And finally, with IT support, adaptable organizational structures that lead to significant cost reductions are made possible. As there are other variables (such as employees' competences and qualification, raw material quality, technology level of the machinery in use, etc) which affect manufacturing group performance and are not included in our model, we can only hypothesize:

Hypothesis 7: *There is a positive relationship between IT support and the manufacturing group performance.*

The use of four IT functions (coordination of business tasks, support of decision making, facilitating teamwork and access to information in data bases) has been evaluated, in relationship to manufacturing performance, by means of an ad hoc question.

The five variables incorporated in our model are structured upon a socio-technical perspective that adopts an holistic approach (Pan and Scarbrough 1998). Based on this view, mutual trust and influence, related to the organizational structure and culture as well as to the employees, are considered social variables while, on the other hand, IT is considered a technical variable. For purposes of clarity, most studies consider the impact of social and technical variables independently, a precaution we are also adopting in this study. In the next section, we are presenting the methodology of our research.

RESEARCH DESIGN

In an ideal situation, investigation samples are selected randomly. This is done, among other reasons, for the external validity criteria to be *a priori* fulfilled. The maxim applies to the selection of companies, manufacturing units, and, to a certain extent, to the selection of individuals who answer the questionnaires. As the sample of our study included every company that has accepted to participate we can not disregard a possible selection bias. Finally 51 medium to large size industrial companies, representing 5 sectors (alimentation, automotive, chemical and pharmaceutical, electro-mechanical, and textile) participated in the research. The unit of analysis is the manufacturing group, since the intent of this study is to explain the relationship of organizational subunits (the three collaborating groups) rather than that of individuals. The size of the company has been used as a criterion and it was convenient that several of the selected companies had multiple manufacturing groups (or departments/lines as they were named) who cooperated with a central R&D and/or quality group.

This has allowed for the research to be addressed to a big number of manufacturing groups, out of which 112 have participated by responding to the relevant questionnaires. Table 1 shows the industrial sectors represented, the number of companies contacted and participated as well as the identified and participating manufacturing units for each one of them. The final sample size, of 112 manufacturing units, is considered sufficient in order to perform path analysis (Pedhazur 1982) and the participation rates achieved in our study (62% at company level and 68% at the unit of analysis level) are considered satisfactory (Cook and Campbell, 1979).

The research responders have been chosen based on the key-informant methodology developed by Phillips and Bagozzi (1986) and included–for each company–manufacturing, R&D and quality group managers or their deputies, as well as senior managers. As the measurement of organizational characteristics requires research methods different from those used for measuring the characteristics of individuals, key-informant methodology is a frequently adopted approach. (Table 1)

Two symmetrical relationship questionnaires, worded in a reverse form, were addressed to Production and Quality or R&D managers -and their assistants- and aimed at portraying the opinion and the attitude of the two collaborating groups towards each other, in terms of sharing knowledge. In addition, the role and level of contribution of Information Technology, both as a tool and/or enabler in supporting sharing knowledge among the collaborating groups was investigated and a last, ad hoc question evaluated the use of commonly used IT infrastructure for inter-firm knowledge sharing.

A third, performance questionnaire –attempting to measure manufacturing group performance– was addressed to senior managers or their assistants. They have been asked to compare the manufacturing group under question, to other comparable manufacturing groups they have managed. In addition, the level of contribution of Information Technology to manufacturing group performance was investigated and again, a last ad hoc question evaluated the use of specific IT functions on four knowledge sharing issues, closely

Table 1. Study participants by sector, company and unit of analysis

Sector	Companies		Manufacturing Units	
	Contacted	Participated	Identified	Participated
Alimentation	26	14	47	31
Automotive	8	6	25	15
Chemical & Pharmaceutical	7	5	22	19
Electro-Mechanical	25	18	54	35
Textile	16	8	17	12
Total	82	51 (62%)	165	112 (68%)

related to the group performance. The questions used, with their indicative numbers, are listed in Appendix I, where we analyze the indicators used for each construct measurement.

The two relationship questionnaires were pilot tested using Production and Quality or R&D managers, and the performance questionnaire was tested using senior executives from a small group of companies not participating in the final phase of our research. Following the completion of each pilot questionnaire, the pilot test informant was debriefed to determine if any questions were confusing for any reason. They were also questioned, whether in their opinion, any significant indicators have been left out of the questionnaire. Based on the results of the pilot test, a number of initially used questions were determined to be poor and were deleted or rephrased. The most important lessons learned through design and pilot testing of the questionnaires are:

1. In designing the questions, it is essential, to word them in as simple terms as possible and to anchor each question to one specific relationship;
2. Each question must be customized to include the exact name of the department, as it is used in the company in question.

Despite the above precautions we experienced that the key-informant does not always share the same understanding with the researcher regarding the terminology in use.

Two types of measures have been used to assess the organizational characteristics of shared knowledge, mutual trust, mutual influence, information technology and manufacturing performance. General measures, where each informant is asked to assess the overall level of interaction for a specific characteristic of a particular relationship and multiplicative or interaction measures, where each informant is asked, for example, to assess the role of manufacturing and either R&D or quality group for each characteristic separately. Using the conceptualization of fit as interaction, proposed by Venkatraman (1989), the measurements have been operationalized as "manufacturing role X R&D or quality role", by multiplying the two responses together.

There are a number of advantages to this measurement scheme, as indicated by Churchill (1979) and Campbell and Fiske (1959): (a) the two types of measures (general and multiplicative) can be thought of as different methods; (b) it provides a stronger test of the validity of the measurement scheme, and (c) it balances possible threats to validity inherent in either type alone.

Manufacturing group performance has been conceptualized in two parts; as operational and service manufacturing performance. Operational or 'inward' performance is operationalized as: (a) the quality of the manufacturing group's work product; (b) the ability of the manufacturing group to meet its organizational commitment, and (c) the ability of the manufacturing organization to meet its goals (first three questions of the performance questionnaire). Service or 'outward' performance is operationalized as: (a) the ability of the manufacturing group to react quickly to R&D and/or quality needs, (b) its responsiveness to the R&D and/or quality group and (c) the contribution that the manufacturing group has made to the R&D and/or quality group's success in meeting its strategic goals (questions four to six of the performance questionnaire).

ANALYSIS OF THE RESULTS

In order to assess the validity of our evaluation model (Figure 1) we empirically tested it using path analysis as the method for studying patterns of causation within the set of independent, mediating and dependent variables used in our evaluation model. For the casual model under consideration, the following preconditions, given by Pedhazur (1982) are essential:

1. The relations among the variables in the model are linear, additive and causal.
2. Each residual is not correlated with the variables that precede it in the model.

This implies that:

a. The residuals are not correlated among themselves
b. All relevant variables are included in the model
c. Each endogenous variable is perceived as linear combination of exogenous and/or endogenous variables in the model plus a residual
d. Exogenous variables are treated as ‘given’ and when are correlated among themselves, these correlations are also treated as ‘given’ and remain unanalyzed.

3. There is a one-way causal flow in the system.
4. The variables are measured on an interval scale.
5. The variables are measured without error.

And Pedhazur concludes that “…given the above assumptions, the method of path analysis reduces to the solution of one or more multiple linear regression analyses” (p. 580).

It is under these assumptions that we have concluded to the use of Figure 2, as the research model for our investigation. With one exception: Not all variables affecting Manufacturing Performance are included in the model. Essential variables like skills and qualification of workers, technological level of the machinery in use, and quality of the raw material –just to mention some very basic ones- have not been taken into consideration simply because they do not relate to the focus of our investigation, which is the contribution of shared knowledge and information technology to manufacturing performance. This means that the result of the regression of Manufacturing Performance versus Shared Knowledge could only be considered as a partial causal effect.

Two multiple regressions were run for each of the two dependent variables, manufacturing performance and shared knowledge. Testing the hypotheses requires testing the significance of paths I, II, III, Va, Vb, VI and VII as presented in

Figure 2. Regressions in the evaluation model

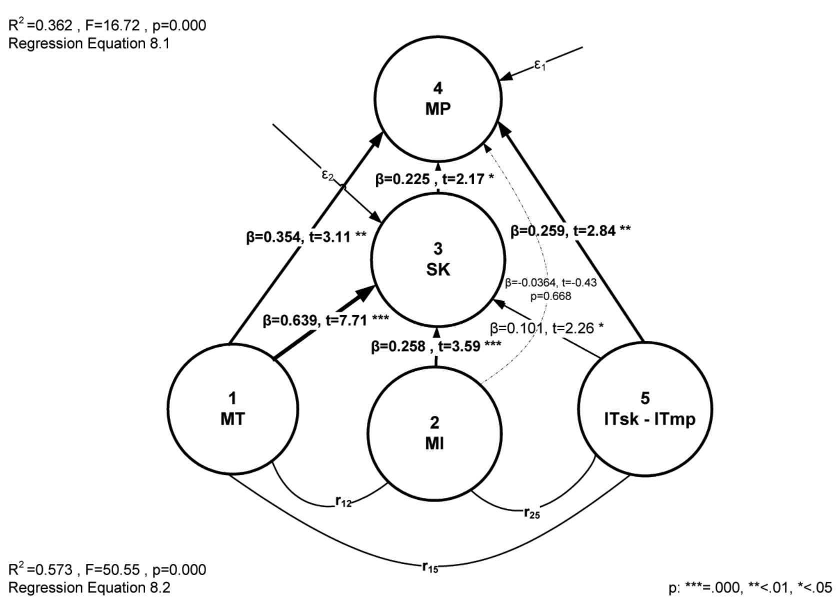


Figure 1. The results of this analysis are schematically shown in Figure 2 and in the generic regression equations below:

For manufacturing performance:

$$MPC = \alpha + \beta_1\ SKC + \beta_2\ MTC + \beta_3\ MIC + \beta_4\ ITmpC + e \quad (8.1)$$

For shared knowledge:

$$SKC = \alpha + \beta_1\ MTC + \beta_2\ MIC + \beta_3\ ITskC + e \quad (8.2)$$

Two points need to be clarified in the above equations:

1. β's, the normalized path coefficients, indicate the direct impact of a variable hypothesized as a cause on a variable taken as an effect. Wright (1934) defines a path coefficient as: "The fraction of the standard deviation of the dependent variable (with the appropriate sign) for which the designated factor [here, the independent or mediating variable] is directly responsible…" (p. 162). Under the previously analyzed preconditions, path coefficients take the form of ordinary least squares solutions for the β's (Pedhazur 1982, pp. 582-584).
2. The third letter C, added to the two-letter acronym used for each one of the variables, indicates that we are referring to its Construct. As at least two indicators have been used to assess every variable in the research model, the construct is the mean of these indicators. In the acronym of information technology, the indicators mp and sk are used to distinguish: (a) ITskC, the IT construct measured through the two relationship questionnaires, in reference to shared knowledge, and (b) ITmpC, the IT construct measured through the performance questionnaire, in reference to manufacturing performance. As these two types of questionnaires have been filled in by different key-informants we could not use a possible IT Construct (ITC) produced as the mean of ITskC and ITmpC.

Regressions in the evaluation model have been conducted in hierarchical order. First, we examined the relationship between manufacturing performance and each one of the variables affecting it; shared knowledge, mutual trust and influence, and information technology as described in the first regression equation. And the resulting equation is:

$$MPC = 6.98 + 0.354\ MTC - 0.0364\ MIC + 0.225\ SKC + 0.259\ ITmpC + e_1$$

At this point, and for the better understanding of the analysis following, some more statistical terms need to be clarified:

1. R^2, in the case of multiple independent variables, indicates the squared multiple correlation, i.e. the proportion of variance of the dependent variable accounted for by the independent variables.
2. The t-value ($-\infty < t > +.\infty$) determines the level of significance of the β's, and finally,
3. F, the ratio of the mean square regression to the mean square residual, provides a statistic for testing the null hypothesis. When the calculated F exceeds the tabled value of F, with the associated degrees of freedom and at a preselected level of significance p (i.e. $p=0.000$, or $p<.05$), the conclusion is to reject the null hypothesis.

In this first regression mutual trust, information technologies and shared knowledge are found to affect manufacturing performance significantly, while mutual influence does not (β=-0,0364, t=-0.43, p=0.668). The regression model described by the equation 5.1 is significant (F=16.72, p=0.000), but R^2=0.362 suggests that only 36.2 percent of the variance is explained by the five variables involved. This is something we expected, as we have already noted, upon founding hypothesis 7, that there are significant factors affecting manufacturing performance which are not included in our model.

Then, we examined the relationship among shared knowledge, mutual trust and influence, and information technology, as described by the second regression equation, and here are the results:

$$SKC = 1.08 + 0.639\ MTC + 0.258\ MIC + 0.101\ ITskC + e_2$$

In this second regression, mutual trust, mutual influence and information technology are all found to affect shared knowledge with variable strengths. The regression model described by the equation 5.2 is significant (F=50.55, p=0.000) and R^2=0.573 suggests that 57.3 percent of the variance is explained by these three variables.

Consistency of the model with the data, however, does not constitute proof of the theory; at best it only provides support to it. Following Popper's (1959) basic argument that all one can achieve through investigation is the falsification of theory, we would have to conclude that the theory has survived the test, in that it has not been disconfirmed. Thus, in direct connection with our investigation hypotheses, the regression results indicate that:

1. Hypotheses 1, 2, 3, 6 and 7 are directly supported by the significance of paths I, II, III, VI and VII respectively. This means that: (a) Shared knowledge among Manufacturing, R&D and Quality groups, as perceived by the manufacturing organization, leads to improved manufacturing group performance. (b) The perception of increased levels of mutual trust among Manufacturing, R&D and Quality groups leads to increased levels of shared knowledge among these groups. (c) Increased levels of mutual influence among Manufacturing, R&D and Quality groups lead to increased levels of shared knowledge among these groups. (d) There is a positive relationship between IT support and the Knowledge sharing process. (e) There is a positive relationship between IT support and the manufacturing group performance.
2. Hypotheses 4 and 5 are each only partially supported as they could not both together stand true. This means that: (a) Shared knowledge acts as a mediating variable only for mutual influence, while mutual trust appears to also significantly affect manufacturing performance in a direct way (significance of path Va). (b) Mutual influence does not directly affect manufacturing performance (statistically insignificant *beta* for path Vb).

There is an important note to be made at this point. To the extent that *beta* values reflect the strength of the cause-effect relationship, we may say that IT does not affect shared knowledge in the same significant way that it affects manufacturing performance. This result may first be explained by the fact that information technologies mainly affect transfer and sharing of explicit knowledge, while in the environment of our study (shared knowledge among manufacturing, quality and R&D groups) tacit knowledge plays a dominant role. The result is also in accordance with findings of other studies. Lee and Choi (2003) have found that IT support is significantly related only with knowledge combination (explicit to explicit knowledge transactions) while they have noticed no significant relation with any of the other three knowledge creation processes (socialization, externalization and internalization) where tacit knowledge is also involved.

The second explanation has to do with the research instruments. In our investigation, the two constructs of information technology (ITskC and ITmpC) were measured on two separate instruments, the symmetrical relationship questionnaires, and the performance questionnaire. The two separate instruments were filled out by different key-informants at different levels within the organization. It is anticipated that collaborating group managers on one hand, and senior managers on the other, might have different background conditions, when asked to judge the same concept. Pedhazur (1982) attributes these differences to the personal characteristics of key-informers, like cognitive styles, self-concept, ego strength and attitudes.

Use of IT Infrastructure

The last question in the two relationship questionnaires is examining the use of certain IT infrastructure as tools and enablers for sharing knowledge, among Manufacturing, Quality and/or R&D groups. Study results indicate that managers or their deputies of the three collaborating groups strongly use E-mail (86.6%), Intranets (71%) and Internet (42.85%), and at lower, but still noteworthy percentages, Data Warehouse software (30%), Extranets (23.65%), Groupware software (20.95) and Workflow software (11.6%) in their daily work. Percentages here and in the following paragraph refer to the sum of 'strong' answers (grouped Likert ratings 5, 6 and 7).

Use of IT Functions

The last question in the manufacturing performance questionnaire is investigating the use of certain IT functions by the company as a whole. According to our study, senior managers report that group managers use at relatively high percentages all four IT functions, in order to: facilitate access of information in Data Bases (84.4%), coordinate business tasks (82.6%), facilitate team members to work together (76.4%) and support decisions making (69.2%).

Confirmatory Tests

Four confirmatory tests of the research model were performed and the results obtained are briefly presented here. Cronbach's *alphas* (all ranged from 0.7819 to 0.9994) were utilized to reassure the reliability of the instruments used (Nunnally, 1978).

Convergent and discriminant validity has been checked by the Multi-Trait Multi-Method correlation matrix and all correlations within constructs have been found to be higher than any correlations across constructs (Campbell and Fiske, 1959).

Linearity and collinearity tests are essential for the assumptions of regression analysis to be met. Because the scatter plots of individual variables did not indicate any nonlinear relationships, the linearity was guaranteed. In addition, we tested the plots of residuals against the explanatory variables. As they showed no model inadequacies, we assume that no variable violates the constant variance. Collinearity among the variables involved in the two regression equations was tested by the Variance Inflation Factors which in our study ranged from 1.1 to 2.3 (in the first regression equation) and from 1.1 to 1.3 in the second. Hence, we have taken for granted that there is no multicollinearity problem (Neter et al, 1996).

Finally, the analysis of variance was used to check via an alternative method, two of the results obtained through Multiple Regression (Pedhazur, 1982; Draper and Smith, 1980).

1. The corresponding values of r (or $R\text{-}S_q$) were re-calculated and found in accordance with the previously calculated R's:
   r= 0.3846 compared to R= 0.362 for the first regression equation, and
   r=0.58406 compared to R= 0. 573 for the second regression equation.
2. The regression models used were found significant because both F-ratios were larger than the corresponding critical F-values:
   F=16.72 >> F(0.01; 4, 107) = 3.50 for the first regression equation, and
   F=50.55 >> F(0.01; 3, 108) = 3.96 for the second regression equation.

The statistical results of the two regression equations and those of the confirmatory tests are presented in Appendix II.

LIMITATIONS AND FUTURE RESEARCH

We acknowledge two limitations for our study. The first one is theoretical:

1. The development of mutual trust and influence leading to shared knowledge and the influence of information technology are all ongoing phenomena. In our study, these constructs were measured at a static point in time rather than as they develop. A future research could possibly investigate the relationship of ongoing changes to manufacturing group performance, maintaining the same company sample. It would also be interesting to possibly relate the changes noted over time, with actual changes in both the social (mutual trust and influence) and the technical (information technology) subsystems within the organization.
2. The study was conducted in Spain. A new multinational study in three more European Union countries, namely Finland, Greece and Hungary is currently under development and we hope that it will further support our findings.

CONCLUSION

The results of this study demonstrate the positive contribution of shared knowledge and information technology to manufacturing performance. Based primarily on the above results and to a certain extent on the literature reviewed, we come to the following socio-technical conclusion. Sharing knowledge in a meaningful manner requires a well balanced merge of technology with the company's culture, in a way that creates an environment supporting collaboration. Trust has been identified, through our study, as one of the company's core values. Management has to create a climate of trust in the organization, for knowledge sharing to become reality. In such an environment scientists from different groups (Manufacturing, Quality and R&D) feel comfortable to look for others with the 'missing piece of individual and social knowledge' to share. As shown by this study, influence is the second necessary condition for, and can lead to cooperative behavior among individuals and groups, especially where tacit knowledge has to be shared. It is only in such an environment that the IT made available may lead to innovative products.

The findings of this study indicate that Manufacturing, Quality and R&D groups have the opportunity to develop mutual trust and influence through repeated periods of positive face-to-face or IT-based communication, social interaction and common goal accomplishment. Such behavioral features result to increased shared knowledge regarding the groups' common problems, procedures and know-how. It is clearly illustrated that it is in the hands of management to increase manufacturing performance by improving the channels for individual and social knowledge to be shared among the three groups and by selecting the information technologies that best fit the innovative efforts and competitive strategy of their organization.

KEY TERMS AND DEFINITIONS

Influence: Nelson and Cooprider (1996, p. 414) define mutual influence as "the ability of groups to affect the key policies and decisions of each other." As organizational groups engaged in joint work are often dependent upon each other, influence relationships are created. One way influence is developed, is through the law of reciprocity. People expect payback for contribution to an exchange. The perception of reciprocal benefits leads to mutual influence and success in future exchanges among the groups. In our study, trust and influence have been recognized as antecedents of shared knowledge.

Information Technology: Davenport & Short (1990, p. 11) define Information Technology (IT) as "…the capabilities offered by computers, software applications, and telecommunications" and further explain that "IT should be viewed as more than an automating or mechanizing force; it can fundamentally reshape the way business is done" (p. 12) and that "IT can make it possible for employees scattered around the world to work as a team" (p. 19). Applegate, McFarlan & McKenney (1999; p. vii) identify IT as: "…computing, communications, business solutions and services…" and further down (note in p. 3) they explain that "…IT refers to technologies of computers and telecommunications (including data, voice, graphics, and full motion video)."

Performance: Under an industrial business management approach, manufacturing performance has three main activities: (i) the selection of goals; (ii) the consolidation of measurement information relevant to an organization's progress against these goals, and (iii) the interventions made by managers in light of this information with a view to improving future performance against these goals. Although presented here sequentially, typically all three activities will run concurrently, with the interventions made by managers affecting the choice of goals, the measurement information monitored, and the activities being undertaken within the organization.

Scientific Knowledge: Science is the process used everyday to logically complete thoughts through inference of facts determined by calculated experiments. As science itself has developed, the so produced scientific knowledge has developed a broader usage within scientists. The development of scientific methods has made a significant contribution to our understanding of scientific knowledge. To be termed scientific, a method of inquiry must be based on the collection of data through observation and experimentation, and the formulation and testing of hypotheses.

Shared Knowledge: "… an understanding and appreciation among [collaborating] groups and their managers, for the technologies and processes that affect their mutual performance" (Nelson & Cooprider 1996, p. 411). Appreciation and understanding are the two core elements of shared knowledge. Appreciation among diverse groups must be characterized by sensitivity to the point of view and interpretation of the other group, in order to overcome the barriers caused by the different environments and languages used. A deeper level of knowledge must be shared in order to achieve mutual understanding and this is often characterized as organizational knowledge Badaracco (1991).

Social Knowledge: Individuals develop social knowledge through their interactions with the social environment. Stable systems of social knowledge are organized around certain domains; the collaborating groups in our study. According to Turiel (1983) the acquisition of social knowledge can be interpreted in two different ways: (i) it can be knowledge transmitted to the individual by other persons, and in this case the knowledge acquired is dependent on what is transmitted; or (ii) it can be knowledge constructed by individuals specifically about certain social phenomena. The social dimension of scientific knowledge is of significant importance, as well. We perceive the social character of science as a matter of the aggregation of individuals, not their interactions, and social knowledge as simply the additive outcome of mostly scientists, members of the three groups, making sound scientific judgments.

Trust: has been defined as "a set of expectations shared by all those in an exchange" (Zucker, 1986) or as "the expectation shared by the [involved] groups that they will meet their commitments to each other" (Nelson and Cooprider, 1996, p. 413) or finally as "… maintaining reciprocal faith in each other in terms of intention and behaviors" (Lee and Choi, 2003, p. 190). The significance of trust has been given considerable attention and has even been described as a 'business imperative' (Davidow and Malone, 1992; Drucker, 1993 among others).

APPENDIX A: QUESTIONNAIRES AND CONSTRUCT MEASUREMENT

For reasons of economy of space the three Questionnaires (Relationship Questionnaires Type A and B and Performance Questionnaire Type C) are not presented separately. All the questions are listed, with their indicative number, upon analyzing the Indicators used for each Construct Measurement. In every question below, titles in brackets were customized to reflect the exact names of the participating organizations and functional groups, as they are used in every firm.

1. **Relationship Questionnaires** (Type A and B) included twelve questions aiming to measure:
   - Dependent or mediating variable Sharing Knowledge (3 questions)
   - Independent variable Mutual Trust (2 questions)
   - Independent variable Mutual Influence (4 questions)
   - The role and level of contribution of Information Technology (ITsk), both as a tool and/or enabler in supporting sharing knowledge among Manufacturing, Quality and/or R&D groups (2 questions)
   - The use of IT infrastructure –under the above described concept (1 question with multiple sub questions. Results are given in pie-chart form and are not presented here.)

Please characterize the general working relationship that currently exists between the

[Manufacturing] group and the [Quality or R&D] group → (Questionnaire Type A), or
[Quality or R&D] group and the [Manufacturing] group → (Questionnaire Type B).

Use Table 2 to measure constructs.

Table 2.

1	2	3	4	5	6	7
Extremely Weak	Weak	Moderately Weak	About Average	Moderately Strong	Strong	Extremely Strong

Shared Knowledge*

The three indicators of shared knowledge have been designed to assess the level of understanding or appreciation which the members of the three groups have of each others' work environments. Indicators 1 and 3 assess the level of appreciation that each participant has for what their partners (in the other group) have accomplished, by using general and multiplicative assessments respectively. The second indicator measures the level of understanding that the members of the three groups have of each others' work environments.

Shared Knowledge Indicator 1: (General Assessment, **Mean 5.2991**; SD 0.6957; Range 4)

A1/B1: The level of appreciation that the [Manufacturing] group and the [Quality or R&D] group have for each other's accomplishments is:

A1: (**Mean 5.35714**; SD 0.79250; Range 4)

B1: (**Mean 5.24107**; SD 0.84091; Range 4)

Shared Knowledge Indicator 2: (Multiplicative Assessment, **Mean 25.152**; SD 8.604; Range 44)

The product of the responses to the following:

A2: The level of understanding of the [Quality or R&D] group for the work environment (problems, tasks, roles, etc) of the [Manufacturing] group is:

(**Mean 4.84821**; SD 1.10045; Range 6)

B2: The level of understanding of the [Manufacturing] group for the work environment (problems, tasks, roles, etc) of the [Quality or R&D] group is:

(**Mean 5.17857**; SD 0.91252; Range 5)

Shared Knowledge Indicator 3: (Multiplicative Assessment, **Mean 26.652**; SD 8.157; Range 40)

The product of the responses to the following:

A3: The level of appreciation that the [Quality or R&D] group has for the accomplishments of the [Manufacturing] group is:

(**Mean 5.07143**; SD 0.97458; Range 4)

B3: The level of appreciation that the [Manufacturing] group has for the accomplishments of the [Quality or R&D] group is:

(**Mean 5.17857**; SD 0.91252; Range 5)

Shared Knowledge Construct: The mean of the above indicators (**Mean 19.034**; SD 5.180; Range 23.667).

Mutual Trust*

The two indicators of predisposition measure the extent to which the two partner groups trust each other. The first indicator directly assesses the level of trust between the groups, through a general assessment. The second indicator is a multiplicative assessment that evaluates the reputation of each group for meeting its commitments.

Mutual Trust Indicator 1: (General Assessment, **Mean 5.4509**; SD 0.8620; Range 4)

A4/B4. The level of trust that exists between the [Manufacturing] group and the [Quality or R&D] group is:

A4: Mean 5.54464; SD 1.10599; Range 5

B4: Mean 5.35714; SD 0.92860; Range 4

Mutual Trust Indicator 2: (Multiplicative Assessment, **Mean 28.304**; SD 8.374; Range 43)

The product of the responses to the following:

A5: The reputation of the [Quality or R&D] group for meeting its commitments to the [Manufacturing] group is: **Mean 5.44643**; SD 0.96646; Range 4
B5: The reputation of the [Manufacturing] group for meeting its commitments to the [Quality or R&D] group is: **Mean 5.13393**; SD 0.97256; Range 6
Mutual Trust Construct: The mean of the above indicators, **Mean 16.877**; SD 4.452; Range 21.5.

Mutual Influence*

The three indicators of mutual influence assess the level of influence and the ability to affect that members of the groups have on each others' key decisions and policies. The first indicator directly assesses the level of influence and the ability to affect between the groups, through a general assessment. The second indicator is a multiplicative assessment that evaluates the level of influence that the members of the groups have on each other's key decisions and policies. The third indicator is a multiplicative assessment that evaluates the ability to affect that the members of the groups have on each other's key decisions and policies

Mutual Influence Indicator 1: (General Assessment, **Mean 4.8973**; SD 0.7478; Range3.75)

The average of the responses to the following:

A6/B6: In general, the level of influence that members of the [Manufacturing] Group and the [Quality or R&D] have on each other's key decisions and policies is:
A6: Mean 5.01786; SD 0.97705; Range 5
B6: Mean 4.85714; SD 0.98509; Range 5
A7/B7: In general, the ability of members of the [Manufacturing] group and the [Quality or R&D] group to affect each other's key decisions and policies is:
A7: Mean 5.00000; SD 1.04838; Range 5
B7: Mean 4.71429; SD 1.06904; Range 5
Mutual Influence Indicator 2: (Multiplicative Assessment, **Mean 22.089**; SD 7.986; Range 33)

The product of the responses to the following:

A8: In general, the level of influence that members of the [Quality or R&D] group have on key decisions and policies of the [Manufacturing] group is:
Mean 4.81250; SD 0.92543; Range 4
B8: In general, the level of influence that members of the [Manufacturing] group have on key decisions and policies of the [Quality or R&D] group is:
Mean 4.50893; SD 1.17017; Range 6
Mutual Influence Indicator 3: (Multiplicative Assessment, **Mean 22.911**; SD 7.905; Range 33)

The product of the responses to the following:

A9: In general, the ability of members of the [Quality or R&D] group to affect key policies and decisions of the [Manufacturing] group is:
Mean 4.93750; SD 0.84129; Range 3
B9: In general, the ability of members of the [Manufacturing] group to affect key policies and decisions of the [Quality or R&D] group is:
Mean 5.57143; SD 1.19845; Range 5
Mutual Influence Construct: The mean of the above indicators, **Mean 16.632**; SD 5.099; Range 22.750.

(*) Questionnaire items for shared knowledge, mutual trust and mutual influence used in our study had been validated and used by Nelson and Cooprider (1996) upon exploring the concept of shared knowledge between Information Systems (IS) groups and their line customers as a contributor to IS performance.

Information Technology and Sharing Knowledge (ITsk)

By means of the relationship questionnaires (Type A and B) we are measuring the role and level of contribution of IT in supporting shared knowledge. We, thus, use the marker (sk) to distinguish from the IT indicators used in the performance questionnaire.

ITsk Indicator 1: (Multiplicative Assessment, **Mean 27.732**; SD 8.514; Range 40)

The product of the responses to the following:

A.10: In general, the role and the level of contribution of Information Technology (IT) as a tool and/or enabler, in supporting shared knowledge between [Manufacturing] group and [Quality or R&D] group is: (**Mean 5.25893**; SD 0.8776; Range 4)
B.10: In general, the role and the level of contribution of Information Technology (IT) as a tool and/or enabler, in supporting shared knowledge between [Quality or R&D] group and [Manufacturing] group is: (**Mean 5.19820**; SD 1.10223; Range 5)
ITsk Indicator 2: (Multiplicative Assessment, **Mean 29.223**; SD 8.379; Range 33)

The product of the responses to the following:

A.11: In general, the use of the Information Technology (IT) infrastructure in the [Manufacturing] group is: (**Mean 5.21429**; SD 0.90473; Range 5)
B.11: In general, the use of the Information Technology (IT) infrastructure in the [Quality or R&D] group is: (**Mean 5.54128**; SD 0.95774; Range 4)
Information Technology and Sharing Knowledge Construct (ITskC): The mean of the above indicators, Mean 28.478; SD 7.601; Range 34.

2. **Performance Questionnaire** (Type C) included nine questions aiming to measure:
   - Operational manufacturing performance (3 questions)
   - Service manufacturing performance (3 questions)

- The level of contribution of Information Technology (ITmp) to Manufacturing group performance (2 questions)
- The use of IT functions –under the above described concept (1 question with multiple sub questions. Results are given in pie-chart form and are not presented here.)

The following questions ask you to compare the [Manufacturing] group to other such Manufacturing groups. In relation to other comparable groups you have observed, how does the [Manufacturing] group rate on the following:

Use Table 3 to measure constructs.

Table 3.

1	2	3	4	5	6	7
Non-Existent	Very Weak	Weak	About Average	Strong	Very Strong	Extremely Strong

Manufacturing Performance

The indicators used to measure the two constructs of manufacturing performance in our study, are given in detail, here below. For reasons related to our initial study, we treated the answers separately (A for Manufacturing and B for Quality or R&D stakeholders), although this does not affect results here. As in approximately 95 per cent of the manufacturing units under investigation, the two stakeholders that completed the performance questionnaire were related, one to Production and the second to Quality or R&D (in most cases Production or Quality Directors) we have used multiplicative assessments of interaction for the questions relating manufacturing performance to collaboration among the groups.

Operational Manufacturing Performance

Operational MP Indicator 1: (Multiplicative Assessment)

The product of the two stakeholders' responses (from Manufacturing and Quality or R&D) to the following:

C1: In general, the quality of the work produced by the [Manufacturing] group for the [Quality or R&D] group is:

CA1: Mean 5.29464; SD 0.77852; Range 4

CB1: Mean 5.50000; SD 0.69749; Range 3

Operational MP Indicator 2: (General Assessment)

The average of the responses to the following:

C2: In general, the ability of the [Manufacturing] group to meet its organizational commitments (such as project schedules and budget) is:

CA2: Mean 5.33929; SD 0.87563; Range 5
CB2: Mean 5.33929; SD 0.72972; Range 3
Operational MP Indicator 3: (General Assessment)

The average of the responses to the following:

C3: In general, the ability of the [Manufacturing] group to meet its goals is:
CA3: Mean 5.41964; SD 0.74300, Range 3
CB3: Mean 5.37500; SD 0.77256; Range 3
Operational MP Construct: The mean of the above indicators, **Mean 13.385**; SD 2.641; Range 14.333.

Service Manufacturing Performance

Service MP Indicator 1: (Multiplicative Assessment)

The product of the two stakeholders' responses (from Manufacturing and Quality or R&D) to the following:

C4: In general, the ability of the [Manufacturing] group to react quickly to the [Quality or R&D] group's changing business needs is:
CA4: Mean 5.29464; SD 0.92647; Range 4
CB4: Mean 5.41964; SD 0.71834; Range 4
Service MP Indicator 2: (Multiplicative Assessment)

The product of the two stakeholders' responses (from Manufacturing and Quality or R&D) to the following:

C5: In general, the responsiveness of the [Manufacturing] group to the [Quality or R&D] group is:
CA5: Mean 5.18750; SD 0.92543; Range 4
CB5: Mean 5.27027; SD 0.79711; Range 4
Service MP Indicator 3: (Multiplicative Assessment)

The product of the two stakeholders' responses (from Manufacturing and Quality or R&D) to the following:

C6: In general, the contribution that the [Manufacturing] group has made to the accomplishment of the [Quality or R&D] group's strategic goals is:
CA6: Mean 5.41071; SD 0.95441; Range 5
CB6: Mean 5.25893; SD 0.86728; Range 4
Service MP Construct: The mean of the above indicators, **Mean 28.591**; SD 7.294; Range 37.667.
Manufacturing Performance Construct: The mean of Operational MP and Service MP constructs, **Mean 20.988**; SD 4.658; Range 21.25.

Information Technology and Manufacturing Performance (ITmp)

By means of the performance questionnaire (Type C) we are measuring the role and level of contribution of IT in supporting the performance of the manufacturing group. We therefore use the marker (mp) to distinguish from the IT indicators used in the relationship questionnaires (Type A and B).

ITmp Indicator 1: (Multiplicative Assessment, **Mean 28.348**; SD 7.673; Range 41)
C.A7: In general, the level of the Information Technology (IT) Contribution to the [Manufacturing] group performance is: (**Mean 5.17857**; SD 0.91252; Range 5)
C.B7: In general, the level of the Information Technology (IT) Contribution to the [Manufacturing] group performance is: (**Mean 5.38393**; SD 0.72591; Range 4)
ITmp Indicator 2: (General Assessment, **Mean 5.3170**; SD 0.8383; Range 3.5)
CA/B8: In general, the use of the Information Technology (IT) infrastructure, among the three groups is: (**Mean 5.22321**; SD 0.94640; Range 4)
Information Technology and Manufacturing Performance Construct (ITmpC): The mean of the above indicators, Mean 16.833; SD 4.069; Range 21.75.

It is noticeable that no significant difference is observed between responders of questionnaires A and B, regarding questions C.1 to C.7. Questions CA/B.8, due to their nature, have been analyzed as one.

APPENDIX B: REGRESSIONS AND CONFIRMATORY TESTS

General Note: Symbols used in our study and in the MINITAB extracts, included in the Appendixes, correlate as following:

β = Coef, t = T, p = P, r = R-Sq, R^2 = R-Sq(adj), and **F = F**.

ANOVA Table symbols:

DF=Degrees of Freedom, SS=Sums of Squares, MS=Mean Squares (SSR = SS Residual, SSTO = SS Total)

First Regression: MPC vs (MTC, MIC, SKC, ITmpC)

The regression equation is

```

Chapter 60
Group Decision Making for Advanced Manufacturing Technology Selection Using the Choquet Integral

Cengiz Kahraman

İhsan Kaya
Selçuk University, Turkey

ABSTRACT

Advanced manufacturing technology (AMT) is defined as a modern method of production incorporating highly automated and sophisticated computerized design and operational systems. Hence, an investment decision to adopt AMT is a strategic decision. A group decision making process is stressful when group members have different views under multiple and conflicting criteria. Satisfying group members' opinions has a critical impact on a decision. In this chapter, a multiple criteria group decision making problem under a fuzzy environment is used for the selection among AMTs. Choquet integral methodology is used for this selection. A strategic investment problem of a company for a suitable Automated Storage/Retrieval System (AS/RS) is considered and discussed.

INTRODUCTION

The developments of science and technology have led to many new concepts and products, which are replacing the old ones. Flexibility, improvement in productivity and quality, faster response to market shifts, shorter throughput and lead time and savings in inventory and labor costs, enable customer demands to be met in a shorter time. Changing customer preferences and tastes oblige the manufacturer to change his products frequently. Increased consumer awareness has led to the manufacture of high-quality goods.

DOI: 10.4018/978-1-4666-1945-6.ch060

The manufacturing process has to be faster to meet market demands at the appropriate time and to overcome competition. All these factors have led to changes in manufacturing processes, which have prompted many manufacturers to adopt computer-integrated manufacturing, namely advanced manufacturing technology (Aravindan & Punniyamoorthy, 2002).

The term ‘‘advanced manufacturing technology’’ (AMT) is broadly defined to include any automated (usually computer oriented) technology used in design, manufacturing/service, and decision support. Components of AMT include computer-aided engineering, factory management and control systems, computer-integrated manufacturing processes, and information integration. Different researchers have defined AMT in various ways. Typical items constituting AMT include: robotics, automated guided vehicles (AGVs), computer numerically controlled machines (CNC) machines, flexible manufacturing systems (FMS), computer-aided design (CAD), computer-aided manufacturing (CAM), information technology, cellular manufacturing and the use of just-in-time (JIT)/kanban system in the plant (Das and Jayaram, 2003)

AMTs provide many important benefits such as greater manufacturing flexibility, reduced inventory, reduced floor space, faster response to shifts in market demand, lower lead times, and a longer useful life of equipment over successive generations of products. Like many real-world problems, the decision of investing in advanced manufacturing technology frequently involves multiple and conflicting objectives, such as minimizing costs, maximizing flexibility, minimizing machine down times and maximizing efficiency. Application of traditional capital budgeting methods does not fully account for the benefits arising from intangible factors of AMTs (Kahraman et al., 2000).

The rapid growth of the AMT industry is creating problems in new directions. Prospective firms face the situation of having to make a decision among several AMTs, all of which are capable of performing a specific task. Since the development and use of appropriate assessment approaches are crucial to ensuring that the analysis of each AMT project considers all benefits and costs, the selection of a suitable AMT is becoming a more and more complex problem. Therefore the evaluation of the AMT is a multiple criteria problem and group decision making is generally preferred to solve these kinds of problem (Chuu, 2009). Group decision making requires considering multiple perspectives obtained from a group consisting multiple members (Lu et al., 2007). A group decision is required in two situations: (1) when a problem becomes too complex such that the knowledge of a decision maker is inadequate, as in product design, investment decisions and supplier selection and (2) when there are conflicting ideas that influence the decision makers like presidential elections. While the first one is called cooperative group decision making, the second one is called non-cooperative decision making. The common features of both decision making problems is to satisfy multiple decision makers’ preferences. Therefore, there are several kinds of group decision making methods in the literature such as authority rule, majority rule, negative minority rule, ranking rule, and consensus rule.

In this chapter, a multiple criteria group decision making problem under fuzzy environment is discussed to select an appropriate AMT by using the Choquet integral since the problem is related to both subjective and objective criteria. For a long time, it has been recognized that an exact description of many real-life physical situations may be virtually impossible. This is due to the high degree of imprecision involved in real-world situations.

Zadeh (1965, 1968) in his seminal papers proposed fuzzy set theory as the means for quantifying the inherent fuzziness that is present in ill-posed problems. Fuzziness is a type of imprecision which may be associated with the sets in which there is no sharp transition from membership to nonmembership. Many problems in the real world deal with uncertain and imprecise data so conventional approaches cannot be effective to find the best solution. To cope with this uncertainty, fuzzy set theory has been developed as an effective mathematical algebra in a vague environment. Although humans are comparatively efficient in qualitative forecasting, they are not good at making quantitative predictions. Since fuzzy linguistic models permit the translation of verbal expressions into numerical ones, thereby dealing quantitatively with imprecision in the expression of the importance of each criterion, some methods based on fuzzy relations are used. When the system involves human subjectivity, fuzzy algebra provides a mathematical framework for integrating imprecision and vagueness into the models (Zimmermann, 1991; Kaya & Çınar, 2008). A major contribution of fuzzy set theory is its capability in representing vague knowledge. In multiple criteria decision making problems, data very often are imprecise and fuzzy. Hence, a decision maker may encounter difficulty in quantifying such linguistic statements so they can be used in deterministic decision making.

The rest of this chapter is organized as follows: In Section 2, the basics of group decision making and a literature review on AMTs are presented. The selection criteria are discussed in Section 3. The fundamentals of the Choquet integral are given in Section 4. A case study is presented in Section 5. Finally, concluding remarks are given in Section 6.

LITERATURE REVIEW: GROUP DECISION MAKING AND AMTS

Group decision making consists of multiple individuals interacting to reach a decision. Each decision maker (expert) may have unique motivations or goals and may approach the decision process from a different angle, but have a common interest in reaching eventual agreement on selecting the "best" option(s). To do this, experts have to express their preferences by means of a set of evaluations over a set of alternatives (Herrera-Viedma et al., 2007). Group decision-making studies reveal that differences in the process by which groups reached decisions may help explain the different findings, generally within the group decision making literature. In some cases, group members privately considered information about a problem and formed individual judgments before meeting as a group. In other cases, groups are exposed to problems for the first time as a group (Moon et al., 2003). The main characteristics of group decisions are described as follows (Lu et al., 2007): (1) A group performs a decision-making task. (2) A group decision covers the whole process of transfer from generating ideas for solving a problem to implementing solutions. (3) Group members may be located in the same or different places. (4) Group members may work at the same or different times. (5) Group members may work for the same or different departments or organizations. (6) The group can be at any managerial levels. (7) There can be conflicting opinions among group members in a group decision process. (8) The decision task might have to be accomplished in a short time. (9) Group members might not have complete information for decision tasks. (10) Some required data, information or knowledge for a decision may be located in many sources and some may be external to the organization. In the following, some studies on AMTs from the literature are briefly summarized. The results of the literature review will be summarized in a comparative manner later.

Demmel and Askin (1992) introduced a multiple objective decision model for the evaluation of AMT, whereby the AMT selection attributes were classified into three categories: (1) pecuniary objective, (2) strategic objective, and (3) tactical objective. The pecuniary objective is based upon discounted cash flow techniques. Shang and Sueyoshi (1995) proposed a selection procedure for an FMS employing the AHP, simulation, and data envelopment analysis (DEA). Sambasivarao and Deshmukh (1997) devised a decision support system for selection of AMT. The system provided the decision-makers with a base of knowledge and approaches to building a justification model, and emphasized that AMT attributes could be classified into two groups, namely, tangible (objective) and intangible (subjective). They suggested AHP, TOPSIS, and a linear additive utility model as alternative multi-attribute analysis methods. Small and Chen (1997) discussed the results of a survey conducted in the US that investigated the use of justification approaches for AMS. According to their findings, manufacturing firms using hybrid strategies, which employ both economic and strategic justification techniques, attain significantly higher levels of success from advanced technology projects.

Kotha and Swamidass (1998) hypothesized that nationality of the firm was an important factor in AMT use. To test the effect of the nationality variable on AMT use they compared the use of 18 AMTs in the US and Japan in an exploratory study using data from 160 US firms and 125 Japanese firms. There was clear evidence that the nationality of the firm was a factor in AMT use; that was AMT use is significantly different in the two countries. O'Kane et al. (2000) reported that simulation modeling could be used for the justification phase of AMT. Efstathiades et al. (2000) investigated the transfer and implementation processes of AMT in developing countries using the Cypriot manufacturing industry as a case study. They also addressed two critical steps: (1) the management processes followed during the transfer of technology into the manufacturing environment, and (2) the steps followed both before and after implementation and productive operation of the technologies. They indicated that despite the distance between the manufacturer and the technology suppliers, no difficulties were experienced in acquiring information about the available technologies and the suitability of these technologies for the specific manufacturing environment.

Arvanitis and Hollenstein (2001) empirically investigated the decisions of firms to adopt AMT based on a comprehensive specification of a rank model of technology adoption using firm-level data for Swiss manufacturing. Chan et al. (2001) presented an overview and guidance for manufacturing companies which planned to invest in AMT. They explained the reasons why the company might encounter problems while adopting AMT and explained the many suggestions offered by the relevant literature for improving the performance of evaluation in AMT investment. According to the four major steps in adopting AMT (i.e. strategic planning, justification, training and installation, and routinization and implementation), they aimed at assisting managers or investors to recognize problems at each step, thus offering appropriate ways to avoid and/or solve those problems. Yusuff et al. (2001) applied the Analytic Hierarchy Process (AHP) to determine the priority weights in predicting the success of AMT implementation because of its capability to structure complicated, multi-decision maker, multi-alternative and multi-attribute problems hierarchically. They applied AHP to forecast the success of AMT implementation by taking into account two possible outcomes, which were predicted according to seven influential factors and called the successful and unsuccessful implementation. Kengpol and O'Brien (2001) applied AHP and cost/benefit analysis to select an advanced technology by incorporating quantitative and qualitative factors. Karsak and Tolga (2001) proposed a fuzzy multiple attribute decision-making (FMADM) procedure for evaluating advanced manufacturing system investments. This approach applied fuzzy discounted cash flow analysis and decision-makers' linguistic assessments to the economic criterion and strategic criteria, respectively. The decision algorithm aggregated the experts' preference ratings for the economic and strategic criteria weights, and the suitability of AMS investment alternatives versus the selection criteria to calculate fuzzy suitability indices. The fuzzy indices were then used to rank the AMS investment alternatives. Abdel-Kader and Dugdale (2001) proposed a FMADM model for assessing AMT investments. This model applied the mathematics of the analytical hierarchy process and fuzzy set theory to aggregate the two major dimensions of financial and non-financial attributes. Gupta and Whitehouse (2001) examined the impact of size of an organization on the manufacturing strategy.

Aravindan and Punniyamoorthy (2002) developed a new model to justify the investment in AMT using the extended Brown–Gibson model which was developed for evaluating alternative plant locations using certain objective and subjective factors. They showed that investment in AMT was attractive if the benefits accruing from the subjective factors were considered. Yurdakul (2004) utilized a combination of AHP and goal programming for selection among computer-integrated manufacturing technologies. The model used AHP to determine attribute weights in goal programming. Sener and Karsak (2007) presented a new decision making approach based on fuzzy regression with non-symmetric coefficients and fuzzy optimization for FMS selection.

Sener and Karsak (2008) proposed a decision model based on fuzzy linear regression and fuzzy multiple objective programming for AMT selection. Thakur and Jain (2008) explored the issues of measurement and comparison of the current state of AMT adoption in India, including important information technology (IT) factors. Comparisons were made between Indian firms, firms in a developed country (Canada), and in a developing country (China) for a worldwide perspective.

Chang and Wang (2009) investigated the potential use of AHP by applying the consistent fuzzy preference relations to predict advanced AMT implementation. They pointed out that the AHP method was not efficient enough because it performed complex computation procedures in paired comparisons and obtaining consistency indicators. To reduce the judgment times and avoid checking inconsistency, they employed the consistent fuzzy preference relations, which inherited some advantages of AHP (distinct hierarchy, effective numerical assessment), to overcome certain drawbacks resulting from this conventional pairwise comparison approach. They also reviewed several methods which are utilized to fulfill the requirements of AMT selection, evaluation, assessment, justification and prediction issues, such as simple estimation methods, breakeven approaches, systems value analysis, scoring models, analytic hierarchy process, simulation and strategic methods. Chuu (2009) developed a fuzzy multiple attribute decision-making method for the group decision-making to improve advanced manufacturing technology selection process. In the proposed approach, a new fusion method of fuzzy information was developed for managing information assessed in different linguistic (multi-granularity linguistic term sets) and numerical scales. Also an application for the Taiwanese bicycle industry was employed. Costa and Lima (2009) presented the rationality for the organizational design development related to AMT adoption. For the development of the organizational design process, it was suggested a specified sequence of activities, in order to consider all the dimensions that define the content of the organizational design.

A result from the literature review is that the Choquet integral has not been used up to date although various MCDM methods have been used for the solution AMT selection problem. In this chapter, it is the first time that Choquet integral is used as a group decision making technique for the solution of the AMT selection problem.

In Table 1, the results of the literature review are summarized in a comparative manner with respect to methods, purpose, and criteria.

SELECTION CRITERIA FOR ADVANCED MANUFACTURING TECHNOLOGY

Many companies are currently strengthening their competitive positions by updating the technologies used in the manufacturing processes. The selection of the appropriate technology that achieves or matches with the organization objective must be made on the basis of sound decision-making process. The decision to implement AMT is a major decision for many organizations. The success or failure of the organization could be due to this decision, and therefore it is very important that proper consideration be given to all aspects of implementation before a final commitment is made. This is necessary to ensure that all the expected benefits of the decision are realized (Yusuff et al., 2001).

Chan et al. (1999) used the following criteria in Table 2, to evaluate the tangible and intangible benefits for the selection of AMT.

THE CHOQUET INTEGRAL

In this chapter, we are interested in using the Choquet integral which is a generalization of the Lebesgue integral, defined with respect to a non classical measure, often called fuzzy measure, or non-additive measure or also capacity. When the underlying universe is finite, the Lebesgue integral reduces to a (convex) linear combination hence can be assimilated to a particular class of regression models, where the coeffcients are all positive and sum up to one. Hence, the Choquet integral offers a more general model, more precisely, it offers a set of (convex) linear models, each of them being defined in a simplex (Grabisch et al. 2007). The Choquet integral was applied to multi-criteria evaluation by many researchers (Ishii & Sugeno, 1985; Onisawa et al., 1986; Labreuche & Grabisch, 2003; Kojadinovic, 2004; Karsak, 2005; Tsai & Lu, 2006; Grabisch et al., 2007; Berrah, et al., 2008a, 2008b; Schmitt et al., 2008; Saad et al., 2008; Narukawa & Murofushi, 2008; Shieh et al., 2009). The Choquet integral is a method which measures the expected utility of an uncertain event. In imprecise probability theory, the Choquet integral is used to calculate the lower expectation induced by a 2-monotone lower probability, or the upper expectation induced by a 2-alternating upper probability. A fuzzy integral is a sort of general averaging operator

that can represent the notions of importance of a criterion and interactions among criteria. The most important feature of a fuzzy integral is its ability to represent a certain kind of interaction among criteria, ranging from redundancy (negative interaction) to synergy (positive interaction). According to Grabisch (1998), there is almost no well established method to deal with interacting criteria, and usually people tend to avoid the problem by constructing independent criteria (or criteria that are supposed to be so). This ability of the fuzzy integral is the reason for its success in various fields of multi-criteria decision-making. The disadvantage of fuzzy integral is complexity of the model, since the number of coefficients involved in a fuzzy integral model grows exponentially with the number of criteria to be aggregated. The main difficulty is to identify all these coefficients, either by some learning data, or by a questionnaire, or both.

To define fuzzy integrals, a set of values of importance is needed. This set is composed of the values of a fuzzy measure. So, a value of importance for each subset of attributes is needed. In the following, some definitions are given to explain the basics of the Choquet integral (Modave & Grabish, 1998):

Definition 1. Let I be the set of attributes (or any set in a general setting). A set function μ: $P(I) \rightarrow [0, 1]$ is called a fuzzy measure if it satisfies the three following axioms:

- $\mu(\emptyset) = 0$: an empty set has no importance,
- $\mu(I) = 1$: the maximal set has a maximal importance,
- $\mu(B) \leq \mu(C)$ if $B, C \subset I$ and $B \subset C$: a new added criterion cannot make the importance of a coalition (a set of criteria) diminish.

Therefore, in a problem where $card(I) = n$, a value for every element of $P(I)$ including 2^n values is needed. Assuming that the values of the empty set and of the maximal set are fixed, $(2^n\text{-}2)$ values or coefficients to define a fuzzy measure are needed. So, there is clearly a trade-off between complexity and accuracy. However, the complexity can be significantly reduced in order to guarantee that fuzzy measures are used in practical applications. A fuzzy integral is a sort of weighted mean taking into account the importance of every coalition of criteria.

Definition 2. Let μ be a fuzzy measure on $(I,P(I))$ and an application $f: I \rightarrow \Re^+$. The Choquet integral of f with respect to μ is defined by:

$$(C)\int_I f d\mu = \sum_{i=1}^{n}\left(f\left(\sigma\left(i\right)\right) - f\left(\sigma\left(i-1\right)\right)\right)\mu\left(A_{(i)}\right) \tag{1}$$

where σ is a permutation of the indices in order to have

$$f\left(\sigma\left(1\right)\right) \leq \ldots \leq f\left(\sigma\left(n\right)\right),$$
$$A_{(i)} = \left\{\sigma\left(i\right),\ldots,\sigma\left(n\right)\right\} \quad \text{, by convention.}$$
$$and \quad f\left(\sigma\left(0\right)\right) = 0$$

It is easy to see that the Choquet integral is a Lebesgue integral up to a reordering of the indices. Actually, if the fuzzy measure μ is additive, then the Choquet integral reduces to a Lebesgue integral.

Now we will illustrate how fuzzy measures can be used in lieu of the weighted sum and other more traditional aggregation operators in a Multi-criteria decision making framework. It is shown in Modave and Grabisch (1998) that under rather general assumptions over the set of alternatives X, and over the weak orders $\succ_i$, there exists a unique fuzzy measure μ over I such that:

$$\forall x, y \in X,\; x \succeq y \Leftrightarrow u\left(x\right) \geq u\left(y\right) \tag{2}$$

where

$$u(x) = \sum_{i=1}^{n} \left[u_{(i)}\left(x_{(i)}\right) - u_{(i-1)}\left(x_{(i-1)}\right) \right] \mu\left(A_{(i)}\right) \quad (3)$$

which is simply the aggregation of the monodimensional utility functions using the Choquet integral with respect to μ.

The global importance of a criterion is given by evaluating what this criterion brings to every coalition it does not belong to, and averaging this input. This is given by the Shapley value or index of importance.

Definition 3. Let μ be a fuzzy measure over I. The Shapley value of index j is defined by:

$$v(j) = \sum_{B \subset I | (j)} \gamma_I(B) \left[\mu\left(B \cup \{j\}\right) - \mu(B) \right] \quad (4)$$

with $\gamma_I(B) = \frac{\left(|I| - |B| - 1\right)!.|B|!}{|I|!}$, $|B|$ denotes the cardinal of B.

The Shapley value can be extended to degree two, in order to define the indices of interactions between attributes.

Definition 4. Let μ be a fuzzy measure over I. The interaction index between i and j is defined by:

$$I(i,j) = \sum_{B \subset I | \{i,j\}} \xi_I(B) .\left(\mu\left(B \cup \{i,j\}\right) - \mu\left(B \cup \{i\}\right) - \mu\left(B \cup \{i\}\right) + \mu(B) \right) \quad (5)$$

with $\xi_I(B) = \frac{\left(|I| - |B| - 2\right)!.|B|!}{\left(|I| - 1\right)!}$.

The interaction indices belong to the interval [−1,+1] and:

- *I(i, j)* > 0 if the attributes *i* and *j* are complementary;
- *I(i, j)* < 0 if the attributes *i* and *j* are redundant;
- *I(i, j)* = 0 if the attributes *i* and *j* are independent.

Interactions of higher orders can also be defined, however we will restrict ourselves to second order interactions which offer a good trade-off between accuracy and complexity.

Definition 5. A fuzzy measure μ is called 2-additive if all its interaction indices of order equal or larger than 3 are null and at least one interaction index of degree two is not null.

In this particular case of 2-additive measures, the following theorem can be given:

Theorem. Let μ be a 2-additive measure. Then Choquet integral can be computed by:

$$(C)\int_I f d\mu = \sum_{I_{0J} \succ 0} \left(f(i) \wedge f(j)\right) I_{ij} + \sum_{I_{0J} \prec 0} \left(f(i) \vee f(j)\right) \left|I_{ij}\right| + \sum_{i=1}^{n} f(i) \left(I_i - \frac{1}{2} \sum_{j \neq i} \left|I_{ij}\right| \right) \quad (6)$$

Note that this expression justifies the above interpretation of interaction indices, as a positive interaction index corresponds to a conjunction (complementary) and a negative interaction index corresponds to a disjunction (redundant).

The success of a Choquet integral depends on an appropriate representation of fuzzy measures, which captures the importance of individual criteria or their combination. In this chapter, the generalized Choquet integral proposed by Auephanwiriyakul et al. (2002) will be used, in which measurable evidence is represented in terms of intervals, whereas fuzzy measures are real numbers, and is an extension of the standard Choquet integral. In contrast to Auephanwiriyakul et al. (2002), Tsai and Lu (2006) proposes another generalization that involves linguistic expressions as well as information fusion between criteria to overcome vagueness and imprecision of linguistic terms in questionnaires.

Steps of the Methodology

The methodology is composed of eight steps (Tsai and Lu, 2006):

Step 1: Given criterion i, respondents' linguistic preferences for the degree of importance, perceived performance levels of alternative locations, and tolerance zone are surveyed.

Step 2: In view of the compatibility between perceived performance levels and the tolerance zone, trapezoidal fuzzy numbers are used to quantify all linguistic terms in this study. Given respondent t and criterion i, linguistic terms for the degree of importance which shows the weight of a criterion is parameterized by $\tilde{A}_i^t = \left(a_{i1}^t, a_{i2}^t, a_{i3}^t, a_{i4}^t\right)$, perceived performance levels which indicates score of an alternative by $\tilde{p}_i^t = \left(p_{i1}^t, p_{i2}^t, p_{i3}^t, p_{i4}^t\right)$, and the tolerance zone which represents specifications of a criterion by $\tilde{e}_i^t = \left(e_{i1L}^t, e_{i2L}^t, e_{i3U}^t, e_{i4U}^t\right)$. In this case study, t=1,2,3,4,5, i=1,2,…,n_j, j=1,2,3,4, n_1=3, n_2=2, n_3=4, n_4=3; where n_j represents the number of criteria in dimension j.

Step 3: Average $\tilde{A}_i^t$, $\tilde{p}_i^t$ and $\tilde{e}_i^t$ into $\tilde{A}_i$, $\tilde{p}_i$, and $\tilde{e}_i$, respectively using Equation (7).

$$\tilde{A}_i = \frac{\sum_{t=1}^k \tilde{A}_i^t}{k} = \left(\frac{\sum_{t=1}^k a_{i1}^t}{k}, \frac{\sum_{t=1}^k a_{i2}^t}{k}, \frac{\sum_{t=1}^k a_{i3}^t}{k}, \frac{\sum_{t=1}^k a_{i4}^t}{k}\right) \tag{7}$$

Step 4: Normalize the location value of each criterion using Equation (8).

$$\tilde{f}_i = \underset{\alpha\in[0,1]}{\Big\|} \overline{f}_i^{\alpha} = \underset{\alpha\in[0,1]}{\Big\|} [f_{i,\alpha}^-, f_{i,\alpha}^+] \tag{8}$$

where $f_i \in F(S)$ is a fuzzy-valued function. $\tilde{F}(S)$ is the set of all fuzzy-valued functions $f, f_i^{\alpha} = \left[f_{i,\alpha}^-, f_{i,\alpha}^+\right] = \dfrac{\overline{p}_i^{\alpha} - \overline{e}_i^{\alpha} + [1,1]}{2}$, $\overline{p}_i^{\alpha}$ and $\overline{e}_i^{\alpha}$ are α-level cuts of $\tilde{p}_i$ and $\tilde{e}_i$ for all α=[0,1].

Step 5: Find the location value of dimension j using Equation (9).

$$(C)\int \tilde{f} d\tilde{g} = \underset{\alpha=[0,1]}{\Big\|} \left[(C)\int f_{\alpha}^- dg_{\alpha}^-, (C)\int f_{\alpha}^+ dg_{\alpha}^+,\right] \tag{9}$$

where $\overline{g}_i : P(S) \to I(R^+)$, $\overline{g}_i = [g_i^-, g_i^+]$, $\overline{g}_i^{\alpha} = [g_{i,\alpha}^-, g_{i,\alpha}^+]$, $\overline{f}_i : S \to I(R^+)$, and $f_i = [f_i^-, f_i^+]$ for i=1, 2, 3,..., $n_{j.}$

To be able to calculate this location value, a λ value and the fuzzy measures $g(A_{(i)})$, i=1,2,...,n, are needed. These are obtained from Equations (10-12) (Sugeno, 1974; Ishii and Sugeno, 1985):

$$g\left(A_{(n)}\right) = g\left(\left\{s_{(n)}\right\}\right) = g_n \tag{10}$$

$$g\left(A_{(i)}\right) = g_i + g\left(A_{(i+1)}\right) + \lambda g_i g\left(A_{(i+1)}\right), \quad \text{where} \quad 1 \le i < n \tag{11}$$

$$1 = g\left(S\right) = \begin{cases} \dfrac{1}{\lambda}\left\{\prod_{i=1}^{n}\left[1 + \lambda g\left(A_i\right)\right] - 1\right\} & \text{if } \lambda \neq 0 \\ \sum_{i=1}^{n} g\left(A_i\right) & \text{if } \lambda = 0 \end{cases} \tag{12}$$

where, $A_i \cap A_j = \varphi$ for all i, j = 1,2,3,…,n and $i \neq j$, and λ∈(-1,∞].

Step 6: Aggregate all dimensional performance levels of the location alternatives into overall performance levels, using a hierarchical process applying the two-stage aggregation process of the generalized Choquet integral.

Equation 13.

$$\left.\begin{array}{l} main\ \ criterion_{(1)} = (C)\int fdg \\ \quad\vdots \\ main\ \ criterion_{(m)} = (C)\int fdg \end{array}\right\rangle \quad V = (\mathrm{C})\int main\ \ criterion\ \ dg$$

This is represented in Equation (13). The overall performance levels yields a fuzzy number $\tilde{V}$.

Step 7: Assume that the membership of $\tilde{V}$ is $\mu_{\tilde{V}}(x)$; defuzzify the fuzzy number $\tilde{V}$ into a crisp value *v* using Equation (14) and make a comparison of the overall performance levels of alternative locations.

$$F\left(\tilde{A}\right) = \frac{a_1 + a_2 + a_3 + a_4}{4} \qquad (14)$$

Step 8: Compare weak and advantageous criteria among the locations alternatives using Equation (8).

A CASE STUDY

Flexible material flow, delivery to the point of use, small lots, short production lead times, and high inventory turnover characterize modern manufacturing and distribution operations. Therefore, an automated storage and retrieval system (AS/RS) is used to satisfy the necessities of modern manufacturing systems. AS/RS is a system which consists of a variety of computer-controlled methods for automatically placing and retrieving loads from specific storage locations. The high throughput and short processing times of Automated storage/retrieval systems, promote improved inventory management practices and rapid material handling, and play an essential role in integrated manufacturing and distribution systems. Additional AS/RS benefits generally include high space utilization, labour savings, protection from pilferage and damage, better safety, and real-time material control (Park, 2004). There are five main categories of AS/RS. These

are; *(i)* unit load AS/RS, *(ii)* mini load AS/RS, *(iii)* deep-lane AS/RS *(iv)* man-on-board AS/RS, and *(v)* automated item retrieval system. The unit load AS/RS is used to store and retrieve loads that are palletized or stored in standard-sized containers. The mini load AS/RS is designed to handle small loads such as individual parts, tools, and supplies that are contained in bins or drawers in the storage system. A mini load AS/RS is generally smaller than a unit load AS/RS and allows storing more material in less space. The deep-lane AS/RS is a high-density unit load storage system that is appropriate for storing large quantities of stock. The man-on-board AS/RS system allows storage of items in less than unit load quantities. The system permits individual items to be picked directly at their storage locations. The automated item retrieval system is designed for retrieval of individual items or small product cartoons.

In our case study, one of the biggest logistic firms in Turkey plans to install an AS/RS system into its warehouse. The firm will make a selection between a deep-lane AS/RS and a unit load AS/RS by using Choquet integral methodology.

Step 1: The criteria given in Table 3 are selected from the literature to evaluate the alternatives (Chan et al., 1999). Three experts assign their linguistic preferences as seen in Table 4.

Step 2: Trapezoidal fuzzy numbers given in Table 5 are used to quantify the linguistic terms in Table 4.

Step 3: The aggregation of experts' assessments obtained by Equation (7) is given in Table 6.

Step 4: By using Equation (8), the evaluation values are normalized for each criterion.

Step 5: At different α levels, the values of all criteria in the same dimension are aggregated by using Equation (9). To illustrate the calculation procedure in Steps 4 and 5, an example is presented for deep line AS/RS alternative under innovativeness criterion. Using Equation (8),

$$f, f_i^{\alpha} = \left[f_{1,0}^{-}, f_{1,0}^{+}\right] = \frac{\left[0.667,\ 0.93\right] - \left[0.2,\ 0.9\right] + \left[1,\ 1\right]}{2} = \left[0.283,\ 0.783\right]$$

and $\left[f_{2,0}^{-}, f_{2,0}^{+}\right] = [0.183,\ 0.683]$ are obtained. Their corresponding degrees of importances are

C51	(0.283,0.417,0.683,0.783)	(0.383,0.5,0.783,0.867)	0.542	**0.633**
C52	(0.183,0.333,0.583,0.683)	(0.217,0.367,0.617,0.717)	0.446	**0.479**

$\bar{g}_1^{\,0} = \left[0.533,\ 0.833\right],\ \bar{g}_2^{\,0} = \left[0.4,\ 0.6\right],$ respectively. First, the sequence $f_{i,0}^{\,-}$ is sorted, where i=1 and 2, as follows: $f_{2,0}^{-} < f_{1,0}^{-}$. The corresponding degrees of importances are $\bar{g}_{1,0} = 0.4$ and $\bar{g}_{2,0} = 0.533,$ respectively. By solving the equation $0 = \frac{1}{\lambda}\left\{\prod_{i=1}^{2}\left[1 + \lambda \bar{g}_i\right] - 1\right\},$ λ=0.313 is obtained. Then, their fuzzy measures are derived from as follow;

g(A(2)) = g2 = 0.533

g(A(1)) = g1 + g(A(2)) + λ g1 g(A(2)) = 1

The aggregated Choquet integral values for the main criterion C5 are calculated as $(C)\int \tilde{f} d\tilde{g} = \left[0.237,\ 0.753\right]$

Step 6: Similar to Steps 4 and 5, the overall values are obtained for AS/RS systems, as shown in Table 7.

Step 7: From Table 7, the defuzzified overall values of AS/RSs using generalized Chouqet Integral are obtained as 0.710 and 0.713. Hence Unit Load AS/RS is the best alternative for the firm.

Step 8: Weak and advantageous criteria for alternatives are clarified in Table 7 by normal and bold characters, respectively. The numbers in bold characters in Table 7 represent that the alternative has more advantage than the other for that criterion.

CONCLUSION

In this chapter, a multiple criteria group decision-making problem under a fuzzy environment has been discussed. To illustrate the chapter, a selection problem between AS/RSs has been taken into consideration by using the Choquet integral. The characteristic feature of the problem is that it includes both objective and subjective and conflicting criteria. Hence, three experts' expertise is used in order to cope with the complexity of the problem. To satisfy the group decision, the arithmetic mean method has been used. The Choquet integral has provided an excellent tool for the solution of our advanced manufacturing technology selection problem including conflicting criteria.

For future research, another aggregation method from the literature may be used in order to compare the results and put forward the consistency of the group decision.

KEY TERMS AND DEFINITIONS

Advanced Manufacturing Technology (AMT): A modern method of production incorporating highly automated and sophisticated computerized design and operational systems.

Automated Storage and Retrieval System (AS/RS): Consists of a variety of computer-controlled methods for automatically placing and retrieving loads from specific storage locations.

Choquet Integral: A generalization of the Lebesgue integral. Choquet integral is a way of measuring the expected utility of an uncertain event.

Decision Making: Can be regarded as an outcome of mental processes leading to the selection of a course of action among several alternatives.

Fuzzy Logic: A form of multi-valued logic derived from fuzzy set theory to deal with reasoning that is approximate rather than precise.

Fuzzy Sets: Are sets whose elements have degrees of membership and are extension of the classical notion of set.

Group Decision Making: Is decision making in groups consisting of multiple members.

Multi-Criteria Decision Making (MCDM): A discipline aimed at supporting decision makers who are faced with making numerous and conflicting evaluations.

This work was previously published in Technologies for Supporting Reasoning Communities and Collaborative Decision Making: Cooperative Approaches, edited by John Yearwood and Andrew Stranieri, pp. 193-212, copyright 2011 by Information Science Reference (an imprint of IGI Global).

Chapter 61
Operator Assignment Decisions in a Highly Dynamic Cellular Environment

Gürsel A. Süer
Ohio University, USA

Omar Alhawari
Royal Hashemite Court, Jordan

ABSTRACT

Operators are assigned to operations in labor-intensive manufacturing cells using two assignment strategies: Max-Min and Max. The major concern is to see how these two approaches impact operators' skill levels and makespan values in a multi-period environment. The impact is discussed under chaotic environment where sudden changes in product mix with different operation times are applied, and also under non-chaotic environment where same product mix is run period after period. In this chapter, operators' skill levels are affected by learning and forgetting rates. The Max-Min strategy improved operators' skill levels more significantly than Max in this multi-period study; particularly in chaotic environment. This eventually led to improved makespan values under Max-Min strategy.

INTRODUCTION

Cellular manufacturing is considered as a collection of manufacturing cells that is dedicated to manufacture part families or assembly cells that are dedicated to process product families (see Askin & Standridge, 1993). The cellular manufacturing systems can be either machine-intensive or labor-intensive. In labor-intensive cells, it is easier to reconfigure cells when a product is ready to be processed. Moreover, moving equipment is much easier than it is in machine-intensive cells. Basically, in labor-intensive cells, most of the operations require light-weight, and small machines as well as equipment that require continuous operator attendance and involvement (Süer & Tummaluri, 2008). Labor-intensive manufacturing cells have been observed in apparel, jewelry manufactur-

DOI: 10.4018/978-1-4666-1945-6.ch061

ing, electromechanical assembly, sewing, shoe manufacturing, medical devices, and car seat manufacturing industries. The operator's role in machine-intensive cells is limited due to the presence of automatic machines. On the other hand, the operator has a key role in labor-intensive cells, and the number of operators and their assignment to operations has a great impact on the cell's production rate. In some cases, the number of operations is less than the number of operators. This creates the possibility that multiple operators are assigned to perform the same operation. It is important to control operator assignments; however, when the number of cells and the number of operators increase, keeping track of operator assignment becomes difficult.

In this chapter, concepts such as learning and forgetting rates are discussed to show how operator skill level varies from time to time; thus, the assignment decision is affected. Forgetting and learning rates affect the operator's skills and they are affected by their current skills. Learning takes place when the operator performs an operation continuously for a period of time, consequently, the operator will be more familiar with performing an operation. On the other hand, forgetting happens when the operator does not perform an operation in a number of consecutive periods. This chapter addresses both operator assignment and cell loading decisions. Operator assignment determines which operators are assigned to perform each task and cell loading identifies the products to be run in each cell.

The work undertaken in this chapter is an extension of work by Süer and Tummaluri (2008). The operator assignment can be made by using two different strategies; 1) Max, 2) Max-Min. Max considers only the current state of the operator skills for operator assignment to maximize output rate. On the other hand, Max-Min considers long-term effect of assignment decisions and attempts to develop more homogeneous work force without sacrificing output rate. This homogeneous work force may be more effective in dealing with drastic variations in demand and product mix in the long-term.

The objective of this chapter is to propose better mathematical models for operator assignment and also compare the performance of two major strategies, Max and Max-Min, in highly dynamic cellular environments. The main hypothesis is that Max-Min is a better strategy in operator assignment in the long-run. We want to show that long-term planning may help companies to better prepare their workforce for long-term operation than short-sided approach where only the immediate periods are considered. This approach is especially important in highly fluctuating demand environments and also in companies where product mix can quickly change. It is easier to implement such a strategy in companies where workforce is stable with low turnaround rate.

BACKGROUND

In the literature, some researchers addressed areas related to this subject such as cell loading, operator assignment, skills, learning and forgetting rate and product sequencing. Süer (1996) discussed, in his paper, the subject of optimal operator assignment and cell loading in labor-intensive manufacturing cells. He stated that the operator assignment to cells influences production rate that each cell can produce. He proposed a two-phase methodology. In phase 1, he generated operator assignments for alternative manpower levels by using a mixed integer mathematical model. In phase 2, he found the optimal manpower levels for each cell and optimal product assignment to cells.

Nembhard (2001) discussed a heuristic approach for assigning workers to task based on individual learning rate. Basically, he ran experiments based on two conditions: a long production run and a short production run. Results were interpreted and showed that the heuristic approach have an impact on overall productivity. Best results were found when workers learn more gradually.

Nembhard and Osothslip (2002) discussed, in their paper, the operator behavior in terms of learning and forgetting rates; particularly, in the case of performing complex tasks. A study was conducted at a textile manufacturing plant, where different manual sewing tasks were available. Data was collected by studying the behavior of each worker over a period of one year. They used a model of individual learning and forgetting rate, which was introduced first by Nembhard and Uzumeri (2000) in order to measure the productivity rate. This model was applied to each operator, and operator learning and forgetting parameters were considered as dependent variables, whereas task complexity was considered as independent variable. Results were captured and then statistical analysis was done to find if there is a relationship between the variability of learning and forgetting rates with task complexity. Results indicated task complexity significantly affects the variance of worker learning and forgetting rates. For higher task complexities, workers are more varied in their learning and forgetting rate than they are at lower task complexities. The impact of task complexities on worker learning and forgetting affects worker assignment and productivity. Slomp et al. (2005) discussed cross-training decisions in a cellular manufacturing environment. They wanted to minimize the load of the bottleneck worker. In their study, they presented an integer programming model to calculate which workers have to be trained for which machines. Based on this model, they discussed the trade-off between the operating costs of the manufacturing cell, the costs of cross-training, and the workload among workers, they showed that the connection between workers and machines is really important to form chaining and this produces an efficient cross-training situation. In this case, workload can be shifted from heavier loaded worker to less loaded worker. Labor flexibility is needed in these environments. Unbalanced load may give feelings of unfairness in a team. Bidanda et al. (2003) presented the importance of focusing not only on technical issues, but also human issues in cellular manufacturing environments. Technical issues include cell formation and cell design, whereas human issues involve such as worker assignment strategies, skill identification, training, communication, autonomy, reward system, conflict management, and teamwork. They conducted a survey to show the importance of human issues in cellular manufacturing. The number of participants in the survey was 40, and consists of workers, managers and academicians. They were asked to rank the human issues. Their response was analyzed. The results showed that three major human issues in cellular manufacturing are communication, teamwork and training. The degree of autonomy was found the least important among all. The reward system was in the middle. The assignment strategies were found significant among academicians. The skill identification was found significant among managers and academicians whereas conflict management is significant among workers.

Shirase et al. (2001) developed a system of distributed production system which consists of some cell groups. They discussed a dynamic operator assignment method. In this cooperative method, they considered that whenever any cell in a group of cells is unable to meet the due date of certain part, it has the option to ask for one operator as a support from other groups. Eventually, cooperation is taking place between cell groups until all due dates are met. They generalized the idea in which some disturbances in a production system can be treated by cooperation between subsystems. Fan and Gassmann (1997) discussed allocation functions between worker and machines could influence the performance of manufacturing cells over a long period of time considered as 15 months. They concluded that skills development and knowledge are really important for keeping long-term competitiveness. Allocation of functions has an impact on the long term performance, in which the long period will give more vision to make the work smooth through absorbing the complexity of the nature of manufacturing environment.

Wirojanagud et al. (2005) discussed a strategic way to model worker differences for workforce planning. Impact of individual differences on management decisions is considered and then discussed. A problem of job shop environment has been formulated in a form of a mixed integer programming model. The major concern was to identify number of workers who will be hired, fired and cross-trained at a minimum cost. Experiments are run and then results are analyzed. Workers differences are playing a major role in making decisions in manufacturing system environment.

Suksawat et al. (2005) discussed the concept of evaluating the skill levels of workers. They developed a skilled worker–based scheduling method based on the skill evaluation and genetic algorithm application. They focused on the objective of improving the production rate by considering workers' skill levels. Süer and Dagli (2005) discussed manpower decisions in their paper. They considered two issues in their paper; product sequencing in a cell and cell loading. For the first issue, they target to minimize intra-cell manpower transfers. A three-phase methodology is proposed, in which optimal manpower level for each operation is found by using a mathematical model, a matrix for manpower transfers between products is formed, and traveling salesman problem is solved. For the second issue, they aim to find the optimal assignment of products to cells. Their objective is to minimize makespan and number of machines. Cesani and Steudel (2005) presented a research concerning labor assignment strategies, and their impact on the cell performance in cellular manufacturing environment. The term labor flexibility was discussed and referred to the movement of operators between cells and inside the same cell. Labor assignments, such as dedicated assignment, in which an operator is assigned to one or more machines, shared assignment in which two operators or more are assigned to one or more machines, and combined in which an operator is assigned as dedicated and shared together. They made their discussions based on workload sharing, workload balancing and bottleneck operations. Experiments and simulation models were implemented and discussed. They concluded based on results, that the balance in the operators' workload and the level of machine sharing are important factors to determine cell performance and behavior. They also referred to the importance of cross-training issue in improving cell performance.

Mahdavia et al. (2010) developed an integer mathematical model to design cellular manufacturing systems. They consider a dynamic environment as well. Their model deals with worker assignment as well as dynamic configuration of the cellular system. The overall objective is to minimize the total cost of inventory holding and backorder costs, inter-cell material handling cost, machine and reconfiguration costs and hiring, firing and salary costs of workers.

Süer, Arikan, Babayigit (2008) and Süer, Arikan, Babayigit (2009) developed fuzzy mathematical models for cell loading in labor-intensive cells subject to manpower restrictions. Süer, Cosner and Patten (2009) developed various mathematical models for cell loading and product sequencing in manufacturing cells. Süer, Subramanian and Huang (2009) developed several heuristic procedures and mathematical models for cell loading and product sequencing in a shoe manufacturing company.

Süer and Tummaluri (2008) discussed the problem of operator assignment to operations in labor-intensive cells. The operators are assigned to operations in multi-period context considering their skill levels, forgetting and learning rates. They developed a three-phase hierarchical methodology to solve this problem. The first phase is generating alternative operator levels for each product using operation standard times. The second phase is determining cell loads and cell sizes using standard times. The third phase is assigning operators to operations. A mixed integer mathematical model is used in all phases. Two different strategies (Max and MaxMin) are proposed for solving the operator assignment in the third phase. The results showed that when using Max Strategy, lower makespan allocation values are obtained, whereas Max-Min improved the skill levels more regularly. The work undertaken in this paper is an extention of their work. They found that Max-Min is superior to Max Strategy in terms of improving operator skill levels; however, they could not show that Max-Min Strategy is better in minimizing makespan as a result of improved skill levels. Their work assumed a static cellular environment, in which there are no new products entering the system and no product is leaving the system (i.e. product mix remained the same throughout the study). They have classified labor skills into nine categories following normal distribution. Their work also showed that some non-bottleneck operations became bottleneck after assigning operators. The reason for that is that they have done initial operator assignment based on standard times. When they reflected the effect of skills on processing times, some non-bottleneck operations became bottleneck and adversely affected output rates. In some cases, operators had to be re-assigned to fix the problem.

PROBLEM STATEMENT

This chapter introduces several improvements to work by Süer and Tummaluri (2008) where, 1) Max and Max-Min strategies are compared in a highly dynamic environment where product mix changes. i.e., new products enter the system and some products leave the system. It is believed that this will show the benefits of Max-Min strategy better in terms of minimizing makespan, 2) number of skill levels are reduced to seven. It is believed that this is more practical and realistic approach than having nine skill levels, 3) skill-level based processing times are used directly during operator assignment process. This helps to avoid re-computing of bottleneck operation, output rate and re-assignment of operators.

Methodology

In this section, the methodology used is described in detail.

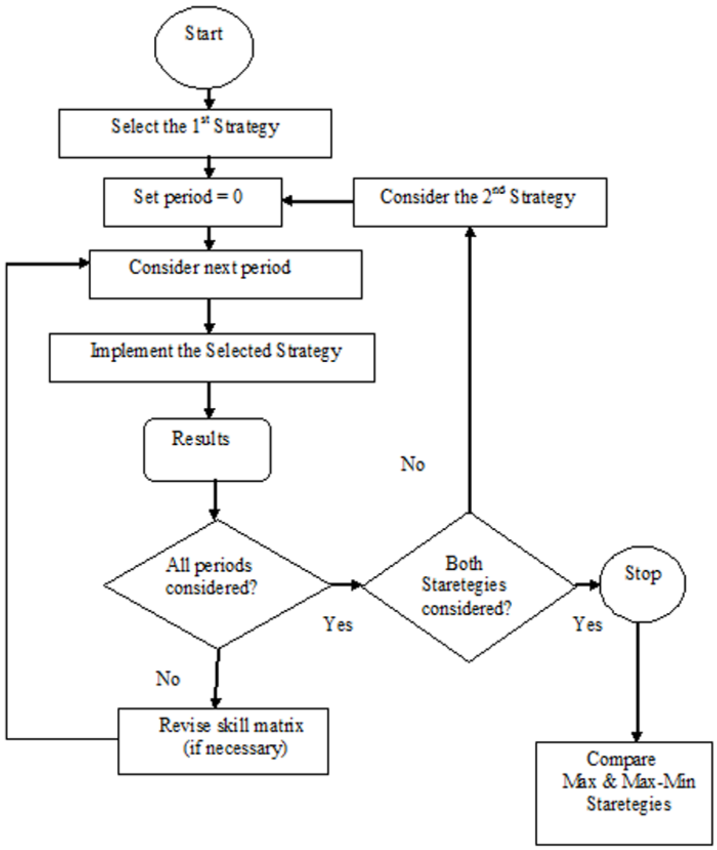
General Methodology

This study is carried out in a multi-period environment. The number of periods included in this study is 16 and each period represents a week. This allows us to see the impact of the strategies in the long-term. Based on the assignments made in the previous periods, an operator's skill level may be adjusted. Figure 1 includes the multi-period methodology in which the proposed approach is implemented and the results are captured. These results may affect the operator skill levels; hence, they need to be revised each period. Once all periods are considered for the first strategy, then the same procedure is applied for the second strategy, and finally the results are compared.

Overview of Strategies

The major phases of the Max strategy as shown in Figure 2a are: (1) find optimal operator assignment using an integer mathematical model. In this phase, the number of workers needed for each operation is determined for each product so that production rate is maximized with the available manpower level. (2) determine cell loads to minimize makespan by using an integer mathematical model. In this phase, decision about what cell to use to produce each product is made. (3) determine product sequence in each cell by using a simple scheduling rule, SPT (Shortest Processing Time). In this phase, the products in each cell are sequenced in the increasing order of processing time to minimize average flow time as well. The first three phases of the Max-Min Strategy is similar to the Max Strategy. However,

Figure 1. Multi-period methodology



two more phases are included in the Max-Min Strategy (see Figure 2b), and they are: (4) identify bottleneck and non-bottleneck operations for each product in the cell. The slowest operation (lowest output) for each product is identified as bottleneck operation. (5) re-assign low-skilled operators to non-bottleneck operations using the Min-skill principle. In this phase, the focus is on non-bottleneck operations and workers are assigned to operations where their skill level is not very high as long as it does not adversely affect the production rate of the cell. By doing this, we expect that operators with low skills will get a chance to perform these operations and eventually improve their skill levels.

Performance Measures Used

The performance measures used for each task are summarized in Table 1. Production rate measures the number of units manufactured per unit time. Makespan is defined as the maximum completion time of all jobs (Equation 1) and flowtime measures how long a job remains in the system (Equation 2).

$$MS=C_{\max} \quad (1)$$

$$f_i=c_i-r_i \quad (2)$$

where

c_i completion time of job i

Figure 2. The general overview of the strategies

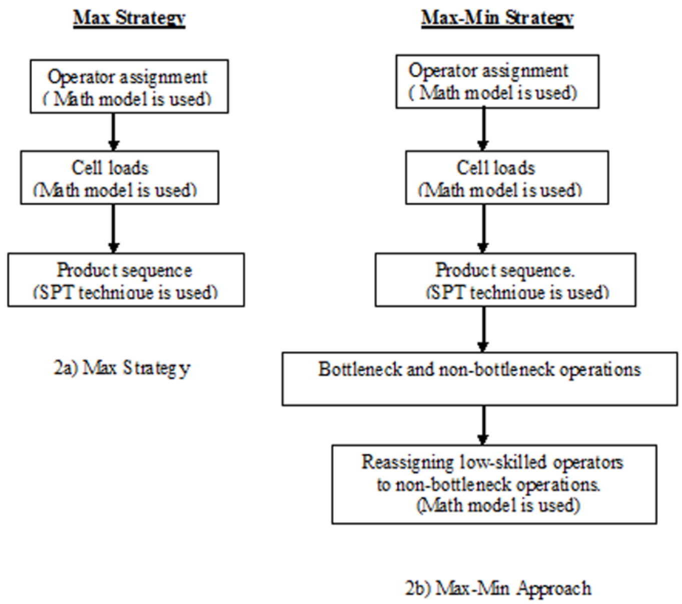


Table 1. Performance measures used for each task

Task	Max Strategy	Max-Min Strategy
Operator Assignment	Maximize Production Rate	Maximize Production Rate
Loading Cells	Minimize Makespan	Minimize Makespan
Product Sequencing	Minimize Average Flow Time	Minimize Average Flow Time
Re-assigning low-skilled operators	-----	Minimize Total Skills Without Violating Original Production Rate

f_i flowtime of job i
r_i ready time of job i

Skill Levels

In this study, each operator is assumed to have a skill level for each operation he performs. These skill levels follow the normal distribution (as shown in Figure 3), in which μ represents the mean value and σ represents the standard deviation. The skill levels are divided into seven categories and their corresponding probabilities are shown in Table 2. Level 4 represents the average skill, level 7 represents the best and level 1 is the worst. This is an assumption used in this study. Süer and Tummaluri (2008) also used a similar classification except they used 9 skills as opposed to 7 suggested here.

Operation Times

Operation times are calculated according to the operator skill levels. The standard processing time for each operation is considered to be the average time, hence, the operator with skill level 4 is considered to have the average operation time. Other skills below or over will follow the normal distribution. Table 3 provides an example for different skills of an operation with a standard deviation of 5% of the mean. The σ for operation

Figure 3. The normal distribution curve for skill levels

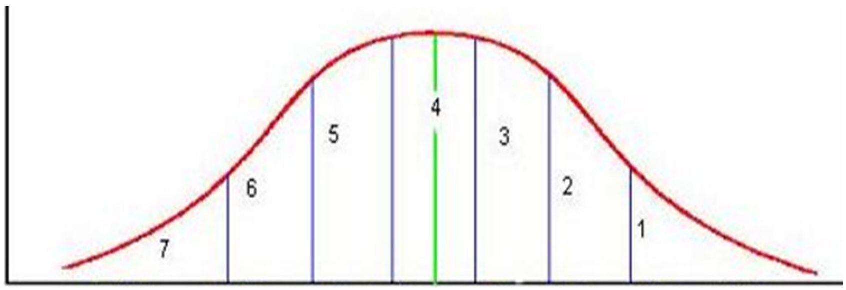

Table 2. The skill levels and probability

Skill Level	Time	Probability
1	μ +3σ	0.0062
2	μ+2 σ	0.0606
3	μ+σ	0.2417
4	μ	0.383
5	μ -σ	0.2417
6	μ-2 σ	0.0606
7	μ -3σ	0.0062

1 for product X1 is 0.0035 (=.07*.05). As the skill level decreases by 1 level (4 → 3), the operator skilled-based time increases to 0.0735 (=.07 + σ).

Learning and Forgetting Rates

In this study, a skill level is affected by learning and forgetting rates. An operator's skill level increases when he performs an operation for many consecutive periods. In the same manner, the length of interruption interval affects the skill levels adversely; hence, if an operator does not perform a certain operation for a number of consecutive periods, his skill level decreases. Table 4 shows the assumed number of required periods for improving or lowering skill level, and it also shows the probability for that skill to change. The probability values follow the notion that an operator who has been performing an operation for a long time will become more experienced operator, and it will take longer for that skill to deteriorate. As shown in the same table, a skill level can be improved from 1 to 2 with a probability of 0.7, if an operator keeps performing the same operation for 3 periods consecutively. On the other hand, improving skill level from 6 to 7 requires an operator to perform the operation for 6 periods consecutively (with a probability of 0.3). Meanwhile, an operator's skill level can deteriorate from 2 to 1 with a probability of 0.7, if he does not perform the operation for 4 periods consecutively. Similarly, if he does not perform the operation for 7 periods consecutively, his skill will decrease from 7 to 6 with a probability of 0.3. No empirical study has been done to validate these assumptions due to time restrictions. However, it is believed that these numbers reflect the relations between learning and forgetting rates of workers at different skill levels along with associated probabilities reasonably well. The operator skill matrix is revised on learning and forgetting rates at the end of every period.

Table 3. The operation times for different skill levels with σ = 5% of the mean

		Skills

PROPOSED MATHEMATICAL MODELS

In this section, the proposed models are introduced.

Max Strategy

The Max Strategy uses the skill-based times to assign operators into operations such that maximum output is achieved. An integer mathematical model is used to assign operators. The mathematical model is formulated with the objective function of maximizing the production rate as shown in Equation (3). Equation (4) determines which operators have to be assigned to each operation. Equation (5) ensures that each operator is assigned to only one operation within a cell. Equation (6) shows that y_{kj} is a binary variable. The mathematical model is given below:

Objective Function:

$$MaxZ=R \quad (3)$$

Subject to:

$$\sum_{k\in fj}(a_{kj}y_{kj}) - R \geq 0 \quad j=1,2,3,\ldots,m \quad (4)$$

$$\sum_{j\in fk} y_{kj} = 1 \quad k=1,2,3,..,n \quad (5)$$

$$y_{kj}\in(0,1) \quad (6)$$

Indices:

- k Operator index
- j Operation index

Parameters:

- a_{kj} number of units operator *k* can process if assigned to operation *j*
- m number of operations in the cell
- f_k set of operations that operator *k* can perform
- f_j set of operators who can perform operation *j*
- n Number of operators

Decision variables:

- R production rate
- y_{kj} 1 if operator *k* is assigned to operation *j,* 0 otherwise

This assignment model is run for each product by using ILOG OPL software.

Max-Min Strategy

The Max-Min strategy also uses the skill-based times to find the optimal operator assignment to maximize the output. In this Strategy, first the slowest operation, bottleneck operation, is identified. The same integer mathematical model is used to assign operators and it is solved by using ILOG/OPL. However, another constraint is added to determine production rate for each operation as given in Equation (7).

$$R_j = \sum_{k \in fj} (a_{kj} y_{kj}) \text{ j=1,2,3..m} \quad (7)$$

Obviously, the lowest production rate operation is identified as the bottleneck operation as shown in Equation (8)

$$R_b = \min(R_j / j = 1,2,3,\ldots,m) \quad (8)$$

The Max-Min Strategy keeps the operators assigned to the bottleneck operation the same; however, it re-assigns other operators to non-bottleneck operations to minimize total skills such that the optimal output rate is maintained. A mathematical model is used where the objective function is to minimize the total skills for the remaining operators as given in equation (9). Equation (10) guarantees that the original production rate (optimal) is not violated. Equation (11) shows a constraint in which each operator is assigned to one operation within each cell. Equation (12) shows that y_{kj} is a binary variable.

The math model used is given below as:

Objective function:

$$MinZ = \sum_{k \in fj} \sum_{j \in fk} (s_{kj} y_{kj}) \quad (9)$$

Subject to:

$$\sum_{k \in fj} (a_{kj} y_{kj}) \geq R_b \text{ j=1,2,3,….m} \quad (10)$$

$$\sum_{j \in fk} y_{kj} = 1 \text{ k=1,2,3,…n} \quad (11)$$

$$y_{kj} \in (0,1) \quad (12)$$

where,

Parameters:

s_{kj} Skill level of operator *k* for operation *j*

R_b Production rate of bottleneck operation

The difference between these two strategies is illustrated in Figure 4 using a hypothetical case. Assume; that operation 2 is the bottleneck operation with operators 3 and 7 assigned to it as shown in Figure 4a and the output rate is 80 units/hr. The Max-Min Strategy shown in Figure 4b keeps the same operators in the bottleneck operation but re-assigns other operators to minimize skills without sacrificing the optimal output rate.

Cell Loading and Product Sequencing

Cell loading is the process of assigning products to cells. In this paper, a mathematical model is used to assign products to cells and the primary performance measure is to minimize makespan. Equation (13) shows the objective function, minimizing makespan. Equation (14) shows that the total processing time in each cell should be equal to or greater than the makespan. Equation (15) ensures that each product is assigned to a cell. Equation (16) shows the sign restriction.

Objective function

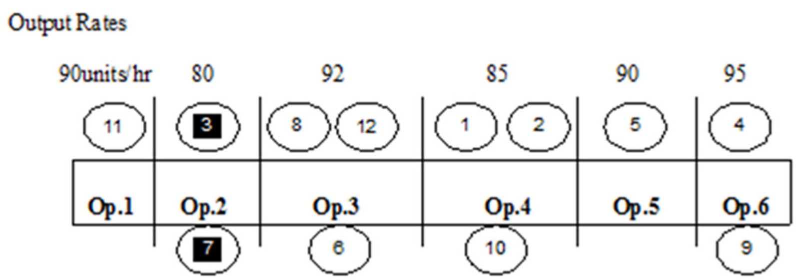
$$MinZ = MS \quad (13)$$

Subject to:

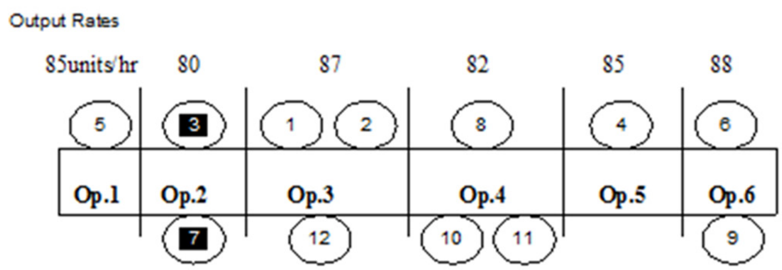
$$MS - \sum_{i=1}^{n} p_{ij} x_{ij} \geq 0 \text{ j=1,2,3,…,c} \quad (14)$$

$$\sum_{j=1}^{c} x_{ij} = 1 \text{ i=1,2,3,…,n} \quad (15)$$

Figure 4. Manpower assignment using both strategies



4a. The optimal operator assignment using the MAX Strategy



4b. The optimal operator assignment using the Max-Min Strategy

$x_{ij} \in (0,1)$ (16)

Where,

Indices:

c Number of cells

n Number of products

Parameter:

p_{ij} Processing time of product i in cell j

Decision Variable:

x_{ij} 1 if product i is assigned to cell j, 0 otherwise

Product sequencing usually comes after cell loading in which products are arranged in such a way, that a selected performance measure is completed. In this chapter, average flow time is considered as a secondary measure and it is minimized by using the shortest processing time technique (SPT). SPT rule orders jobs in the increasing order of processing times.

DATA USED IN EXPERIMENTS

In this section, the data used in experiments are given.

Standard Times

The standard times for operations correspond to a skill level of 4. The standard times for product groups X and Y are randomly generated from a random uniform distribution in the intervals shown in Table 5. These two product groups are used to create the dynamic environment mentioned earlier.

Product Demand

The product demand for all products is randomly generated from the uniform distribution in the interval of [2200, 8500] for all periods. Table 6 shows these demand values.

Table 5. Uniform distribution intervals for standard times for product groups X and Y

Operator Skills

The total number of operators included in the study is 30. Each operator is assumed capable of performing 3 operations. These operators are divided into two cells with 12 operators in cell 1 and 18 operators in cell 2. The initial skill matrix is established randomly by following probabilities given in Table 2. The initial skill matrix for all operators is given in Table 7.

EXPERIMENTS

Several experiments are conducted using 10 products of type X and 10 products of type Y. Each product requires 6 operations. The experiments performed are listed below:

1. Periods 1-14, no chaos
2. Periods 1-9, no chaos; Periods 10-11, chaos
3. Periods 1-14, no chaos; Periods 15-16 chaos
4. Periods 1-14, no chaos; Period 15 chaos with new standard deviation

Experiment 1

This experiment includes runs using Max and Max-Min strategies starting from period 1 to period 14. The results are analyzed below:

Impact on Operator Skill Levels

It was found that Max-Min improves operator skill levels more significantly than Max did. Benefits come from the Max-Min assignment strategy in which it finds the optimal operator assignment to maximize the output. Later, this strategy keeps the operators assigned to the bottleneck operation the same but re-assigns the low skilled operators to non-bottleneck operations. This strategy allows an operator to perform an operation that he or she is not skilled at; hence his or her skill does not deteriorate and certainly improves. Tables 8 and 9 show the comparison of these two strategies at the end of period 14 in terms of average operator skill levels for cells 1 and 2, respectively. In cell 1, it was found that not only the average operator skill levels is greater than the initial average skill levels when Max-Min was used, but also is greater than operators average skill levels when Max was used. On the other hand, when Max was used, 5 operators had an average skill levels greater than their initial ones, 3 operators kept the

28	3.33	5.33	5.33
29	4.33	5.33	4.67
30	4.67	6	6.67

same average and 4 operators were found having lower average skill levels.

In cell 2, it was found that the average operator skill level is greater than the initial average skill levels when Max-Min was used. However, 15 operators had greater average skill levels than when Max was used, but 2 operators had the same average skill levels and 1 operator had lower average skill levels. As to Max strategy, 14 operators had an average skill levels greater than their initial ones, 1 operator kept the same average and 3 operators were found having lower average skill levels than their initial ones.

Impact on Operations

Max-Min Strategy improved operator skill levels on each operation more apparently than Max did. Table 10 shows average skill levels on each operation. It was found that operation 1 deteriorated when Max was used; however average operator skills on all operations were greater when Max-Min was used.

Impact on Makespan

The results have shown that both strategies were tied in terms of makespan for the first 11 periods. Starting period 12, Max-Min performed better in minimizing makespan by 0.2%, 0.2% and 0.1% compared to Max approach in periods 12, 13 and 14, respectively. Table 11 shows the comparison of these two strategies in terms of makespan from period 1 to period 14.

Experiment 2

In this section, chaos is applied in periods 10 and 11 to create a big shock in the system to see how both strategies behave in terms of makespan. This is accomplished by introducing new products with very different processing times. The results have shown that when 5 products of type Y entered the system and 5 products of type X left the system, Max-Min gave better results (with 0.4% reduction

Table 10. Average skill levels on each operation

14	49.04	48.99	0.1%

in makespan) in period 10. In period 11, the entire set of products of type Y is manufactured (no product X in the system). Max-Min still worked better (with 0.4% improvement in makespan). Table 12 shows the results of makespan using these two strategies in periods 10 and 11. Table 13 shows another chaotic scenario by entering all products of type Y and releasing all products of type X in period 10. In this case, the improvement with Max-Min over Max was 0.7%.

Table 12. Impact on makespan under chaos in periods 10 and 11

	Max-Min	Max	Difference (%)
Period 10 (5 products)	71.15	71.43	0.4%
Period 11 (5+5 products)	81.68	82.02	0.4%

Table 13. Impact on makespan under chaos in period 10

	Max-Min	Max	Difference (%)
Period 10 (10 products)	94.3	94.92	0.7%

Experiment 3

The chaos was applied in periods 15 and 16 as we did in experiment 2. The results have shown that when 5 products of type Y entered the system and 5 products of type X left the system, Max-Min gave better results (with 1.7% reduction in makespan) in period 15. In period 16, the entire set of products of type Y is manufactured (no product X in the system). Max-Min still worked better (with 1.2% improvement in makespan). Table 14 shows the results of makespan using these two strategies in periods 15 and 16. Table 15 shows another chaotic scenario by entering all products of type Y and releasing all products of type X in period 15. In this case, the improvement with Max-Min over Max was 2.2%.

Experiment 4

In this phase, we wanted to show that the improvement in operators' skill levels should have better impact than what happened in previous experiments. We changed the standard deviation from (0.05μ) to (0.2μ) to extend the gap of operator-operation times, and then we applied these new times in period 15 by entering all products of type Y in the system. Results have shown that there was better gain in terms of minimizing makespan

Table 14. Impact on makespan under chaos in periods 15 and 16

	Max-Min	Max	Difference (%)
period 15 (5 products)	66.48	67.6	1.7%
period 16 (5+5 products)	88.6	89.7	1.2%

Table 15. Impact on makespan under chaos in period 15

	Max-Min	Max	Difference (%)
Period 15 (10 products)	86.81	89.01	2.2%

Table 16. Impact on makespan under chaos in period 15

	Max-Min	Max	Difference (%)
period 15 (10 products) (SD = 0.2)	55.23	58.02	5%

and total time. Max-Min performed better by 5% than Max approach. Table 16 show these results.

CONCLUSION AND FUTURE WORK

In this chapter, operators were assigned to operations to maximize the production rate using two assignment strategies: Max-Min and Max. The major concern is to see how these two approaches impact operators' skill levels, as well as their impact on makespan values. The impact is discussed under a chaotic environment where sudden changes in product mix with different operation times are applied and under a non-chaotic environment where the same product mix is run period after period. In this study, a skill level is affected by learning and forgetting rates. An operator's skill level increases when he performs an operation for many consecutive periods; on the other hand, if an operator does not perform a certain operation for a number of consecutive periods, his skill level decreases. Max-Min did improve operators' overall skill levels more significantly than Max in multi-periods. This is due to the fact that Max-Min does not only assign operators to maximize production rate, but also it re-assigns operators to operations where they are not very skilled; thus, operator's skill levels continue to improve. On the other hand, Max is only assigning operators to operations to maximize production rate. Moreover, the previous work assumed a stable cellular environment, in which they assumed that there are no new products entering the system. Thus, in this paper, we introduced a highly dynamic cellular environment, in which new products with different processing times entered the system and some of the existing products left the system. Max-Min acts well under chaotic environment because it increases operators' skill levels well enough to face the shock applied, where the shock contains products with new processing times and this requires different manpower allocation. We also concluded that the standard deviation used in operator time matrix is an important factor for helping Max-Min approach to expand the gain in terms of minimizing makespan and total time. A standard deviation of 5% of the mean is used in operator matrix for experiments 1 and 2. In period 15, when we replaced the whole set of products of type X with products of type Y, we found the highest gain that shows Max-Min is better in minimizing makespan among all periods. This gain was captured using a standard deviation of (0.05μ); however, when we used a standard deviation of (0.2μ), we found that the gain is higher than using (0.05μ). A possible extension to this work is to take manpower level decision for each cell as a variable as opposed to using fixed manpower levels. A further expansion would be to allow operators shift from one cell to the next as opposed to fixing them to the same cell all the time. Obviously, this increases flexibility in assigning operators to cells. However, this increases computational complexity as well.

Chapter 62
Capacity Sharing Issue in an Electronic Co-Opetitive Network:
A Simulative Approach

Paolo Renna
University of Basilicata, Italy

Pierluigi Argoneto
University of Basilicata, Italy

ABSTRACT

In recent years, manufacturing companies have entered a new era in which all manufacturing enterprises must compete in a global economy. To stay competitive, companies must use production systems that only produce their goods with high productivity, but also allow rapid response to market changes and customers' needs. The emerging new paradigm of inter-firm relations involving both cooperative and competitive elements, called co-opetition, seems well face this issue. The chapter proposes a multi agent architecture to support different coordination policy in an electronic co-opetitive network in which plants are willing to exchange productive capacity. An innovative approach based on cooperative game theory is proposed in this research and its performance is compared with the prevalent negotiation approach. A discrete event simulation environment has been developed in order to evaluate the related performances. The case in which no relation exists among plants has been considered as a benchmark. The obtained results show that the proposed approach outperforms the negotiation mechanism form many point of view.

INTRODUCTION

In this era of downsizing and outsourcing, where the business landscape is changing rapidly, the management of the external relations of the firm and the combining of this with internal operations represent a new problem and opportunity. Increasingly firms are recognizing the development and management of relationships both directly and indirectly with other members of the value producing system, conscious of the fact that they cannot survive and prosper solely through their own individual efforts: each firm's performance depends in important ways on the activities and performance of others and on the nature and quality of the direct and indirect relations as firm develops with these counterparts. Inter-firm relations involve a mix of cooperative and competitive elements. Firms simultaneously cooperate to expand the total amount of rewards and resources available to them and compete over the means to do this and over the division of rewards and resources. They compete to develop cooperative relations with counterparts such as customers and suppliers that are beneficial in order to create competitive advantages in creating value for final customers. Matching competition and cooperation (hereafter C&C) is a great and hard challenge for firms in this globalization era. The novelty of the topic proves the importance and the absolute relevance of research efforts aiming at providing a better understanding of this new organizational issue. Although some works are present in literature, identifying and providing evidence of the reasons of both competitive and cooperative relationships among firms, analyzing keys of success and causes of failures of these strategies are still open questions in both conceptual and empirical literature. On the other hand, determining strategies in these situations and studying their beneficial or detrimental effects on firms, consumers, suppliers and social welfare, designing proper mechanisms and providing incentives are absolutely open issues. When a rapport among firms includes elements of both cooperation and competition, i.e. these firms can compete and cooperate simultaneously, the relationship is called co-opetition. In order to better understand the reasons for assuming co-opetitive behavior, we should first reflect on the concepts of C&C. Competition occurs when many firms are producing the same or related products and are fighting for consumers, suppliers and/or resources, excluding collaboration with other companies. In pure competition the boundaries between competitors are sharp and distinct. Conversely, in pure cooperation there are frequent exchanges among partners, including business, information and social exchange. Inter-firm cooperation produces strong ties that cross the boundaries between firms in order to share complementary capabilities, assets and interests. The functioning of cooperative relationships may be regulated by formal contracts and/or informal agreements built upon social relations and the development of trust. It should be noted that cooperation and competition between firms are neither spontaneous nor exogenous, but are actions that depend upon the contextual conditions, i.e. the determinants of their level evolve over time, thus it is likely that the level of C&C between organizations will undergo variations (Luo, 2005). Some of the various determinants of competition are: a high level of overlapping in the market, a slight differentiation between the products sold by different firms, a lack of entry barriers to a market and a strong contractual position enjoyed by clients and/or suppliers. Instead, some determinants of cooperation among firms are: an inability to achieve their goals with their own resources, a need to share the risks of a new initiative and an improvement in efficiency through the sharing of activities to obtain economies of scale. For all that reasons, various hybrid forms of co-opetitive relationships occur between the extreme forms of pure inter-organizational competition and pure inter-organizational cooperation. Following the seminal work of Brandenburger and Nalebuff (1996), a number of articles regarding the private sector argued that C&C among firms cannot be considered mutually exclusive (Bengtsson and Kock, 1999; Luo, 2004; Oliver, 2004) but, in spite of authors' suggestion few of them have used game theory to model situations in which both competitive and cooperative behaviors arise. Game theory makes it possible to move beyond overly simple ideas of C&C to reach a vision of co-opetition more suited to topical needs. This theory is a branch of mathematics that is concerned with the actions of individuals who are conscious that their actions affect each other. It is divided into two branches, called the non-cooperative and cooperative ones, differing in how they formalise interdependence among the players. In the non-cooperative theory, a game is a detailed model of all the moves available to the players. By contrast, the cooperative theory abstracts away from this level of detail, and describes only the outcomes that results when the players come together in different combinations. Though standard, the terms non-cooperative and cooperative game theory are perhaps unfortunate. They might suggest that there is no place for cooperation in the former and no place for conflict or competition in the latter. In fact, neither is the case: especially in business field the real value of game theory comes when both approaches are put into practice. It, therefore, could be used to study settings in which co-opetition might be used, determine strategies of co-opetition and analyze their effects on outcome in order to evaluate possible advantages and/or disadvantages from single firm, other stakeholders and the whole system. For example, consider a situation where a number of firms (players) are connected in some network relationship. The applications could be quite wide and varied, ranging from friendships and social relationships, to communicating information about job openings, to business partnerships, to international trade agreements and political alliances. What is in common to these situations is that the way in which players are connected to each other is important in determining the total productivity or generated value. How the total productive value are allocated or transferred among players turns out to be important not only in terms of fairness considerations, but also because it determines players' incentives to form various networks. Particularly the generated value by players depends not only on their identities but also on how they are connected to each other. That is, alternative network structures (e.g., communication lines, alliances, friendships, etc.) connecting the same set of players might lead to very different costs and benefits. Thus, in many situations it will be important to account for network structure and not just coalition structure. Myerson (1977) made a seminal contribution in adapting the cooperative game theory structure to accommodate information about the network connecting players: once the network is fixed its role is simply to define which coalitions can function. The feasible coalitions are the ones whose members can freely communicate via the given network (so that any two players in the coalition are path connected in the network via players in the coalition). In a sense, each network structure and characteristic function (indicating how much value a given coalition can generate) induces a particular cooperative game.

In the last two decades, there have been many relevant examples of co-opetition situations. In the 90s GM and Ford, the major American carmakers, established an e-procurement platform for procuring basic components. The joint venture between Toyota and PSA Citroen-Peugeot, established in 2002, is another very relevant example of co-opetition in automobile industry. The two companies agreed in building a common plant in Czech Republic and using common components for the production of three new separately-owned city cars. In Italy, in 2002, the two biggest motorcycle companies, Aprilia and Piaggio made an alliance for joint-procurement, though competing in the final market. In ICT industry, the Simian joint-venture is among the main mobile wireless telephones manufacturers in the world, Nokia, Ericsson, Panasonic, Samsung, Siemens AG, and the leading company in the mobile digital computing, Psion, which, however, has sold its own shares in 2004. The phenomenon of co-opetition in R&D activities and co-promotion is also very common in pharmaceutical and biotechnology industry. Other straightforward examples of co-opetition can be found in several other industries, such as furniture, tourism, healthcare and retailing. Moreover, all around the world industrial districts and both local or national consortia and co-ops can be considered examples of co-opetition of medium and small businesses in several industries, such textile and clothing, agri-food, hardware and retailing. Also, in the automotive industry, web-based technology opens up opportunity of cooperation among small and medium firms. For instance, Supply On is a successful provider of supply and engineering services founded by suppliers competing in the same market (Meder, 2005). Finally, an interesting empirical research from Quintana-Garcia and Benavides-Velasco (2004) provides evidence of co-opetition in new product development among European small and medium firms in biotechnology industry. Through cooperation in one or more activities, small firms can get same advantages as big companies, however, because of proximity, they inevitably keep competing each others in other activities. The contribution of our chapter is threefold:

- to apply concepts deriving from co-opetitions in an electronic network of geographically distributed plants willing to exchange their productive capacity;
- to evaluate different coordination policy, one based on negotiation and one based on cooperative game theory;
- to simulate the proposed approach by a Multi Agent System able to support the network.

The rest of the chapter is structured as follows: section 2 presents the motivations to develop a network; section 3 provides a general description of the network typology while the co-opetitive approach is introduced in section 4. An overview of the literature is presented in section 5. In section 6 is described the problem context then the Multi Agent Architecture is illustrated in section 7. In section 8 the coordination mechanism proposed are described. The developed simulation environment and simulation results are respectively presented in sections 9 and 10. Finally, conclusions and further research paths are withdrawn in section 11.

WHY NETWORKS ARE NECESSARY

Survival, performance and development of the entrepreneurial firm are at the heart of entrepreneurship research (Shane and Venkataraman, 2000). Entrepreneurial firms are characterized by a lack of internal resources and other start-up handicaps, as expressed in the theoretical constructs of liability of newness and liability of smallness. The strategic use of external resources through inter-firm networks in many different industries (Jarillo, 1989), that are often embedded in regional clusters (Boari and Lipparini, 2000; Lechner and Dowling, 2000) is regarded as one effective means to overcome these liabilities. In this context, inter-firm networks are considered an important model of organization development to enable an entrepreneurial firm to grow and survive (Freel, 2000). The image of atomistic actors competing for profits against each other in an impersonal marketplace is increasingly inadequate (Granovetter, 1985; Gulati, 1998; Galaskiewicz and Zaheer, 1999). Such networks encompass a firm's set of relationships, both horizontal and vertical, with other organizations—be they suppliers, customers, competitors, or other entities— including relationships across industries and countries. These strategic networks are composed of inter-organizational ties that are enduring and include strategic alliances, joint ventures, long-term buyer-supplier partnerships and a host of similar ties. Gulati et Al. (2000) highlight the importance of considering the role of strategic networks resulting from inter-firm ties for fundamental issues in strategy research. Anand and Khanna (2000) provide a unique empirical assessment of the presence of experience benefits to firms from entering frequent alliances. Using a comprehensive data set on abnormal returns to alliance announcements they separate out alliances by contract type and find significant differences in the extent of learning, as measured by abnormal returns, across contract type. They look further within each type and also observe differences in learning effects within joint ventures depending upon the scope of activities within the alliance. They conclude that learning effects are more significant when there is contractual ambiguity. Doz et Al. (2000) examine the creation of R&D firms consortia to uncover the formation processes underlying the formation of cooperative interfirm networks. They identify an emergent process by which environmental changes and shared views among participants facilitate network formation, and also an engineered process in which a triggering entity actually recruits potential members. Together, the identification and elucidation of these two processes provide us with insights into the formation of networks. Baum et Al. (2000) utilize a unique data set on biotech start-ups to examine the role of start-ups' network composition on their innovative performance. Their findings suggest that the structure of their network of ties and the identity of their partners can have a significant influence on their performance. They use these empirical findings to reflect on some implications that may follow for managers of startups. Ahuja (2000) draws on the resource-based view of the firm to study alliance formation. He flags an important issue when he argues that the proclivity of firms to form strategic alliances depends both on alliance opportunities and on the firms' own inducements and resource endowments. Alliance formation thus results from a match between the value-creating resources of the focal firm and those available from other firms in its environment. He identifies three forms of capital resources (technological, commercial and social) and shows that they each contribute to alliance formation. A combination of technical and commercial capital in a firm, however, reduces the likelihood of allying, since such firms are already well endowed and have less need to ally. Rowley, Behrens and Krackhardt (2000) empirically assess the interplay between relational and structural embeddedness for firm performance. While the former highlights the role of the relationships firms are in, they focus on the overall relational structure surrounding the firm. Using data on interfirm strategic alliances from the semiconductor and steel industries they find that the role of both forms of embeddedness on firm performance is influenced by the industry context. Afuah (2000) explains firm-level competitive advantage by explicitly invoking the capabilities available to a firm from its network of supplier and customer firms (co-opetitors). He shows how a firm's performance is lowered in the face of technological change when a firm's network members' capabilities are made obsolete - a contrast from research which has focused on the capabilities of the firm itself in explaining performance. Kogut (2000) theoretically highlights two ways in which a firm's performance can be influenced by the network in which it is embedded. The first is the value that a focal firm's network of ties has for the range and quality of information it receives. This potential information advantage has been widely recognized. What has received less attention, Kogut argues, are the potential benefits that arise from being a part of a dynamic and evolving network that coordinates activities among specialized producers. By highlighting the importance of generative rules that shape the coordination among the members of a network over time.

NETWORK TYPOLOGIES

Generally, research on inter-firm networks has focused on the role of the entrepreneur in network building, on the initial size of an entrepreneurial firm's network in regard to firm performance, or on structural characteristics of networks. Different types of relations define different types of networks even if the same units are connected, that means that firms can be involved in different types of networks in different development phases. All this value-added networks go beyond economic relationships and includes:

- **social networks:** relationships with other firms based on strong personal relationships with individuals such as friends, relatives, long-standing colleagues that became friends before foundation, and so forth;
- **reputational networks:** made up of partner firms that are market leaders, or highly regarded firms or individuals, and where one of the main objectives in entering into this relationship is to increase the entrepreneurial firm's credibility;
- **marketing information networks:** relationships that allow for the flow of market information through distinct relationships with other individuals/firms;
- **co-opetitive networks:** relationships with direct competitors;
- **cooperative technology networks:** technology alliances involving joint technology development or innovation projects.

Moreover, network research distinguishes three components: network content, network structure and network governance in order to explain the role of networks in firm performance. According to the theory of structural embeddedness, network structure and a firm's network position are considered to be both opportunities and constraints. Favorable positions are regarded as network resources; over-embeddedness, however, can lead to inability to act. A rich literature suggests that networks are a particular governance form in which the development of trust plays a major role in influencing resource exchange and costs compared to market coordination or integration of activities. In this sense, inter-firm networks constitute a third way of organizing the business, which is neither by markets nor by hierarchies. Recently, it was shown that specific kinds of relations (network content) are more important in a different economic context. Research on firm networks as a mode of transaction governance, the role of strong and weak ties, and the analysis of structural properties of networks has produced important insights. First of all, many studies have shown that the entrepreneurs' personal and social networks probably are the most important strategic resources for the firms' start-up (Ardichvili et al., 2003). Organizational networks or inter-firm networks are relations between organizations that can have various functions, also called sub-networks according to their relational content. The merging of personal and organizational networks seems to be a common feature of young firms. Founders and the firm are inseparable at startup. As the firm grows, the founders' personal networks and firm networks merge (Cooper, 2002). These merged networks can be considered an organizational form. Initially, it seems that networking for entrepreneurial firms is based on pre-existing relationships, which become more complex over time by having different functions and being more socially embedded: social relations are transformed into socio-economic and, finally, into more complex relations. Previous research has shown that the overall network structure changes from an unplanned to a planned and, finally, a structured network. Once structured, however, it seems that both over-embeddedness and a firm's limited relational capability, i.e. the capability to establish, maintain, and develop relationships (Lechner and Dowling, 2003), poses a potential barrier to growth. However, this research does not explain which network types are most important to manage or how firms should overcome these growth barriers. Research on network types and performance has focused on pre-start-up activities in order to explain nascent entrepreneurship (i.e. personal networks have been analyzed at or prior to the creation of the company in terms of size and networking activity). Context-specific research investigated the positive or negative role of social networks at start-up, but which types of network matter most for firm performance have not been studied extensively. Some research was conducted on the role of single network types such as reputational and cooperative technology networks, but little is known for example about the role of co-opetition networks. Lechner and Dowling (2003) proposed a network development model based on varying network types. Based on case study research in a German Information Technology cluster, they identified that firms use relationships for a variety of purposes and that every firm has an individual relational mix. They argued that the relational mix (i.e., the different types of networks) changes over time in order to enable firm growth. Finally, they proposed a four-phase development model of entrepreneurial firms. In phase 1, firms seek to overcome liability of newness by basing the development of the network mainly on social (understood as strong ties such as family and friends) and reputational networks (relationships with prominent firms that can lend the young firm reputation). While the relative importance of social and reputational networks decreases with the firms' development, electronic co-opetitive networks (i.e., cooperation with competitors) increase over time. In phase 2, firms use marketing information and electronic co-opetitive networks to overcome the usual period of unstable sales growth; in phase 3, co-opetition remains a relevant issue but cooperative technology networks are most important. Finally, in phase 4, firm growth is limited by path-dependent relational capability that eventually reaches its limits and leads to the reconfiguration of a more stable network by introducing hierarchic levels within the network or to the integration of activities previously performed outside the firm. This qualitative study seems to be one of the few where different network types were used to understand the role of networks at and beyond foundation, but their impact on the performance of the entrepreneurial firm have not been tested empirically with larger samples.

WHY WE ARE INTERESTED TO THE ELECTRONIC CO-OPETITIVE NETWORK

Electronic co-opetitive networks involve relationships with direct competitors. The management literature generally considers industries to be collections of firms bound together by rivalry, therefore questioning the value of relationships with competitors (Dollinger, 1985). Firms can use competitors as subcontractors in times where the firm has temporarily reached full capacity. This cooperative behavior, especially with regional competitors, will increase the likelihood of the favor being returned. Overall, relationships with competitors can give access to temporarily needed resources or lead to the temporary pooling of resources, which should positively influence firm performance especially in the years after foundation, when sales tend to grow discontinuously (Lechner and Dowling, 2003). While it has been argued that electronic co-opetitive networks at foundation might be harmful because such relationships could lead to the disclosure of competitive information, lack of co-opetition can also constrain firm development in the years following foundation. Entrepreneurial firms that view competitors not only as pure rivals but also as a potential resource should therefore be more successful. Building on the theoretical framework of co-opetition, according to which both C&C are needed in inter-organizational relationships to allow firms to obtain reciprocal advantages (Bengtsson and Kock, 2000), it could be useful to understand whether (and how) co-opetition could be applied in capacity sharing case. There are many areas of management in which co-opetition may be used. However it is far from being clear in which circumstances a strategy of co-opetition should be used and in which it should not, what the consequences of cooperating and competing at the same time are for all the stakeholders, which variables and parameters involved in co-opetition decisions drive the main results and how managers should design and handle them to make co-opetition work out well. Literature is still far from providing complete analysis of the suitability of co-opetition strategies in given business settings. Research on the topic has just begun. Therefore, a substantial research effort is required to make the picture clearer and provide useful frameworks and tools for firms to decide, design and manage co-opetition. Our goal is to provide a first, and of course not exhaustive, analysis of co-opetition in given production areas. We analyze simultaneous cooperating and competing strategies in capacity sharing case: co-opetition in production, to the best of our knowledge, is not treated at all. The lack of (also) analytical works in this field (see the following section 5) opens up a high number of directions and questions to investigate. Many authors, in fact, have addressed the problem of capacity sharing in multi-unit factory geographically distributed, but nobody using co-opetitive approach. Tonshoff et al. (2000), for example, described a conceptual framework in a decentralized production environment concerning several sales unit and production sites geographically distributed. The capacity allocation plan in this case is made by a mediator in a centralized approach. Ip et al. (2000) proposed an approach concerning planning and scheduling problems in a multi-products manufacturing environment by using Genetic Algorithm. Therefore, the approach is centralized and not applicable in an environment with independent factories. Christie and Wu (2002) proposed an approach to manage the capacity planning in a multi-fabs environment. Each fab is modelled as a single resource with variable production level. Several discrete scenarios are considered in a multi-period, multistage and stochastic programming model. The goal is to minimize the expected mismatch between planned and actual capacity allocation as defined in the scenarios. Chen et al. (2007) proposed model enables a collaborative integration for resource and demand sharing. A negotiation algorithm is utilized to sharing capacity from factory that selling to factory that requires extra capacity. Each factory applies an economic resource planning model based on Genetic Algorithm to improve its local objectives. The model is tested only between two factories: one seller and one buyer. Renna and Argoneto (2008) proposed a distributed approach, for a network of independent enterprises, to facilitate the resources sharing process. The distributed architecture is based on Multi Agent Architecture paradigm and the coordination mechanism was performed by a negotiation protocol. In this work just two performance indexes has been considered: the total profit of the network and the total unsatisfied capacity. Anyway, co-opetition concepts from procurement, marketing and R&D can be also adapted to this area and, therefore, open many spaces for research. To use a sentence from Brandenburger and Nalebuff (1996), in any case, the goal of a firm is to do well for its self-interest, but, especially in a globalized context, to pursue an objective, such as new product development, procurement cost reduction as well as new market entrance, an ally might be necessary. Sometimes, factors such as the knowledge, expertise, technologies, processes and products, the market structure, features and dynamics induce a firm to find the best ally in a competitor getting the way for a win-win result. On the other hand, many other times, a firm can succeed only if able to win out the competition. Therefore a deep analysis of potential benefits and disadvantages of co-opetition strategy is necessary for managers to make proper decisions, design and manage such a new form of business interaction. The doctrine on co-opetition has overcome the positions according to which competition has only negative externalities, while collaboration has exclusively positive effects in an inter-organizational network. In our work, specifically, co-opetition is meant to be jointed in resources procurement among competing firms. That is not the only form of co-opetition in procurement, but it is one of the most common in reality and allows us to easily model the co-opetitive features. In our analysis we investigate advantages and disadvantages of cooperation in presence of competition, by analyzing effects on network, stakeholders and, obviously, on firms. Our results provide useful insights and guidelines for managers involved in this kind of issues, in presence of competition. Because of the novelty of the proposed approach, this work provides basic models to be used as a starting point for further needed developments in the area of production network co-opetition as well as for applications to other business areas.

CO-OPETITION, A LITERATURE OVERVIEW

In spite of the success of the book from Brandenburger and Nalebuff (1996) and although, in the last years, the word co-opetition has been one of the most used and abused in business environments, only few works on the topic are present in the scientific literature. As stated in Dagnino and Padula (2002) scientific investigation on the issue of co-opetition has not gone much farther beyond naming, claiming or evoking it. Some relevant conceptual and/or empirical works in the strategic management literature indirectly face the issue of cooperation among competing firms analyzing strategic alliances formation and firms' networks. One of the main questions addressed by researchers has concerned the reasons behind strategic alliances formation. We have already summarized the most relevant ones. In addition, the Resource Based View perspective contributes to the concept of co-opetition by pointing out that, coming the competitive advantage from resources and capabilities, firms eventually join competitors and interact in networks in order to have access to external critical resources and capabilities and organizational skills (Gulati et al., 2000). The other main question has concerned the keys for an alliance being successful and investigation of failure causes. As pointed out by Bengtsson and Kock (2000), in such stream of literature primarily the cooperative dimension of the relationship is emphasized. In contrast, they argue that both cooperation and competition are simultaneously needed in horizontal relationships since the different relationships may provide the firm with different advantages. In one of the first papers explicitly facing the co-opetition issue, Bengtsson and Kock (2000) use an explorative case study of three industries to show that it is of crucial importance to separate the cooperative part from the competitive part of the relationship. They also show how to separate and manage these two conflicting logics of interaction. More recent contributions organize in a framework different kinds of co-opetitions (Garraffo, 2002), define a typology co-opetition and show how such a strategy may contribute to the value creation or construct a framework to measure intensity and diversity of co-opetition in order to provide some guidelines for building up co-opetitive relationships (Luo, 2007). The papers presented above, even those which explicitly study co-opetition issues, focus on analyzing inter-firms relationships within co-opetition frameworks. None follows the approach suggested by Brandenburger and Nalebuff (1996). They argue for the effectiveness of game theory as a tool to analyze co-opetition, but in spite of their suggestion, only restricted research areas have used game theory to model situations in which both competitive and cooperative behaviors arise. One of these is, surely, the stream of industrial organization which focuses on R&D cooperation in oligopoly: D'Aspremont and Jacquemin (D'Aspremont and Jacquemin. 1988), in their work consider the possibility of cooperation in certain activities among competing firms; specifically cooperation concerns R&D

activities. They compare three cases in presence of spillovers effects: total competition, cooperation in R&D and competition in the final market, total cooperation (collusion), showing that co-opetition and full cooperation do not always have negative impact on social welfare. In the same vein, cooperation in R&D among oligopolists and effects of such cooperation are analyzed in more recent papers (Suetens, 2005). If models of co-opetition are consolidated in the stream of industrial organization that focuses on R&D issues, game-theoretic approaches analyzing co-opetition strategies in other research areas are scattered and their use is far from being considered structured and consolidated. In marketing literature and in agricultural economics, there are some examples of game theoretic approaches, for instance, in analyzing effects and results of joint advertising or co-promotion in presence of competition among partners (Krishnamurthy, 2000; Bass et al., 2005; Isariyawongse et al., 2007). On the other hand, no work in operations and supply chain management seems to focus on co-opetition issues, except some papers (Gurnani et al. 2007) considering simultaneously common and conflicting interests among suppliers and buyers. However, even though in line with the broad definition of co-opetition proposed by Brandenburger and Nalebuff (1996), in these papers, co-opetition does not occur among real competitors, therefore the challenge of analyzing cooperation and competition simultaneously is still missing in operations and supply chain management and in other research areas as well.

This research overcomes the previous researches in the following issues:

- the co-opetion paradigm is efficiently applied to a capacity sharing issue in a network of indipendent plants geographically dispersed;
- a Multi Agent Architecture is properly developed in order to support the network infrastructure;
- game theory is utilised as a policy mechanism to coordinate the network;
- a negotiation approach is developed as a benchmark to compare game theoretical approach;
- a proper discrete event simulation environment, based on open source tool, is developed in order to test the proposed approaches in a dynamic environment.

The conducted experiments allow to highlight the added value of electronic co-opetitive network.

NETWORK GOVERNANCE PROPOSED

Relationships are the focus of substantial investments in time, money and effort and are the means by which knowledge as well as other strategically important resources are both accessed and created. Furthermore, relations are connected to other relations resulting in systems of interdependent relations, henceforth referred to as business networks. Coordination between as well as within relationships becomes a central managerial concern and the means by which the joint productivity of the value system comprising a network of connected business relationships is improved. However, when firms are be involved in co-opetition, a ‘‘coordinator system’’ (or ‘‘intermediate actor’’) is needed in order to plan, coordinate, monitor and appraise inter-organizational relationships. The ‘‘coordinator system’’ should use both formal mechanisms (such as an incentive system) and informal mechanisms (for instance, promoting inter-firm social events for communication and interactions) to adequately balance cooperation and competition. Therefore, the doctrine on competitive relationships has argued that C&C may be managed either through a strategy of separation between competitive and cooperative individuals/subunits or by establishing a ‘‘coordinator system’’ that combines these stimuli in order to maximize system gains from inter-firm co-opetition. Moreover, the emerging new organizational form, allowing for more co-ordination among quasi-independent actors, and, at the same time, more flexibility and autonomy in planning, production and distribution, needs to be properly managed applying right technologies. In the eyes of the authors, the most appropriate tools to model this kind of situation is given by Multi-Agent System (MAS) approach. Being the problem domain particularly complex, large and unpredictable, the only way it can reasonably be addressed is to develop a number of functionally specific and (nearly) modular components (agents) representing firms. This decomposition allows each agent to use the most appropriate paradigm for solving its particular problem. When interdependent problems arise, the agents in the network must coordinate with each other to ensure that interdependencies are properly managed. A MAS can be defined as a loosely coupled network of problem solvers that interact to solve problems that are beyond the individual capabilities or knowledge of each problem solver (Durfee and Lesser, 1989). The characteristics of MAS, and why we use it, are that:

- each agent has incomplete information or capabilities for solving the problem and, thus, has a limited viewpoint;
- there is no system global control;
- data are decentralized; and
- computation is asynchronous.

Sophisticated individual agent reasoning can increase MAS coherence because each individual agent can reason about non-local effects of local actions, from expectations of the behavior of others, or explain and possibly repair conflicts and harmful interactions. Indeed, as previously discussed, a distinguishing feature of a MAS is the fact that the decision making of the agents can be distributed. This means that there is no central controlling agent that decides what each agent must do at each time step, but each agent is to a certain extent responsible for its own decisions. The main advantages of such a decentralized approach over a centralized one are efficiency, due to the asynchronous computation, and robustness, in the sense that the functionality of the whole system does not rely on a single agent. In order for the agents to be able to take their actions in a distributed fashion, appropriate coordination mechanisms must be additionally developed. A typical situation where coordination is needed is among co-opetitive agents that form a network, and through this network they make joint plans, compete for resources and try to pursue common goals. Planning for a single agent is a process of constructing a sequence of actions considering only goals, capabilities, and environmental constraints. However, planning in a MAS environment also considers the constraints that the other agents' activities place on an agent's choice of actions and the constraints that an agent's commitments to others place on its own choice of actions. The development of protocols that are stable (non-manipulable) and individually rational for the agents is the subject of mechanism design. The approaches utilized for this last issue, in this chapter, are negotiation and cooperative game theory. Negotiation is seen as a method for coordination and conflict resolution. It has also been used as a metaphor for communication of plan changes, task allocation, or centralized resolution of constraint violations. The main characteristic of negotiation is the presence of some sort of conflict that must be resolved in a decentralized manner by self-interested agents under conditions of bounded rationality and incomplete information. When one does build negotiation and enforcement procedures explicitly into the model the results depend very strongly on the precise form of the procedures, on the order of making offers and counter-offers and so on. But problems of negotiation are usually more amorphous; it is difficult to pin down just what the procedures are. More fundamentally, there is a feeling that procedures are not really all that relevant; that it is the possibilities for coalition forming. Instead, cooperative game theory abstracts away altogether from procedures and concentrates on the possibilities for agreement. It deals with situations, where a group of players cooperate by coordinating their actions to obtain a joint profit. It is usually assumed that binding agreements between the players are the mean of the cooperation. In the following, we use both this coordination mechanisms to appreciate their weaknesses and strengths in a network co-opetitive circumstances.

THE AGENT-BASED NETWORK MODEL

Sophisticated individual agent reasoning can increase MAS network coherence because each individual agent can reason about non-local effects of local actions, form expectations of the behaviour of others, or explain and possibly repair conflicts and harmful interactions. Numerous works in Artificial Intelligence (hereafter AI) research try to formalize a logical axiomatization for rational agents. This axiomatization is accomplished by formalizing a model for agent's behaviour in terms of beliefs, desires, goals, and so on. An agent will be considered *rational* if it always selects an action that optimizes an appropriate performance measure, given what the agent knows so far. The performance measure is typically defined by the user (the designer of the agent) and reflects what the user expects from the agent in a specific task. For the purpose of this chapter, it will be considered a discrete set of time steps $t = 1,\ldots,n$, in each of which the agent must choose an action a_t from a finite set of available actions A. The complete history of action up to time t to an optimal action is called the *policy* of the agent. Obviously, when the agent takes an action, the "external world" changes as a result of this action. A transition model specifies how the world changes when an action is executed. If the current world state is s_t and the agent takes action a_t, the transition model maps a state-action pair $(s_t; a_t)$ to a single new state s_{t+1}. In classical AI, a goal for a particular task is a desired state of the world. Generally, an agent may hold preferences between any world states. A way to formalize the notion of state preferences is by assigning to each state s a real number $U(s)$ that is called the utility of state s for that particular agent. Formally, for two states s and s' holds $U(s) > U(s')$ if and only if the agent prefers state s to state s', and $U(s) = U(s')$ if and only if the agent is indifferent between s and s'. Intuitively, the utility of a state expresses the *desirability* of that state for the particular agent; the larger the utility of the state, the better the state is for that agent. Equipped with utilities, the question now is how an agent can efficiently use them for its decision making. Namely, what we need is a mechanism able to give the better, in terms of related utility function, *world state* for each involved agent. Specifically two coordination mechanisms are utilised in this chapter: the first is a negotiational one and the second is given by cooperative game theory. They not only differ for the theoretical approach, but for the exchanged information too. The common variables considered for the network formalization are: the market price of the *kth* product, the associated productive cost, related to the price by a mark-up strategy, the productive capacity of each plant and the quantity of each product required by the market. Specifically:

$price_p^k$ is the market price of *kth* product, for the generic *pth* plant;

$\cos t_p^k$ is the production cost of *kth* product, for the generic *pth* plant. It is a function of productive and managerial costs. It also takes into account the efficiency of the plant and its relative geographical dispersion. It is obtained with a mark-up strategy;

C_p^k is the productive capacity of *kth* product, for the generic *pth* plant;

R_p^k is the quantity of *kth* product required by the market, for the generic *pth* plant.

For both approaches, agents are identified and classified in overloaded $OG = \{1,\ldots,i\ldots,N\}$ and underloaded $UG = \{1,\ldots,j\ldots,M\}$. Afterwards each of them respectively compute the capacity it needs to produce a given product *k*, RC_i^k, or the one it can offer, OC_j^k, to other plants of the network. The only variable all agents take into account is the price to pay to obtain -or make over- their capacity.

COORDINATION MECHANISM

Negotiation is one of the most common approaches used as a coordination mechanism when the actors involved have conflicting goals. In particular, when the system is distributed the negotiation is the prevalent approach used. For all these reasons, it is an opportune benchmark to evaluate different coordination mechanism, as the game theoretic one proposed in this chapter. The motivation in finding a new approach lies in the following drawbacks that affect the performance of the negotiation process:

- **Function Definition:** The agents' strategies and the generative function typology for each role (creative or reactive offer) have to be defined and the output strongly depends on this choice;
- **Maximum Number of Rounds:** the performance strongly depends on the number of rounds;
- **Information Exchange:** For example, one agent can simple refuse the proposal or could indicate the terms to improve and so on;
- the negotiation ending criteria, that has to be defined.

Instead, the proposed game theory approach could be implemented in only one step and no strategies have to be designed (a cooperative approach is considered). Therefore, the main advantages are the following:

- the reduction of time to reach an agreement;
- the reduction of information exchange;
- the "intelligence" of the agents can be limited.

Negotiation

The agent architecture in here adopted is the following: each plant belonging to *OG* is represented by a *Capacity Offering Agent* (*COA*) who is in charge of negotiating the capacity with *RCAs* (i.e. *Requiring Capacity Agent*) representing the plants that require it, belonging to the *UG* set. Finally, there is a *Mediator Agent* (*MA*) who is in charge of allowing communication and coordination among *COA*s and *RCAs*.

The negotiation process is characterized by the following constraints (Negotiation constraints):

- the negotiation is a multi-lateral one and it involves one to many agents;
- the negotiation is an iterative process with a maximum number of rounds, r_{max} ; after that an agreement is reached or the negotiation fails;
- during each round (r) the OCA can submit a new counter-proposal (N) to the RCA while, at $r = r_{max}$, it can only accept (A), reject (R) or ask for last counter proposal. Obviously, the RCA answer at generic round r, can be referred as $(A \vee R \vee N)_r$;
- the agreement is reached only if the RCA accepts the OCA counter proposal at round $r < r_{max}$; in this case the agents sign an electronic contract; if there are multiple agreements, the first OCA that satisfies the RCA signs the agreement.

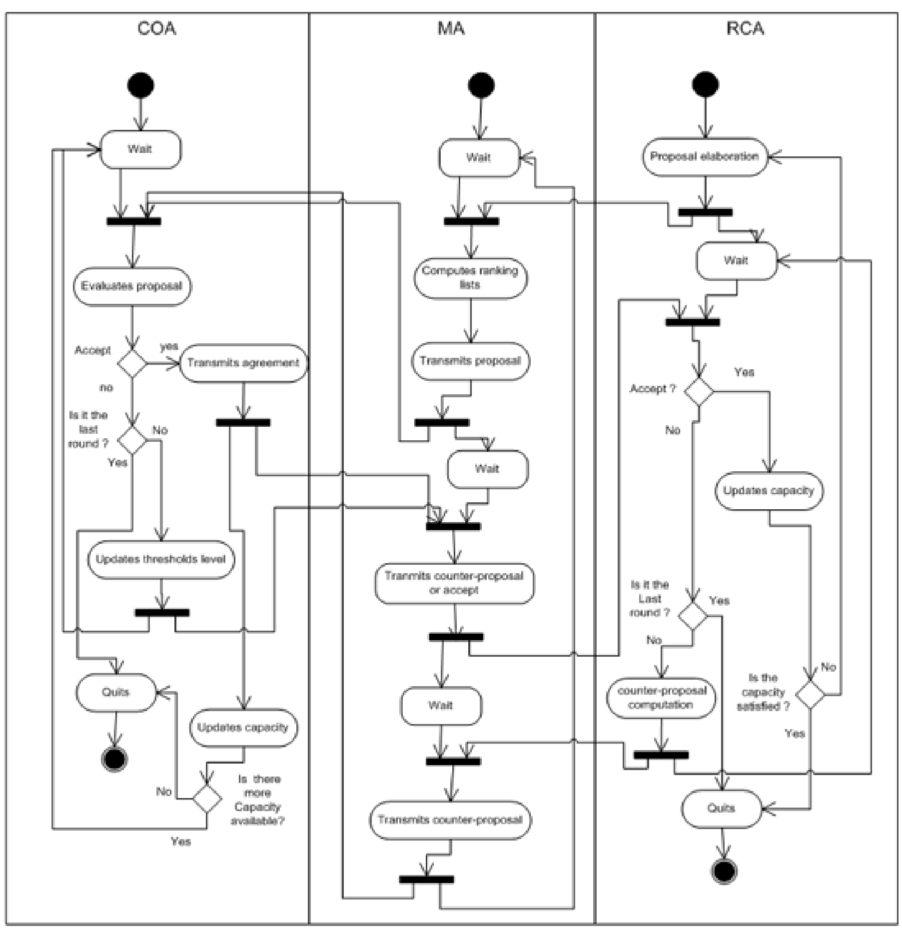
- the agents behavior is assumed to be rationale according to their utility functions;
- the RCA does not know COAs' utility functions and vice versa.

The UML activity diagram of Figure 1 shows the agents' interaction workflow. As the reader can notice three swim lines, corresponding to the above described agents, have been located in the diagram.

Specifically, for the *COA* the following activities can be highlighted:

- **Wait**: the agent is in its initial state of waiting for a proposal (from *RCA*);
- **Evaluates proposal:** the *COA* evaluates the proposal of the *RCA* in terms of required capacity and offered price. At the first round the *COA* communicates the amount of capacity it is willing to offer (the minimum value between the one requested by the *RCA* and its own unused capacity). Subsequently, the *COA* communicates to the *RCA* if it accepts or refuses the proposed price to exchange the promise amount of capacity. Then the *COA* evaluates the proposal of the *RCA* by a threshold function given by (1):

Figure 1. UML Activity Diagram



$$val_j^{k,r_1} = \left[price_j^k - (price_j^k - \cos t_j^k) \cdot \frac{r_1 - 1}{r_{\max} - 1} \right] \cdot M_{ij}^k \quad (1)$$

being

$$M_{ij}^k = \min(RC_i^k, OC_j^k) \quad (2)$$

Expression (1) computed by the COA is a threshold level. Starting from the market price value, during the negotiation the variable r_1 increments and the threshold level decreases until the value of production costs. In this case the generated profit is null.

At this point, the following expression is checked:

$$val_i^{k,r_1} \geq val_j^{k,r_1} \quad (3)$$

If (3) is verified, the *jth* plant supplies the requested capacity of the *ith* plant: they reach an agreement and each ones can update their available capacity.

- **Updates threshold level**: if the *COA* refuses the price submitted by the *RCA*, it updates the threshold level for the next round of negotiation (increases the value of *r* in expression (1)); if the algorithm reached the last round, the *COA* simply quits the negotiation.
- **Updates capacity**: if the negotiation reaches an agreement, the *COA* updates the capacity it owns. In case no more capacity resources are available it quits, otherwise it goes in its Wait state.

The *RCA* performs the following activities:

- **Proposal elaboration**: the *RCA* elaborates a proposal in terms of price and amount of capacity to acquire, and transmits this information to the *MA*. The submitted price is obtained by the following expression:

$$val_i^{k,r_1} = \left[price_i^k - (price_i^k - \cos t_i^k) \cdot \frac{r_{\max} - r_1}{r_{\max} - 1} \right] \cdot M_{ij}^k \quad (4)$$

Expression (4) computed by the RCA starts with a price equal to production costs: the generated profit is the same obtained when the products are produced by its own plant. During the negotiation the price is increased until the value given by the market price. In this case the generated profit is null.

- **Wait**: the *RCA* waits for counter-proposal by the *COAs*.
- **Counter-proposal computation**: if the *COA* refuses the proposal and the negotiation is still running, the *RCA* computes a new counter-proposal (increases the value of *r* in expression (4)). Otherwise (i.e. it is the last round of negotiation), the process ends with no agreement.
- **Updates capacity**: if the negotiation reaches an agreement, the *RCA* updates their information; if the acquired capacity is exactly the required one it quits, otherwise it computes a new proposal for the residual capacity it needs.

The *MA* performs the coordination activities between *COA* and *RCA*. In particular it:

- **Wait**: the *MA* is in its initial state of waiting for a proposal (from the *RCA*).
- **Computes raking list**: the *MA* computes a ranking list among all the plants that requested capacity. The way it does it is depending on several variables; in this research the ranking is done favoring first plants with high need of capacity, allow-

ing them to better satisfy the customers' requests.

- **Transmits proposal**: the *MA* transmits the proposal computed by *RCA*, at the ranking list of *COAs*.
- **Wait**: the *MA* is in state of waiting for the counter-proposal by all the *COAs*.
- **Transmits counter-proposal**: the *MA* transmits the counter-proposal of the *COA* to the *RCA*.

After having uploaded all the necessary values, the generic *ith* plant that does not reach the entire capacity it needs is again inserted in the ranking list. At this point the negotiation starts again. To avoid a deadlock, the agent that does not reach any agreement at the end of the negotiation process is removed by the ranking list.

Game Theory

In this coordination mechanism, all agents communicate each other the capacities they need (offer) and the price they are willing to pay (accept) for the exchange. Properly, the situation can be formalized like an *assignment game*. The outline is a quadruple $AG^t = (OG^t, UG^t, Val^t, O^t)$, where:

- OG^t and UG^t are the already defined vectors at generic time t;
- Val^t is a vector whose element, $val_j^{k,r}$, represents the monetary value (*val*) that *jth* plant, belonging to UG^t, assigns to its own residual capacity to sell it. This value is calculated by the (5):

$$val_j^{k,t} = \cos t_j^k \cdot M_{ij}^k \tag{5}$$

computed as the value under which the *jth* plant does not have any convenience to exchange capacity.

- O^t is a matrix whose generic element $O_{ij}^{\ t}$ is the price the plant $i \in OG^t$ offers for the capacity offered by each player $j \in UG^t$ using the Formula (6):

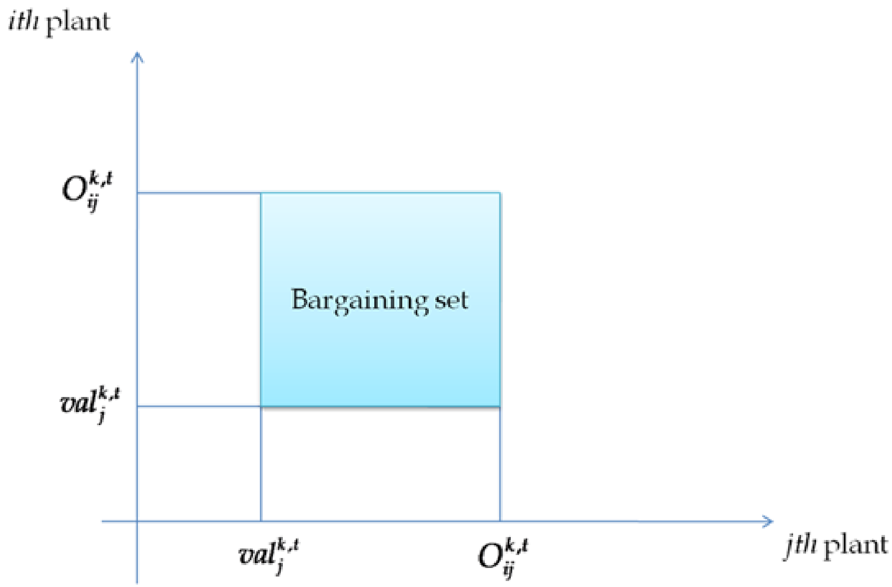
$$O_{ij}^{k,t} = price_i^k \cdot M_{ij}^k \tag{6}$$

computed as the maximum value above which the *ith* plant does not has any convenience to exchange capacity.

Generally speaking, a subset of players is called a coalition. A function v, assigning a value to every possible coalition S, with $v(\emptyset) = 0$, is called a *characteristic function*. The value $v(S)$ is interpreted as the maximum total profit that coalition S can obtain through cooperation. Assuming that the benefit of a coalition S can be transferred between the players of S, the situation is called a cooperative game with transferable utility (TU-game). In reality, the players are not primarily interested in benefits of a coalition but in their individual benefits that they make out of that coalition. A division is a payoff vector specifying for each player its benefit. A division has to be *efficient* and *individually rational*. Efficiency is achieved when some specific criterion is maximized and no allocation of utility could yield a higher value according to that criterion, while individual rationality means that every player gets a quantity of utility at least as much as what he could obtain by staying alone. The set of all individually rational and efficient divisions, the *core game*, is reported in the following Figure 2.

In words, the *core* is the set of imputations under which no coalition has a value greater than the sum of its members' payoffs. Therefore, no coalition has incentive to leave the grand coalition and receive a larger payoff. Specifically for the proposed model, a *transfer utility game* is associated to the quadruple AG^t; in that the whole players are given by $\Gamma^t = OG^t \cup UG^t$ and the characteristic function is defined, given that plants i and j make a coalition, as it follows:

Figure 2. The bargaining set



$$v(i,j) = h_{ij}^{\ t} = \begin{cases} O_{ij}^{k,t} - val_j^{k,t} & \text{if } \ O_{ij}^{k,t} - val_j^{k,t} > 0 \\ 0 & \text{if } \ O_{ij}^{k,t} - val_j^{k,t} \le 0 \end{cases} \tag{7}$$

The set of $h_{ij}^{\ t}$ defines the following assignment problem:

$$\max\left(\sum_{i=1}^{N}\sum_{j=1}^{M} h_{ij}^{\ t}\cdot z_{ij}\right), \tag{8}$$

$$z_{ij} = \begin{cases} 1, \text{if } i \text{ and } j \text{ make a coalition} \\ 0, \text{ otherwise} \end{cases} \tag{9}$$

subject to the following constraints:

$$\sum_{i=1}^{N} z_{ij} = 1; \ \sum_{j=1}^{M} z_{ij} = 1, \text{ if } N = M \tag{10a}$$

$$\sum_{i=1}^{N} z_{ij} = 1; \ \sum_{j=1}^{M} z_{ij} \le 1, \text{ if } N < M \tag{10b}$$

$$\sum_{i=1}^{N} z_{ij} \le 1; \ \sum_{j=1}^{M} z_{ij} = 1, \text{ if } N > M \tag{10c}$$

After having created the assignment among plants, it is necessary to consider the way to subdivide the generated surplus. In order to do this, the optimizing charge belonging to the *core game* is computed. According to Owen's theorem (Owen, 1975), a core allocation, in a linear assignment game, can be obtained starting from an optimal solution of the dual program:

$$\min\left(\sum_{i=1}^{N} y_i + \sum_{j=1}^{M} y_j\right), \tag{11}$$

subject to: $y_i + y_j \ge h_{ij}^{\ t}$ (12)

The residual capacity are then uploaded for each plant involved in the game and the algorithm starts again (t=t+1), formulating a new assignment game, until one of the two following condition -no more workload excess (13) or no more extra capacity (14)- is verified:

$$\sum_{i=1}^{N} RC_i^t = 0 \quad (13)$$

or

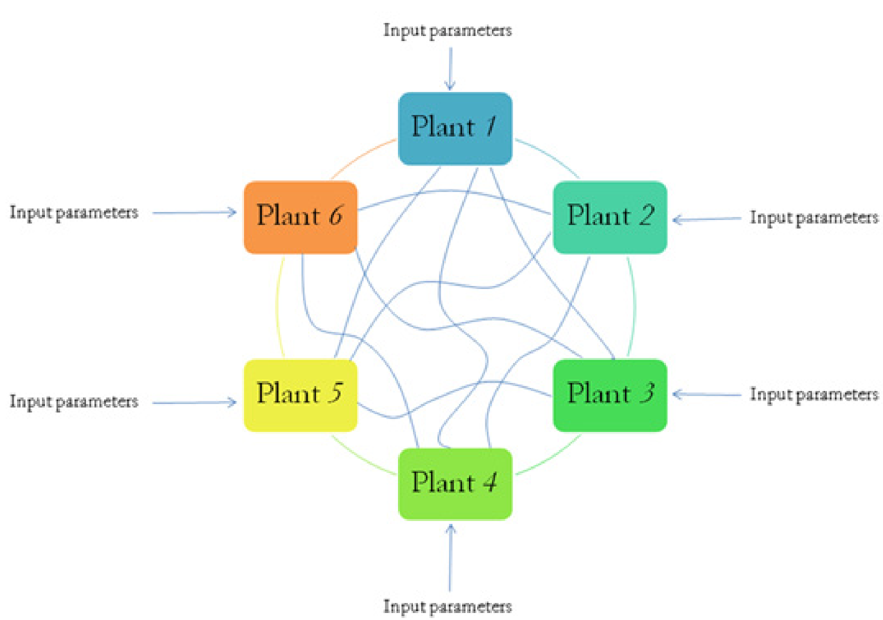
$$\sum_{j=1}^{M} OC_j^t = 0. \quad (14)$$

SIMULATION ENVIRONMENT

It has been developed a distributed simulation environment based on the proposed Multi Agent Architecture to simulate the electronic co-opetitive network represented in Figure 3.

It consists of a simulation environment, developed by using Java development kit package, able to test the functionality of the proposed approaches and to understand the related advantages and/or limits. The modeling formalism in here adopted is a collection of independent agents interacting via messages. This formalism is quite suitable for MAS development. In particular, each object represents an agent and the system evolves through a message sending engine managed by a discrete event scheduler. Specifically, the following objects have been developed: the *COA*, the *RCA*, the *MA* deeply described in the previous section-, the *Scheduler*, the *Model* and the *Statistical agents*. The *Scheduler* agent is in charge of the system evolution by managing the discrete events of the simulation engine. Differently, *Model* agent is in charge of the agents' interaction. Finally, the *Statistical* agent collects the output data -at the end of each run of simulation- and it generates reports and statistical analysis. A proper interface has been developed to connect the *MA* with a Lingo solver in order to solve the mathematical models related to the game theory approach. The simulation network reply 12 periods; in each of them the market price of *kth* product, for the generic *pth* plant $(price_p^k)$ and

Figure 3. The electronic co-opetitive network



the customers demand R_p^k have been randomly generated by using uniform distributions (see Table 2). These parameters are external to the plants and they only depend on the market conditions in which each plant operates. Differently, the "internal" parameters (C_p^k, plant capacity and $\cos t_p^k$, the production cost of *kth* product, for the generic *pth* plant) have been randomly generated at the beginning of each period. Because of the use of a statistical distribution for all parameters, each experiment class has been replicated in order to achieve a confidence degree equal to 95% and a 5% of confidence interval for each performance index (see Table 3). In order to test the proposed coordination strategies, under different network conditions, two levels of variability for each parameter have been considered: *low* (10% of variance) that leads to homogenous network (i.e. plants and markets with similar characteristics) and *high* (50% of variance) that leads to an inhomogeneous network (plants and markets have different characteristic). Thus, combining different levels of all four parameters, 16 simulation classes of experiments have been obtained (see the following Table 1).

The following performance measures have been considered to compare the proposed coordination strategies:

- the *total profit* (**TP**) reached by the whole network; it has been computed as the sum

Table 1. Experimental classes

Experiment classes	Mark-up $\cos t_p^k$	Plant capacity C_p^k	Customer demand R_p^k	Price $price_p^k$
1	L	L	L	L

16	H	H	H	L

Table 2. Input parameters (distribution of)

	low	*high*
Mark-up $(\cos t_p^k)$	Uniform[0.9,1)	Uniform[0.7,1)
Plant capacity (C_p^k)	N(100,10%)	N(100,50%)
Customers demand (R_p^k)	N(100,10%)	N(100,50%)
Price $(price_p^k)$	N(10,10%)	N(10,50%)

Table 3. Average results over all experimental classes

Performance	**no network *vs* Negotiation**	**negotiation *vs* game theory**
TP	17.02%	14.89%
TUD	-44.62%	11.29%
TUC	-43.87%	10.56%
PDI	-55.78%	-61.59%
NAL	-	-31.18%
DAL	-	-85.28%
TV	-	47.09%
DOT	-	-94.50%

of each single profit generated by all the plants of the network;

- the *total unsatisfied demand* (**TUD**): it is the difference existing between the quantity of products required by the market and the one the network has been able to satisfy. It could be considered as a customer performance;
- the *total unutilised capacity* (**TUC**): it is the difference existing between the whole capacity of the network and the unallocated capacity;
- the *profit distribution index* (**PDI**): this value computes the capability of the proposed coordination mechanisms to distribute the whole profit among the plants of the network. To compute it, first is necessary to evaluate the average profit of the network as reported in (15):

$$average\ profit = \frac{1}{P}\sum_{P=1}^{P} profit_p \tag{15}$$

being P the number of plants and $profit_p$ the generic profit reached by the *pth* plant. Then, the index is calculated as:

$$PDI = \sum_{p=1}^{P} \frac{\left|profit_p - average\ profit\right|}{average\ profit} \tag{16}$$

- the *number of activated links* (**NAL**) among plants. This performance is an index explaining how much could be complicated the logistic management of the network;
- the *transactions value* (**TV**). It is the quantity of money exchanged among plants, depending on the particular coordination mechanism.
- the distribution of the activated links (**DAL**). This index point out if some preferential links is established. The performance index is computed as it follows. First we compute the number of average links as reported in (17):

$$average\ links = \frac{1}{P \cdot \frac{1}{2}(P-1)} \sum_{p=1}^{P}\sum_{w>p}^{P} link_{wp} \tag{17}$$

being $P \cdot \frac{1}{2}(P-1)$ the total amount of links that can be potentially activated among P plants. The variable $link_{wp}$ is a binary one. It is equal to the unit when the link is activated, otherwise it is null. Then we compute the unbalance index as (18):

$$DAL = \sum_{p=1}^{P} \sum_{w>p}^{P} \frac{\left| link_{wp} - average\, links \right|}{average\, links} \tag{18}$$

The distribution of transactions among plants (**DOT**). This index emphasizes the evaluation of preferential links by considering the amount of exchanged money. The performance index is computed evaluating (19):

$$average\, transactions = \frac{1}{P \cdot \frac{1}{2}(P-1)} \sum_{p=1}^{P} \sum_{w>p}^{P} transactions_{wp} \tag{19}$$

being $transactions_{wp}$ the amount of money exchanged between the *wth* and *pth* plants. Then the index is computed as (20):

$$DOT = \sum_{w=1}^{P} \sum_{w>p}^{P} \frac{\left| transaction_{wp} - average\, transactions \right|}{average\, transactions} \tag{20}$$

RESULTS

All the simulations have been conducted with a network of six plants. Each index –except the mark-up that comes up from an uniform distribution- is considered randomly drawn from a normal distributions *N(μ;σ)* whose parameters are reported in Table 2 (*low* and *high* are referred to the standard deviations size):

The difference among the standard deviations of the statistical input is done to easily highlight the difference between the coordination approaches in both homogenous (*low level*) and inhomogeneous (*high level*) network. The simulation results (the average over the all experimental classes) have been reported in Table 3. Specifically: in the first column the performance indexes are reported using the notation described in the previous paragraph; the second column reports the percentage difference between results obtained in case of no relations among plants and the one in which the network is coordinated by using a negotiation approach. Last column shows the dissimilarity obtained comparing the results coming from negotiation and game theory. The considered performances have been obtained as average values over all the experimental classes.

From the analysis of the previous results, the following considerations can be summarised:

- coordination among plants is a real added value both for plants belonging to the network and for customers. Indeed, comparing the performances with the case in which no relations exist among plants, **TP** increases and, at the same time, **TUC** decreases;
- the negotiation approach leads to a better performances in terms of **TUD** and **TUC**;
- game theory coordination leads to better performance of **TP** reached by the network;
- game theory reduces the number of activated links (**NAL**): that means that this coordination approach simplifies the logistic management among plants involved in the network. At the same time, the high value of TV highlight that, in spite of this reduction, this coordination mechanism increases the amount of each single transaction;
- Considering the unbalanced indexes, **PDI** and **DAL**, as the reader can notice, game theory outperforms the negotiation mechanism: that means that there's a better distribution of the added value of the network and a simpler logistic management.

More relevant results over all the experimental classes are graphically showed in the following Figures 4, 5 and 6.

Figure 4. Profit distribution over 16 experimental classes

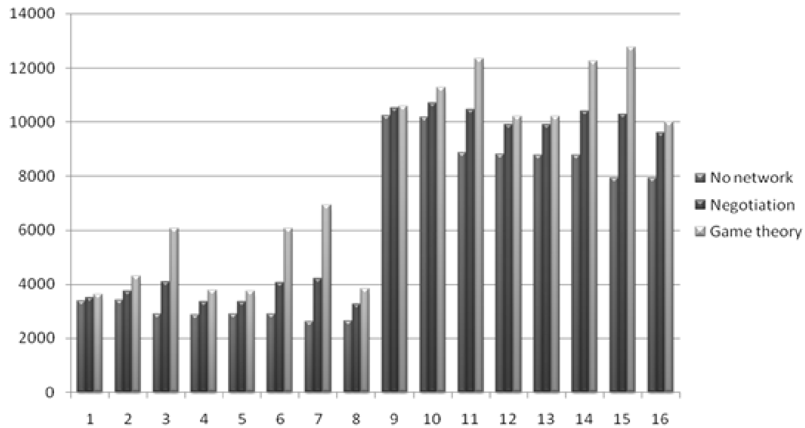

Figure 5. Unsatisfied demand (TUD) over 16 experimental classes

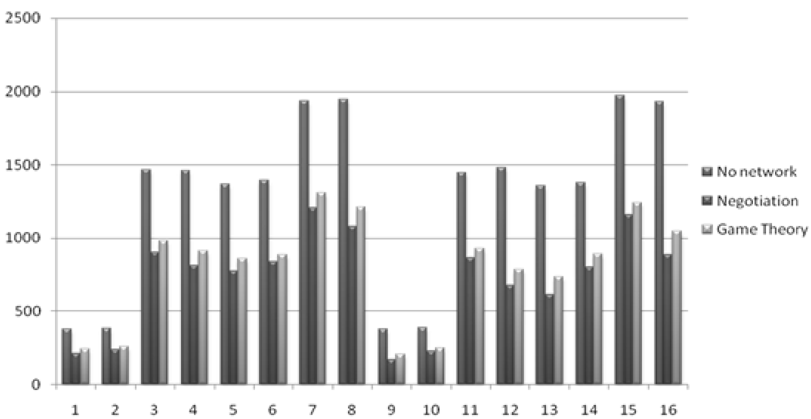

Figure 6. Transactions distribution (DOT) over 16 experimental classes

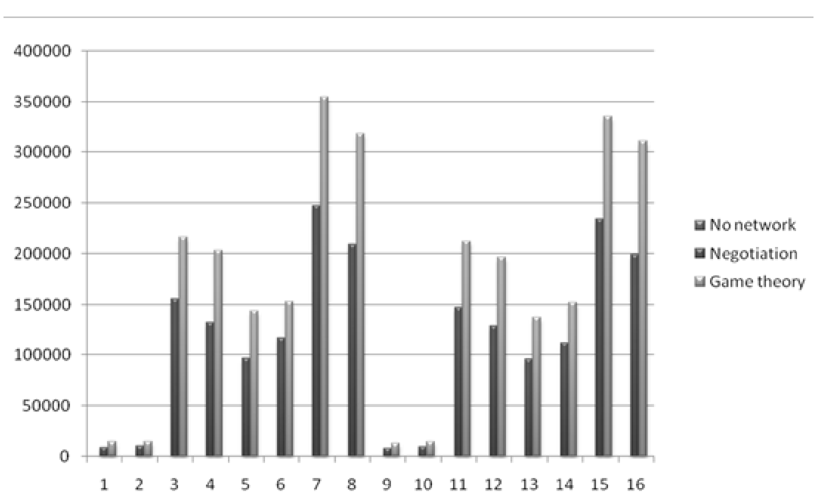

Figure 4 shows the amount of **TP**-reached by the network- for each experiment. Differences among configurations become relevant in the following classes: 3,6,7,11,14 and 15. Being the mark-up variability low (in 3,6 and 7) and high (in 11,14 and 15), it is possible assert that the highlighted differences between negotiation and game theory are not affected by the variability of this parameter. Moreover, they have a comparable reaction when the high level variability of the price is combined with a high variability of the demand (see classes 3 and 11) or of the capacity (see classes 6 and 14), or both the two (see classes 7 and 15).

Figure 5 shows the **TUD** performance of the network, for each experiment class. **TUD** is very low for classes with low variability of input parameters (see classes 1,2,3 and 4). In other cases, the coordination approaches lead to comparable values of this performance, with a little bit minor value for the negotiation approach.

Figure 6 shows the **DOT** performance of the network. For experimental classes with low variance of input parameters (see 1,2, 9 and 10) the amount of transactions is very low. For all the other, the value of transactions obtained using game theory is always greater than in the negotiation case.

SUMMARY, CONCLUSION AND FUTURE DEVELOPMENT

The chapter deals with the real added value in an electronic co-opetitive network of plants that can exchange productive capacity among them. Results of this research can be located at two levels. Concerning the specific plant coordination problem here addressed, the following conclusion can be drawn:

- different coordination strategies lead to a different performances for the networked enterprises; therefore the coordination strategy play a fundamental role for the goal the network would pursue;
- the proposed negotiation mechanism leads to a better performance for the customers: the unsatisfied demand is very low. From the network point of view, the profit is minor than in the game theory case and the distribution among plants is less homogeneous. Moreover, the negotiation approach increases the number of activated links with a minor amount of individual monetary transaction. This characteristics leads to make more difficult the management of the network from the logistic point of view. Finally, the negotiation approach implies the creation of preferential links that could marginalize some plants.
- The proposed game theory approach leads to better performances, from the networked plants point of view. In particular, this approach outperforms the negotiation in terms of generated total profit, uniformity of profit distribution and homogeneity of monetary transactions concerning the activated links. The logistics problem is simpler than in the previous case, because game theory creates minor links with higher individual monetary exchange.

At strategic level, this research shows that:

- Multi Agent System is a suitable approach to implement a distributed architecture for the capacity exchange issue that often characterize electronic co-opetitive network of enterprises;
- Discrete event simulation is a powerful tool to test coordination strategies and highlight the real added value of these approaches in an electronic co-opetitive network. This tool reduces the risk related to the ICT investment and agent based technology. Moreover it can encourage enterprises to

adopt the "stay together" approaches for real business applications.

Obviously the network is not a permanent fixture, but is something that is either being formed or might change. From this point of view, and generally speaking, the allocation of value at a given network can and should depend on the value that might accrue to alternative potential networks. In particular, evaluating the contribution to value of a given link depends on the contribution of that link to various networks, and perhaps more importantly, which to what extent other links might serve as a substitute. To understand why this issue arises it is important to recognize that larger networks might have higher costs associated with them than some smaller networks. For instance, the value generated by the complete network might be much less than the value generated by some sub-network. This means that generally, the most efficient network (in a value maximizing sense) might not be the complete network. This introduces some important considerations in the allocation of value to consider in future development of this work.

Chapter 63
Evaluation of Remote Interface Component Alternatives for Teaching Tele-Robotic Operation

ABSTRACT

The Internet developments as well as the increase in PCs' capabilities and bandwidth capacity have made remote learning through the internet a convenient and practical learning preference, leading to a variety of new learning interfaces and methods.

This chapter discusses a remote learning study conducted at the Computer-Integrated-Manufacturing (CIM) Laboratory in Tel-Aviv University. The goal is to provide remote end-users with an interface that enables them to teleoperate a robotic arm in conditions as close as possible to hands-on operation in the laboratory. This study evaluates the contribution of different interface components to the overall performance and the learning ability of potential end-users. Based on predefined experimental tasks, the study compares alternative interface designs for teleoperation. The three performance measures of the robot operation task are (1) the number of steps that are required to complete the given task, (2) the number of errors during the execution stage, and (3) the improvement rate of users. Guidelines for a better design of remote learning interfaces in robotics are provided based on the experimental results.

DOI: 10.4018/978-1-4666-1945-6.ch063

INTRODUCTION

This chapter focuses on the design of an interface for remote learning of robotics operations. The interface design, which is supported by technical guidelines, is general and applicable for a wide variety tools for teaching tele-robotic operation. It differs from previous research in the field, which often focuses on a specific applicative interface.

The proposed interface includes aspects of remote manipulation of robots with aspects of remote learning. The motivation for such integration is to enable users to practice not only the remote activation of a robotic cell but also the availability of learning, redesigning and optimizing the work plan in the cell. The chapter starts by considering three possible design schemes: a "Home-based," a "Lab-based" and a "Website-based." It identifies different interface components that support a remote telerobotic-learning. Then it measures and evaluates the interactions among these components as well as their effects and usability within a proposed remote learning interface. Such an evaluation is conducted by running a set of experiments, requiring the users to execute specific robotic tasks from a remote location while examining their performance over various interface settings. The performance of the remote users is also compared with hands-on operation, which is used as a benchmark setting.

The evaluation tool of the web-based interface for the telerobotic learning is called the *Test-Oriented-Interface* (TOI). As the chapter unfolds, elements within this interface are evaluated, focusing on their contribution to the remote learning assignments. A full set of guidelines for designing a remote learning interface is extracted from the evaluation of the TOI. The objective of these guidelines is to maximize the benefits obtained from the interface for the users (e.g., students) as well as for the hosting institute (e.g., university). Finally, we present how the new web-interface for remote learning of robotic operations is implemented and fully operated in the CIM laboratory.

BACKGROUND

Remote Learning Interfaces for Robotics

Remote control and manipulation of robots has been used to perform predetermined tasks, often in a hostile, unsafe, inaccessible or remote environment (Siegwart and Saucy, 1999 and Bukchin et al., 2002). NASA, for example, keeps track and provides free access to active telerobotic systems through the NASA Telerobotics Web-page.

Architecture of a WWW-based system for a remote telerobotic operation was presented in 1999 by Belousov et al. (1999). Their system was mainly oriented for reliability and efficiency and was based on a 3D Java visualization tool that overcame bandwidth restrictions that existed at the time. Belousov et al. (2001) presented a similar architecture with an addition of a tool that supports the remote programming of the robot.

Among many variations of teleoperation systems, one can mention Wang and Liu (2004) with a teleoperation paradigm for Human-Robot interaction, Hu et al. 2001)) with a system for remote controlling a robot with visual feedbacks over a simulated map, Kofman et al. (2005) with a hand-arm-gesture method for teleoperation, Hu et al. (2001) with a pioneering work networked telerobotic systems for tele-training, and Siegwart and Saucy (1999) with a modular framework for mobile robots on the web and many other applications.

New integration protocols were used to combine 3D simulation tools with remote control and manipulation interfaces, enabling the management of complicated tasks in flexible robotic cells. Candelas et al. (2005) present a system focused on the training of kinematics and trajectory design of robotic arms. Their work was among the first to use a learning platform with full interactivity in the teleoperation process. Michau et al. (2001) present in detail the expected benefits of web-based learning for engineers. They express the need for remote learning tools within virtual laboratories, stating that although simulations cannot replace real experiments, remote laboratories provide new ways for practicing hands-on-experiments (Gravier et al., 2008).

Integrating simulations within real implementation activities is considered a necessity in contemporary engineering education (Khan and Al-Kahtani, 2002; Fernandes and Martins, 2001). An example for such integration is found in Calkin et al. (1998), with visualization, simulation and control of a robotic system relying on internet technology. This virtual learning mechanism was later referred to by Goldstain et al. (2007) as the "Home-Based" design scheme. Similarly, Puente et al. (2000) use simulations as a learning tool when suggesting general system architecture. Yang et al. (2004) introduce an internet-based teleoperation scheme of a robot manipulator for educational purpose. Their system integrates a virtual off-line simulation with an actual teleoperation module, including a visual feedback. In their conclusion they suggest the development of a more general control system that later was presented in Goldstain et al. (2007) as the "Web-based" design scheme.

Enrique Sucar et al. (2005) consider virtual modules as a primary tool in teaching robotics. In their work, a virtual laboratory based on simulation was developed and assessed without evaluating the required interface components as done in this chapter. A modern, fully developed interface for remote learning and programming of a robot arm was also presented by Marin et al. (2005).

Remote Interfaces Design

Siegwart and Saucy (1999) describe the basic specifications and major difficulties when designing an interactive platform for remote learning of robotics systems. Their suggested modules include a video feedback module, a robot guidance module, and a virtual representation module.

Enabling a user to learn and optimize a work plan in addition to remotely operating given robotic tasks requires more than basic manipulation tools for remote control (Kahn et al., 2002). A three-dimensional (3D) simulation tool is one of the most popular tools when dealing with "on-site" learning (Candelas et al., 2005; Enrique Sucar et al., 2005). Candelas et al.(2005), Tzafestas et al. (2006), Marin et al. (2005), and others offered different variations of both off-line and online 3D simulation tools. More advanced simulation tools, like the one used in Goldstain et al. (2007), provide another important feature for the learning process, which is the ability to create and record a program for the simulated system and then implement it to run the physical system itself.

The main feedback for a remote operation of a robotic cell is often considered to be visual feedback (Hu et al., 2001; Eliav et al., 2005; Aktan et al., 1996). Unlike local settings, the remote setting often relies on various visual sensors to provide visual feedback (Bukchin et al., 2002; Bochiccio and Longo, 2009). In virtual laboratories in particular, this feedback is gained through a 3D model, as implemented in Belousov et al. (1999) and Belousov et al. (2001) using Java. Another, more advanced feedback for robotics is presented in Tzafestas et al. (2006) and Goldstain et al. (2007). These works consider a positional feedback, providing the user with valuable information regarding the positioning of each axis in the robotic arm. This type of feedback can be used to reconstruct the robot's movement or even to completely re-evaluate the robotic cell layout.

Adams (2002) suggests critical considerations for human-robot interface development. His concepts of User Centered Design and Situation Awareness guided the design of the proposed framework. Goldstain et al. (2007) presented a methodology, which we used for the design of experiments presented in the next section. Their suggested methodology is based on the framework presented by Yang et al. (2004) and by Chen et al.(2001), preaching for the use of virtual laboratories as an essential tool for learning, prior to the execution of "on hand" experiments. This chapter follows the above mentioned guidelines and suggestions. It focuses on the analysis of the main components in an interface for remote-learning of robotic operations and provides guidelines for an efficient design of such tool.

Integrating Remote-Learning and Teleoperation

The main challenge addressed in this chapter is how to enable multiple remote users (e.g. students) to simultaneously design and optimize the operation of a robotic cell. The users are required to learn, mainly through a "trial-and-error" process, the appropriate way to operate the robotic cell previous to its online activation. This supports cognitive (or mental) learning, as opposed to a motoric (or mechanical) learning, which is required when operating a robotic cell on site (Bukchin et al., 2002; Calkin et al., 1998; Cooper et al., 2002).

There are several alternative approaches that can be considered for remote teaching of robotic operation (Bukchin et al., 2002; Calkin et al., 1998; Tzafestas et al., 2006). The first that we considered is the *Lab-based* approach which uses designated software packages, i.e. Virtual VNC, to enable a full remote control of the robotic cell's controller PC, while receiving all feedbacks remotely. The Lab-based approach allows users to operate and react as if they are physically located in the laboratory. On the other hand, it requires a considerably broad bandwidth from both the client's and the server's computers. It also lacks the possibility of administrating several users simultaneously, and bares with it many security IT problems.

Second to be considered is a *Home-based* approach. This approach provides the users with a simulation program and an accurate scaled 3D model file of a cell's layout, enabling them to initiate the learning at home without being dependent on the robot's availability at the lab. In this approach the users are required to simulate and optimize the entire robotic operations on their home computer and then send the final programmed tasks to the robot's controller PC to be executed while they can observe the execution through a video feed (Calkin et al., 1998). The Home-Based approach, although safer and cheaper in terms of bandwidth demand, lacks the interactivity part that is so essential to support a real "trial-and-error" learning process.

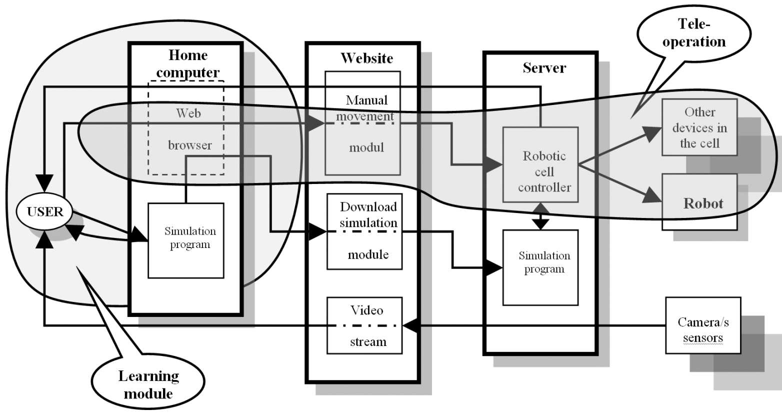
Finally, a third approach is investigated by combining the above-mentioned two approaches. It is named the *Web-based* approach and relies on a specially-designed website that is integrated with a 3D simulation program installed on the user's computer. Goldstain et al (2007) claim that this approach has several significant advantages: it is safer, it enables future developments for other types of lab equipment, it supports administrating multiple users, it controls the system's usage, and it keeps the laboratory's computer invisible to the end users, thus, reducing the associated safety problems (Candelas et al., 2005; Chiculita and Frangu, 2002). The methodology used in the web-based design relies on client-server interactions (Chen et al., 1999; Chiculita and Frangu, 2002; Saliah et al., 2000). Such interactivity was found to be essential to provide the users with the necessary information to refine their actions to achieve a more accurate performance of the required task. A survey conducted among 60 users of a beta version of this website and presented in Goldstain et al. (2007) indicated a high level of user satisfaction.

METHODOLOGY

In this section a conceptual methodology is proposed to integrate a remote learning process with teleoperation, based on the web-based approach presented above. The integration of remote learning and teleoperation within the web-based approach is presented in Figure 1.

The web-based solution includes the following modules: (1) a user-client PC running a simulation

Figure 1. "Web-based" design scheme



program and a web browser; (2) a website containing video capabilities, manual movement controls and files-upload protocol; and (3) a web server running the robotic cell controller as well as the simulation program. These combined modules support both the learning through "trial-and-error" and a teleoperation mechanism.

Basic Modules of Remote Learning of Robotic Operations

Enabling a user to learn, operate and optimize given robotic tasks requires more than basic manipulation interface for remote control. For example, a 3D simulation tool is one of the most popular tools for dealing with hands-on learning (Candelas et al., 2005; Enrique Sucar et al., 2005). The simulation provides the users with the ability to analyze their performance and to redesign the process up to the required level. Advanced simulation tools provide another important feature to the learning process–namely, the ability to create and record a robotic program and then apply it to actually run the physical system. When using a recorded program, the users can easily implement changes to the system layout or to the sequence of performed actions by using historical knowledge. Both the simulation and the optimization processes are based on the interaction between the human operator and the manipulation interface of the robot itself. A feedback from the system allows the users to change and better design their program, thus supporting the process and improving learning skills and abilities.

The basic feedback for a remote operation of a robotic cell is the visual feedback (Eliav et al., 2005; Aktan et al., 1996; Hu et al., 2001). In remote systems, several visual sensors can be used to provide such feedback, often a closed-loop TV system or a streaming video. The latter provides the operator with a somewhat rough knowledge regarding the work cell's layout and the system state following each phase of the operation; however, it is rarely accurate enough to enable fine tuning of the robotic arm tasks, as it provides the users with a two dimensional picture of a three dimensional reality. When considering the visual feedback module, the main objective is to obtain a clear online feed from a few different view angles of the work cell. An issue that remains unsolved is the visual feedback gap between the 3D reality vs. a 2D image (Doulgeri. and Matiakis, 2006; Yang et al., 2004). It is found that it is almost impossible to operate a robotic task depending only on a single video feed that shows the cell from a single angle.

While investigating the learning process of robotic cells operation, it is found that the 3D view of the cell is a vital ingredient for the success of the learning process. A common way for teaching robotic operation is through 3D simulation programs, enabling the users to learn and experience with a variety of simulated work cells, some of which differ from the existing work cells in the lab. The next step was to find a way to combine the capabilities offered by the simulation program with basic teleoperation tools, creating not only a remote control interface but an actual remote learning mechanism.

Goldstain et al. (2007) present a schematic integration between Remote-Learning and teleoperation, significantly improving the learning process of the users and yielding an efficient use of equipment and resources. This integration enables the user to participate in a remote learning process on top of being able to operate a robotic system. The added value of such integration is in the ability to apply it to the available equipment and to different lab experiments (Michau et al., 2001; Ammari and Ben-Hadj, 2006).

The Compared Interfaces

Two different design platforms were used throughout the experiment: an INTERNET (Web-based) platform based on our Test Oriented Interface (TOI), as detailed later in the chapter, and a (wired) Robocell platform, which was operated either remotely or locally for comparison purposes. More specifically, four different interfaces were tested for the evaluation of teleoperation tasks:

- **INTERNET:** a Test Oriented Interface operated remotely (based on our methodology)
- **LRC:** a Robocell interface operated locally
- **VRC:** a Robocell interface operated remotely with Virtual Real-Time Presentation (VRTP)
- **RRC:** a Robocell interface operated remotely without VRTP

It is important to note that although the LRC is included within the compared interfaces, it is not a remote interface setting. This setting represents the everyday hands-on execution of robot operation locally in the laboratory and is used here as a benchmark to compare to the other settings, enabling evaluation of their proximity to hands-on operation performance.

The compared interfaces are described in the next sections.

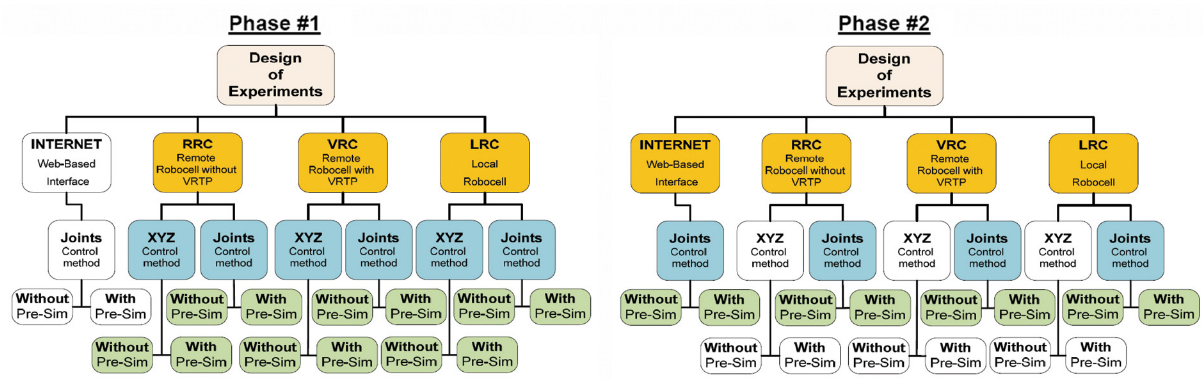
The Design of Experiments

As not all of the factors were technically able to be integrated into all the emulated interfaces, a partial factorial design was generated to include the available combinations of factors that could be tested. The partial design is motivated by practical and methodological considerations, as each interface was introduced with slight variations of the components for practical reasons. To avoid partial designs, the evaluation tests were divided into two congruent phases, each phase was evaluated as a full factorial model on its own, and together they covered all the design variations that were technically available.

Figure 2 describes the experimental tree for the design phases. The transparent branches represent the excluded parts of the experiment in that phase (Phase 1 lacks the Axis-XYZ control parameter and, in Phase 2, we aim at maintaining a balanced hierarchical experiment that includes the internet interface).

The first evaluation phase examines (1) the effect of the control method on the execution and the learning process and (2) the contribution of the VRTP module (integrated in the VRC interface). The second evaluation phase examines (1) the difference between the different RoboCell interfaces (LRC, RRC and VRC) and the designed remote Internet interface and (2) the contribution of the preliminary simulation tool in all the remote interfaces (Internet, RRC, VRC).

Figure 2. The two evaluation phases of the experiment



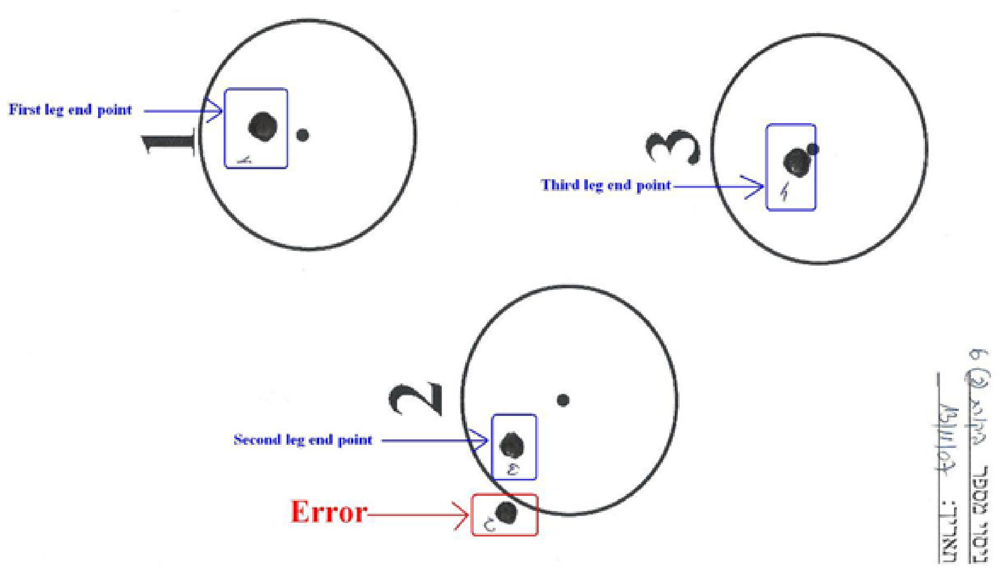
THE EXPERIMENT: INTERFACE COMPONENTS ANALYSIS

This section describes the experimental study. The goal of the experiment is to evaluate the effect of different interface components on the usability of the remote learning interface. This section presents the task and the performance measures and main design factors.

The Experimental Task

The designed task for the experiment was a simple "Pick-and-Place" task. It was adjusted to suit a remote operated system in the following way: the users were instructed to manipulate a robotic arm with a marker attached to its gripper in a way they will reach and mark a dot within three pre-placed circles. Figure 3 shows an actual result page of an experiment, describing the three pre-placed circles and the actual marked points.

Figure 3. An example of a completed worksheet



As the learning goal of the task is an efficient operation of the robot while using a remote interface, the users were instructed to try to perform the task in as an efficient way as possible, i.e. in the least number of movements possible, and with as few as possible markings outside the designated circles. The circles were placed in the exact same location in all different variations of the experiment. The starting point was defined as the "homing point" of the robotic arm.

Three performance measures were considered in the experiments, as discussed next.

Number of Movements Required to Complete a Leg

In the experiment, a user step (movement) was defined as a single press on one of the controller's buttons. In the examined designs, the movement was recorded as long as the button was pressed and was stopped when the button was released. Obviously, several movements were required to move the robot's arm from point to point. Every single movement was recorded on a data-recording sheet and was associated with one of the legs. A leg was defined as the period between reaching and marking each of the circles. Thus, the first leg includes all movements recorded from the homing point until marking the first circle; the second leg was defined between marking the first circle and the second circle, and so on.

Such steps assessed the overall performance of an operator and provided quantitative input regarding the improvement in performance during the whole task execution.

Number of Errors Recorded

Errors were defined as a marking made outside of the designated circles (for example, see the indicated error in Figure 3). Every mark on the worksheet was numbered and recorded, and the number of markings outside the circles was later analyzed. The number of errors provided information regarding the complexity of the task or the settings and helped to evaluate the performance of various interface designs.

Improvement Measure (Learning Curve)

An improvement measure was evaluated by using the number of movements measured in the legs. The learning rate (termed for simplicity reasons) was defined as follows:

$$LR = (N_{total} - N_{H_{to}1}) / N_{total}$$

where N_{total} is the total number of movements and $N_{H_{to}1}$ is the number of movements in the first leg (from the homing point to first circle). Dividing the number of movements required for legs two and three by the number of total required movements was used as an approximate criterion to assess the improvement and the learning pace during the execution. The lower this ratio was, the larger the part of the total movements was required by the first leg. In such a case, the subsequent two legs required significantly fewer movements, and therefore, one could conclude that the improvement from the first leg to the next ones was greater.

Evaluated Design Factors

Three components were defined as main design factors and evaluated through a set of experiments. The design factors were (i) use of a simulation tool prior to the task's execution; (ii) use of VRTP during the robotic task's execution; and (iii) the type of control method for the robotic arm. Each of these factors is presented next.

Preliminary Simulation

The used 3-D simulation tool is based on the Robocell© software cell-setup module. This tool allows the operator to experience and learn in advance (i.e., in an off-line mode) the robotic system and its environment. It provides the operator with a virtual working cell, similar to the one in the actual site, viewable from all directions and angles. It integrates the SCORBASE© robotic control software with interactive three-dimensional solid modeling simulation software in that it replicates the actual dimensions and functions of the real equipment, providing users with a fully simulated robotic learning environment and a graphic tracking view of the robot's operations.

This preliminary simulation tool was available in all the considered interfaces. It was expected to improve the execution of the task and to shorten the learning period required during the online operation of the robotic cell. For analysis purposes, the different interface settings were examined both with and without the use of preliminary simulation. To support a transfer of the practice from the simulation to the real operation, the preliminary simulation manual control modul was designed as similar as possible to the tele-robotic control interfaces.

Virtual Real-Time Presentation (VRTP)

In certain settings, the 3-D simulation tool can be operated not only in advance but also during the online execution of a task. When operated in an online mode, we refer to it as VRTP. The VRTP tool provides the operator with an extra view of the working area, including the possibility of changing the viewpoint in direction and orientation during the actual execution.

While this tool seems unnecessary when operating the robotic cell locally via eye contact, it may provide valuable information for a remote operator. The reason is that the remote operator receives 3D information on a 2D media channel, which may cause a misinterpretation or misperception of the environment. Unfortunately, due to its technical complexity, this tool is not integrated in most of the currently used remote learning interfaces. For this reason, it was not integrated into the TOI. Instead, for analyzing the contribution of this tool, we considered two different remote designs: one with and one without the VRTP tool, and called them the VRC and RRC interfaces, respectively.

Control Method of the Robotic Arm

Two common methods are available for controlling a robotic arm: the Axis-XYZ control method and the Joints control method.

The Axis-XYZ control method allows the operator to move the robotic arm along the axis of an imaginary Cartesian workspace. The linear movement is intuitive, but it requires greater computing resources as the robot's controller needs to calculate the exact direction and force for each joint motor and operate multiple motors simultaneously to achieve a linear movement. For these reasons, it was technically impossible to implement the required matrix into the TOI, and therefore, the Axis-XYZ control method was tested only in the LRC, RRC and VRC interfaces.

The Joints control method, although not as intuitive, is technically and mechanically much simpler. This control method is based on activating a single joint motor at a time, resulting in a nonlinear movement (in the case of a polaric joint). Consequently, it is more complicated for the inexperienced operator to control a robot using this method.

EXPERIMENTAL SETTINGS AND APPARATUS

Using the "web-based" design scheme, a dedicated website interface was designed to represent the Internet interface in the experiments. The website combined a remote controlling interface for the robot's arm along with a module for simulating and optimizing the operation, recording it, and downloading a pre-tested program to the robot's controller.

Physical Layout

A dedicated remote workstation was assembled to support the experiments. The workstation was equipped with two screens to standardize the visual feedback size and its position for all the experimented settings. The first screen was used for visual feedback only, displaying two live video feeds of the robotic cell: an overall view - an isometric view of the cell, and a zoom-in top-view of the work area. The second screen was used to support the actual teleoperation of the robotic cell. Both the Robocell software and an Internet browser were installed in the work station and alternately operated, depending on the experimental stage. Another workstation was used in the local site to host the servers of the website and the live video feeds.

Four interface versions were examined, dictating four slightly different settings for the local and the remote stations, as explained next.

Local Robocell (LRC) Interface

The local Robocell was used as a control group in the experiments. The LRC was executed right next to the robotic cell itself. In these experiments, the Robocell software was executed without adding any visual feedback. Since the experiments took place within eye-contact distance of the cell, it provided the operator with the opportunity to actually observe the robot and decide on the next required step.

Remote Robocell (RRC) Interface

The Remote Robocell workstation was equipped with a dedicated software package that was installed on the remote teleoperation computer and supported the preliminary simulation module. The teleoperation computer itself was wire-connected to the robot's controller via an amplified USB port. The remote workstation was placed in a remote room, preventing any eye contact between the operator and the robotic cell. These interface settings were designed for the examination of a modern teleoperation system that can support both the Axis-XYZ control and the joints control methods.

When using the RRC settings during the experiment, the operator had a presentation of the manual movement module of the Robocell software on one screen and two live video feeds of visual feedbacks on the other screen. In experiments where the preliminary simulation was used, the software was initially set to the off-line working mode. This means that the simulation module was presented to the users for an unlimited time, according to their choice, before turning into the online operation itself. Once changed to the actual online operation, the simulation module was shut down automatically.

VRTP-Enabled Remote Robocell (VRC) Interface

The VRTP-enabled remote Robocell mainly refers to the online option for simulation with the Robocell software.

The settings of both local and remote workstations were identical to those described for the RRC. The main difference between the two was the ability to keep the simulation module also running during the online operation stage. Such an option enabled the operator to have, on top of the visual feedback of the live feeds, a virtual visual feedback from the simulation module that was updated simultaneously with the movements of the robotic arm.

Potentially, such an option provided the users with both an advantage and a disadvantage with respect to the RRC. On one hand, they could change the orientation, angles, and zooming of the view in the VRTP module and gain better information than that obtained from the video feeds alone. However on the other hand, the virtual simulation could never be as accurate as the real video feed and could have resulted in operation errors, especially when the users reached the edge of the robot's working envelope.

INTERNET Interface

The Internet workstation contained, in addition to the standardized visual feedback mentioned above, a web browser. Setting only the internet browser was used to execute the teleoperation at the remote site.

The web browser was used to log into the proposed TOI and then to remotely operate the robotic arm through it. The visual-feed module in the TOI was not operated during the experiments to keep the same visual feedback for all interfaces, as required for analysis purposes. Instead the operator was provided with a separate visual feedback on the second screen, as happened in all the other remote settings. If a preliminary simulation had to be used in the experiment, the Robocell software was initially operated on the same computer, but only in an offline working mode, and the simulation module was presented to the operator for an unlimited time before turning into the online operation through the website. Once changing to the website TOI online operation, the Robocell software was shut down.

The Subjects Group

The subject group for the conducted experiments were senior (fourth year) students, at the CIM Lab in the IE Department at Tel-Aviv University. Each subject performed only a single experiment, randomly allocated to him. Each valid permutation of the design (14 in total) was performed by nine different subjects, and the results shown later are a mean over these repetitions. The subjects' age range lies from 20 to 30. The gender distribution was 53% males and 47% females. All subjects had a technical background resulting from their engineering education. Overall, 126 experiments were conducted throughout five semesters. The selection of this field of subject is obvious based on the results of this work, as engineering students are most likely the target end users of any system that might be developed.

EXPERIMENTAL RESULTS

Findings from Phase 1 of the Experiments

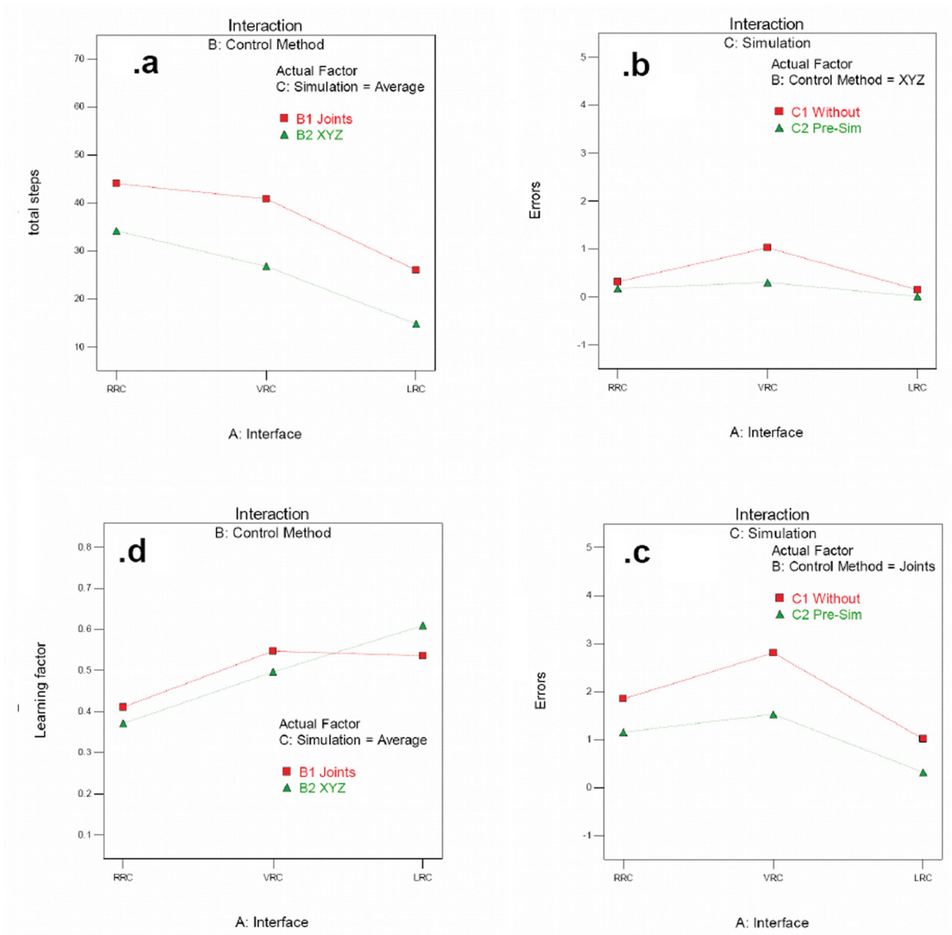
Phase 1 of the experiments focused on the evaluation of the three Robocell interfaces: the local Robocell interface (LRC), the remote Robocell interface that includes the VRTP (VRC), and the remote Robocell interface without the VRTP (RRC). As indicated earlier in the chapter, the evaluation focused on the XYZ vs. the Joints control method and on the contribution of the preliminary simulation tool prior to execution of the task.

The Total Number of Required Steps

The total number of steps required to complete the task was measured from the homing point (the location of the gripper after the calibration of the robot) until the completion of the entire task, i.e., after marking the third circle. This measure provided information and an intuitive understanding regarding the complexity level of the used interface.

Figure 4.a presents the average total number of steps required in each of the three Robocell-based interfaces, (starting from the RRC on the left hand side of the chart, continuing with the VRC in the middle and ending with the LRC on the right) and for each of the control methods. Note that as the interface approaches a realistic local setting, the number of steps decline. One can clearly see that the Joints control method results in a significantly

Figure 4. Selected graphs from phase 1 of the experiments



larger number of steps compared to the axis-XYZ control method. This trend is consistent through all the tested interfaces. This result is quite intuitive, as the Axis-XYZ control method is less complex and is more intuitive.

Examining the influence of the preliminary simulation tool on the total number of required steps, one can see that the preliminary simulation often leads to lower number of steps.

Number of Errors During the Tasks' Execution

The number of errors was measured by counting the number of marks made by the operator outside the designated circles in the working area. As mentioned for the previous factor, this factor gives some indication regarding the complexity of the task and points to the expertise improvement of the operator while completing the task. We expect the number of errors to be lower in designs that support better learning, as the user is expected to adapt faster to better control over the system and therefore to perform more accurately and with fewer errors.

The graphs in Figures 4.b and 4.c present again the average number of execution errors. This time, squares represent settings without a preliminary simulation and triangles represent settings with the use of a preliminary simulation.

Figures 4.b and 4.c explore the interaction between the control method and the preliminary simulation module when using the axis-XYZ or the Joints control, respectively. These show the effect of the control method used by the operator on the number of errors. As expected, the axis-XYZ control method reduces the number of errors with respect to the Joints control method and for all the examined interfaces in this phase. Surprisingly, the highest number of errors was obtained in the VRC interface rather than the RRC interface (the one without the VRTP). This result can be explained by the attractiveness of the VRTP feature, causing the users to rely on the virtual feedback even when it causes errors. The virtual feedback (VRTP), as informative as it is, is not as accurate as the online video feedback. When using the RRC interface without the virtual feedback, the operator had to wait for the video buffering delay to end, and therefore every movement took a longer time to finish. A possible explanation is that the operators gave a higher attention to each robotic move before actually executing it. We assume that the extra time and attention led to fewer errors.

Note that for the local-LRC interface, the advantage of the axis-XYZ with respect to Joints is smaller than the advantage in the remote interfaces. In fact, for the LRC interface, the control intervals overlap in contrast to the other interfaces. This fact emphasizes the importance of the control method when designing a remote interface.

While using the axis-XYZ control method (Figures 4.c), the average number of execution errors for both the local LRC interface and the remote RRC interface (without the VRTP) are found to be almost indistinguishable, regardless of the use or absence of the preliminary simulation module. In the VRC interface, on the other hand, a lower number of execution errors is obtained when implementing a preliminary simulation.

Note that for the Joints control method, the use of preliminary simulation results in a lower average number of errors in comparison to a situation without the preliminary simulation. This observation is consistent throughout all three different interfaces.

In both Figures 4.b and 4.c, one can see that the contribution of the preliminary simulation tool to decrease the number of execution errors is affected by the chosen control method. Preliminary simulation results in better execution (hence, better learning) when using an interface operated by the Joints control method.

The effect of the preliminary simulation on the number of errors while using the VRC interface seems to be almost indifferent to the control method in use. In this case, preliminary simulation results in a lower number of errors for both control methods, speculating that the VRTP module reduces the complexity gap between axis-XYZ and Joint control methods.

Learning and Improvement Measures

The learning and improvement rate, as defined earlier, is calculated by dividing the total number of steps required to perform the second and third legs, by the total number of steps required to complete the task. Such a measure is expected to be lower for a higher learning rate. A lower measure will indicate better learning, as it represents a significantly higher number of movements for the first leg and, therefore, a greater margin between the legs. This will indicate improved performance and an efficient learning process.

Figure 4.d presents the average learning function as calculated for the three interfaces that were considered. When using the local LRC interface, the Joints control method resulted in a better (lower) learning factor. This result is explained by the simplicity of the task when performed locally and with the simplest control method (axis-XYZ). A simple task leaves very little room for improvement, as its execution requires almost the minimal number of steps possible, those already from the first leg.

When using the remote interfaces (RRC and VRC), the axis-XYZ control method results in a slightly better improvement rate than the Joints control method. The best improvement and learning rate is obtained for the RRC interface, either with the axis-XYZ or with Joints control method. This result can also be explained by the complexity of the task to the remote users, leaving much room for learning and improvement.

Findings from Phase 2 of the Experiments

Phase 2 of the experiment focuses on the evaluation of the differences between the Web-based remote interface (INTERNET) and the three Robocell-based interfaces: the local settings (LRC), the remote settings with the VRTP module (VRC) and the remote settings without the VRTP (RRC). All four interface settings were operated with the Joints control method to evaluate the effect of the preliminary simulation tool prior to the online execution of the task. The results of Phase 2 are demonstrated in Figure 5.

The Total Average Number of Required Steps

Figure 5.a addresses the interaction between the interface type and the use of a preliminary simulation tool. When considering the three remote interfaces (the three most left interfaces in the abscissa), we see that the effect of the preliminary simulation to decrease the average total number of steps is most significant for the INTERNET interface. Such an effect barely exists in the VRC interface. Yet, the preliminary simulation also affects the total number of steps when using the local LRC interface.

Out of these three remote interfaces, the VRC interface is surprisingly indifferent to a preliminary simulation (as observed in Phase 1 of the experiment) and results in the same average number of steps both with and without using the preliminary simulation tool. Such a result may be explained by the fact that using the advanced VRTP tool during the task's execution makes the preliminary simulation, which is based on the same simulation tool, redundant regarding minimizing the number of steps. However, as explained in the next subsection, the preliminary simulation is useful regarding minimizing the number of errors.

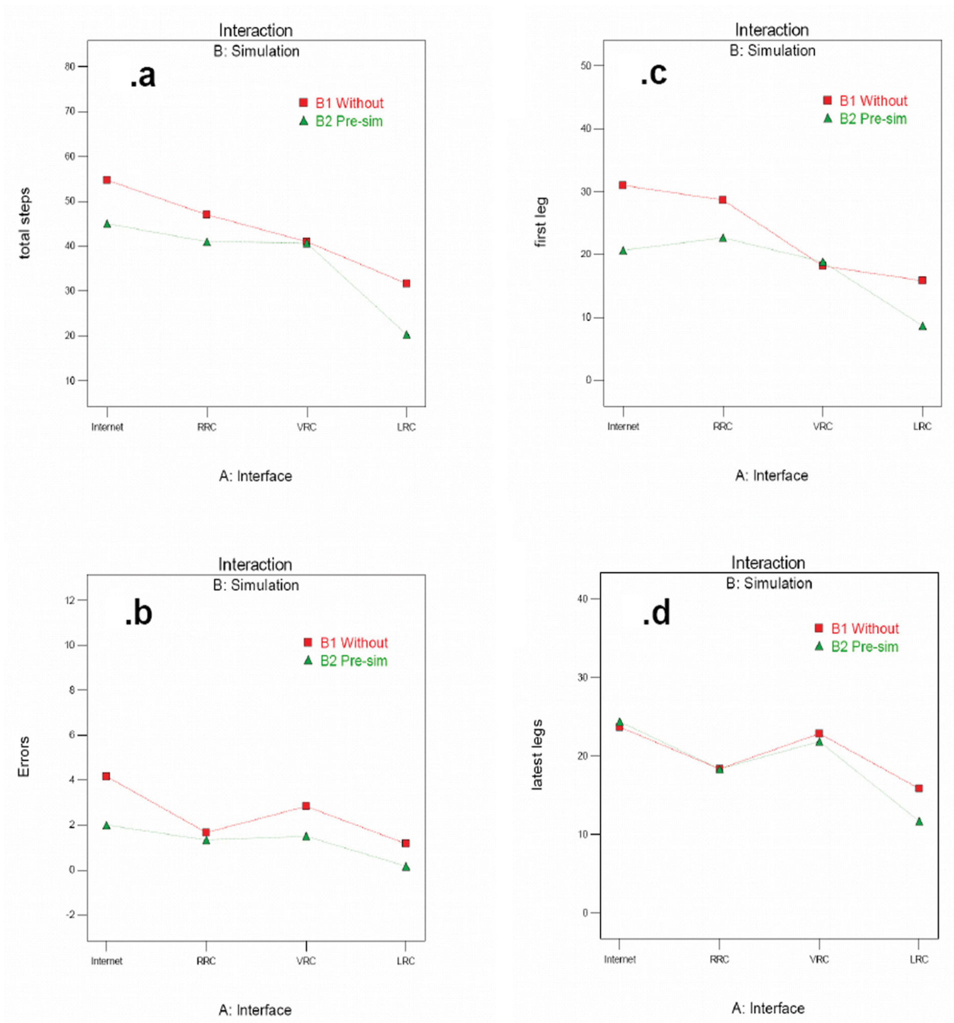
The Number of Occurred Errors

Figure 5.b presents the average number of execution errors for each of the four interfaces with or without the preliminary simulation tool. One can see that when using the preliminary simulation (marked by triangles), the difference between the three remote interfaces is negligible (less than 0.5 errors in average). Moreover, when the preliminary simulation is not used (marked by squares), the remote RRC interface lead to less errors than the other remote interfaces, obtaining an error rate, which is close to the one obtained by the local LRC test interface.

Learning and Improvement Measured

Next, the improvement in the learning rate of the users is presented. We show the learning rate for each of the legs as a function of the interface type and the use of a preliminary simulation. Figures 5.c and 5.d present the number of steps required for the first leg (marked as “H-to-1”) and for the later legs (marked as “1-to-3”), respectively. The results in each graph separately represent the use (by squares) or the lack of use (by triangles) of the preliminary simulation. As seen from the total number of required steps (Figure 5.a) and from the learning graphs (Figure 6), the use of a preliminary simulation results in fewer steps required to complete the first leg for all interfaces except for the VRC interface. Figure 5.d shows that the number of steps required to complete the later legs is indifferent to the use of a preliminary simulation, i.e., resulting in a roughly similar performance that is measured both with and without the use of the preliminary simulation tool prior to the execution.

Figure 5. Selected graphs from phase 2 of the experiments



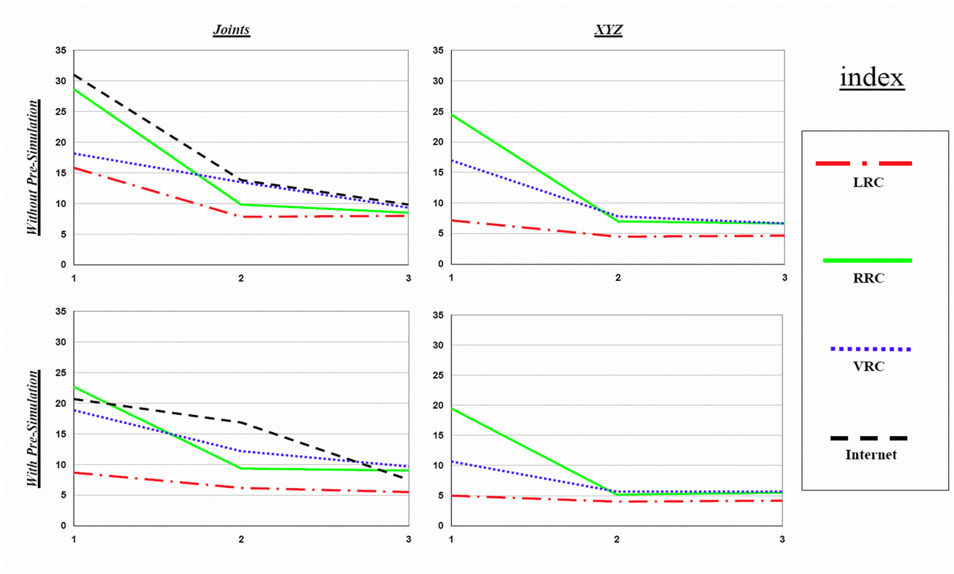
These results suggest that the ability to simulate movements in the cell before an actual execution provides the operator with an early stage of learning. This results in an improved performance at the beginning of the execution. The effect of such learning diminishes in later stages when the operator gains experience in remote operation. Another interesting result that is evident from these two graphs is that when a VRTP module is available, the contribution of the preliminary simulation is limited. Therefore, the use of VRTP can save time when the task is learned.

Learning Curves for Different Designs

The graphs shown in Figure 6 emulate the learning curves of the task execution for four combinations of the examined factors.

The horizontal axis represents the three legs of the experiments, starting from the homing point at the left hand side, through to the end of the execution on the right. The vertical axis shows the number of steps required for the specific leg of the execution. The right hand-side graphs show three different curves differentiated by the control

Figure 6. Learning curves for the experiments



method used and by the chosen interface (Internet interface excluded). The left hand-side graphs are showing four different curves differentiated by the use or absence of preliminary simulation and by the chosen interface (all four types of interfaces are included).

Comparison within Control-Method Factor

The two graphs on the right side of Figure 6 present the results of Phase 1 of the experiments. In each examined interface, both the Joint and the axis-XYZ control methods result in very similar slopes of the learning curve differing only in their heights. These differences result from the heights of start points, which are lower for the (more intuitive) axis-XYZ control method. The improvement throughout the steps seems to be almost unaffected by the actual control method in use. However, we see that while the end-points of all curves are bounded by a narrow margin between four to ten steps required to complete the last leg, the curves have greater margin at their starting points. This result leads to the conclusion that the actual improvement of execution achieved during the task is greater in the RRC interface and the lowest in the local LRC benchmark interface.

Analyzing the Preliminary-Simulation Factor

The two graphs on the left side of Figure 6 present the results of Phase 2 of the experiments. Unlike the right side graphs, the learning-curve slopes in each interface are different when considered with or without a preliminary simulation. For both the RRC and the local LRC interfaces, we observe steeper curves for experiments without preliminary simulation, indicating that the actual improvement of execution achieved during the task is greater when operating the system without a preliminary simulation. Nevertheless, we note that the curves of each interface end closely to each other, as the users reach the same average number of steps in the last leg of the execution, regardless of the use of a preliminary simulation. This observation leads to conclude that preliminary simulation supports the learning prior to the tasks' execution, thus it is recommended for use.

These conclusions are also supported by the learning curves of the Internet interface. In this more difficult working interface, the difference between the curves is noticeable, suggesting that when using a preliminary simulation, most of the learning occurred during the simulation part and leaving little room for improvement and providing a better start point to the operators at the online stage.

The curves for the VRC interface support our assumption that the VRTP tool and the preliminary simulation are superfluous to each other. This is supported by the almost identical curves (both in slope and in height), indicating indifference to the presence or absence of the preliminary simulation in the process.

Although the Internet interface is the most complex interface among the considered ones, when combined with a preliminary simulation tool, it provides almost as good results as the rest of the remote interfaces (in terms of the number of steps required). The same conclusion is drawn with respect to the number of errors. We believe that the ability to reconsider a movement once it has been chosen, yet before it is executed has a significant influence when explaining the success of this interface.

GUIDELINES AND FINAL DESIGN

When required to design a remote teleoperation interface, we need to choose the appropriate combination of components to meet our learning/teaching goals. If the goal is, as in our study, an accurate operation, then the suggested control method should be the axis-XYZ control, as it leads to a lower number of errors. However, since sometimes part of our robot operation teaching would benefit from teaching alternative control methods and as it seems that selecting either control method will not affect the achieved learning rate of the user, it is suggested to have both control methods available if and whenever it is possible.

A preliminary simulation module is highly recommended on the design of a remote telerobotic interface. The only module that was found to have the same impact as the preliminary simulation tool in terms of improving the operators learning and performance was the VRTP module. The VRTP module provides the user with the same learning qualities as the preliminary simulation tool, but this time during the actual online work. If the designed system has to service a large number of users by relying on short online time windows for each user, then a preliminary simulation is the most effective tool for learning. However, if one can provide each user with enough online access time to the robotic cell, then it is recommended to integrate a VRTP module into the interface.

A main feature that differs in the Internet interface from the other considered interfaces was the ability to reconsider a movement prior to its execution. We believe that this feature affected the higher learning rate found for this interface and recommend facilitating such mechanism into future designs of remote telerobotic interfaces.

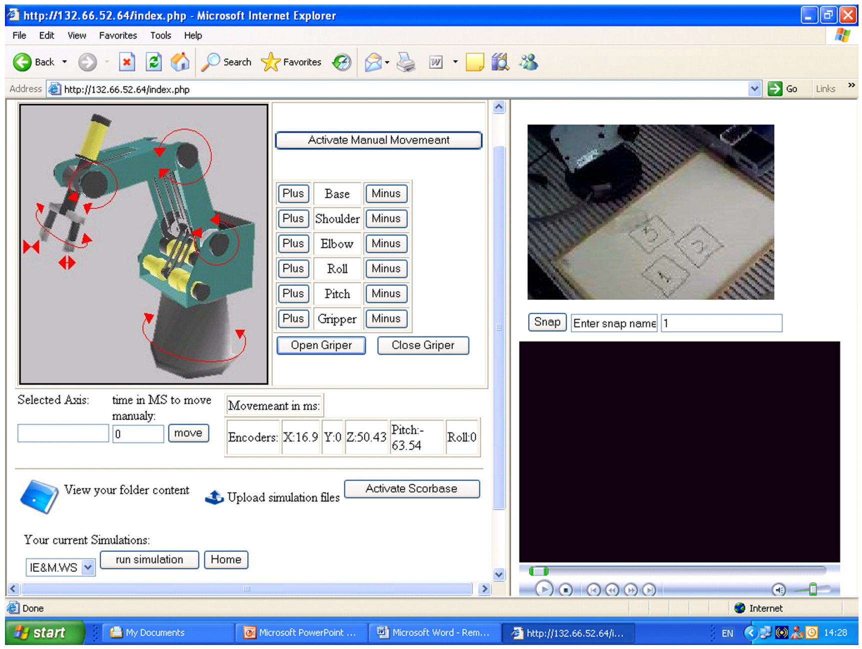
The design of the revised TOI designed based on the presented research is now presented.

Proposed Implementation

The web-based interface, shown in Figure 7, was programmed using html and PhP programming languages and was stored on an Apache server on the local computer (similar to Yang et al., 2004). The designed interface utilizes the Robocell simulation software as a platform.

Users were administrated with an SQL database, and the sessions were limited in time to avoid blockage of the system. The code for a single movement was based on measuring the time a specific push-button was pressed in the control module, identifying the joint and the direction represented by this button and then sending an operation command through the server and to the robot's controller. The response from the controller, composed of the new encoder values,

Figure 7. The web interface (© 2007, Taylor & Francis. Used with permission)



was presented on the website interface in response. A detailed description of the TOI modules is given next.

The Joint Control and Data Feedback Module

The Joint control and the data feedback module refer to the upper left hand-side of the interface, shown in Figure 7. This module controls directly each motor of the robot, enabling Joints control of the arm. Although the XYZ-axis control method was recommended as well for implementation, it does not appear in this design, as the implementation was too complex at the time of the actual design. A later work on the design should include the implementation of control method choice for the users.

There is a major difference between these two controllers and the Robocell interface controller described in previous sections. When using the Robocell controller, the action of clicking on a direction of movement results in an immediate response from the robotic arm, and the robot keeps moving in the desired direction until the push button is released. On the Internet interface presented here, pushing a controller button starts a timer (shown in Figure 7 under the Java application) running until the button is released. The operator can choose whether to send a movement signal to the robot for the selected axis and for that amount of time or to change the time/axis before sending the actual movement signal only after releasing the button. Such a feature potentially provides operators with greater control over their actions.

Once a movement was completed, a data feedback from the robot's encoders is presented to the operators (in the middle of Figure 7), enabling them to compare the actual positioning of the robotic arm to the one predicted by the virtual simulation.

The Visual Feedback Module

Two video feeds, as seen in the right hand side of Figure 7, are available for the users. These feeds provide the users with two different viewing angles of the workstation: an isometric overall view (the lower feed) and a zoomed top view (the upper feed). The top view also enables the users to snap a picture of the work area and to save it in their folder on the server. This option is introduced to support the maintenance of lab reports by future users of the system.

The Data Interaction Module

The bottom left side of Figure 7 shows the data interaction module serving three purposes: 1) uploading files to the server, 2) viewing the personal folder of the logged user, and 3) running simulation files stored in this folder. This module is not used during this research and was extensively described in Goldstain et al. (2007).

FURTHER RESEARCH

This chapter addresses the learning aspects related to the usage of different interface settings for remote control and manipulation of a robotic cell. Various interface components are evaluated and recommendations are provided.

Further research in this field can address the effect of integrating a VRTP tool and an axis-XYZ control method into an Internet interface. Results drawn from this research suggest that such integration can yield the best remote learning performance. Other research could focus on visual aspects associated with remote telerobotic learning, examining positioning and orientation of cameras and their effect on the user's comprehension of the three-dimensional work area as well as on their learning performance. In relation to teaching laboratories, useful work can be done for designing remote-compatible tasks for learning robotics, as not all available routines for teaching robotics are applicable for remote learning without the presence of an instructor on the site.

KEY TERMS AND DEFINITIONS

Home-Based: a design scheme for remote labs based on installing simulation and programming tools on the user's computer, sending batches of pre-planed code to be implemented on laboratory equipment.

INTERNET: A Test Oriented Interface operated remotely (based on our methodology)

Lab-Based: a design scheme for remote labs based on enabling direct remote access to laboratory equipment and computers.

LRC: A Robocell interface operated locally.

RoboCell: Robotic control software providing a user-friendly tool for robot programming and operation.

RRC: A Robocell interface operated remotely, without VRTP.

Scorbase: The language used by RoboCell's interface to program a robotic cell.

VRC: A Robocell interface operated remotely, with VRTP.

Web-Based: an integrated design scheme for remote labs based on a designated server running a pre-programmed website, detaching the user from the physical lab computer, while providing full control over laboratory equipment.

This work was previously published in Internet Accessible Remote Laboratories: Scalable E-Learning Tools for Engineering and Science Disciplines, edited by Abul K.M. Azad, Michael E. Auer and V. Chapter 64
Cell Loading and Family Scheduling for Jobs with Individual Due Dates

Gürsel A. Süer
Ohio University, USA

Emre M. Mese
D.E. Foxx & Associates, Inc., USA

ABSTRACT

In this chapter, cell loading and family scheduling in a cellular manufacturing environment is studied. What separates this study from others is the presence of individual due dates for every job in a family. The performance measure is to minimize the number of tardy jobs. Family splitting among cells is allowed but job splitting is not. Even though family splitting increases number of setups, it increases the possibility of meeting individual job due dates. Two methods are employed in order to solve this problem, namely Mathematical Modeling and Genetic Algorithms. The results showed that Genetic Algorithm found the optimal solution for all problems tested. Furthermore, GA is efficient compared to the Mathematical Modeling especially for larger problems in terms of execution times. The results of experimentation showed that family splitting was observed in all multi-cell solutions, and therefore, it can be concluded that family splitting is a good strategy.

INTRODUCTION

Cell Loading is a decision making activity for planning the production in a Cellular Manufacturing System (CMS) including more than one manufacturing cell. The products are assigned to the manufacturing cells where they can be processed. This assignment is done based on the demand, processing times and due dates of the products and the production capacity and capability of the manufacturing cells (Süer, Saiz, Dagli & Gonzalez, 1995 and Süer, Saiz, & Gonzalez, 1999). Family Sequencing is a task of deciding the order by which product families are processed in a particular cell as determined by the Cell Loading process. In this chapter, a product

DOI: 10.4018/978-1-4666-1945-6.ch064

family can be split and they can be sequenced in the same cell or different cells. Obviously, each time a new family starts in a cell, a new setup is required. Finally, Family Scheduling consists of determining start times and completion times of the product families and the individual products based on the family sequence established. Typically in a complex cellular system, we need to address Cell Loading, Family Sequencing and Family Scheduling tasks all in a satisfactory manner to obtain the desired results in terms of the selected performance measure.

In this study, we are considering minimizing the number of tardy job as the performance measure. Even though the problem has been observed in a shoe manufacturing company, it is applicable to many cellular systems. The products are grouped into families based on their processing similarity. On the other hand, products in a family might have different due dates. The overall objective of this chapter is to solve cell loading and product sequencing problem in such a multi-cell environment. To accomplish this, we propose two different approaches to tackle this complex problem namely, mathematical modeling and genetic algorithms. An experiment is carried out using both approaches and later the results are compared and a sensitivity analysis is also performed with respect to due dates and setup times.

BACKGROUND

Group Technology (GT) is a general philosophy where similar things are grouped together and handled all together. GT is established upon a common principle that most of the problems can be grouped based on their similarities and then a single solution can be found to the entire group of problems to save time and effort. This general concept has been also applied to the manufacturing world. This approach increases productivity by reducing work-in-progress inventory and improves delivery performance by reducing leadtimes, thus helping manufacturing companies to be more competitive. Thus, a Cellular Manufacturing System can be specified as an application of GT to the manufacturing system design (Askin & Standridge, 1993). Cellular Manufacturing System aims to obtain the flexibility to produce a high or moderate variety of low or moderate demand products with high productivity. CMS is a type of manufacturing system that consists of manufacturing cell(s) with dissimilar machines needed to produce part family/families. Generally, the products grouped together form a product family. The benefits of CMS are lower setup, smaller lot sizes, lower work-in-process inventory and less space, material handling, and shorter throughput time, simpler work flow (Suresh & Kay, 1998).

In this chapter, the performance measure used is minimizing the number of tardy products (n_T). If a product is completed after its due date, then it is considered as tardy product. If product is completed before its due date, then the tardiness for this product will be zero (early or on-time product). Therefore, tardiness for a product takes a value of zero or positive, $T_i = \max\{0, c_i - d_i\}$; where T_i is the tardiness for product (i), c_i is the completion time of product (i), and d_i is the due date for product (i). The number of tardy jobs is computed as $n_T = \sum_i^n g(T_i)$ where g(x) = 1 if x > 0, and zero otherwise.

The problem has been observed in a shoe manufacturing company where twelve product families have been already defined. There are multiple cells and the most critical component of each cell is the rotary injection molding machine. Even though Rotary Molding Machine is a single machine, scheduling shoes on that machine resembles to a parallel machine scheduling problem as it can hold multiple pairs of molds/shoes at any time. The Rotary Molding Machine is defined in detail in Section 3.

Several researchers focused on cell loading problem [Süer, Saiz, Dagli & Gonzalez, (1995) and Süer, Saiz, & Gonzalez (1999a)] developed simple cell loading rules to minimize number of tardy jobs. Süer, Vazquez, & Cortes (2005) developed a hybrid approach of Genetic Algorithms and local optimizer to minimize nT in a multi-cell environment. Süer, Arikan, & Babayigit (2008) and (2009) focused on cell loading subject to manpower restrictions and developed fuzzy math models to minimize nT and total manpower levels. A few works have been also reported where both cell loading and product sequencing tasks are carried out. Süer & Dagli (2005) and Süer, Cosner & Patten (2009) discussed models to minimize makespan, machine requirements and manpower transfers. Yarimoglu (2009) developed math model and genetic algorithms to minimize manpower shortages in cells with synchronized material flow. However, these work ignored setup times between products and families.

Some other researchers focused on group scheduling problem with a single machine or a single manufacturing cell. Nakamura, Yoshida & Hitomi (1978) focused on minimizing total tardiness and considered sequence-independent group setup. Hitomi & Ham (1978) also considered sequence-independent setup times for a single machine. Ham, Hitomi, Nakamura & Yoshida (1979) developed a branch-and-bound algorithm for the optimal group and job sequence to minimize total flow time with the minimum number of tardy jobs. Pan and Wu (1998) considered a single machine scheduling problem to minimize mean flow time of all jobs subject to due date satisfaction. They categorized the jobs into groups without family splitting. Gupta and Chantaravarapan (2008) studied the single machine scheduling problem to minimize total tardiness considering group technology. Individual due dates and independent family setup times have been used in their problem with no family splitting.

This paragraph summarizes the work done in the past which focused on scheduling jobs on the Rotary Injection Molding Machines. Süer. Santos, & Vazquez (1999b) have developed a three-phase Heuristic Procedure to minimize makespan in the Rotary Molding Machine scheduling problem. Subramanian (2004) has attempted to solve this problem as a part of the cell loading and scheduling process. The objective was to minimize makespan and unlimited availability of the molds was assumed. Later, Urs (2005) introduced limited mold availability into the problem for the same objective. The most recent research was done by Süer, Subramanian, and Huang (2009) includes some heuristic procedures and mathematical models for cell loading and scheduling problem.

The most important feature of the scheduling problem studied in this chapter is the presence of individual due dates for every job even in the same family (no common due dates), and family splitting is allowed to minimize the number of tardy jobs. To the best knowledge of the authors, this real problem observed in a cellular environment has not been addressed in the literature before. As a result, we decided to tackle this complex problem here and propose multiple solution approaches to deal with it.

THE PROBLEM STUDIED

This section discusses the problem studied in detail.

Family Splitting vs. Setup Times

Typically, in cellular manufacturing similar products are grouped together and processed together as a family to reduce the number of setups and thus total setup time. However, literature does not address the possibility of having different due dates for the jobs in the same family. Even though it is important to reduce the setup times, it is also important to meet the customer due dates. There is a natural conflict between meeting due dates of jobs versus reducing total setup times between families. This point can be illustrated

Figure 1. Family splitting not allowed vs. allowed

	Setup Fam1	Job1 Fam1	Job2 Fam1	Setup Fam2	Job3 Fam2	Job4 Fam2
ci	2	5	10	12	16	22
di		6	19		12	20
Ti		0	0		4	2

a) Family splitting not allowed

	Setup Fam1	Job1 Fam1	Setup Fam2	Job3 Fam 2	Setup Fam1	Job2 Fam1	Setup Fam2	Job4 Fam2
ci	2	5	7	11	13	18	20	26
di		6		12		19		22
Ti		0		0		0		4

b) Family splitting allowed

in Figure 1 where there are two families and two jobs in each family.

If we do not split (preempt) the families, we get two jobs in the second family. On the other hand, if family splitting is allowed then number of tardy jobs is reduced to one even if the number of setups increases from two to four. We can observe that when all of the jobs for a family are scheduled all together, setup times are reduced. However, this may also force several other jobs in the following families to be delayed and increase the possibility of becoming tardy. On the other hand, when a family is split several times, the number of setups increases thus reducing the productive time and hence may adversely affect the number of tardy products. This study attempts to find a balance between family splitting and meeting due date such that the total number of tardy products is minimized. As mentioned before, among the published papers in the literature, there is no work reported about Cell Loading and Family Scheduling subject to Individual Due Dates with group splitting allowed considering more than one manufacturing cell.

Case Study

This section describes the problem in depth. The following subsections explain the important features of the problem.

Products

This problem was observed in a shoe manufacturing plant. Products have five attributes; Gender, Size, Sole Type, Color, and Material. For shoes manufactured for men (Male (M)), there are 18 different sizes, 2 sole types (Full Shot (FS), Mid Sole (MS)), 4 colors (Black (B), Dark Green (G), Honey (H), Nicotine (N)), and 3 materials (Polyurethane (PU), Polyvinyl chloride (PVC), Thermo Plastic Rubber (TPR)). For shoes manufactured for women (Female (F)), there are 13 different sizes and the remaining attributes (Sole Types, Colors, and Materials) are similar to those of males. Besides these product types, there are also different upper designs that will be referred as models from now on. Each model will have its own identification designation (Model ID).

Cells/Minicells

There are six manufacturing cells in the plant and they are independent from each other (machine sharing, and thus inter-cell transfers are not allowed). In the plant, every manufacturing cell includes Lasting Minicell, Rotary Molding Machine Minicell (RMMM), and Finishing/Packing Minicell as shown in Figure 2. Lasting Minicells prepare the shoes for injection molding process. Rotary Molding Machine Minicells inject the materials into the molds. Finishing/Packing Minicells remove extra materials from the injected shoes, finish the shoes, and also pack the shoes.

Rotary Molding Machine

This study focuses only on scheduling Rotary Molding Machine Minicells (the bottleneck of the manufacturing cell). The Rotary Molding Machine has a capacity of six pair molds as shown in Figure 3. In Figure 2, P1 is the injection station where the material is injected inside the mold. P2, P3, P4, and P5 are the cooling off stations, so that worker can handle the shoes. P6 is the loading and unloading station that the worker removes the pair injected and cooled off, and then loads the new pair that will be injected in the injection station. The Rotary Molding Machine is rotated anti-clockwise, so it is rotated exactly one position at the end of every cycle time.

Figure 2. Manufacturing cells in the shoe manufacturing plant

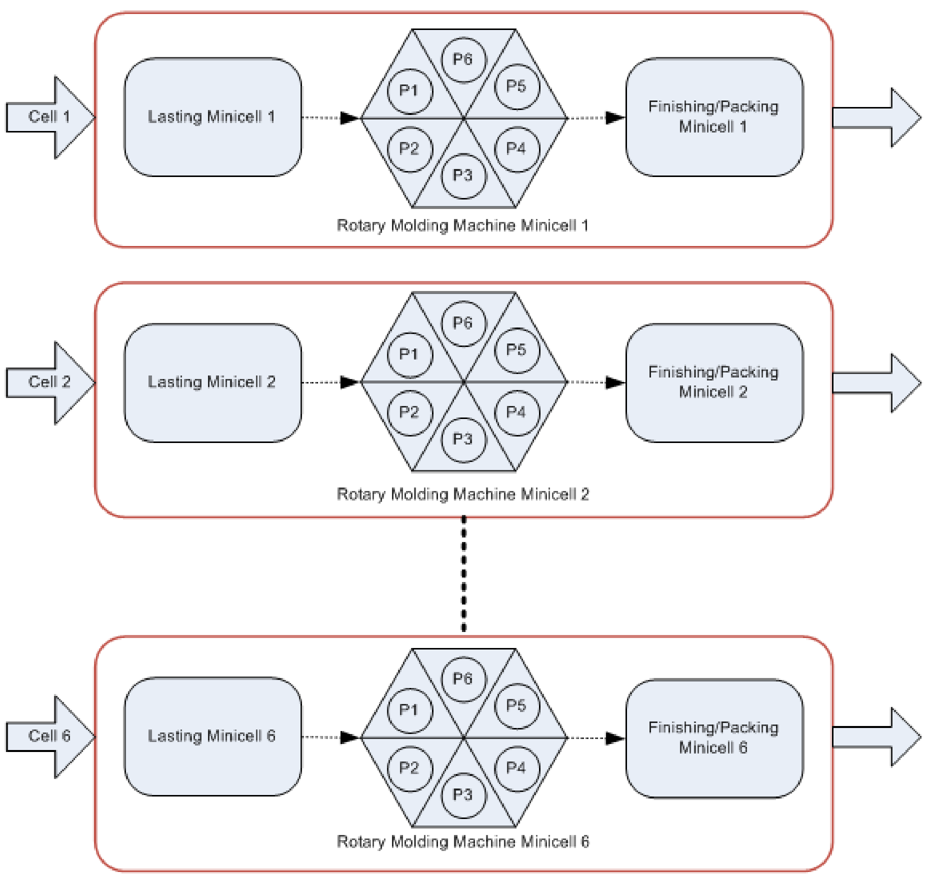

Figure 3. The rotary molding machine minicell

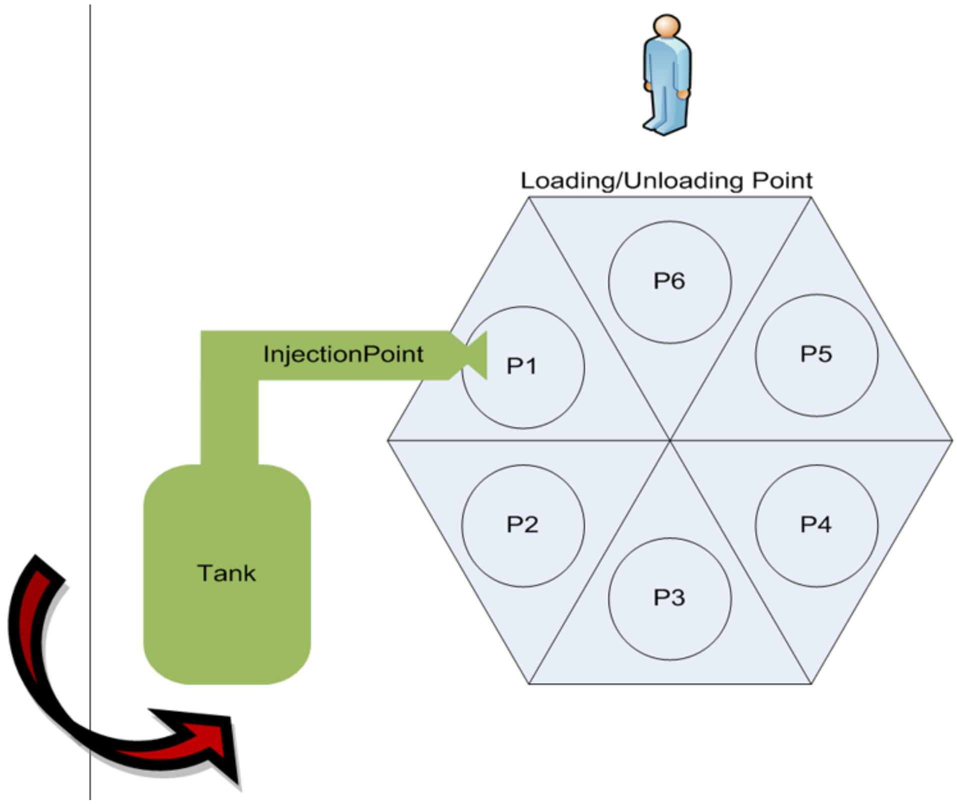


Injection time is defined as the time required for injecting the material inside the mold. The injection time is affected by the size of the shoe, i.e. larger shoe sizes need longer injection times, because the material injected by the Rotary Molding Machine per minute is constant. Because of the schedule of products in the specific cell, different sizes can be run in the Rotary Molding Machine at the same time. When this happens, the cycle time is set to the injection time of the biggest size (maximum injection time).

Product Families

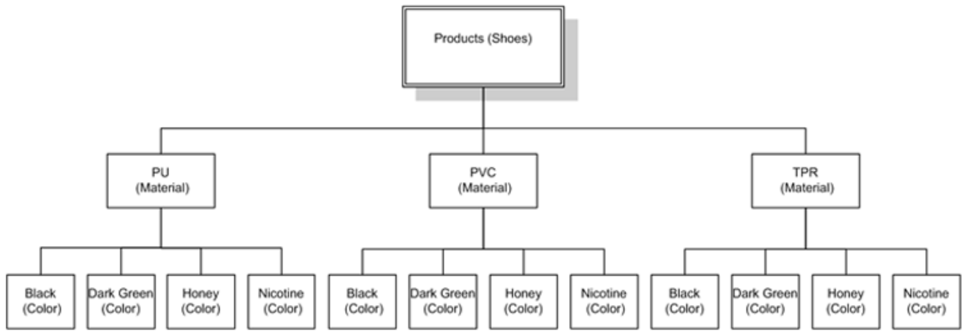
A representation code is formed as "MC" to form and identify the product families. In the MC code form: M denotes the Material (PU: U, PVC: P, TPR: T), and C denotes the Color (Black: B, Dark Green: G, Honey: H, Nicotine: N). There are 12 product families (= 4 colors * 3 material types) as shown in Figure 4.

In this study, all of the sizes of a specific order (with the same Model ID, Gender, Sole Type, Material, Color, and Due Date) is called a job. Different sizes of a job can have different demand. All of the sizes included in a job are assumed to have the same due date. The reason for this is that the entire job will have to be shipped to the customer all together.

Example: Family Formation

An example of customer orders that consists of 32 jobs is presented in Table 1. From the customer orders in Table 1, the families can be obtained as shown in Table 2.

Figure 4. Structure of families



Example: Possible Cases

This study focuses on assigning products to Rotary Molding Machine Minicells considering their families, i.e. cell loading. Family splitting among Minicells is allowed but job splitting is not. As an illustration of this, examples of the possible minicell loading cases are shown in Figure 4. The processing times of jobs in families F1, F5, and F12 are given in Table 3. While loading minicells, the families may not be divided as shown in Figure 5a, or families may be divided in the same minicell (like preemption) as shown in Figure 5b, or a family may be assigned to multiple minicells as shown in Figure 5c.

Other Issues

The molds used in the Rotary Molding Machine for injection molding vary by size, gender, and sole type. It is assumed that there is not any restriction on the availability of molds. Therefore, the same size pairs of a job can be run on all locations of the Rotary Molding Machine simultaneously. In this study, setup times between jobs in the same family are assumed negligible. However, setup times (for material or color or both changes) between families is assumed to take 20 minutes. The jobs can be back-scheduled in the Lasting Minicells and forward-scheduled in the Finishing/Packing Minicells based on the schedule of Rotary Molding Machine Minicells. However, scheduling in Lasting Minicells and Finishing/Packing Minicells are not within the scope of this work.

PROPOSED SOLUTION TECHNIQUES

The Cell Loading and Family Scheduling problems introduced in this chapter involve constraints on the number of product families, individual due dates, machine capacity, and sequence-independent setup times. This version of the problem is more difficult than the Classical Cell Loading and Group Scheduling problem. Both mathematical model and genetic algorithms approaches are proposed. The Mathematical Model guarantees the optimal solution, but it takes too much time to find the optimal solution. The Genetic Algorithm is a much faster procedure, but it cannot guarantee the optimal solution. The performance of these two procedures is compared with respect to execution time and the frequency of the optimal solutions. Genetic Algorithms Software Application (GASA) has been coded by using C# object-oriented programming language. The Mathematical Model is solved by using ILOG OPL 5.5. The methodology introduced in chapter is not restricted to the case study discussed here and can directly be used in similar cellular environments.

Mathematical Model

The objective function is to minimize n_T and it is given in Equation (1). Each job can be processed only once as shown in Equation (2). Equation (3) shows that each position in each cell can be assigned to at most one job. Equation (4) enforces jobs to be assigned consecutively in each cell. Equation (5) controls setup requirements. If the consecutive jobs are from different families, then this constraint adds setup between those consecutive jobs. In Equations (6), (7.a) and (7.b), If-Then constraints are used to

Table 2. Families for orders given in Table 1

Family No.	Jobs (due dates)

eliminate the nonlinearity in the model. Equation (6) checks if a position is occupied by a job. If so, Equations (7.a) and (7.b) calculate the completion time of the job in that position. Equation (8) determines the tardiness value of a job. Equation (9) identifies if a job is tardy.

Notation

Indices:

- i Family index
- j Job index
- k Position index
- m Cell index

Parameters:

- n Number of jobs
- n_i Number of jobs in family *i*
- f Number of families
- M Number of cells
- P_{ij} Process time of job *j* from family *i*
- D_{ij} Due date of job *j* from family *i*
- S Setup Time
- R Very big number (larger than maximum possible tardiness value)

Decision Variables:

- Y_{mk} 0 if k^{th} position in cell *m* is occupied, 1 otherwise.
- X_{ijmk} 1 if job *j* from family *i* is assigned to the k^{th} position in cell *m*, 0 otherwise.
- C_{mk} Completion time of the job in k^{th} position in cell *m*
- T_{mk} Tardiness value of the job in k^{th} position in cell *m*
- W_{mk} 1 if setup is needed before the job in k^{th} position in cell *m*, 0 otherwise.
- nT_{mk} Coefficient for determining the tardiness of the job in k^{th} position in cell *m*. 1 if the job which is assigned to the k^{th} position in cell *m* is tardy, 0 otherwise.

Objective Function:

$$\min Z = \sum_{m=1}^{M}\sum_{k=1}^{n} nT_{mk} \quad (1)$$

Subject to:

$$\sum_{m=1}^{M}\sum_{k=1}^{n} x_{ijmk} = 1 \text{ for } i=1,\ldots,f,\ j=1,\ldots n_i \quad (2)$$

$$\sum_{i=1}^{f}\sum_{j=1}^{n_i} x_{ijmk} \le 1 \text{ for } m=1,\ldots,M,\ k=1,\ldots,n \quad (3)$$

$$\sum_{i=1}^{f}\sum_{j=1}^{n_i} x_{ijmk} \ge \sum_{i=1}^{f}\sum_{j=1}^{n_i} x_{ijm(k+1)} \text{ for } m=1,\ldots,M,\ k=1,\ldots,n-1 \quad (4)$$

$$1 + W_{mk} \ge \sum_{j=1}^{n_i} x_{ijmk} + \sum_{j=1}^{n_q}\sum_{q\in(f/i)} x_{ijm(k-1)} \text{ for } m=1,\ldots,M,\ k=2,\ldots,n \quad (5)$$

$$\sum_{i=1}^{f}\sum_{j=1}^{n_i} x_{ijmk} \le R * (1 - Y_{mk}) \text{ for } m=1,\ldots,M,\ k=1,\ldots,n \quad (6)$$

$$-C_{m1} + \sum_{i=1}^{f}\sum_{j=1}^{n_i} x_{ijm1} * P_{ij} \le R * Y_{m1}\ m=1,\ldots,M \quad (7a)$$

$$C_{m(k-1)} - C_{mk} + S * W_{mk} + \sum_{i=1}^{f}\sum_{j=1}^{n_i} x_{ijmk} * P_{ij} \le R * Y_{mk} \text{ for } m=1,\ldots,M,\ k=2,\ldots,n \quad (7b)$$

$$C_{mk} - \sum_{i=1}^{f}\sum_{j=1}^{n_i} x_{ijmk} * D_{ij} \le T_{mk} \quad (8)$$

for $m=1,\ldots,M,\ k=1,\ldots,n$

$$T_{mk} \le R^* nT_{nk};\ \text{for } m=1,\ldots,M,\ k=1,\ldots,n \quad (9)$$

Definition of Variables:

$x_{ijmk}\in\{0,1\}$; for $i=1,\ldots,f$, $j=1,\ldots,n_i$, $m=1,\ldots,M$, $k=1,\ldots,n$

$W_{mk}\in\{0,1\}$; for $m=1,\ldots,M$, $k=1,\ldots,n$

$nT_{mk} \in \{0,1\}$; for $m=1,\ldots,M$, $k=1,\ldots,n$

$Y_{mk} \in \{0,1\}$; for $m=1,\ldots,M$, $k=1,\ldots,n$

$C_{mk} \geq 0$; for $m=1,\ldots,M$, $k=1,\ldots,n$

$T_{mk} \geq 0$; for $m=1,\ldots,M$, $k=1,\ldots,n$

Genetic Algorithm

First, the initial population of n chromosomes is formed randomly. Then, mating partners are determined using mating strategies to perform crossover. The crossover and mutation operators are performed to generate offspring. For selecting the next generation, parents are added to the selection pool along with offspring. The next generation is selected from this pool based on their fitness function value. These steps are repeated until the number of the generations specified by the user is reached. Finally, the best chromosome obtained during the entire generations is determined as the final solution.

Chromosome Representation

The chromosome representation is used as an individual solution including genes corresponding to jobs. For each gene, the following representation code is used: (X, Y) where X denotes the Job Number and Y denotes the cell to which Job (X) is assigned. The sequence of genes in a chromosome also determines the sequence of jobs in the cells. As an illustration, an example is shown in Figure 6 where Jobs 1 & 3 are assigned to the first cell and Jobs 4 & 2 are assigned to the second cell in the order stated.

Figure 6. A Chromosome representation for a 4-job and 2-cell problem

1, 1	4, 2	3, 1	2, 2

Mating

Three different mating strategies are used to determine mating pairs; Random (R), Best-Best (B-B), and Best-Worst (B-W). The reproduction probabilities of the chromosomes are calculated according to their fitness function. The next step depends on the selected mating strategy.

If the Random Mating Strategy is selected, the mating pairs are determined randomly with respect to their reproduction probabilities by using Roulette Wheel approach. In this mating strategy, each chromosome and its randomly determined partner give one offspring. If the Best-Best Mating Strategy is selected, all chromosomes are ranked with respect to their reproduction probabilities in descending order. Then, the best chromosome is paired with the second best chromosome, the third chromosome paired with the fourth chromosome and so on. In addition, the first X% of the pairs produce 3 offspring, the next Y% of the pairs give 2 offspring, and the last Z% of the pairs produce 1 offspring. If the Best-Worst Mating Strategy is selected, all chromosomes are ranked with respect to their reproduction probabilities in descending order. Then, the best chromosome is paired with the worst chromosome; the second best chromosome is paired with the second worst chromosome and so on.

Crossover

Two different strategies are used to perform the crossover operation. Those crossover strategies are Position-Based Crossover (P-B) (Syswerda, 1999) and Order Crossover (OX) Strategies (Davis, 1985). The crossover operation is applied to the identified pairs with a probability of P_C. The first parent is copied as the offspring if crossover is not performed. The crossover operator affects the sequence of jobs but not their cell assignment.

In other words, the crossover is applied to the genes' X element and not to Y element.

Mutation

Two steps are used in the mutation operator. The first one is used for job sequence and only Reciprocal Exchange (R-E) Mutation Strategy is used [(see Gen and Cheng (1997)]. The mutation for job sequence is performed with a probability of P_{MJ}. The second step involves mutating cell assignments. In the mutation of cell assignments, two different mutation strategies are used, Random (R), and Reciprocal Exchange Mutation. The mutation of the cell assignment is performed with a probability of P_{MC}.

Selection

In this study, selection pool consists of all offspring and some of the parents. The next generation is selected from this pool. The selection from parents is a two-step process. First, the parents are ranked with respect to their reproduction probability in descending order. Then, the best P_E% parents are directly selected to advance to the selection pool. Then, the remaining (100-PE)% chromosomes are selected from the parents randomly based on their reproduction probability using Roulette Wheel Selection.

Once the selection pool is identified, the chromosomes are ranked with respect to their reproduction probability and a final selection is made from this pool to generate the next generation. In some experiments, we also allowed a certain percentage of lowest performers (Pw%) to advance automatically to the next generation to avoid immature convergence of the population.

ANALYSIS OF RESULTS

The results are grouped in four sections. 1) Genetic Algorithm Application, 2) Comparison of Mathematical Models with Genetic Algorithm, 3) Due Date Sensitivity Analysis, and 4) Setup Time Sensitivity Analysis. The experimental conditions are mentioned first and then the results obtained are discussed.

Data Sets Used

Nine data sets are used in the experimentation. The details of data sets are listed in Table 4. The data sets 1, 2, and 3 are realistic data sets obtained directly from the shoe manufacturing company. The data sets 4, 5, and 6 are relatively smaller data sets and they are generated from data sets 1, 2, and 3, respectively for only one cell. Similarly, for multiple cells; smaller data sets 7, 8, and 9, are generated from data sets 1, 2, and 3, respectively, by reducing batch sizes and due dates.

Genetic Algorithm Application

In this experiment, data sets 1, 2, and 3 are used. Initially, default parameters that are given in Table 5 are used. Then, the values of the GA parameters are changed one at a time in order to obtain better combinations. These parameters are listed in Table 6. Ten replications are performed.

The best solution is 3 tardy jobs for all three data sets. The frequencies of the best solution as well as the average values for better combinations are given in Tables 7, 8 and 9. For data set 1, four combinations stood out as the best combinations. Combination 1 has the highest frequency of the best solution. However, there is no significant difference among them according to ANOVA test results ($P=0.292 > \alpha$-value=0.05). For data set 2, top six combinations are determined as given in Table 8. The combination 3 has the best frequency among all combinations. Since there is significant difference between six combinations ($P=0.008<alpha=0.05$), Fisher Test is applied. The results show that combination 5 is significantly different (worst) than other five combinations. For data set 3, top six combinations are listed in

Table 4. Details of data sets

Data Set	Number of Families	Number of Jobs	Total Processing Time (minutes)	Number of Cells	Available Production Capacity (minute/cell)
Data 1	12	41	6465	3	2400
Data 2	12	33	6603	3	2400
Data 3	12	44	7995	4	2400
Data 4	5	11	2015	1	2400
Data 5	9	12	2146	1	2400
Data 6	9	13	2077	1	2400
Data 7	6	20	3222	3	1200
Data 8	5	13	2283	3	800
Data 9	6	22	4060	4	1200

Table 5. The default parameters for GA

Setup Time:	20 minutes
Population Size:	1000
Number of Generations:	1000
Elite Ratio:	0.2
Worst Ratio:	0.1

Table 9. Combination 2 has the largest frequency for the best solution. Since there is significant difference (P=0.034<α-value=0.05) between six top combinations, Fisher Test is applied. The results show that Combinations 1 and 2 are significantly different than Combinations 5 and 6. Combination 3 and Combination 4 are also eliminated as they are not significantly different than Combinations 5 and 6.

Comparison of Mathematical Models and Genetic Algorithms

In this section, the results of the Mathematical Models are compared with the GA results for the modified data sets. The experimental conditions that are detailed in 1 are utilized in GA application. The Mathematical Model solutions (optimal solutions) and GA solutions for data sets 4, 5, and 6 are given in Table 10; for data sets 7, 8, and 9 are given in Table 11.

GA found the optimal solution ten times out of ten replications for both one cell and multiple cells (except data set 7). For data sets 4, 5, and 6, Mathematical Model has a better execution time compared to GA (except data set 5) due to small problem size. When data sets 7, 8, and 9 are considered, the GA has significantly better execution time compared to the Mathematical Model. This is expected since as the problem size increases; the execution time of the Mathematical Model increases dramatically. The details of data set 8 and corresponding Gantt chart for the mathematical model results are given in Appendix for illustration purposes.

Due Date Sensitivity Analysis

For due date sensitivity analysis, data set 1 is used. Combination 4 is selected as the parameters of GA to perform this experiment. In this experiment, due date sets of loose (Loose 1), looser (Loose 2),

tight (Tight 1), and tighter (Tight 2) are generated in addition to the original due date set (Medium). The cumulative probabilities of those due date sets are given in Table 12. The results of ten replications for the due date sets are given in Table 13. As expected, the number of tardy jobs increased as due dates got reduced.

Setup Time Sensitivity Analysis

The set up times varied from 0 to 100 for data set 1. Similarly, Combination 4 parameters were used in this experiment. The results of GA for the various setup times are given in Table 14. The number of tardy jobs increased as the setup time increased. This was expected, however, in some cases setup times doubled (from 5 minutes to 10 minutes; from 10 min to 20 min; from 20 min to 40 min) but number of tardy jobs increased only by one. On the other hand, when setup time increased from 40 minutes to 80 minutes, the number of tardy jobs increased by three. This shows that system can tolerate increase in setup times to a certain extent, beyond which its impact will be bigger.

CONCLUSION AND FUTURE WORK

In the problem studied in this chapter, every job has individual due dates even the ones in the same family. This property of the problem completely separates this study from other cellular manufacturing scheduling problems. The reason of this complexity is because of the natural conflict between meeting due dates of jobs and reducing total setup times. If the entire family is scheduled together, then the total setup time is at minimum. But, the jobs in the consecutive families may be forced to be postponed and probably become tardy. In contrast, splitting a family several times may increase the number of setups which reduce the productive time, and finally have an adverse effect on the number of tardy jobs.

The Mathematical Model is one of the solution techniques which guarantee to find the optimal solution. It is not practical to solve larger problems using the mathematical models because of the complexity. As a result, there is a need to use other approaches to solve such problems. We proposed and used Genetic Algorithm approach in this Chapter.

Genetic Algorithms found the optimal solution in all problems with varying frequency. The execution time of Mathematical Model was reasonable only for small problem sizes. GA clearly outperformed Mathematical Model with respect to execution times.

The results showed that family splitting occurred in all multi-cell problems. Due to limited space, we presented only one in this chapter. The occurrence of family splitting in these problems show us that the system used the feature of family splitting since it was beneficial in terms of reducing the number of tardy jobs. Another conclusion that can be drawn is that the impact of setup times and due dates on the system performance was as expected.

We are planning to extend this work to sequence-dependent setup times in the future and also use other metata-heuristic techniques. This work can also be extended to include other performance measures and job-splitting option.

Chapter 65
Evaluation of Key Metrics for Performance Measurement of a Lean Deployment Effort

Edem G. Tetteh

ABSTRACT

To meet customer's needs for high-quality goods and avoiding risks of product-liability, global firms continually evaluate the performance of their supply chain for optimum design. Lean management is one of the key techniques businesses adopt in redesigning their processes. The technique is a vital strategy to increase productivity and effectiveness with respect to the movement of goods. Multivariate Analysis of Variance (MANOVA) was utilized to evaluate the performance of work cell, shift, worker's experience, and kaizen event participation level during a lean enterprise deployment effort at a multinational organization. The significance of the effects of these variables were assessed based on various lean supply chain factors such as First In First Out (FIFO), Setup Wheel System (SWS), Standard Operating Procedures (SOP), Clip System(CS), and Key Performances Indicators (KPI). The results support the criticality of metrics and their impact in implementing a lean manufacturing process in a global supply chain environment.

INTRODUCTION

Lean manufacturing has been shown to improve the competitiveness of organizations. The concept of lean started first with the Toyota Production System (TPS). Then, the idea was expanded by a research group at Massachusetts of Institute of Technology (Womack & Jones, 1996). The philosophy of lean uses a process of waste reduction, thus producing higher quantity and better quality products with the least resources possible. The

DOI: 10.4018/978-1-4666-1945-6.ch065

goals are zero lead time, zero inventory, and zero defects, resulting in higher customer satisfaction (Tapping, Luyster, & Shuker, 2002).

Lean manufacturing strives for continuous improvement towards an ideal through relentless reduction of waste, where ideal means delivering what the customer requests on time, on demand, and free of defects (Miller, 2005). Lean process can be traced back to the early 1900s, when Henry Ford introduced the notion of mass production in 1913 (Miller, 2005). However, according to Soderquist and Motwani (1999), Taiichi Ohno was the first to present lean manufacturing to eliminate production waste at Toyota (Soderquist & Motwani, 1999). Source of wastes identified by Ohno include: errors that require recertification, product defects, process steps that are not needed, goods or employee movement without any purpose, goods and services that don't meet the needs of the customers, and any waiting time due to bottlenecks. Taiichi Ohno classified these wastes into seven basic types: overproduction, transportation, process waste, operator movement, inventory, idle time, bad quality (Bateman & David, 2002). Continuous improvement with a focus on the seven wastes is part of lean manufacturing.

It uses a team focused methodology requiring knowledge to be pulled from everyone (from the hourly worker to the upper management), and driven by continuous improvement (Kaizen). The team focuses on continuous improvements and uses tools and techniques to identify and eliminate wastes. Harris and Donatelli (2005) stated that value-stream mapping is the foundational tool used by any company that is on the cutting edge of transformation from a traditional organization to a lean enterprise. Value-stream mapping of products was started through the Toyota production system of lean manufacturing. Ninety-four percent of manufacturing errors or problems belong to systems, and lean manufacturing attacks these systems with the common goal of cost reduction or improvement of production (Deming, 1986).

Kaizen events are ways of accelerating improvements to worker productivity. These events help management to find new ways to gain substantial savings in time, space and labor output (Alukal & Manos, 2006). During Kaizen events, worker's ideas are highly encouraged for frequent and small improvements. This results in shrunken lead times, dramatic reduction in work-in-process, and reduction of scrap and defects, while minimizing the need for capital expenditures (Mika, 2005). They are important because they provide an excellent return on investments of financial and human resources. Furthermore, continued improvements will compound the return, since Kaizen never really ends (Mika, 2005). The events often eliminate the need for costly overtime by improving processes while collapsing lead times, and dramatically reducing work-in-process. It helps focus on improving material flow, information flow, and process quality of a business.

The rest of the chapter will cover the following sections: First, a description of lean techniques is covered. Next, various lean enterprise tools are discussed. Finally, a case study of a firm is presented. The research method, data collection, analyzes, and results are covered.

LEAN TECHNIQUES

One of the primary lean techniques is Poke Yoke. It was developed by Shingo Shigeo in the 1960's, and can be seen as the art of error proofing (Elbadawi, McWilliams and Tetteh, 2010). The process is designed to make it hard to make mistakes or at least easy to be detected and corrected. According to the authors, Shingo explained that a mistake is something a human cannot avoid, but a defect is allowing such a mistake to reach the customer. Therefore, defects are totally avoidable. Poke Yoke utilizes set-up devices or inspection techniques to ensure that the process is done correctly. Standardized works set a foundation that facilitates future change and continuous improvement (Zimmerman, 2010). In many organizations, work procedures called standardized work are written with highly detailed descriptions, but still holding their simplicity (Emiliani, 2008). These work procedures remove unneeded variation and confusion, allowing the process to flow smoothly.

Another technique used by companies to tackle waste is quick changeover. It's the act of changing from the last good piece of a product run to the first good piece of the next run. Quick changeover minimizes the time that operators use during changeover operations, since the excess time doesn't add any value to the products or process. The goal is to spend less time changing from one job to the other. This allows new employees to comprehend complicated operations easily and cover other operations that are not their specialization (Shingo, 1985). The technique helps achieve a smooth flow of value on a production line of different products. One more lean technique that goes along with quick changeover is 5S. It's a series of lean manufacturing standards used to improve the work place (Cross, 2008). 5S are cleansing methods that provide workers with a comfortable and efficient workspace enabling them to perform at their most effective level.

Furthermore, Total Productive Maintenance (TPM), another lean technique, was introduced by Seiichi Nakajima in the late 1970's (Elbadawi, McWilliams & Tetteh, 2010). It aims to ensure the effectiveness of production equipment. TPM focuses on ridding time loss due to breakdowns and stoppages. The origin of TPM is Nipponese, a Japanese manufacturer of automotive electrical parts. The method exerted a major influence over the economic progress made by Japanese manufacturers in the late 1970's. It's based on a continuous improvement strategy that embraces all aspects of the organization maximizing the productivity of the equipment. It also contributes to a successful strategy towards zero breakdowns, zero defect, and lower cost, which can be achieved by observing the equipment's life span. The most popular performance measure in TPM is the Overall Equipment Effectiveness (OEE) defined as follows (Smith & Hawkins, 2004):

OEE= Equipment Availability × Performance Efficiency × Rate of Quality

The world-class level of OEE starts at 85% based on the following values: 90% equipment availability, 95% performance efficiency, and 99% quality rate (Evan & Lindsay, 2004). This is achievable in concordance with Total Quality Management (TQM). Evan & Lindsay (2004) described TQM as the integration of all functions and processes within an organization to achieve a continuous improvement in the quality of goods and services. The technique is used to improve continuously all areas of a company's operation to satisfy customers' requirements (Liang, 2010).

Kanban is a key element in a just-in-time system (Widyadana, 2010). It's a signaling system that gives instructions on when to manufacture or supply a component based on the actual usage of the material. It also informs on what, when and how much should be produced. However, the technique can cause dramatic spikes in demand with the influx of new orders. Kaizen events can be used to minimize the disruption. It's a technique that focuses on structured improvement projects, using a dedicated cross-functional team to improve a targeted work area, with specific goals, in an accelerated timeframe (Farris et al., 2009). Six Sigma methodology and Lean management tools are utilized to find the root causes of issues in many areas of an organization. This provides organizations with management tools needed to make their processes more efficient and effective to serve customers better.

LEAN ENTERPRISE TOOLS

First In First Out (FIFO) is a useful lean tool when dealing with logistics and inventory management. It facilitates order sequencing and control approach

Figure 1. FIFO sign with 18 reels maximum

in fulfilling demands. It prevents earlier orders from being delayed in favor of newer commands. FIFO is used to help operators to complete orders in the sequence that they are received, and up to the maximum. An example of an application of FIFO is displayed in Figure 1. This allows the company to ensure that customer's orders received first are completed and shipped first.

For a maximum efficiency of FIFO, a customized tool namely setup wheel was designed. As illustrated in Figure 2, this tool was based on a set of racks used to stop the reels from moving freely. The tool facilitates the organization of work area by physically straightening up the reels to reflect the sequences in the orders. Prior to use of this tool, it was difficult for operators to prevent the reels to roll or move to undesired locations.

Standard Operating Procedures (SOPs) are written instructions that outline the steps or tasks needed to complete a task operate a piece of machinery or plant. SOPs are effective parts of a quality system with a purpose to assist workers to carry out operations correctly and consistently. The tool enables the workers in the study plant to understand the steps in performing their task. As shown on Form 1, the instructions were written in a brief manner with simple language that all operators are able to read and understand.

One additional tool that helped the implementation of the FIFO is the clip system. It consists of customized color coded clips designed to signify the maximization of the FIFO lanes when they are at full capacity. One of its main goals is to prevent the overflow of the setup wheel system, and help the management of the orders. The colors were used to identify bathes. For example, the color red can be used to identify the first order of twenty reels on a thirty reels maximum FIFO lane and the yellow color will be used for a second set of ten reels on the same lane. Other basic customer information such as customer's names, locations, order and cell numbers, and operator's identification were printed on the clip.

All the lean tools discussed in the previous paragraphs constituted the key performance indicator (KPI). In lean manufacture, KPI is a useful tool for measuring and developing metrics that support and facilitate the achievement of the critical goals of the organization (Vorne, 2011). Key performance indicators are important for understanding and improving manufacturing performance both from lean manufacturing perspective of eliminating waste and from corporate point of view of achieving strategic goals. The tool can be highly effective for exposing, quantifying and visualizing muda, the lean term for waste (Vorne, 2011). To be efficient, the measures must provide meaningful, reliable, and accurate information. They are to be as specific as possible based on

Figure 2. A cell using a FIFO system

data collected. Companies' goals and desires are often vague, but KPIs are to craft them to be very specific.

STUDY METHOD

Study Settings

The study was conducted at a world-class manufacturing plant that makes signal transmission products primarily for the entertainment, residential, industrial and security markets. The plant is located in one of the Midwestern States of the United States, and it is home to one of the firm's global manufacturing divisions along with a distribution and an engineering center. At the site, workers design, manufacture, and market various product types such as cables, ethernet switches, and industrial connectivity for the following markets: industrial; audio and video; security; networking; and communications.

The company is one of the largest U.S. based manufacturers of high-speed electronic cables with specialty on electronics and data networking products. It has presence in the following four segments: Americas segment, Europe, Middle East, and Africa (EMEA) segment, Asia Pacific segment, and the Wireless segment.

The Americas segment contributed approximately 54%, 52%, and 57% of the company consolidated revenues consecutively in 2009, 2008, and 2007 respectively with an industrial market to include applications ranging from advanced industrial networking and robotics to traditional instrumentation and control systems. Their cable products are used in discrete manufacturing and process operations involving the connection of computers, programmable controllers, robots, operator interfaces, motor drives, sensors, printers, and other devices. They also cover other industrial environments, such as petrochemical and other harsh-environment operations, which require cables with exterior armor or jacketing to endure physical abuse, exposure to chemicals, extreme temperatures, and outside elements.

Procedure

The goal of the study was to assess performance metrics through a worker's level of satisfaction and learning after a 30 days deployment of a lean enterprise effort. During a month long intervention that preceded the survey, an audit form shown in Figure 3 was used to collect the work cells level of compliance with the FIFO, Setup Wheel, Standard Operating Procedures (SOP), Clip, and KPI systems.

The tasks consisted of the shift supervisors conducting a walk-through every hour to assess the following for compliance:

1. Is the number of reels exceeding the requirement on the FIFO sign?
2. Are the reels stored in an orderly manner on the tracks/lanes provided?
3. Are all colored clips accounted for? (All 10 clips for each color should either be on a reel or on a stack.)
4. Are any reels in the FIFO track/lane without an attached colored clip?

In the case of non-compliance, a shift supervisor would proceed to provide feedback to the operators in the work cell in question, providing them instructions on how to avoid a non-conformance in the future. The same evaluation course of action was repeated every hour during the three shifts for thirty days. Along with the short guidance provided by the shift supervisors for non-compliances, workers participated in many Kaizen events during the entire time of the study. At the conclusion of the 30 days intervention period, a learning and satisfaction assessment survey was given to the workers. One of the work cells in the plant, the "R cell", was used as a control group: workers assigned to that cell didn't participate in

any kaizen events, and received no feedback or instructions from their shift supervisors.

Analysis and Results

The independent variables (IV) were cell at four levels (C cells, H cell, M cells, and R cell); shift at three levels (1st, 2^{nd} and 3^{rd} shifts); worker's experience at five levels(Less than a year, 1-5 years, 6-15 years, 16-30 years, and more than 30 years); and worker's participation in Kaizen events at two levels (participation and non-participation. As illustrated in Table 1, the dependent variables (DV) were the work cell performance scores in the learning and satisfaction with lean tools such as FIFO, Setup Wheel, SOP, Clip System, and KPI.

SAS 9.1 software was used to analyze the data with the alpha level set at *0.05*. Tests were conducted to determine if there are statistical differences between and among the performance in work cell assignment, shift, experience, and worker's kaizen event participation based of the

Table 1. Description of the variables

Variable	N	Mean Score	Standard Deviation	Min	Max

SOP	147	40.080056	38.956114	0	100
Clip System	147	42.507987	41.473942	0	100
KPI	147	36.457426	35.543168	0	100

cell performance on the following lean tools: FIFO, Setup wheel system, SOP, Clip System, and KPI.

A multivariate analysis of variance (MANOVA) was performed since there are five performance measures, some or all of which may be correlated.

The results showed that the MANOVA test is significant for *cell,* Λ=.72, $F(15, 339.95) = 2.89$, p <.001, and for *kaizen*, Λ=.86, $F(5, 123) = 3.98$, p =.002 as illustrated in Table 2. All the four cells are statistically different based on the variables FIFO, Setup wheel, SOP, Clip system, and KPI. This can be interpreted as people who participated in Kaizen events and those who did not significantly differ from each other.

On the basis of the previous results, another MANOVA was performed to test the main and interaction effects of variables *cell* and *kaizen.* They are found to be the only two dependent variables that significantly affect the set of variables under question 5. The results shown in Table 3 demonstrated that the interaction is not significant Λ=.93, $F(15, 353.75)$ =.62, p =.86. There were only main MANOVA effects of Kaizen and cell on the set of dependent variables under consideration. More specifically, cells means on FIFO, Setup wheel, SOP, Clip system, and KPI, as a set, are not equal, Λ=.75, $F(15, 353.75) = 2.63$, p <.001. Furthermore, the results show a significant association between participation in kaizen events and the same set of variables, Λ=.91, $F(5, 128) = 2.62$, p <.05. This can be interpreted as the performance of people who participate in Kaizen events differed significantly from employees who didn't take advantage of the training.

Since significant results were found in MANOVA, a Univariate analysis, namely an unbalanced two-way ANOVA, followed by multiple comparison procedure, was performed as a follow-up to verify which of the independent variable(s) is (are) associated with *cell* and *kaizen* respectively. The results show that the cells significantly differ on Clip system, $F(3, 132) = 5.17$, p <.01) whereas the differences between the cells are statistically non significant with regard to FIFO, Setup wheel, SOP, and KPI. The multiple

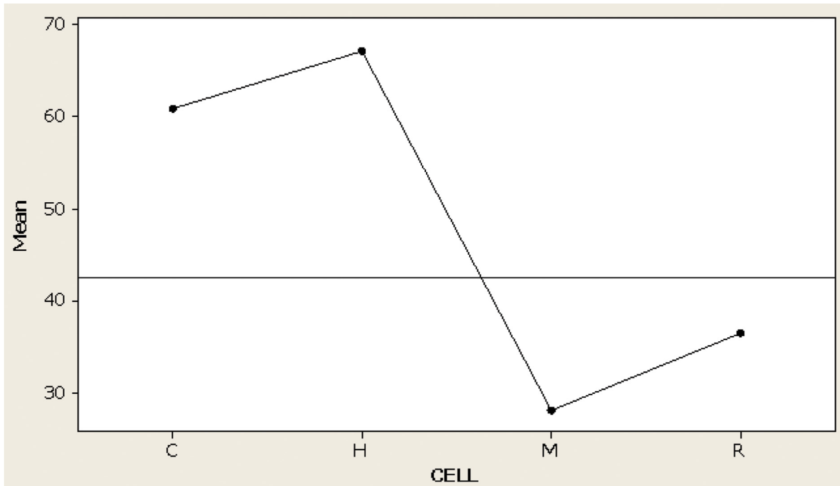
Table 2. MANOVA test for cell, shift, experience and kaizen effects on lean tools

	Λ	*F*	*dl*	*p*	η²
cell	.72	2.89	15, 339.95	<.001	.28
shift	.93	.91	10, 246	.525	.07
exp	.83	1.21	20, 408.89	.240	.17
kaizen	.86	3.98	5, 123	.002	.14

Table 3. MANOVA test for cell and kaizen effects on lean tools

	Λ	*F*	*dl*	*p*	η²
cell	.75	2.63	15, 353.75	<.001	.25
kaizen	.91	2.62	5, 128	.027	.09
Cell*kaizen	.93	.62	15, 353.75	.86	.07

Figure 4. Main effect for clip system



comparison analysis based on Dunnett procedure, reveals that cell R (the control group) differs from cell C and cell H but not from cell M. Contrary to what could be expected, theses groups know about lean tools better than the control group as illustrated in Figure 4.

Two models of MANOVA were tested. In the first model, Question 8 and Question 10 were included separately (or count as individual variables) in the set of the dependent variables. In the second model, the two variables were merged to create one variable called *cell performance*. To create *cell performance* we took the mean of Question 8 and Question 10 after Question 10 score was reversed. The results of these analyses are shown below in Table 4.

Table 4. MANOVA test for cell, and kaizen effects on lean tools

	Λ	*F*	*dl*	*p*	η²
cell	.75	2.63	15, 353.75	<.001	.25
kaizen	.91	2.62	5, 128	.027	.09
Cell*kaizen	.93	.62	15, 353.75	.86	.07

The result for the first model show that MANOVA test is significant, Λ=.85, $F(12, 365.41) = 1.94$, $p < .05$ as illustrated in Table 5; meaning that all the four cells have not equal means on the set of the variables comprising Question 7-Question 10.

As in the case of the lean tools, a univariate analysis of variance using GLM method was performed to identify which, if any, of the in dependent variables were associated with the variable *cell*. The univariate analysis results including multiple comparison show that the cells differ with regard to Question 7, $F(3, 141) = 4.18$, $p < .01$ and Q9 $F(3, 141) = 4.23$, $p < .01$.

The control group tends on average to be more satisfied by the way FIFO was implemented than the group in cell M. The two groups also differ with regard to Question 9, with cell R more likely to avoid confusion than cell M. Compared to the two remaining groups (cell C and cell H) the dif-

Table 5. MANOVA test for cell effect on Q7-Q10

	Λ	*F*	*dl*	*p*	η²
cell	.85	1.94	12, 365.41	.03	.15

Table 6. MANOVA test for cell effect on Q7, Q9 and cell performance

	Λ	*F*	*dl*	*p*	η²
cell	.88	2.11	9, 338.44	.03	.12

ferences are not statistically significant. These facts were expected because, by not having a direct participation in the lean effort at the plant, the workers in cell R were satisfied with the lean implementation effort. Cell R didn't have enough exposure and involvement to provide a good assessment of the FIFO system implementation.

The results of the second model are similar to the previous ones, except that cell performance is associated with cell. Thus MANOVA test is significant, Λ=.88, $F(9, 338.44) = 2.11$, $p < .05$ as shown in Table 6.

The univariate analysis of variance shows that each of the three independent variables is associated to variable *cell*. The results demonstrate that the means of the four cells regarding Question 7 are not all equal $F(3, 141) = 4.18$, $p < .01$and the same is true for Q9 $F(3, 141) = 4.23$, $p < .01$ and variable *cell performance* $F(3, 141) = 2.64$, $p = .05$.

Nonetheless, the multiple comparison results for the *cell performance* do not yield significant differences between the four groups. This is not a big surprise, since the exact *p* value for the omnibus test is.052, and the likelihood of finding significant differences through multiple comparisons was very slim. As for the results for Question 7 and Question 9, they remain unchanged.

CONCLUSION

The purpose of a lean system is to increase the throughput of an organization to meet customers' product demands. This will provide any firms with what they want, when they want it, and at the same time meets their customers' quality expectations. In a global supply chain environment, the identification of key performance measures and their assessment is critical to improve processes continuously. The results of this study showed that the reliance on systematic strategies using lean tools and principles as well as the emphasis on training are the key elements to a successful lean enterprise deployment in a global supply chain environment.

KEY TERMS AND DEFINITIONS

First In First Out: Is an inventory management strategy enacted to ensure that quality is upheld on all shipped products and components.

Global Supply Chain: Refers to the network created among different worldwide companies producing, handling, and distributing specific goods and/or products.

Kaizen Event: Is a short, focused project aimed at eliminating production waste in a particular area of an organization.

Lean Manufacturing: Is a manufacturing strategy that seeks to produce a high level of throughput with a minimum of inventory.

Metrics: Meaningful measures that target continuous process improvement actions.

Quality: Is the customer's perception of how a good or service is fit for their purpose and how it satisfies stated and implicit specifications.

Standard Operation Procedures: Is a document containing instructions on how to perform a task. It ensures that routine jobs get performed safely and in compliance with applicable regulations.

This work was previously published in Customer-Oriented Global Supply Chains: Concepts for Effective Management, edited by Ephrem Eyob and Edem G. Tetteh, pp. 224-235, copyright 2012 by Business Science Reference (an imprint of IGI Global).

Chapter 66
Direct Building Manufacturing of Homes with Digital Fabrication

Lawrence Sass
Massachusetts Institute of Technology, USA

ABSTRACT

Architecture, engineering, and construction industries maintain a long standing desire to enhance design communication through various forms of 3D CAD modeling. In spite the introduction of Building Information Modeling (BIM), designers and builders expect varying amounts of communication loss once construction has started due to indirect construction techniques or hand based methods to manufacture buildings. This is especially true for houses and small structures, buildings that makeup the core of villages and suburbs. Unfortunately, paper documentation and reading 3D CAD models on screen continue the trend of indirect production defined in most manufacturing industries as error. The emerging application of CAD/CAM within design and construction industries provides hope for elevated communication between design and building. With CAD/CAM, it is possible to manufacture buildings of all types and sizes directly from CAD files similar to mass produced artifacts, thus reducing complexity in communication between parties. This chapter is presentation of one process of direct manufacturing from CAD and the emerging possibilities for small building production using digital fabrication. The chapter will focus on houses to illustrate the potential of direct manufacturing of buildings from CAD data.

1. INTRODUCTION

For centuries, architects and builders have pursued systematic ways to design and deliver homes at low cost in production and high quality in output. New arguments around home production are directed at machine based manufacturing of buildings opposing common handcraft construction techniques (Kiernan & Timberlake 2005). This process, typically described as prefabrication, is a century old, westernized system of home production in factories by assembly of large units with cranes on site. It has survived many decades of reinvention while also struggling for

DOI: 10.4018/978-1-4666-1945-6.ch066

broad acceptance as a worldwide industrialized system of building production (Davies 2005). In particular prefabrication has not caught on in developing countries or as a means to produce low cost housing in westernized environments.

This chapter argues prefab is complex in production maintenance, it suffers from the limitations of space and skilled labor, both impede the number of modules produced daily when demand for prefabricated homes is high. These factors also jeopardize the financial security of each manufacturer when unit sales are low. Also noted is the high cost of factory startup and operations curtailing new ventures within impoverished countries and states.

Digital fabrication or CAD/CAM is emerging as the next method of building delivery with built examples as experimental and exotic structures (Sass 2006) (Iwamoto 2008). It is a low cost, high precision manufacturing from CAD data commonly used today for furniture manufacturing. Specific to home construction one benefit of digital fabrication is that it can expand the range of production beyond the local contractor. With digital production manufacturers of metal, stone, plastic and wood based trades can fabricate components anywhere and at anytime. Manufactured components can be delivered to the project site or factory supporting assembly only production systems with low skilled labor. Digital fabrication of components assures component assembles with few discrepancies between the digital representation in CAD and the physical artifact. As a production system it allows for replication and recombination of digital models potentially supporting mass customized home manufacturing (Duarte 2005). Best is that digital fabrication can increase the efficiency of Building Information Modeling (BIM) by empowering *direct building manufacturing* from CAD based product models (Eastman 2008).

The grand challenge for *direct building manufacturing* will be discovery of new process pathways that bridge the physical divide between 3D building information models and machine data. This limitation stems from industry maintenance in hand tooling and assembly with handheld machinery as the core production method. For wood framed housing the standard material is dimensional lumber processed with standard tools such as power saws, screwdrivers and nail guns. Power tools and dimensional lumber do not take advantage of the efficiency of CAD modeling or CAD/CAM machinery. Precise machine cutting of is often difficult without special machine setups and rigging, the industry of wood framed housing maintains a need for highly skilled crafts people.

The aim of this chapter is to provide a context for digital fabrication as a mode of building production from a design by presentation of a process with two built examples. The chapter starts by presentation of industrialized manufacturing as the background for our home product manufacturing goals (Section 2). Next, past methods of controlled home manufacturing is presented illustrating the limitations and error in construction leads to higher cost and lower quality construction (Sections 3-5). Digital fabrication is presented as a method of production along with and explanation of its limitations (Sections 6-7). Materializing Design is systematic way to compute a design model for digital fabrication along with illustrations of the transformation process (Sections 8-9). The chapter ends by discussion on next steps as they related to the integration of other building systems such as plumbing, electrical, solar, etc.

2. INDUSTRIALIZED MANUFACTURING

As we stand at the threshold of new demands for energy-efficient green homes, we are also faced with the need for advanced systems that control design and home delivery. More than ever before, consumers expect new homes to perform in ways similar to mechanical products like automobiles, computers, and airplanes. Demands for increased building performance, reduction in cost, and speed in delivery all drive the desire for homes to be built in controlled environments.

The American housing industry supports three common home-delivery systems. The first—wood framing on site with dimensional lumber—is considered to be the least controlled by the designer. Here methods of production are governed by the local contractor and vary between contractors. The second form is factory-built homes as an assembly of framed boxes or prefabricated housing. Units are designed and manufactured in a factory setting as a way to control labor and materials processing. Last is a panelized system. The process starts with metal or timber framing infill with wood or metal panels. Both panelized and box fabrication require delivery by truck and on-site assembly with the assistance of cranes. All of the three methods are used by many home manufactures and designers.

The production of a prefabricated house starts with the customer's selection of predetermined designs from a catalog of glossy photos and renderings. Design styles are limited to rectangular shapes for easy transportation; cylindrical and nonplanar building shapes are uncommon. Once the order is placed, designers can then tailor each home to meet the environmental and regulatory needs of the town and site.

The efficiency of prefabricated production is its ability to standardize the mode of production. For example, the structural framing of most homes is assembled from dimensional lumber and plywood. In spite of the standards, though, every factory-made home requires some number of design changes due to variations in building site, codes, utility hookups, and the foundation. Therefore, paper drawings are generated for each new home project to guide the workers through production on the factory floor. After factory fabrication, local contractors are responsible for attaching the prefabricated boxes or panels to the foundation, as well as adding exterior siding, electrical and plumbing hookups, roofing, and finishes.

Unlike in the building industry, the design and production of goods in other major industries (e.g., automobile, computer, cell phone, aeronautical) is made up of *Original Equipment Manufacturers* (OEMs) whose responsibility is based on the assembly of products in factories (wheels, body panels, etc.), the result of which are branded products (Herbig & O'Hara 1994). The definition of OEM is not clear; each industry has its own terms and definition. In this chapter "OEM" refers to the producer of the home. Unlike home manufacturers, the assembler physically produces a minority of the assembled components; rather, they design, integrate parts, and assemble purchased products.

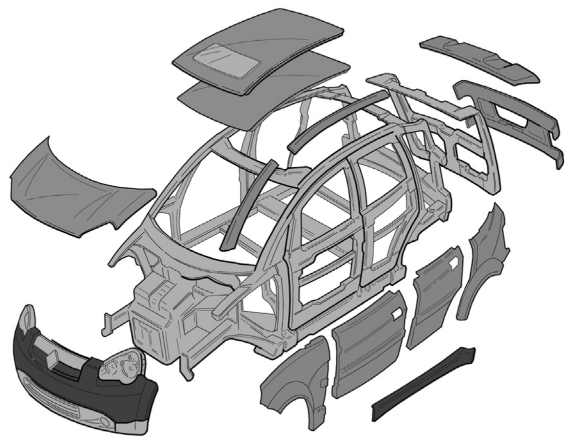
Digital fabrication makes this type of production possible by including the same or similar CAD data used in design as part of the machine manufacturing and assembly process. In the automobile industry, for example, integrated CAD systems are a critical part of manufacturing plastics and thin metal auto-body parts (Stauber & Bollrath 2007). Efficient production of plastic auto-body parts from a variety of vendors is possible because the design models from the assembler are shared by the designer and plastics fabricators (Figure 1).

Prefabricated-housing factories aspire to operate and to manufacture homes in ways similar to the OEM model. They fall short of this goal, however, due to wasteful processing and low precision. Although it is not a typical constraint in building construction, precision in manufacturing allows for the perfect fit between parts. Once high precision is available, manufacturers can have subcontractors compete to provide the factory with precisely fitting components at the lowest possible cost.

3. CONTROLLING DESIGN WITH DRAWINGS

A common theme in design control over quality, cost and time is controlled through documentation such as instructional books, CAD models,

Figure 1. Exploded diagram of a CAD model for a car produced by an automobile assembler. The chassis is built by one manufacturer, whereas panels, dashboard, and mechanical components are built by other manufacturers and then factory-assembled.



and design automation. One standing tradition is the control of style and process with rules illustrated on paper a method that dates back to the architectural treatise: Vitruvius (Vitruvius 1960) Palladio (Palladio 1965), Alberti (1986), and Serlio (1996). The seventeenth-century architect Durand pursued a similar interest through his *Précis des Leçons d'Architecture*, published in 1819—a text illustrating ways to build public buildings and statues (1802). A current form of design control can be found in architectural pattern books, which guide the production of styles and functions at the scale of a town or community (Gindroz & Robinson 2004). It is important to note that pattern books do not propose individual designs as an assembly of elements, such as columns, stairs, or window and door details, the way a treatise might. Instead, pattern books detail ways of organizing the physical elements of a community (streets, statues, street signs, etc.).

Contemporary design control as an automated process has been explored through shape-grammar methods and generative systems (Stiny 1980). A shape grammar produces designs in a certain architectural language via the application of shape transformation rules. These transformational rules allow for shape evolution from an initial shape. One example of shape-grammar production is the Queen Anne Grammar developed by Ulrich Flemming. The drawings that resulted from the grammar were used to produce designs for a pattern book as part of Pittsburgh's redevelopment initiative in the 1980s (Flemming 1987) (Flemming et. al 1986). More recently, a modern shape grammar called Malagueira Grammar was used to generate house designs in the style of Alvaro Siza (Duarte 2005). Both housing styles—Queen Anne and Malagueira—were generated by a grammar that resulted in 3D representation as drawings or CAD models. One valuable reason to consider shape grammars as a method of design generation is that the process can be automated. Unlike generating designs one at a time through keyboard entry of commands into a CAD program, an automated shape grammar program can, in minutes, generate hundreds of alternative design schemas based on a particular style. The customer can then select the best fit.

Unfortunately, all three examples (treatises, pattern books, and shape grammars) only demonstrate a way to produce design concepts and details as drawings for interpretation by builders. They do not control physical production, cost, or final product quality. Once the design is complete, all of these methods still require many laborious physical steps to build a home.

4. CONTROLLED DELIVERY WITH MACHINES

Alternatively, there are those who venture control over production by combining design and delivery. Architects and builders such as Karl Strandlund, Walter Gropius, Frank Lloyd Wright, and Konrad Wachsmann built delivery systems they hoped would make well-designed houses affordable. They collapsed the extensive relationship between the designer and contractor into companies that provided both.

Sears and Roebuck started the process through the sales of traditional and arts-and-crafts home styles from their catalog in 1895. They brought craft to the masses with a factory-based delivery system that employed artisans who had once built fine products from furniture to houses. A delivery system for housing was invented that gave access to customer-driven home design and delivery; no two houses were alike (Sears 1990) (Cooke & Friedman 2001). Variation was a major factor in sales and marketing. In time, over 400 designs, in many traditional styles, were offered to customers. Sears and Roebuck employed many artisans to manufacture components with handheld tools and machines in a well-lit factory. For efficient delivery, lumber pieces were precut and labeled before shipping by U.S. rail. The resulting assembly on-site was a balloon-framed structure clad with a variety of materials from shingles to brick. Sears and Roebuck survived as a home producer until the late 1930s, when it began offering financing as part of home sales, which unfortunately led to the company's destruction. Sears and Roebuck had positive sales combined with a negative cash flow.

By contrast, Walter Gropius, founder of the Bauhaus, an influential school of art in the twentieth century, was interested in a standardized, rational approach to design and home delivery (Gropius 1956). It was his way of countering crate-based variation in cost and quality due to variations at the hand of the artisan. His interest in moving past craft-based delivery systems to machine-based production was shared in the United States by his business partner, Konrad Wachsmann; together they started the General Panel Company in 1942 (Wachsmann 1961). Their product—The Packaged House—was a modest modern-style building expected to be factory built, delivered by truck, and assembled on-site with no postfactory production. It is clear in Wachsmann's writing that he thought machines and mass production were a means of controlling quality and cost. The machines enabled some automation in production. Wachsmann focused on the concept of element modularity as a way of controlling assemblies between machine-produced metal components. The Gropius–Wachsmann standardized building system considered ways of repeating the manufacture of one type of joinery with variations in panel production. They worked with standard metal machines of the 1940s set up in large spaces ready for building the components of many houses at one time. Unfortunately, the company was reduced to building only doors, and after five years of startup and preparation, it was unable to secure any housing contracts.

Finally, a notable contribution to the industry of home delivery was the Lustron House developed by Carl Strandlund in 1945. His houses were also factory-based products that took advantage of industrial machining and new materials processing. His company produced 2,500 homes from a handful of designed models available in four different color finishes. Exterior and interior walls were manufactured steel panels with a porcelain finish, assembled on-site with nuts and bolts (Knerr 2004). Each house was assembled from over 30,000 small components, which required many manhours in labor. In fact, the manhours needed to screw bolts and gaskets drove the house price out of the affordable range. The company lasted only nine years. It was not the concept of precise machinery in a comfortable controlled environment (i.e., the factory) that made the Lustron a short success. Its demise was due to a laborious assembly system and inflexible panel making that limited variations between designs.

Today's best prefabricated systems resemble the processes employed by Strundland and Wachsmann/Gropius—hand based, hand tooled with inflexible machinery—with the exception of a few factory-based methods in Japan (Noguchi 2003) and Europe and the use of digital design. Prefabricated housing companies continue the legacy of low-precision, high-cost production at the hand of the artisan. A notable step forward in production-based research can be found in a system that integrates a structural system into the design computing system (Benros & Duarte 2009).

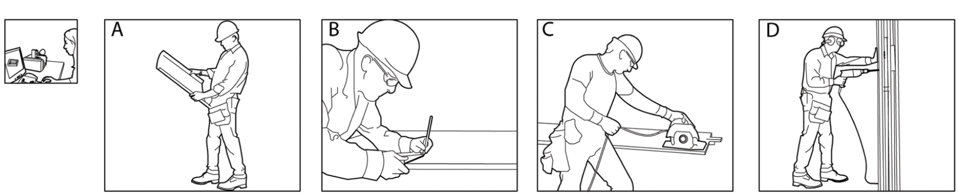
5. ERROR AND THE ARTISAN

As mentioned earlier, this is not the case in the manufacturing of common industrialized products—such as cell phones, computers, and automobiles—that use the OEM model. In any product design process, prediction and elimination of error is a key activity in the design process (Goh et al. 2005). In contrast to product design, error in home construction originates from overlapping operations between construction workers and the process of visual interpretation of the drawings. This conflict is due to measuring and cutting components with manual tools, then re-measuring previously assembled building elements and new cutting. In construction, design and shop drawings merely illustrate "design intent." Workers can and do deviate from notations on the drawing due to unforeseen obstacles in the field. For example, the process steps in Figure 2 show a designer who produces data output as drawings. These are interpreted by construction workers (a). The information from the drawing is manually transferred to a material substrate (b), hand cut (c), and assembled with handheld tools (d). This low-precision process requires time for measuring and cutting each new element. Steps c, d and e in Figure 2 are then repeated for each new element (as when fabricating a stud wall), so time is needed in order to measure previously assembled studs and to deal with any inaccurate cutting of new studs. As the complete artifact is assembled, the elements may well have little or no relationship with the designer's drawings and models. In craft-based construction, every component is hand measured, hand cut, and assembled with little dimensional relationship with the original drawing.

6. CREATIVE USE OF DIGITAL FABRICATION

For higher precision in cutting and assembly, CAD drawings can be sent to a digital fabrication device for precise measuring and cutting. Digital fabrication is a flexible three-part process from digital modeling to a fabrication device and hand or machine assembly that brings together a relationship between materials, machining and CAD modeling. In contrast to the artisanal work discussed in the previous section, digital fabri-

Figure 2. Traditional craft-based home production starting with CAD drawings



cation is computer-based measuring, computer-controlled cutting, and hand assembly of precise components. An extensive explanation of digital fabrication machinery, machining methods with examples is found in Schodek (2007). There are two flavors of digital production for the field of architecture.

The first being project based digital design and digital manufacturing. Digital fabrication in the field of architecture is defined by architects who create one-of-a-kind buildings as sculptural artifacts. Design commissions completed by architects such as Frank Gehry who fabricates buildings of metal and wood, theorist Greg Lynn and Bernhard Cache postulates ideas about fabrication through prototyping. Lisa Iwamoto, Nader Tehrani and Mark Goulthorpe are proof of the creative potential behind these new technologies by fabrication free form exhibitions of fabrication. These architects represent their designs with advanced curved surfaces as well as solid and parametric modeling software, and then physically produce complex designs by CAD/CAM manufacturing. They employ a combination of sophisticated technologies such as curved surface CAD modeling tools to simplify areas of design complexity. For most design and construction professional direct manufacturing is reserved for a few areas of construction such as building exterior only, interior surfaces, and the structural members only. A summary of one-of-a-kind projects and methods of production including both traditional and CAD/CAM fabrication can be found in Bernstein (2010). One built example of a creative design can be found in the Amsterdam Pavilion in lower Manhattan built of digitally fabricated plywood components. This project was modeled in CAD traditionally with key board entry of modeling commands. Components and assembly are with metal fasteners and a hand finished surfacing (www.unstudio.com). An example to follow is a project built by the Institute for Advanced Architecture Catalonia of a solar paneled house. This project is also a digitally fabricated plywood structure with assemblies sustained by metal fasteners (www.iaac.net/projects/fab-lab-solar-house-3).

The second type of digital fabricated architecture is as a production system where multiple iterations of a design are generated and manufactured. The first example Contour Crafting is one example of rapid digital fabrication of houses by using layered concrete dispensed from a computer-controlled machine. The greatest potential of Contour Crafting relates to housing in developing countries in need of original and replacement concrete structures (Koshnevis 2004). A second example of a production system is defined as materialization. It is a systematic method of subdividing geometry into constructible components ready for digital fabrication. A pilot project built summer of 2005 demonstrated the potential of digital fabrication as a system of building production. The project was a small cabin built completely of interlocking plywood components manufactured from CAD/CAM machines. The structure measured of 8' x 10' x 15', was elevated 24" off the ground. A detailed description of the process and computation can be found in Sass (2005) (2007). A second example of a materialized design was also constructed using from interlocking plywood components three year later. This version was constructed as part of a museum exhibition was assembled with few tools and assemblies that were sustained by friction from part interlocking (Bergdoll 2008). From these two examples of digitally fabricated structures it is possible to mass produce many of these buildings from the same data. It also means manufacturing is possible anywhere using similar machines controlled by computers. A series of construction rules were developed from the two examples.

Digitally Fabricated Structures:

1. Computer generated designs are manufactured from computer controlled machines
2. A variety of complex components can be manufactured by the machine

3. The structure is built of layers of materials that compose a lattice & surface
4. Each element includes interlocking geometry for direct association with other components
5. Elements are fabricated as 2D parts
6. Parts are assembled with few tools possible to sustain by friction

7. PROBLEMS WITH DIGITAL FABRICATION

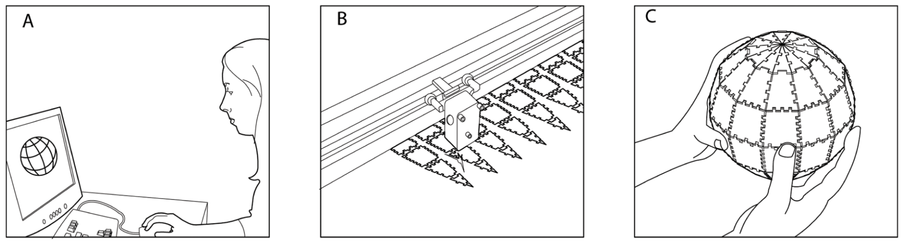
A core problem in digital design and fabrication is the many design steps associated with modeling physical objects in CAD as described by Sass and Oxman (2006). The paper outlines three limitations in design production: complexity in component design, generating assembly descriptions in CAD and scaling models from physical prototypes to full scale construction. Design automation can address these problems with computer programs built for rapid model generation. Researchers in electronic design automation use CAD tools and libraries to design and generate information for printed circuit boards (Jansen 2006). For digital fabrication automated CAD systems will aid in conversion of 3D design models to 2D data for digital fabrication CAD/CAM. An integrated process of design generation will elevate the impact that computational analysis and optimization tools have on designs and fabrication.

8. MATERIALIZING A DESIGN

A systematic process of object production is discussed here as a pathway towards building physically based automated design tools. This process, defined as *materializing* is intended for production of many 3D artifacts, the process assumes each artifact to differ in shape or composition of shapes with the same physical language of production. This system of production is alternative to methods used by design architects to build a kind of sculptural artifacts. *Materializing* is a computational production system that allows designers to rapidly realize visual and physical goals from three-dimensional CAD models. In summary, *materialization* is a three-stage process of shape transformation from (*a*) an initial shape model to (*b*) CAD/CAM manufacturing and (*c*) assembly by hand or with robots (Figure 3). The contribution of this system defines the mathematical relationship between the designer's CAD model and the physical building production—the critical step in the relationship between computer-aided design to computer-aided manufacturing. As for buildings a close relationship between flexible CAD modeling and flexible digital fabrication will lower process and material waste by removing process steps commonly found in craft based construction. The work in this chapter is not automated with CAD tools as mentioned above, however the format and steps provide a format for building product automation.

Alternative to the three part physical shape production illustrated above, building production requires many steps in translation. With computation quality and time is controlled by converting steps that would otherwise be handcrafted steps to computable steps. Figure 4 is an illustrated process summary that shows three of many computational steps in converting a design model generated in CAD to sets of machine tool paths. Each pathway assists full scale assembly of components with computable features between components. The first step captures geometric characteristic of the starting Shape for structural analysis and data storage (Figure 4). If the shape is structurally sound the next steps are focused on structural contours along the three axes (x, y & z) or a new shape is generated and edited for structural compliance. The new shape is composed of structural contours as interlocking geometries of varying depths depending on loading and location. The second step is the addition of attachment features to each contour, these features join the surface geometry with the contour geometry. Here

Figure 3. Three step materializing process from a shape model (a) in CAD to laser cutting (b) and hand assembly (c)



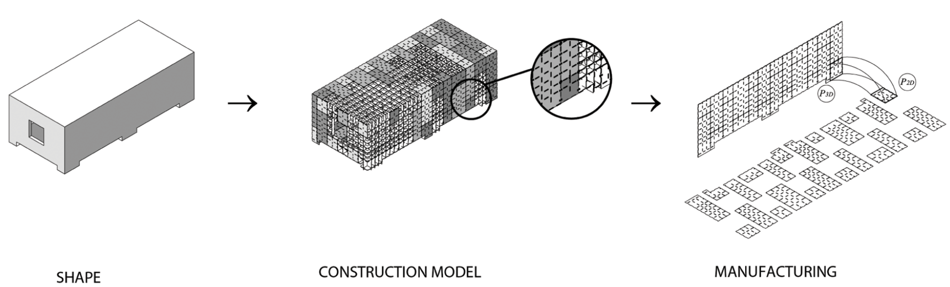
the assembly alignment and final attachment between each element is an integral part of the elements geometry. Integral attachments of this type were popularized by research in plastics as a way to measure and manufacture plastic fasteners. The fourth step in the process is subdivision of exterior surface and contours into smaller parts related to the machine and material constraints. The resulting geometric model in a finished collection of elements defines a construction model (*Construction model)*). The last function is translation or development of three-dimensional elements to two dimensions *(*Manufacturing)a function is common in the field of descriptive geometry. Developed elements and their attachment features are packed and sorted in two-dimensions before final CAD/CAM fabrication. Construction modeling of the type in Figure 4 is complex, labor intensive CAD modeling through keyboard entry of commands.

9. CONCLUSION

This chapter starts by descriptions of houses as manufactured products designed digitally yet manufactured by hand. The claim is that a physical disconnect between tools in design and physical construction lead to errors in production unfortunately considered the rule and precision based construction is the exception. This imprecision in production results in many process steps in manufacturing from hand measuring and re-measuring by hand of previously built components.

Digital fabrication for home construction introduces precision in manufacturing, assembly and component integration. Precision manufacturing throughout the design and construction process elevates the impact and purpose of computation analysis tools and design optimization. The resulting components can be assembled on site with low skilled labor due to semantic nature of each piece.

Figure 4. Broad steps in materializing a model of a building from a shape model to a series of interlocking components



Beyond this chapter, a search for holistic approaches to building design, computation and production requires further development in methods to generate component descriptions. In this text computational systems decompose an initial shape into sets of components for digital fabrication in ways similar to carpenters on site. This system also illustrates how the shape of a building can be analyzed and optimized for assembly and fabrication controlling cost and the quality of design delivery. Illustrated are abstract steps in construction modeling for the internal structure, external surfacing and final production data. It is considered first steps leading to design automation for digital fabrication only for the structure of a building.

Future work will seek integration of other building systems beyond structure into interrelated systems such as rain-screens, insulation, air-handling, electrical, plumbing, etc. It is believed that most if not all of these systems can be fabricated through CAD/CAM design as well. It also means that each of these systems requires re-invention and development beyond the three dimensional methods of common construction towards 2D productions that assemble into 3D buildings. New research in digitally based construction systems will lead to similar breakthroughs in construction where all systems can be designed rapidly in CAD and manufactured with machines.

ACKNOWLEDGMENT

The author thanks Dennis Michaud and Daniel Smithwick for their dedicated service in building the exhibit structure, the Department of Architecture at MIT, and the Rockefeller Foundation, which was the primary sponsor of the MoMA exhibit. Additional thanks go to the American Institute of Architects and Boise Cascade, as well as to Shopbot Tools for fabrication.

KEY TERMS AND DEFINITIONS

BIM: Generation and management of building data, typically a 3D model, throughout its life cycle representing spaces, products and some means and methods of production. The model can be updated for changes made between design, finished construction and renovation.

Construction Modeling: 3D component based description of a design in CAD. This description challenges component at the scale of assemblies. Each digitally fabricated component is represented in 3D.

Design Modeling: 3D description of a design in CAD. This description is a formal representation used for visual evaluation of a design.

Development: Development follows the term developable, as in geometry that can be flattened to 2D from a 3D shape.

Digital Fabrication: Direct manufacturing of physical artifacts from CAD files.

Layered Manufacturing: Similar to additive manufacturing where artifacts are produced from layers of material. Each wafer thin layer is manufactured from a CAD model and automatically assembled to the previous layer.

Materialization: Translation of a 3D design model into 2D elements for CAD/CAM manufacturing.

OEM: Original equipment manufacturer is the company that originally manufactured a specific product.

Rapid Prototyping: Automated production of a physical 3D object from a CAD description.

ABSTRACT

Motivated by the increasing demand for software engineering professionals, in particular project managers, by the dissemination of the use of games as an attractive instrument in the learning process and by the universalization of the Web platform as a catalyst of human relations nowadays, this chapter proposes the use of a Persistent Browser-Based Game as a support in the qualifying process for new professionals of Project Management. Following the pedagogical theory of the Project-Based Learning - PBL, the game gives the player the opportunity to experience real situations of Project Management by proposing challenges commonly faced in most enterprises. These ever present challenges include unpredictability in the software manufacturing organizations, by means of the use of intelligent agents to assign challenges and common barriers to Software Projects.

INTRODUCTION

The importance and the real needs of the adoption of methods and principles of the Project Management (PMI, 2004) in organizations are currently widely discussed and accepted. In these organizations, the main role of the Project Manager is the task of conducting a project to its successful conclusion. However, that is not what usually happens in software projects (Brewer, 2005).

DOI: 10.4018/978-1-4666-1945-6.ch067

In an attempt to explain the high number of projects that fail due to reasons related to bad management, some studies have discussed a possible relationship between the lack of certain abilities by managers and the traditional teaching methods. This is one of the consequences of acquiring knowledge without an experience in some real project or complementary educational approaches, such as games and simulations.

In order to provide a solution for this deficiency, in this chapter we propose a tool to provide a new way of learning that is not only attractive, but efficient and collaborative as well. This tool meets the needs of users with distinct routines and schedules. This chapter proposes the eRiskGame tool, which is a Persistent Browser-Based Game for educational purpose. The game is about the tasks that a Project Manager must perform in an organization. Its focus will be on Risk Management, more specifically in the Planning, Control and Monitoring (budget, time schedule and software quality).

This serious game uses PBL to bring the player a way to acquire knowledge on project management, particularly in the risk control involved in this process. To that end intelligent software agents were employed in monitoring and controlling of the environment, which is in constant change and affects the professionals, the organization and its customers.

BACKGROUND

This session introduces the background and the important terms involved in the development of this tool.

Technological Aspects and Motivators

We live in a highly dynamic, diverse and demanding society, where new technologies are constantly seeking to supply the needs and take into account the particularities of that heterogeneous public, which have different time availability, locomotion and spaces. These new technologies have the fundamental role of making these differences transparent, allowing persons with distinct dispositions and skills to interact jeopardizing their performance.

In this context, we have the Web as a powerful resource in the process of teaching and learning, through which we can learn and teach in many ways, in different places and at different speeds. This technology allows the expansion and integration of knowledge in a way that could be fast, dynamic and accessible to all providing the construction/reconstruction and socialization of knowledge for a better individual, social and collective context of all involved.

There has been a growing interest in the use of computer games as a didactic-pedagogical tool, for training, qualification or improvement of skills in several knowledge areas. Not only the academy, but also the industry has shown great interest in this market portion, which already moves $20 million per year (Susi et al., 2007), and attracts more and more attention of those seeking a way not only innovative, but effective to transmit knowledge without the common lack of motivation in the traditional distance education methods.

Software Engineering and Teaching Model

In the context of software engineering, numerous initiatives have arisen in order to use the ludic qualities and motivation that the games have in the education or training of new professionals, in an attempt to reduce the limitations imposed by time and/or format of the traditional courses in this area.

In the various educational levels, one of the factors that most concern the teachers is the motivational level of their students. In Sandford et al. (2006) it has been observed that 53% of the teachers see the motivation for their pupils as primary reason for using educational games. However, the authors argue that the use of games in educational environments does not ensure motivation alone. We must look to the characteristics of the games that better encourage the students' commitment.

In addition to motivation, computer games may also be able to introduce integrated techniques, involving a wide range of interaction ways that improve both the learning and the sociability. The Project-Based Learning is a theory that has gained a special interest in the serious games area, because the students not only improve their analytical capacity, but they also assimilate more knowledge. Games also offer experience of collaborative work and improve the ability of players' communication.

PROJECT-BASED LEARNING

Project-Based Learning (PBL) was proposed by Ayas and Zeniuk (2003) as a mean to conduct the education where the personal and collective skills are devised through the development of learning capabilities which allow short term reasoning. This learning theory allows individuals and teams the creation and the sharing of knowledge. This theory presupposes that a project centered on tasks where the pressures of short term prevail, the participants must be in balance between action and reflection, in order to build the competence of the learning capacity (Hsu and Liu, 2005).

The PBL can be understood as an education technique, where situations of an actual context are modeled on a fictitious project in which the students must commit-to-finish it, and thus build knowledge regarding that experience.

A project is defined as a temporary effort, driven by a group of persons, to create a product, service or single result. By temporary we mean that all the projects have beginning and end defined. The end is reached when the goals are achieved, otherwise the project has failed. A project is characterized by having an objective and clearly defined requirements (scope), by complying with the approved budget (cost) and must be finalized within specified term (time) (Schwalbe, 2002).

In the PBL, the learning comes through a process in which the students build a product, working as a team. The product may be something tangible (such as a model / prototype, a system or a robot), a computer product (such as a software, a presentation or a multimedia product), or a written product (such as a report, an assessment or a summary of experimental results). The product must either answer a question, solve a problem, or attend the needs and requirements laid down by the course instructor or identified by the students (Frank, 2008).

PBL is a hands-on approach that is focused on issues that lead students to meet the fundamental concepts and principles of a subject. It helps their abilities of creative thinking, showing that there are many ways to solve a problem. In addition, the education based on projects differs from the traditional education by its emphasis on the artifacts construction by the students themselves to represent what is being learned.

The central idea of the PBL is that the problems of the real world can capture the interest of students and cause serious reflections on how students may acquire and apply new knowledge in a context of problem resolutions (Yadav and Xiahou, 2010; Frank, 2008). The teacher plays the role of the facilitator, working with the students for raising relevant questions. The teacher also helps in structuring significant tasks, improving both the knowledge development and the social skills. In addition, the teacher evaluates carefully what the students have learned from the experience. The supporters say that the PBL helps students to acquire thinking skills besides of the collaboration required in the workplace.

PBL Applied to Software Engineering

The traditional approach in the Software Engineering teaching is based on a reading model.

However, this model brings a big problem for students, mainly due to the little involvement with the theme. Students play a passive role in the educational process, differently of the role of Software Engineer which must be alert to what occurs in the projects which he or she coordinates and make decisions that will be the foundation for their successful conclusion.

Integrating the PBL in the learning of Software Engineering makes it possible to provide the student with a practical experience that cannot be obtained in activities performed in a laboratory (Yadav and Xiahou, 2010). In the traditional approach, the problems are normally adapted and simplified in such a way that they do not appear to be relevant or are linked to solutions already pre-manufactured, which prevent reasoning and gathering of the students' ideas to deal with problems of this nature. In addition, some issues, like process models, appear to be so theoretical that do not show the students how this will be used in practice.

Based on these facts, we see that the PBL, when applied to serious game for the teaching of Software Engineering is as feasible as useful to the students in relation to the practical that the discipline. This combination may also improve the learner's analytical capacity, which concerns the ability to analyze data, not always inter related, and from this analysis produce valuable information or knowledge.

GAME-BASED TRAINING

In the evolutionary rhythm, which the humanity has walked, many paradigms were broken and much has been gained with this. In the education context, what we have seen are new methodologies and educational approaches being created and recreated. The aim is to achieve better pedagogical results with an ever more dynamic and diversified public. One of these approaches is the use of electronic games in the educational context (SGI, 2010), which has been broadly discussed and implemented in formal and non-formal education.

Formal Education represents a set of educational activities with clear and well defined goals which conform to centralized educational directives and are implemented within the limits of schools and universities. The non-formal education is more diffuse, less hierarchical, unbureaucratical and is usually performed outside the limits of the formal educational system.

Some authors consider also the existence of informal education which, although not submitting the rigor and the implementation of traditional educational methods, promotes some means of acquisition of skills and knowledge (Sørensen and Meyer, 2007).

In the several educational models, some factors, such as lack of motivation or involvement with the subject taught often become very difficult obstacles to be transposed and may impair the student's performance. In this sense, games may be integrated to the training models by adding fantasy, visual effects and interaction way more attractive to the students.

Some of the main elements found in games include interaction, flexibility, competition, visual feedback, dramatic effects, usability and fidelity degree to reality (Prensky, 2001). Interactivity is a fundamental characteristic, because the player can easily get bored without an active participation. The flexibility provides the player with a control level and investigation of the available content, in accordance with the rules. The competition represents the challenge, the conflict, the solution of problems that require exploitation and strategic abilities that motivate the player in the search of the goals defined. The game provides feedback to the player actions, evaluating and presenting the player's progress in seeking his or her goals. This feedback is done by means of dramatic effects on the elements that compose the game story. These effects (sound, images, animation, music, humor and stories) can bring entertainment to the learning content, adding a context, characters and dramatization. That allows the student to experience a role and act within the game.

In order to use computer games and games in general for educational purposes, several aspects of the learning process must be supported: i) students must be stimulated to combine the knowledge of different areas to choose a solution or to make a decision in a certain moment; ii) students must be able to test how the game result changes based on their decisions and actions; iii) students must be encouraged to keep contact with other team members to discuss and negotiate the subsequent steps, improving, thus, among other things, their social skills (Pivec et al., 2003).

Software Engineering students in particular can benefit from the use of games in training once the project management depends strongly on past knowledge and experience. Using games students can analyze situations already experienced in other projects and evaluate different paths on the project that he or she could have taken, due to specific decisions that have been made on specific points, thereby improving their abilities on management and decision making.

BROWSER GAMES

Growth of the Web and People Interest on Browser Games

According to research carried out by the International Telecommunications Union (ITU), from 2003 to 2009, the number of people who have Internet access doubled and represents 25% of the world population, and in developed countries this number rises to 64%. Following this perspective of growth, from 2009 to 2010 the number of users that have Internet access at home have passed from 1.4 to 1.6 billion.

In view of the growth of "connected" public, it is increasingly interesting to invest in the Web platform. Along with that growth, it is possible to notice social changes experienced in the past 25 years that have arisen what is known today as Digital Natives. They are people with easy and permanent contact with technology, representing today 50% of the active population and may reach 80% in 10 years.

Aiming to reach that market portion in constant growth, the billionaire electronic games industry has started to invest in multimedia titles totally in Web, focusing on the potential that the platform offers, such as: i) persistence, which is the state maintenance of the game in the server aiming posterior access; ii) platform independence, an increasingly necessary requirement, given the diversification of operating systems and devices for Web access; In addition to the iii) collaboration experienced in Web 2.0 and the explosion of social networks.

The browser games may include all the genres of games, which could be single-player[1] or multiplayer[2], and the latter gained more emphasis due to its additional focus on the social interaction, often on a massive scale. Social networks make use of these games to bring more people, for example the Zynga's Farmville (Zynga Inc., 2011), popular farm browser game running on Facebook.

Persistent Browser-Based Game

In this context, we can define a Persistent Browser-Based Game (PBBG) as an electronic game that can be played and accessed by a Web browser and presents a shared persistent virtual environment, where the events continue to occur even in the absence of user. The user may recover his session later and continue in the game (Project, 2009).

In a heterogeneous audience, with specific requirements of time and resources, the characteristics offered by PBBGs may be the key-point in the success of a learning tool. Since it provides people with separate provisions to interact, compete or exchange experience using the same tool. People who need to move could benefit from the portability of the PBBGs, once the information about the users' profiles are stored in the server, and no special software is necessary, so that they may be accessed from any terminal through a browser and continue from the point where he or she stopped.

PBBGs can also run on mobile devices, most of these with limited capacity. This is possible because most part of browser games do not count on complex graphs or sounds, which normally are compensated with one ludic aspect, thus maintaining their attractiveness.

Due to the frenetic emergence of new multimedia titles, in many styles, qualities and themes, it has been avoided in this work cite examples. However, we can indicate Browser Games (2010) as a wide and detailed list of the main browser games currently available.

WEB COMMUNICATION TOOLS APPLIED TO EDUCATION

Advances in communication technology are changing the way in which people around the world teach and learn. The communication technology offers new alternatives for creation, storage, access, distribution and sharing of didactic material (Chou and Sun, 1996). Since the Internet has become part of the life of most part of students, many Web communications tools are being exploited as an element that aids in the learning process.

Currently, a type of tool widely used in virtual activities and discussion groups is the forum. In an asynchronous interactivity, participants may exchange views and discuss themes proposed, generating an exchange of experiences and questions which motivate users to deepen in problem context and search for more knowledge, since the diverse opinions may cover subjects besides the discussion focus.

The electronic mail is a more direct communication tool. It is normally used for receiving guidelines directly from the teachers and may be applied to provide a private dialog between the parts. Chats offer a synchronous communication between them and allow the creation of discussion rooms separated by issues or user groups. These and other tools aim to fulfill the human need to interact with other persons and not always are included in distance education.

The social interaction promoted by communication tools via the Internet brings other benefits to traditional education methods. The students feel more comfortable to expose their doubts and may receive feedback not only from the teacher, but also from other students, allowing a comparison between the various points of view. This cooperation supports and encourages the sharing of knowledge and individual experiences, bringing to the group a wide range of experience.

The wide use of these tools has given a greater flexibility and freedom to teachers and students regarding the manner in which they organize and obtain progress with their studies and has created a environment in which learning occurs how and when it is convenient (Xakaza-Kumalo, 2010). In this context, it is noticed that learning environments, mainly educational games, need communication tools to encourage knowledge sharing and promote better interaction and collaboration between students and teachers.

INTELLIGENT AGENTS

To improve the effectiveness, or even the autonomy of computational tools, some techniques of Artificial Intelligence (AI) have been employed in various areas. Due to some of their abilities, such as: behavior guided by goals, reactivity, reasoning, adaptability, learning, communication and cooperation, Intelligent Agents have gained space and become very popular in computer games.

According to Russell and Norvig (1995), an intelligent agent is any entity which may receive information from the environment where it lives by means of sensors, and act in that environment by means of actuators, in a rationally manner. In other words, they act in a correct way, tending to maximize an expected outcome.

There are several types of agents, but each one is elaborated in accordance with the environment in which they shall be inserted and the functionalities which they should provide. They may be software or hardware and are normally classified in 4 (four) basic types (Russell and Norvig, 1995):

- The simple reactive agent selects their actions based on the current perception, ignoring the perception history;
- The model-based reactive agent maintains the internal state to control the aspects of the world which are not evident in the current perception;
- The goal-based agent need a description of the current state besides some kind of information about the goals that describe desirable situations. Thus, this agent could achieve the goals;
- Some environment states can satisfy the agent, however, a state may be chosen over another. Thus, the agent based on the utility uses a performance measure which allows a comparison among different states of the world, in order to select which one will be more useful to them.

An autonomous agent set which agents cooperate among themselves aiming to solve a problem that is beyond the capacity of a single agent is considered a Multiagent System (MAS) (Pontes, 2010).

Intelligent Agents in Computer Games

As the games get more realistic, in terms of physics and graphics, the characters and the environment have evolved and became more intelligent. Normally agents are used in computer games to provide to the systems a behavior not very obvious and different in each situation, making the player change his or her strategy and improve his or her performance in order to overcome the difficulties presented.

AI is present in all game styles, more often in RPGs (Role Playing Games) where enemies can be monsters or characters similar to the player, controlled by agents. The enemies should be autonomous and need to interact with dynamic and complex environments, which require reactive behavior, planning and common sense. They need to navigate by the virtual world, requiring (a) "pathfinding"[3], (b) space and (c) temporal reasoning. Advanced agents may have mechanisms to adapt to the strategies of their opponents, and can also learn.

Intelligent Agents may be used in games with many purposes, not only in the representation of opponents or partners, but also in the representation of the environment itself, since the virtual environments try to represent in the real environments the most accurately possible way. These environments are subject to the most diverse circumstances, like climate changing or disasters, among other things that can influence the game progress.

Intelligent Agents Applied to Educational Tools

The use of resources from AI aiming to support the development of educational systems, in addition to enable a great capacity for adaptation to context and personalization of the environment in accordance with the student characteristics, it provides a high interactivity degree between learning ambient and the users. Among the several AI techniques that may be applied in the education field, the intelligent agents are one of them.

In the distance education, students and the facilitator are separated geographically and, sometimes, they do not know each other. That way, the agent may be employed in the detection of compatibilities in students' profiles and help the teacher in the formation of groups (Pontes and Mendes Neto, 2010). That will, among other things, facilitate the dialog between students and learning, since they already have similar skills, knowledge or deficiencies.

Some educational tools have by purpose to provide a personalized teaching, since many students have difficulty assimilating the content due to the way in which this is transmitted. Some of these systems have used the agents to monitor tests and dialogs among students to analyze whether there is any learning. Otherwise, they select, in the knowledge base, another media to expose this content, adapting it to the student.

As seen, intelligent agents have been widely used in educational tools due to their flexibility and mainly their autonomy and capacity to sense and interact with the ambient. Thus, in this work, intelligent agents were used to monitor the players' projects and create challenges; in addition, it makes the environment closer to a real environment, by adding unpredictability and uniqueness to each project. The application will be better exposed in the session dedicated to the game description.

RELATED WORKS

As related works, we can cite some initiatives carried out by researchers in the software engineering area, such as TIM: The Incredible Manager (Dantas et al., 2004), a simulation game with focus on Planning and Control (budget, time schedule and quality) on the Java platform.

We also have the SimSE (Navarro and Hoek, 2004), whose focus is the software project management, including the phases of analysis, design, construction and tests; it is also developed on the Java platform. Another example is the SESAM (Drappa and Ludewig, 2000), which approaches the development software process focused on quality assurance.

E-RISKGAME

This session brings to the reader the serious game developed according to the themes presented here, in addition to the module developed for the teachers, where these evaluate the attitudes taken by players in accordance with the game progression.

Scenario and Storyline Game

The eRiskGame was created to simulate an experience in managing software projects, where the player can get ready to control the expenses, to comply with the targets and deadlines laid down, in addition to accompany the team work productivity. In view of that, as a real company, the work will be subject to changes in the administration of the organization, requiring changes by customers and other risks which may prevent the success of their projects.

The game's storyline consists of a Software House that goes through changes and is seeking new project managers. At the start, the player is involved in this context, which it is presented in the tutorial form, as shown in Figure 1.

The ludic aspect tries to captivate the player, to unwittingly submit concepts and leaving him or her free to reach them when the player considers it necessary to transpose any challenge imposed by the game. Besides the tutorial, an additional material about Risk Management, with integrated questionnaires is made available to the trainee. The questionnaire results may increase the final player's score.

Once inserted in the scenario, the player can start new projects, which have budgets, deadlines and targets, varying in acceptable intervals. This provides a certain dynamics to the game, avoiding that the players get unmotivated with predictable results. Each project is divided into phases which in turn are divided into weeks and days.

Players can monitor the result of their actions by means of numbers and graphics (Figure 2),

Figure 1. Game tutorial

which gives them better prospects of success in their decision making.

In the eRiskGame, the planning of the teams and, consequently, budget is highly important. For this, the user may contract (Figure 3) the most varied professionals and fire them at the time the user may deem advisable. To this end, the game brings a Professional list, with detailed profiles, to analyze their characteristics and determine which of them better fits the needs of the project at the time. Each professional has characteristics such as Teamwork, Leadership, Concentration, Technical Vision, Abstract Vision, Motivation, Hourly Cost, Productivity in Code, among others. These characteristics will influence the performance in the team project. It is up to the player dealing with different profiles so that he or she can maximize the results.

Due to the fact that the game is multiplayer, hiring or firing professionals require that the player remain attentive to other factors besides the professional characteristics. The list which includes the available professionals for recruitment, called market, is the same for all in the

Figure 2. Monitoring graphs

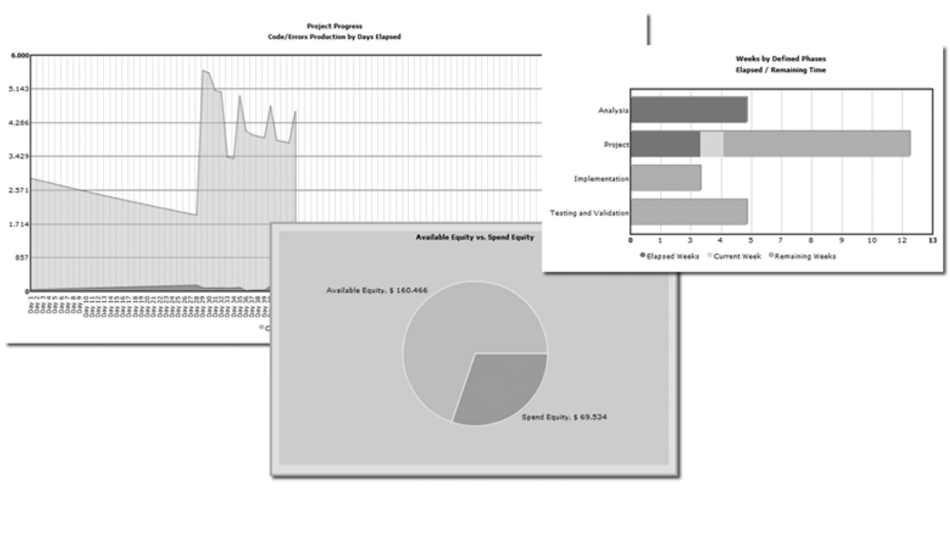

Figure 3. Professionals list

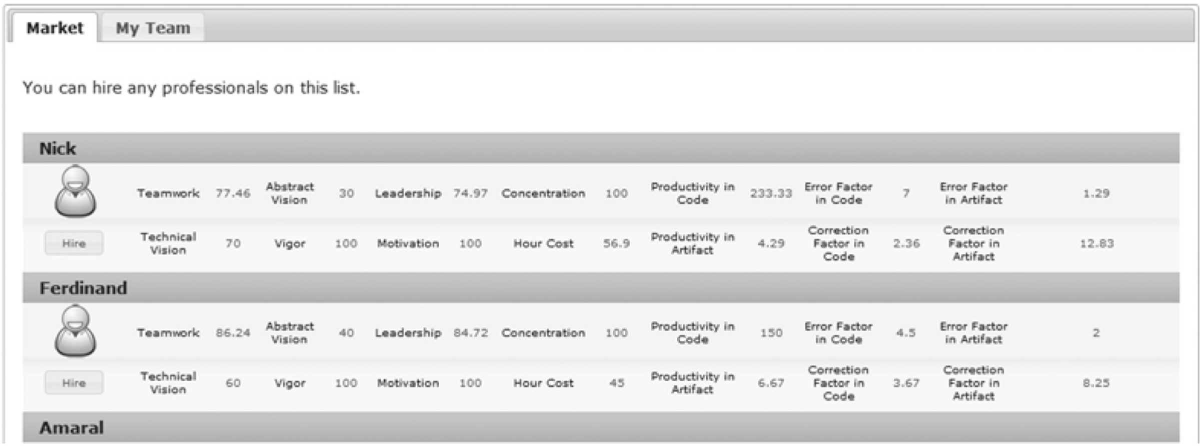


game. Thus the player should be cautious with the deadlines, because a professional that he or she intends to hire just for a specific phase may not be available anymore in that period. This same concern should also be watched over when firing, since in the game, the newly recruited professionals have a smaller productivity curve. That may hinder an exchange of these professionals in the final stages of a project phase.

The amount of available professionals on the market is controlled by the game in order to supply only the needs of ongoing projects. There is no excess of professionals, but it could have a shortage in certain moments.

To confer greater dynamics to the game, the professionals' attributes (Vigor, Motivation, etc) are not static. Over the days, professionals get tired, lose the motivation or even get distracted, affecting their productivity. To deal with this, the player can make new acquisitions, through which he or she can invest and revitalize the staff.

Acquisitions are material assets (printer, coffee maker, among others), courses, conferences (motivational or techniques) or case tools that improve the team productivity in some way. These tools include the overtime, which may be paid to increase the team activity. Other tools have preventive effect, for example, the acquisition of a backup system to avoid possible future problems with loss of data.

A new project, once started, brings fairly detailed planning done to the whole project and also for each stage: budget, time in weeks, artifacts and codes to be produced, among other details. Thereafter, the player's mission is to meet these targets and deadlines in the best possible way. However, it is given the option to negotiate the deadlines or budget. This fact entails a decrease in the project's final score.

Each project concluded, successful or not, gives the player a certain score, calculated in accordance with the fulfillment in a timely manner of each phase, financial balance or loss, production targets and quality affected. These points generate some rankings in which the player can measure his performance compared to other players.

The eRiskGame has its own time. The days elapse without the player's intervention and they progress differently from real time to prevent that the projects prolong for months or even years. This way, the player can prepare his strategy and let the game develop according to his planning, and may recur in his available schedule to verify the game's progress and to take other actions, if necessary.

This feature allows that several days take place without the need of the player to logon to the game. However, the player's absence for a prolonged time may bring the project to irreversible situations, since any inconvenience caused by agents may occur and if no action is taken in a timely manner, the progress of the project may be compromised.

Multiagent System

The focus of this serious game is on Risk Management. We noticed that one of the greatest difficulties of a project manager is to predict the problems that may arise and design plans to minimize their effects. A real project management environment is very complex to be represented, mainly due to the risks of the project that are involved in it, which affect the time schedule or resources, and due to the product risks, which affect software quality or performance. Business risks are also considered. They affect the organization that develops or purchase the software. To help representing this environment, intelligent agents were used to provide the game with some of these risks in different stages and different conditions for each project.

Before explaining a little bit about the logic behind some developed agents, it is convenient to expose which risks and consequences were modeled:

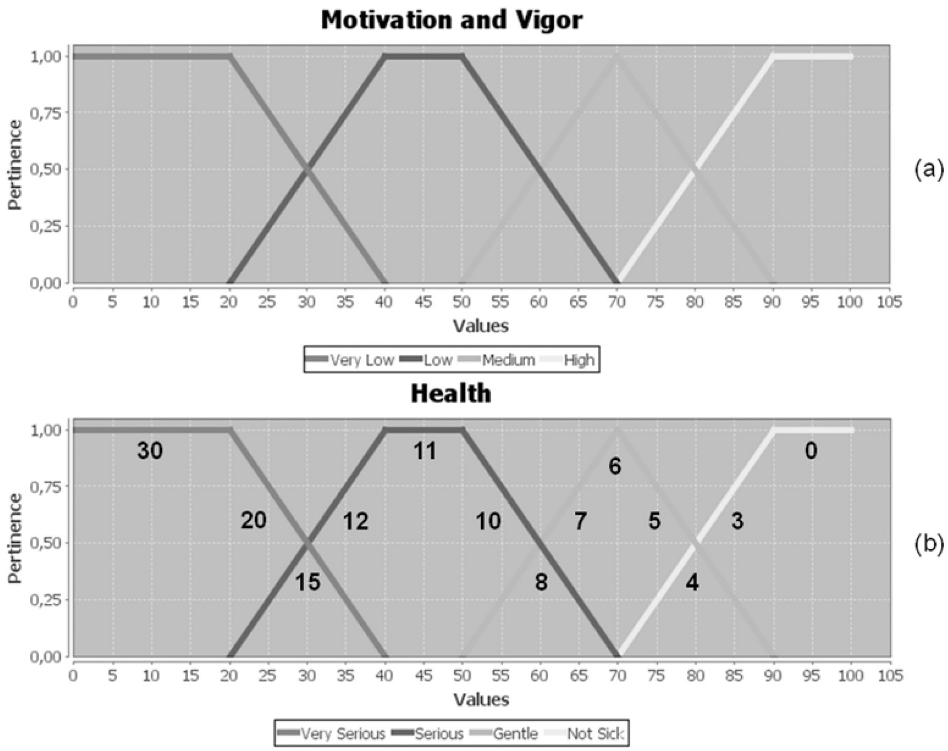
- Professional is ill, having to be away from work by a certain period, but maintaining his costs in the project;
- Valuable professional quits the team;
- Problems in the server resulting in partial or complete loss of the suitable code due to lack of backup system;
- Financial problems in the company forcing a reduction in the project budget;
- New similar software product launched on the market leading to a reduction within the deadline for completion;
- Inspection made in the software detecting several errors;
- Client requires new functionality not expected previously;
- Conflicts between professionals become routine and are starting to affect the productivity;
- Rumors in various aspects and professional relationships problems, affecting the staff concentration, motivation or performance.

Due to the diversity of problems, many agents had to be implemented, being each one of them in charge of monitoring several game aspects to act in their respective risks. However, agents are sociable and when one acts, providing some adverse situation; the others are informed, increasing or decreasing the risk of occurrence of other mishap. For instance, when a professional quits, the agent in charge for "rumors" may influence the other ones concentration.

Besides analyzing the professionals' attributes and the project progress, the agents that have been developed count with a peculiarity: their actions shall be subject to a probabilistic factor. All agents have a numeric attribute that represents the mishap (risk) occurrence probability. Then, when a state of the environment is detected, the action related to it will not always happen. A random number is chosen and compared with this attribute to determine whether the agent will or will not act. This way, we seek to provide a very common and necessary element in management environments: luck.

Some different AI techniques were used to provide intelligence to the agents, being the Fuzzy Logic[4] the most used. One of the applications that use this logic is the agent responsible for examining a professional's health conditions and keeps them off temporarily by medical leave. This is a simple reactive agent that monitors the motivation and the vigor (Figure 4-a) of all professionals who are designated to a project and identifies a health

Figure 4. Fuzzification and defuzzification graphs



condition, as shown in Figure 4-b, to determine how long this professional should be kept away.

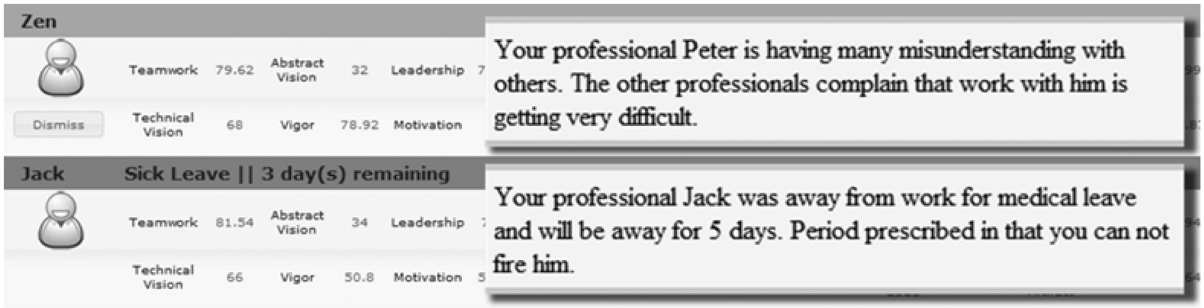
As the degradation of the attributes of the professionals is continuous, if there was not a factor of probability associated to the agents, as soon as a professional's health measured below 90, this one would already be kept off for 3 days, preventing that the physical state get worse until a most critical situation were identified. In this case, the associated probability is a very low number, which avoids the occurrence of deviations and allows that the number of days off be different in most cases.

The agent which creates rumors or discussions between the professionals is a model-based agent. It notes the quantity of professionals in each project, the time elapsed and the quantity of errors in the project, the leadership and team work of each professional for, from time to time, inform the players if any of them is clashing with the team or if the staff is concerned with any factor linked to possible changes in the company organization or even rumors involving the project discontinuity.

To detect certain states, the agent must inform the player about what has been occurred and stores data on this report. Subsequently, if the environment perceptions related to these data have degraded and no corrective action has been registered, the agent will create some situation in the project that will result in lack of concentration or high concern in the professionals, thereby increasing the risk of poor performance of several other agents.

The player is informed about the occurrence of any of these contingencies by means of messages in his inbox in addition to other reports located along the performance focus (Figure 5). The available message inbox is essential to maintain the player updated about the changes occurred in the project and it is one of the main communication tools included in the game.

Figure 5. Notices in the professional and inbox



Communication

The eRiskGame was designed on the Web platform, aiming at potentialization of the relations between students (players) and teachers (evaluators) through the use of a forum, chats and electronic messages. These communication means can be exploited by teachers in application and orientation of the activities developed in the game, besides sharing knowledge and acquired experience.

Students are no longer of passive receptors information in the classroom and become active participants in their learning environment (Xakaza-Kumalo, 2010). Thus, a teaching tool cannot be limited to transmit knowledge, without any feedback. It must allow students to exchange information and discuss about its content, so they could formulate questions and acquire new knowledge.

E-mail in the eRiskGame allows sending messages to only one receiver at a time. If the player wishes to send some information to a user group, he or she must create a favorite group and send the message to it.

As a synchronous communication way, the eRiskGame has a chat system to facilitate the exchange of instantaneous information among players. To access the system, the user will see a list of the existing chat rooms and their respective themes and will have the option of creating a new one and restrict the access with password, if desired. As soon as the user creator leaves the chat room, all participants will also be removed and the chat room shall be automatically closed.

A discussion forum was also developed to promote discussions and information exchanges among the participants. However, the forums' success depends on the number and quality of contributions. Without focus or concern about meeting certain standards, a productive and prosperous debate is impossible. Therefore, the topics and messages may be moderated[5] by any teacher.

These tools make the game more attractive, communicative and efficient. In addition, the communication is a foundation of the learning proposed by PBL, where the debate and the information exchange between the students favor the development of their own concepts and knowledge as well.

Evaluation Module

Education is a kind of characterized service with a high intangibility degree. Contrary to the assets' quality, which can be measured objectively through indicators such as durability and defect number, the educational service quality has a more abstract and intangible nature (Zeithaml et al., 1996). It may be difficult an assessment of its efficacy or even the adequacy of its use.

In these cases some measures may be taken to verify if the student is making proper use of the subjects exposed and if the tool actually works according to its purpose. It is possible to assess the quality perceived by the users, by questioning them if the tool reached their expectations and if they have acquired the worked content, or to evaluate the real knowledge acquired by attributing to the specialists (teachers) the role to analyze the results obtained by means of tests or other evaluation methods.

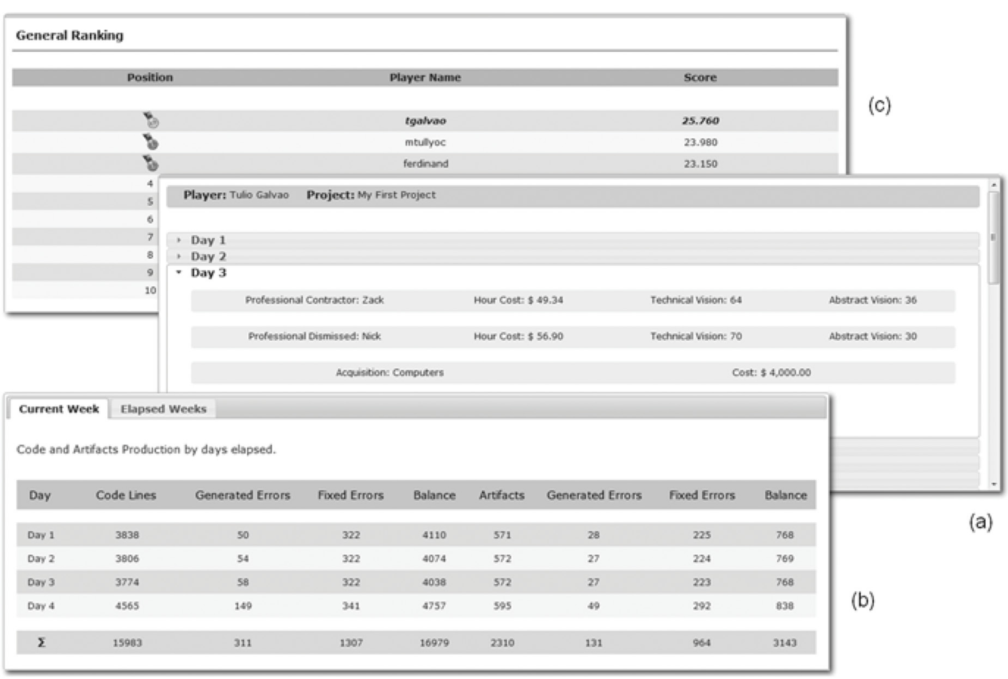
Having some kind of evaluation is important, because it allows the identification of deficiencies and the verification if the students are making progress in a wrong way. This way, teachers can guide when and how to perform in order to achieve better results. The eRiskGame is enabled with a special module designed to help the teachers in the task of monitoring the progress of the trainees and interpret their knowledge, skills and actions, in view of the expected changes in behavior, proposed in the tool goals.

Among these options available in that module, the registered teacher has access to:

- Monitoring the players' actions: all acquisitions, recruitment or any changes that the player makes in the project is recorded and shown in some kind of an interactive list of daily events (Figure 6-a);
- Monitoring the project is progress: the teacher has access to productivity statistics and projects' advancement (Figure 6-b);
- Rankings: the general ranking scores, project score and other classifications may also be accessed (Figure 6-c);
- Communication: the communication tool aggregated to the game can be accessed for guidelines, dialog and debates. The moderations in the forums may only be made by users which have joined through this module.

This set of alternatives allows the teachers to analyze the projects' progress and which actions have been taken at each moment, in addition to being able to compare the scores for a balance

Figure 6. Monitoring options



between the results of a certain player and the average of the others. The rankings provide a numerical comparison, but only through the actions history. The teacher is able to determine in which points the player may have taken some actions which jeopardized his good progress and guide him how to face certain obstacles ahead.

The assessment is an essential didactical task for the teaching work. By presenting a great complexity of factors, it cannot be summarized in simple tests execution and grades attribution. The measurement taken only gives quantitative data which must be appreciated qualitatively. The model used here intends to provide means to support the teachers' work as evaluators and explores their sensitivity to detect when and how to intervene in the learning process of their trainees.

Used Technologies and Utilization Purpose

The eRiskGame was implemented using technologies such as: PHP 5 as the server side scripting language, MySQL 5 as the database management system besides the intensive use of the JavaScript jQuery library, aiming to provide higher interactivity and usability to the game.

This tool may be used in software engineering formal courses (e.g. graduation courses, specialization courses) to train or even assess the abilities of the students in how to deal with situations and common decisions made by project managers. It will also be a good way for aspirants to job positions to exercise their abilities, at the same time that they exchange information and experiences with other players.

CONCLUSION

In this chapter a Persistent Browser-Based Game has been presented, the eRiskGame. This game was proposed as a tool to support the training of new project managers and was designed in line with the increasingly demanding users' needs, with different routines and schedules, motivating its development on the Web platform.

The methodology adopted has used the information technology potentialities allowing the creation of new teaching models. An efficient communication scheme was added to compose an environment where the teaching-learning process occurs in a more spontaneous way and involves the students more easily in the proposed context. In addition, the proposed tool offers a Risk Management practical vision different from the traditional education patterns.

Some earnings are easily noticed when using a game totally designed on the Web and without the need for special software to access it, such as: time flexibility, cost reducing, space flexibility and less interference in work routine. The high accessibility level promoted by this serious game also allows user to start a session in a given place and resume the game from any other place, using any access device. Thus, even people with very dynamic routines can benefit from the use of this tool.

Concerning the sharing and the quality of information exchange, one of the characteristics of the distance education systems, especially those which make use of asynchronous communication tools, such as forums, is that both the teachers and students have the opportunity to ripen their ideas and consult sources beforehand, favoring the preparation for more productive discussions. Thus the exchanged knowledge is better prepared and facilitates the users' understanding with different levels of familiarity with the theme for that matter.

All these benefits make this tool an innovative learning environment with characteristics very important to reach and gather distinct publics, allowing a greater collaboration between students and teachers, and could even be a model for other educational tools involving the most distinct topics.

KEY TERMS AND DEFINITIONS

Game-Based Training: Use of games designed with educational emphasis in training or specific skill qualification.

Intelligent Agents: Artificial Intelligence technique that uses an entity of software or hardware to perceive and perform in a certain environment.

Persistent Browser-Based Game: Computer Game entirely implemented in a browser that does not use any special software to be activated and keep the session data of the

Project Management: Procedure whereby a venture is led to its conclusion taking into account the costs, deadlines, quality expectation and other targets set in advance.

Project-Based Learning: Use of projects which represent a real situation to facilitate the learning and to evaluate the student competences.

Risk Management: Activity linked to the Management Projects which deals with the monitoring and eventual combat to the risks involved in a software project.

Software Engineering: Computer knowledge area oriented for specification, development and software maintenance systems.

ENDNOTES

1. Allow the participation of only one player by match.
2. Allow many players to participate simultaneously of the same match.
3. Generally refers to delineate, by a computer application, of the best route between two points.
4. The Fuzzy Logic can be seen as a research area on the treatment of uncertainty. Is an extension of the Boolean Logic that allows intermediary logic values between the FALSE (0) and the TRUE (1).
5. It is known as any device moderator, human or not, which allows supervise and suppress the messages not complying with the letter for use of the forum or which can cause legal procedures.

ABSTRACT

Supply chain integration (SCI) has received increasing attention from academic researchers and practitioners in recent years, however, our knowledge of what influences SCI, and how SCI influences the performance of supply chains and manufacturers within the supply chain is still very limited. Although researchers in marketing and management have investigated power and relationship commitment issues within and between organizations, few have examined their impact on SCI. This chapter studies the relationship between power, relationship commitment and integration between manufacturers and their customers within a supply chain. The impact of customers' SCI on the customer service and financial performance of manufacturers is also investigated. The authors propose and empirically test a model using data collected from 617 manufacturing companies in China. The results show that customers' use of different types of power has different impacts on manufacturers' relationship commitment. Expert power, referent power and reward power are very important in improving manufacturers' normative relationship commitment, while reward power and coercive power enhance instrumental relationship commitment. The authors also find that normative relationship commitment have a greater impact on customer integration and customer service by manufacturers than instrumental relationship commitment. Customer integration significantly enhanced manufacturers' customer service and financial performance. The improvement in customer service of manufacturers positively influenced their financial performance.

DOI: 10.4018/978-1-4666-1945-6.ch068

INTRODUCTION

Global competition and escalating customer expectations have forced manufacturing companies to focus more on delivery speed, dependability and flexibility to meet changing customer requirements (Boyer & Lewis, 2002; Flynn & Flynn, 2004). To enhance these capabilities, many companies have implemented supply chain integration (SCI) strategies (Bowersox, Closs & Stank, 1999). SCI is defined as the degree to which a firm strategically collaborates with its supply chain partners and collaboratively manages intra- and inter-organization processes, to achieve effective and efficient flows of products, services, information, money, and decisions, with the objective of providing maximum value to customers at low cost and high speed (Bowersox, et al., 1999, Frohlich & Westbrook, 2001). Extensive literature has cited the importance of SCI in achieving a competitive advantage (Bowersox & Morash, 1989; Lee & Billington, 1992, Morris & Calantone, 1991), as well as in enhancing operational performance (Ahmad & Schroeder, 2001; Frohlich & Westbrook, 2001; Johnson, 1999; Narasimhan & Jayaram, 1998; Stank, Keller & Closs, 2001a). However, limited empirical research has been done on the antecedents of SCI. Stank, et al. (2001) classified SCI into six types: internal, customer, material/service supplier, technology and planning integration, measurement, and relationship integration, developing and testing an instrument for measuring the effect of SCI competencies in different types of integration on firm performance, finding that customer integration was the dominant competence influencing overall and individual performance. Because of the importance of customer integration in improving a firm's performance, this chapter focuses on the integration between manufacturers and their customers.

Although researchers and practitioners have realized the importance of SCI, our understanding of what enables SCI is still very limited. Cox (2001) addressed the importance of power in business strategy and operational performance, finding that competence in supply chain management should start from understanding the power and business strategy of suppliers. He indicated that understanding the supplier's power perspective could enhance effective procurement and supply management, introducing a power matrix which illustrated how a buyer can enhance its competence. However, this study was limited to the author's personal observations, with no empirical evidence.

Maloni and Benton (2000) examined the impact of different types of power on the strength of relationship between auto parts suppliers and automobile manufacturers and how it influenced the performance of supplier, manufacturers and the supply chain. Relationship strength was operationalized by five elements: commitment, conflict, conflict resolution, cooperation, and trust. They found that expert and referent power was positively related to the strength of the relationship, while coercive and legal legitimate power were negatively related to it. They also found that a stronger relationship was related to the performance of suppliers, customers and the supply chain. In another study, Benton and Maloni (2005) investigated the relationship between: 1) the use of different types of power by the supplier, 2) strength of the supplier-manufacturer relationship, 3) performance of the supplier, manufacturer, and the supply chain, and 4) supplier satisfaction. The power-affected manufacturer–supplier relationship was positively related to supplier performance and satisfaction, however, they failed to find a causal relationship between performance and satisfaction.

While there is a dearth of research on the factors that influence SCI, marketing researchers have studied factors that influence inter-firm relationships in general. Brown, Lusch and Nicholson (1995) empirically investigated the impact of power and relationship commitment on marketing channel members' performance from a relationship marketing perspective. They found that suppliers' use of power was related to retailers' commitment to the channel relationship, which was associated with the perceived performance of the supplier and subsequent financial performance of the retailer. They demonstrated the moderating effect of power asymmetry within the channel, finding that suppliers' use of non-mediated bases of power was related to retailers' normative relationship commitment, but negatively associated with their instrumental relationship commitment. In contrast, suppliers' use of mediated power negatively was related to both retailers' normative and instrumental relationship commitment. They also found that enhancement in normative relationship commitment was related to improved performance of suppliers and financial performance of retailers. However, higher instrumental relationship commitment was negatively associated normative relationship commitment and, subsequently, had a detrimental effect on performance for all channel members.

Thus, based on our review of the literature on inter-firm relationships, we found that customer integration is very important in improving firm performance. Furthermore, power and relationship commitment are important factors in inter-firm collaboration. However, to the best of our knowledge, there are no solid empirical studies that investigate the relationship between the use of power, relationship commitment, customer integration and the performance of manufacturers within a supply chain. In this chapter, we investigate this relationship. Specifically, our objectives are:

1. To develop and test a measurement instrument for power, relationship commitment, customer integration and manufacturing performance within a supply chain.
2. To propose and empirically test a model that represents the relationship among power, relationship commitment, customer integration and manufacturing performance in a supply chain.
3. To offer guidelines for practicing managers to enhance their performance through integration and better management of customer relationships.

We based our study in China, which has become a very important manufacturing base in the world. The average annual growth of GDP in China has averaged around 10% for the last 15 years, with the manufacturing component of GDP growing at about 40% annually; thus, manufacturing drives the Chinese economy. In order for Chinese manufacturers to compete in the global marketplace, they must strive to improve their supply chain operations, and customer integration is an important of enhancing global competitiveness. China's dynamic competitive environment provides a fertile ground for investigating power, relationship commitment and their impact on SCI. Since most previous studies of power and relationship commitment were conducted in the U.S., basing our research in China allows us to examine whether findings from previous studies can be applied in a rapidly developing economy, with a non-Western national culture.

The chapter is organized as follows: we first address the theoretical background of the study with a conceptual model, proposing associated hypotheses. This is followed by discussion of the research methodology, analysis and results. Finally we summarize our major findings and present the conclusions and limitations of the study.

BACKGROUND

Power and Relationship Commitment

Marketing researchers have investigated the impact of power on cooperation between members of distribution channels (Brown, et al., 1983, Brown, et al., 1995, Goodman & Dion, 2001). Channel power is defined as the ability of one channel member to influence the decisions of another channel member (Brown, et al., 1983; Brown, et al., 1995, Goodman & Dion, 2001). Studies of channel power draw upon the seminal work of French and Raven (1959), who classified power into five types, summarized in Figure 1. They can be further classified into mediated and non-mediated sources of power (Brown, et al., 1995, Maloni & Benton, 2000; Benton & Maloni, 2005), reflecting "…. whether the source does or does not control the reinforcement which guides the target's behavior" (Tedeschi, Schlenker & Lindskold, 1972, p.292). Reward and coercive power are considered mediated because reinforcement is controlled by the customer. The customer, as the source of the power, decides whether, when and how to use its power to influence the manufacturer's (target's) decision and behavior. Expert, referent and legitimate power are considered non-mediated, because the manufacturer, itself, decides whether and how much it will be influenced by them. Non-mediated power is more relational and positive in orientation (Brown, et al., 1995, Maloni & Benton, 2000), while mediated power represents the competitive and negative uses of power traditionally associated with organizational theory (Brown, et al., 1995, Maloni & Benton, 2000).

Another very important concept in inter-organizational relationships is relationship commitment, which is the willingness of a party to invest resources in a relationship (Morgan & Hunt, 1994). Morgan and Hunt (1994) suggest that the propensity for relational continuity and the establishment of a long-term relationship are the primary themes of relationship commitment. It can be classified as normative or instrumental (Brown, et al., 1995). Normative relationship commitment is the willingness of an organization to secure a relationship, due to its identification with and emotional attachment to the goals and values of another party (Morgan & Hunt, 1994; Wetzels, de Ruyter & van Birgelen, 1998). It is intrinsic, based on identification and internalization of the norms and values that are held in common (Brown, et al., 1995). Identification occurs when a manufacturer accepts a customer's influence because it admires the way that the customer manages its business and thus wants to establish or maintain a satisfying relationship with it, and internalization occurs when a manufacturer accepts a customer's influence because it holds values and norms of behavior that are similar to the customer. In contrast, instrumental relationship commitment is based on compliance (Brown, et al., 1995), which occurs when one party accepts influence from another, in the hope of receiving a favorable reaction from the other party. It is driven by the potential for extrinsic rewards or punishment. If a manufac-

Figure 1. Bases of inter-firm power

Power Base	Description	Example of Customer's Use of this Type of Power
Expert power	Source has knowledge, expertise or skills desired by the target	The manufacturer's customer knows what the final customer wants or has knowledge and expertise in designing or distributing new products to the final consumers
Referent power	Target values identification with the source	The manufacturer desires association with the customer because it is well known and admired by the manufacturer. If the customer has developed a strong bond through its demonstrated concern, management style and organizational personality, the customer has power over the manufacturer, based on positive emotional ties (Goodman and Dion 2001)
Legitimate power	Target believes source retains natural rights to influence.	The manufacturer believes that the customer has the right to request and expect things to be done according to its requirements, as part of the supplier and customer relationship. This is a result of the level of importance accorded the customer in the supply chain.
Reward Power	Source retains ability to mediate rewards to target	The customer has the ability to provide rewards that are attractive to the manufacturer, for example, the customer can decide to give more business to the manufacturer.
Coercive power	Source holds ability to mediate punishment to target	The customer has the ability to provide punishments that are detrimental to the manufacturer, for example, the customer can cancel business or reduce the volume of business with the manufacturer.

Adopted from: Maloni and Benton (2000). "Power influences in the supply chain," *Journal of Business Logistics*, Vol. 21, No. 1 2000, p. 54.

turer's willingness to invest in and maintain a relationship is based on calculation of benefits and cost and is driven by rewards and punishment offered by the customer, the relationship commitment is instrumental.

The use of non-mediated power was found to enhance positive attitudes towards channel relationships (Frazier & Summers, 1986) and foster congruence in values and norms between channel members. Therefore, the use of expert, referent and legitimate power leads to a higher degree of normative commitment between partners (Brown, et al., 1995). At the same time, the more one party uses non-mediated power to influence the other party, the more it focuses on common norms and values, as well as on the relationship itself. "As these intrinsic factors become central, extrinsic factors such as rewards and punishments, become less important" (Brown, et al., 1995, p.368). Therefore the use of non-mediated power by the customer decreases the degree of instrumental relationship commitment by the manufacturer. Generalizing this literature to supply chains, we propose the following hypotheses (see Figure 2):

H1a: *Greater expert power by the customer will be associated with stronger normative relationship commitment by the manufacturer.*

H1b: *Greater referent power by the customer will be associated with stronger normative relationship commitment by the manufacturer.*

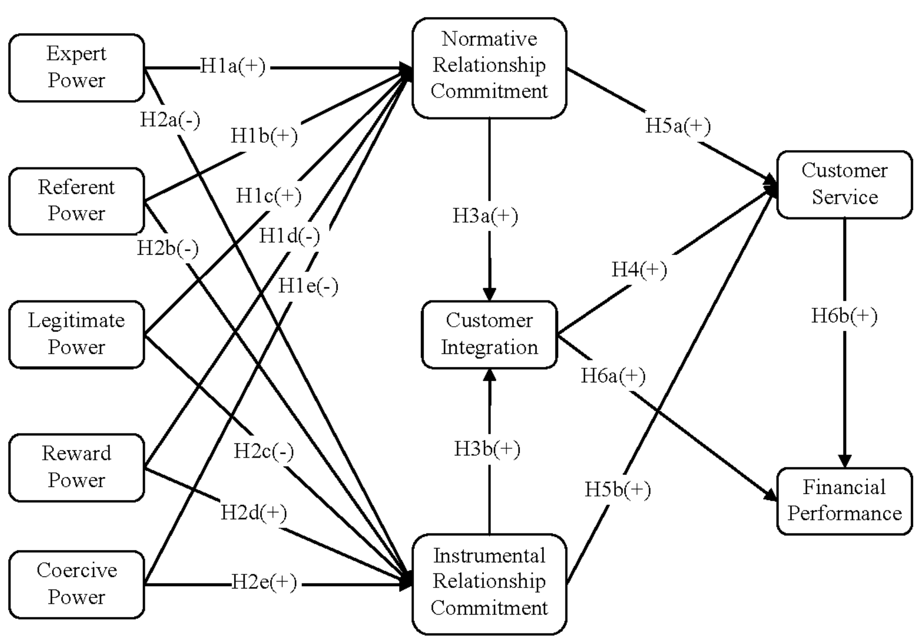
H1c: *Greater legitimate power by the customer will be associated with stronger normative relationship commitment by the manufacturer.*

H2a: *Greater expert power by the customer will be associated with weaker instrumental relationship commitment by the manufacturer.*

H2b: *Greater referent power by the customer will be associated with weaker instrumental relationship commitment by the manufacturer.*

H2c: *Greater legitimate power by the customer will be associated with weaker instrumental relationship commitment by the manufacturer.*

Figure 2. Proposed model



When a customer uses reward and coercive power, it provides extrinsic motivation for the manufacturer's commitment to it, and the manufacturer is driven to comply with the customer's requirements, in order to achieve favorable outcomes. Therefore, we expect that the customer's use of mediated power will foster stronger instrumental relationship commitment by the manufacturer (Kasulis & Spekman, 1980; Brown, et al., 1995). However, the frequent use of mediated power can damage relational norms (Boyle et al., 1997) and cooperation (Skinner, Gassenheimer & Kelley 1992), reducing the strength of the relationship (Benton & Maloni, 2005; Maloni & Benton, 2000). Therefore, we expect that the customer's use of mediated power will decrease normative relationship commitment. Based on the above discussion, we propose the following hypotheses:

H1d: *The perception of greater customer reward power is inversely related to normative relationship commitment by the manufacturer.*

H1e: *The perception of greater customer coercive power is inversely related to normative relationship commitment by the manufacturer.*

H2d: *The perception of greater customer reward power is directly related to instrumental relationship commitment by the manufacturer.*

H2e: *The perception of greater customer coercive power is directly related to instrumental relationship commitment by the manufacturer.*

Impact of Relationship Commitment on SCI

The need for integration in the physical distribution of products has been articulated by researchers since the 1970s, when Lambert, Robeson and Stock (1978) considered distribution activities as a process to be managed. However, not until a decade ago did researchers start to call for a systems approach to supply chain integration (SCI). The purpose of SCI is to integrate the relationships, activities, functions, processes and locations among all channel members of a supply chain (Bowersox & Morash, 1989; Hammer, 1990). This primarily involves planning, coordinating and controlling materials, parts and finished goods from suppliers to customers at the strategic, tactical and operational levels (Stevens, 1989). The goal of integration is to eliminate all boundaries, in order to smooth the flow of material, cash, resources and information (Naylor, Nam & Berry, 1999). Based on this line of thought, SCI should be strategically managed as a single system, as opposed to individually optimizing fragmented subsystems (Vickery et al., 2003).

Stank, et al. (2001a) developed and tested an instrument for measuring SCI competencies, as well as evaluating their relative importance in developing logistic distinctiveness. Among the six areas of SCI they identified, customer and internal integration were the most significant contributors to overall performance. Johnson (1999) developed and empirically validated strategic integration as a center of gravity for building up sustainable integration. His findings revealed that dependence, flexibility, continuity expectations, and relationship age have a positive effect on a distributor's strategic integration with its suppliers, which enhances the distributor's financial performance. Frohlich and Westbrook (2001) investigated supplier and customer integration strategies, in developing scales for measuring SCI, and five types of integration (inward-, periphery-, supplier-, customer-, and outward-facing) were identified in the sample.

Among the types of integration identified in the literature, customer integration has been found to have the most significant impact on performance (Stank, et al., 2001a). It is defined as a core competence derived from better coordination of all critical customers in a supply chain, in order to jointly achieve improved service capabilities, at lower total supply chain cost (Bowersox, et al., 1999). In order to have a higher degree of customer integration, there has to be information sharing, coordination and synchronization of processes between a manufacturer and its customers. Therefore, SCI is created by cooperative, mutually beneficial partnerships between supply chain members (Wisner & Tan, 2000); thus, relationship commitment plays a very important role in SCI.

Morgan and Hunt (1994) proposed and tested a number of hypotheses concerning the relationship between relationship commitment, trust, their precursors and their outcomes. They found that relationship commitment was positively related to acquiescence and cooperation in a relationship, but negatively related to propensity to leave. When there is relationship commitment, supply chain partners become integrated into their key customers' business processes and more tied to established goals (Chen & Paulaj, 2004). Since integration between manufacturers and customers in a supply chain requires an investment of time, human resources and financial capital, return on the investment in integration may not be realized immediately, and normative relationship commitment may be required. If a manufacturer normatively commits to its customer, it will want to operate its company as the customer does, cooperating with it. Thus, normative relationship commitment can improve the extent of customer integration. In order to avoid loss or punishment or obtain rewards from the customer, a manufacturer will integrate with its customer's activities, in order to serve it better. Thus, although instrumental relationship commitment can help with SCI, its impact will be much lower. Therefore, we propose the following research hypotheses:

H3a: *Normative relationship commitment by the manufacturer will be associated with the degree of the integration between a manufacturer and its customer.*

H3b: *Instrumental relationship commitment by the manufacturer will be associated with the degree of the integration between a manufacturer and its customer.*

H3c: *Normative relationship commitment by the manufacturer will be associated with the degree of integration than instrumental relationship commitment.*

Impact of Relationship Commitment and Customer Integration on Performance

A common measure of business performance is financial performance, since the primary goal of a business is to make profits for its shareholders (Chen & Paulraj, 2004). Financial performance can be evaluated on many dimensions (Bender, 1986; Boyer et al., 1997; Boyer, 1999), however, much of the literature (e.g., Dixon, Nanni & Vollmann, 1990; Eccles & Pyburn, 1992; Hall, 1983; Johnson & Kaplan, 1987; Skinner, 1971) pinpoints the limitations of relying solely on financial performance measures. Van Hoek (1998) advocated that supply chain firms devise innovative measurement systems, as opposed to traditional ROI-based systems. For example, Vickery, et al. (2003) included the dimension of service performance in their customer service construct, including pre-sale customer service, product support, and responsiveness to customers, delivery dependability and delivery speed. Supply chain studies (Tan, Kannan & Handfield, 1998; Frohlich & Westbrook, 2001; Vickery, et al., 2003) have used both operational and financial performance as indicators of organizational performance. In this chapter, we included both operational and financial performance of the manufacturer as performance measures.

It has been widely accepted that operations priorities can be expressed by at least four dimensions: cost, quality, delivery, and flexibility (Ward, Duray, Deone & Sun, 1995; Kathuria, 2000; Dangayach & Deshmukh, 2001; Christiansen, Berry, Bruun & Ward, 2003). White (1996) suggested that performance measures derive from operations priorities, including cost, quality, flexibility, delivery reliability and speed. The last two types of performance can be considered delivery performance. Just as Aggarwal (1997) described the seventies as "the decade of productivity", the eighties focused on total quality management," and the nineties belong to flexibility. While cost and quality have been emphasized a great deal by companies in the past twenty years, flexibility has become one of the most important operations priorities in recent years, and on-time, reliable and high-speed delivery are being required by more and more customers. Thus, flexibility, delivery, and customer service are important competitive priories in today's global competitive environment, and SCI is designed to enhance capabilities in all three areas (Davis, Aquilano & Chase, 2003). The performance measures used in this study are customer service related measures, including delivery and flexibility performance.

Several studies have examined the relationship between SCI and performance (Armistead & Mapes, 1993; Daugherty, Ellinger & Gustin, 1996; Tan et al., 1998). Armstead and Mapes (1993) found that greater integration of the supply chain led to improved operating performance. Stank, Keller and Daugherty (2001b) found that collaboration with supply chain partners facilitated internal collaboration, which in turn enhanced logistics performance. Stank, et al. (2001b) described customer integration as the most significant factor in influencing overall and individual performance. Frohlich and Westbrook (2001) demonstrated that supply chain companies with the widest degree of the arcs of integration achieved the highest level of improvement in customer service, on-time delivery, and delivery lead time. Vickery et al. (2003) concluded that SCI can improve service performance. Benton and Maloni (2005) found that the strength of the relationship between suppliers and automobile manufacturers had a positive impact on the performance of suppliers, manufacturers, and the supply chain.

Process integration between manufacturers and customers helps to simplify procedures and synchronize boundary-spanning activities. As a result, manufacturers achieve faster and more dependable deliveries. Information sharing and coordination of activities between organizations further enhances the manufacturers' ability to quickly introduce new products or modify existing products to meet customers' needs. In addition, manufacturers can respond more quickly to changes in demand volume and the mix of products needed in the marketplace. As a result, customer service is improved. Therefore we propose the following hypothesis:

H4: *The extent of customer integration will be associated with manufacturers' customer service.*

In addition to better integration with its customers, relationship commitment can also enhance manufacturers' performance in other ways. Brown, et al. (1995) found that normative relationship commitment was related to the retailer's perception of supplier performance, which, in turn, was associated with the retailer's performance. However, they also found that the retailer's instrumental relationship commitment negatively related to perceived performance of the supplier. When there is a higher level of normative relationship commitment, the manufacturer identifies with and internalizes with the value and norms of the customer. Therefore, they have congruence in their values, management philosophies and norms of behavior, leading to better cooperation and reducing the potential for conflict. As a result, normative relationship commitment is associated with the manufacturers' operational performance. However, when relationship commitment is instrumental, the two parties do not share the same values and norms of behavior, and each is looking for short-term rewards. The result is that there is less cooperation and a greater chance for conflict. Therefore, instrumental relationship commitment will not be strongly related to customer service.

Based on the above discussion, we propose the following hypotheses:

H5a*: Normative relationship commitment will be associated with manufacturers' customer service performance.*

H5b: *Instrumental relationship commitment will be associated with manufacturers' customer service performance.*

H5c: *Normative relationship commitment will be more strongly related to customer service performance than instrumental relationship commitment will.*

Evaluation of manufacturers' financial performance uses financial and market measures to evaluate efficiency and effectiveness, providing a common measure of business performance (Chen & Paulraj, 2004). Chang and Chen (1998) found that there is a relationship between service quality and profitability. Vickery, et al. (1997) showed that delivery performance was related to several different measures of business performance, including ROI, ROI growth, ROS growth, and sales growth. Vickery et al. (2003) found that customer service performance was positively related to financial performance. With customer integration, manufacturers and customers are more likely to share information about forecasting, manufacturing, and inventory with each other. As a result, manufacturers can develop better manufacturing plans, reduce waste and maintain lower inventory levels, reducing inventory costs. Thus, customer integration is associated with manufacturers' financial performance through reducing costs. Customer service performance has a positive influence on financial performance through increasing revenues. If a manufacturer has a high level of customer service performance, it will meet the customers' timeliness and flexibility requirements, and satisfied customers will buy more products or bring in new customers. As a result, the manufacturer's sales are enhanced, market share is improved, and strong financial performance is achieved. In order to examine the importance of a manufacturer's customer service performance in improving its financial performance, we test the following hypotheses:

H6a: *The extent of a manufacturer's customer integration will be associated with its financial performance.*

H6b: *The customer service performance of a manufacturer will be associated with its financial performance.*

The proposed hypotheses are summarized in the model shown in Figure 2. The key constructs and the associated measurements items are shown in Appendix.

METHODOLOGY

Sampling and Data Collection

We collected data from manufacturing companies in China. Since China is becoming a strong global manufacturing base, its manufacturers play an important role in many supply chains. However, little solid empirical research has been done about supply chain management issues using data from China. Therefore, the results from this study can be of great value.

Random sampling was used to collect the data. Since China is very large, we strategically chose five cities, to provide geographic and economic diversity. Chongqing is a traditional industrial base, located in the central part of China. It is at a relatively lower stage of economic reform. Tianjin is an industrial city in northern China and reflects the "average" stage of economic reform and marketization in China. Guangzhou and Shanghai are in southern and eastern China and have enjoyed a higher degree of economic reform.

We also included Hong Kong, because Hong Kong is one of the freest economies in the world, where manufacturers operate in a quite different environment than the other cities of China. Most Hong Kong manufacturers have their manufacturing facilities in mainland China and thus are directly connected to the mainland economy. We believe that this sample provides a good representation of manufacturing activities in China.

To get a representative sample of manufacturing companies in the mainland China cities, we used the Yellow Pages of China Telecom. In Hong Kong, we used the directory of the Chinese Manufacturers Association. One important challenge was how to collect reliable data. After visiting fifteen companies in the pilot study, we determined that the best approach was to designate a key informant in each company who was knowledgeable about supply chain management. Key informants included the supply chain manager, CEO/president and vice president in charge of sales/marketing. Many studies have used a single informant in studying relationship issues between different organizations (e.g., Hewett & Bearden, 2001), however, some have demonstrated that using multiple informants is better (Bruggen, Van Lilien & Kacker, 2002). Due to time and budget constraints, we used single informants in this study.

We made telephone calls to randomly selected companies to find out whether they were manufacturers and identify the contact information of the key informants. We sent the questionnaire to them, along with a cover letter highlighting the objectives and potential contributions of the study. Respondents were encouraged to participate through the promise of a summary report of this study and a small participation incentive gift. Self addressed, stamped envelopes were sent along with the survey, to facilitate the return of the completed questionnaires, and follow-up telephone calls were made to improve the response rate. If there was excessive missing data, respondents were contacted by phone for clarification. Out of the 4,569 companies contacted, a total of 1,356 agreed to receive the questionnaire. After several follow-up calls, 617 usable questionnaires were received. The response rate, based on the number of companies contacted via telephone, was 13.5%, however, it was 45.5% based on the number of questionnaire distributed, comparable or better than the response rates of previous similar studies (Stank, et al., 2001; Frohlich & Westbrook, 2001).

Questionnaire Design

To develop reliable and valid measures of the constructs, we first went through intensive study of the literature to identify valid measures for related constructs. Whenever possible, we adopted measurement items that had been used and tested in previous studies. When the measurements items had not been well documented and tested in the literature, we proposed new measurement items, based on our understanding of the constructs, our observations during company visits and interviews with practitioners knowledgeable about supply chain management.

The measures for expert, referent, legitimate, reward and coercive power were adopted from Brown, et al. (1995). The measures for legitimate power were all related to the natural right of a customer to influence a manufacturer, and no items were designed to measure power based on judicial or legal right. Through our interviews, we found that legal legitimate power was not a big concern for customers, perhaps because the Chinese economy is still developing, and regulations for economic activities are not well formed, with few companies using legal instruments for supplier management. Thus, only traditional legitimate power was used in our study. Respondents were asked to indicate the degree of their agreement with statements concerning their major customer's power, using a Likert scale where "1" indicates "strongly disagree" and "7" indicates "strongly agree." The measures for relationship commitment were also adopted from Brown, et al. (1995). We used a total of six items to measure normative relationship commitment, and instrumental relationship commitment was measured using three measurement items.

The measures for customer integration were selected from items used by Narasimhan and Kim (2002), and Frohlich and Westbrook (2001). We selected those that were most relevant to information sharing and collaboration activities, based on observations during our plant visits and in-depth interviews with executives. Respondents were asked to indicate the extent of integration or information sharing between their organization and their major customer in 11 areas using a Likert scale with "1" being "Not at all", and "7" being "Extensive." Customer service, including flexibility, delivery and level of customer service, was measured by six items. Flexibility was operationalized as a manufacturer's ability to quickly modify products to meet its major customer's requirements, to introduce new products quickly and to respond to changes in market demand quickly, modified from items in several previous studies (Beamo, 1999; Frohlich & Westbrook, 2001). Delivery performance was operationalized as on-time delivery and lead time, and customer service was operationalized as overall customer service to the major customer, adapted from previous studies (Frohlick & Westbrook 2001; Stank, et al., 2001). Financial performance was measured by five items partly adopted from the measurement items in Narasimhan and Kim (2002), which measure the manufacturer's growth in sales, profit, market share, ROI and ROS. These indicators were measured using a Likert scale, with "1" for "much worse", "7" for "much better" than the primary competitor. The questionnaire also included items on the demographic profile of the company. The measurement items are listed in the Appendix.

In order to ensure reliability, an English version of the questionnaire was developed, then translated into Chinese by an operations management professor in China. The Chinese version was then translated back into English by a different operations management professor in Hong Kong, and the translated English version was checked against the original English version for question accuracy. In mainland China, the Chinese version of the questionnaire was used, while, in Hong Kong, the bilingual version was used. Before launching the full-scale study, the questionnaire was pilot tested using a sample of fifteen companies. We visited these companies and conducted face-to-face discussions with executives after they completed the questionnaire. Based on their feedback, we modified the wording of some questions and added or deleted some questions, making our questions more understandable and more relevant to practices in China.

Since we used a single informant to answer the self-reported questions in this study, we checked for potential common method bias. The items comprising the power, relationship commitment, customer integration and performance scales were not highly similar in content and the constructs were measured through 3-11 items. We used Harman's one-factor test of common method bias on the SCI and performance variables (Podsakoff & Organ, 1986; Podsakoff, et al., 2003; Hochwarter, et al., 2004), finding that several distinct factors were obtained among all the variables. Thus, we concluded that common method variance bias was not a problem.

ANALYSIS AND RESULTS

Respondent Profiles

The companies surveyed represent a large variety of the companies from a number of industries. More than a quarter of the companies were from metal, mechanical and engineering, followed by 17.86% in the textiles and apparel industry and 13.15% in electronics and electrical companies. Over 32% of the responding companies had annual sales of less than HK$5 million, while 14.99% had annual sales of HK$100 million or more. 40% of the respondents were top managers.

57% were functional managers and 30% were from marketing. 27% had been in their positions for one to three years, and nearly half had taken their positions in the past 6 years. About a fourth of respondents had been in charge of their department or company for 7 to 12 years, while another quarter had been in their positions for at least 12 years. Three quarters of the respondents had been in their position for more than 3 years. Thus, the respondents were familiar with the companies' activities, and the data collected from them should be reliable.

Measurement Development

A rigorous instrument development process was used to develop and validate the instrument, to ensure content validity, unidimensionality, reliability, convergent and discriminant validity. This procedure was adopted from previous empirical studies in logistics and supply chain management (Chen & Paulraj, 2004; Min & Mentzer, 2004; Garver & Mentzer, 1999). Prior to data collection, the content validity of the instrument was supported by previous literature and pilot tests. After data collection, we performed a series of analyses to test the reliability and validity of the constructs.

Unidimensionality and Reliability

Because few studies about SCI have been conducted in China, most of the measurement items were borrowed from previous research conducted in Western countries. A strict process for scale development was followed, particularly since the scales were being used in a very different national culture. We followed the two-step method used in Narasimhan and Jayaram (1998) to test construct reliability, employing exploratory factor analysis (EFA) to ensure unidimensionality of the scales, then Cronbach's alpha for assessing construct reliability. EFA was used with principal components analysis for data reduction and determining the main constructs measured by the items. The commonly recommended method of varimax rotation with Kaiser normalization was used to clarify the factors (Loehlin, 1998). Some measurement items were dropped, after comparing their loading on the construct that they were intended to measure to their loadings on other constructs. Through EFA, we tested the unidimensionality of the measurement scales. Cronbach's alpha was then computed for each construct, to test for internal consistency. Using the intercorrelation matrix, items with a correlation value below the 0.30 cutoff value were discarded (Flynn, Schroeder & Sakakibara, 1994). These steps were performed iteratively, to determine the items to be deleted.

The results of the factor analysis for the power, relationship commitment, customer integration and performance are shown in Figures 3 and 4. The measurement items all had strong loadings on the construct that they were supposed to measure and lower loadings on the constructs that they were not supposed to measure, indicating unidimensionality. The Cronbach's alpha values are shown in Figure 5. They were all above 0.80, except instrumental relationship commitment, which had an alpha value of 0.667, which is still above the lower limit of 0.60 suggested by Flynn et al. (1990) and Nunnally (1994) for newly developed scales. Although these scales were initially developed by Brown, et al. (1995), they had previously been applied only in Western countries. Thus, we applied the criterion for newly developed scales, finding that our measurements were unidimensional and reliable.

Construct Validity

We assessed construct validity along several dimensions. Convergent validity is the degree to which multiple methods of measuring a variable provide the same results, while discriminant validity is the degree to which measures of different latent variables are unique (O'Leary-Kelly & Vokurka, 1998). O'Leary-Kelly and Vokurka

(1998) suggest that confirmatory factor analysis (CFA) is a more powerful tool for assessing convergent and discriminant validity, requiring fewer assumptions than the traditional Multi-Trait Multi-Method matrix method. In our study, we tested both kinds of validity using CFA models.

In the convergent validity test, we constructed a CFA model using LISREL. Each item was linked to its corresponding construct, and the covariances among those constructs were freely estimated. The model fit indices were Chi-Square= 3786.98 with d.f.= 1130, RMSEA=0.065, NNFI=0.95, CFI=0.95 and standardized RMR=0.056, indicating that the model is acceptable (Hu & Bentler, 1992). A construct with either a loading of indicators of at least 0.5, a significant t-value, or both, is considered to be convergently valid (Fornell & Larcker, 1981; Chau, 1997). All factor loadings were greater than 0.50 and all t-values were greater than 2.0, therefore, convergent validity was demonstrated. In order to assess discriminant validity, we built a constrained CFA model in which the correlations among constructs were fixed to 1. This model was compared with the original unconstrained model, in which the correlations among constructs were freely estimated. A significant difference of Chi-square statistics between the fixed and unconstrained models indicates high discriminant validity (Fornell & Larcker, 1981; Chau, 1997). All the differences of χ^2 were significant at the 0.01 level, therefore, discriminant validity was demonstrated.

Results

We used structural equation modeling (SEM) to estimate the causal relationship among the constructs. SEM examines the relationships between

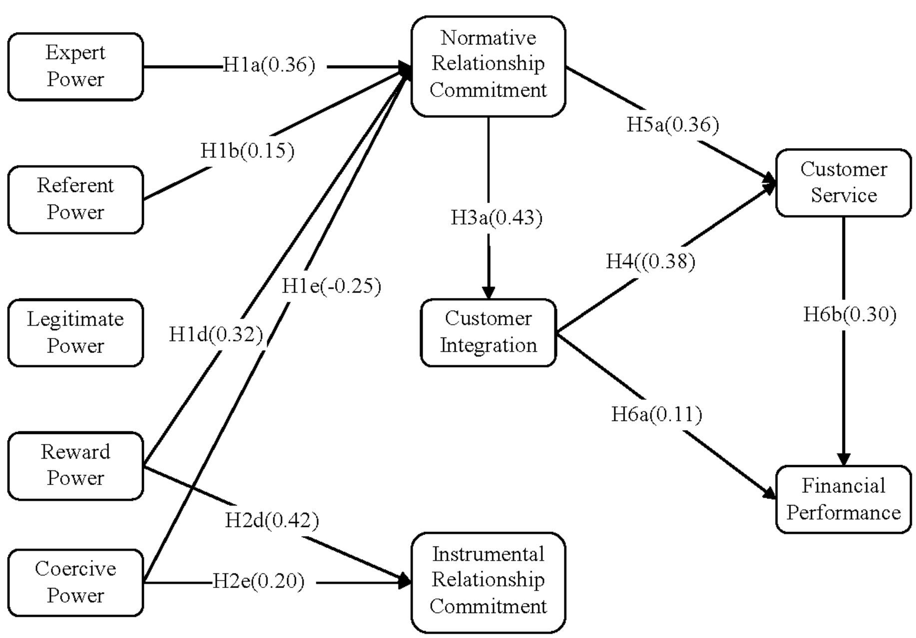
variables as a unit, rather than piecemeal, as in regression, and the assumption of perfectly reliable measures is untenable in regression, while it is easily handled by SEM (Kline and Klammer, 2001). SEM is a confirmatory approach to data analysis, requiring prior assignment of intervariable relationships. It statistically tests a hypothesized model to determine the extent to which the proposed model is consistent with the sample data. The measurement models specify how latent variables are measured in terms of indicator variables, as well as addressing the reliability and validity of the indicator variables in measuring the latent variables or hypothetical constructs. SEM provides an assessment of predictive validity, specifies direct and indirect relations among the latent variables, and describes the amount of explained and unexplained variance in the model (Byrne 1998; Schumacker & Lomax, 1996).

LISREL 8.54 was used to analyze the hypothesized structural equations model. A two-step model building approach was used, wherein the measurement models were tested prior to testing the structural model (Joreskog & Sorbom, 1993; Anderson & Gerbing, 1988). The Maximum Likelihood Estimation (MLE) method was used, because it has desirable asymptotic properties (e.g., minimum variance and unbiasedness) and is scale-free. This method assumes multivariate normality of the observed variables (Raykov & Marcoulides, 2000), and the requirement of normality of the data was met in our data. The structural model was built on the modified measurement model using the MLE method. In structural equation modeling, there is no single test of significance that can absolutely identify a correct model given the sample data (Schumacker & Lomax, 1996), and many goodness of fit criteria has been established (Bentler 1992; Garver & Mentzer, 1999, Cheung & Rensvold, 2001). The goodness of fit indices for our model are Chi-Square=3932.53 with d.f=1148, RMSEA=0.066, NNFI=0.94, CFI=0.95, Standardized RMR=0.068, which are better than the threshold values suggested by Hu and Bentler (1992). Therefore, our model can be accepted. Figure 6 shows the modified structural

Figure 6. Structural equation mode



equation model and the standardized coefficients for the paths that were significant at the 0.05 level.

From Figure 6, we can see that expert power and referent power were positively related to normative relationship commitment, indicating that these types of non-mediated power by the customer are related the manufacturer's commitment, due to identification with and internalization of customer's norms and values. This supports H1a, and H1b. However, the hypothesized relationship between legitimate power and normative relationship commitment was insignificant, and H3c was not supported. Expert power, referent power, and legitimate power were not related to instrumental relationship commitment, which does not support the hypothesized negative relationship between non-mediated sources of power and instrument relationship commitment; this is consistent with Brown, et al.'s (1995) finding that non-mediated power had no or a negative impact on instrumental relationship commitment. In China, when manufacturers perceive a customer to have expert and referent power, they tend to accept them without suspicion about the authority of the power sources. Therefore, non-mediated power was associated with normative relationship commitment, not with instrumental relationship commitment. In other words, the expert and referent power of customers was related to manufacturers' commitment in a normative way and restrains it from being exercised in an instrumental way. The strong relationship between expert power and normative relationship commitment indicates that Chinese people have strong belief in knowledge and authority. The relatively weaker relationship between referent power and normative relationship commitment shows that it plays a less important role in interfirm relationships in China. Legitimate power was not significantly related to either type of relationship commitment, perhaps because Chinese companies pay little attention to the influence of legitimate power in their high power distance culture.

The path coefficients in Figure 6 show that customer reward power significantly related to both normative and instrumental relationship commitment; thus H1d was not supported, but H2d was. Coercive power was positively related to instrumental relationship commitment, but negatively related to normative relationship commitment, thus supporting both H1e and H2e. This shows that punishment plays a significant role in improving instrumental relationship commitment, but is associated with decreasing normative relationship commitment. It is interesting that coercive power was negatively associated with normative relationship commitment, while reward power was positively associated with it, since both reward and coercive power are mediated sources of power. This may reflect the Chinese tendency to use positive feedback to encourage others to commit to their values and norms, while using negative feedback to regulate and manage calculative relationship commitment. The positive relationship between reward power and normative relationship commitment contradicts Brown, et al.'s (1995) finding that mediated sources of power were negatively associated with normative relationship commitment. This might be caused by cultural differences between China and the U.S. (Hofstede, 1983, 1984), particularly in terms of power distance, which is much higher in China than in the U.S. In high power distance cultures, mediated power is more likely to influence others. To confirm our interpretation of these findings, future cross-cultural studies should be carried out to examine the moderating effect of national culture on the relationship between power and relationship commitment.

The path coefficients in Figure 6 show that normative relationship commitment was strongly related to customer-manufacturer integration, supporting H3a. However, the coefficient for the path from instrumental relationship commitment to customer integration was not significant and thus does not support H3b. Comparing the equal coefficients constrained model with the unconstrained model, we find that the two coefficients were significantly different from each other, indicating support for H3c. These results are consistent with earlier finding that relationship commitment positively influences acquiescence and cooperation among channel members (Morgan & Hunt, 1994). However, our study indicates that there was a significant difference between normative and instrumental relationship commitment and their relationship with SCI. Since SCI requires investment of resources in sharing information and improving inter-organizational processes, partners must have a longer-term orientation, as well as congruence in their values, norms of behavior and managerial approaches. Therefore, normative commitment is required, to enhance customer integration. Figure 6 also indicates that the degree to which a manufacturer is integrated with its major customer was strongly related to manufacturers' customer service and financial performance, supporting H4 and H6a. The strong positive relationship between customer integration and performance indicates the importance of SCI in enhancing manufacturers' competitiveness. This finding is supported by previous studies that found that SCI could enhance performance (e.g., Frohlich & Westbrook, 2001; Stank, Keller & Closs, 2001).

The path coefficients for normative relationship commitment show that it strongly is positively related to manufacturers' customer service performance, supporting H5a. The coefficient for instrumental relationship commitment was insignificant, therefore it did not support H5b. Furthermore, through a comparison of the equal coefficients constrained and unconstrained models, we find that the impact of normative relationship commitment on customer service was significantly higher than the corresponding impact of instrumental relationship commitment. Therefore, H5c was supported. The result that normative relationship commitment was related to customer service was consistent with Brown, et al.'s (1995) finding that retailers' normative relationship commitment was positively associated with perceived performance of their suppliers. This is because normative relationship commitment improves congruence in values, management philosophies and norms of behavior. Furthermore, normative relationship commitment enhances acquiescence and cooperation. Therefore, when a manufacturer has greater normative relationship commitment to its major customer, it performs better in customer service, due to cooperative behaviors between them. The finding that instrumental relationship commitment was not related to customer service appears to be consistent with Brown, et al.'s (1995) finding that instrumental relationship commitment did not negatively influence the retailer's perceived performance of the supplier. Figure 6 also indicates that customer service had a positive impact on the financial performance of the manufacturer, supporting H6b. This finding highlights the importance of customer service performance in improving manufacturers' financial performance.

DISCUSSION

This study investigated the relationship between power, relationship commitment, customer integration and manufacturers' customer service and financial performances, based on data collected from manufacturers in China. A holistic model was built, allowing for simultaneous testing of these relationships by SEM analysis. China's manufacturing industries are growing rapidly, and our findings provide significant managerial implications for supply chain practitioners and researchers. In this section, we discuss our major findings and their managerial implications.

How to Improve the Performance of a Manufacturer in the Supply Chain?

Our model shows that the key drivers of manufacturers' financial performance are their customer service and the extent of customer integration. In this study, customer service was mainly measured by delivery and flexibility. Although delivery and flexibility have been cited as important competitive priorities in the operations management literature (Aggarwal, 1997), our study is the first to demonstrate their strong impact on manufacturers' financial performance in China. This indicates that manufacturers in China should emphasize flexibility and delivery, in order to achieve better financial results. Due to keen competition, cost and quality are increasingly becoming order qualifiers for many manufacturers in China. Companies need greater flexibility in meeting the changing needs of their customers and delivering products faster and more dependably, in order to win orders.

Our results also show that customer integration significantly enhanced manufacturers' customer service and financial performance. These results provide strong empirical support for the importance of SCI. Through information sharing and process integration with customers, manufacturers can be more flexible by introducing new products faster, modifying the existing product mix and adjusting production volumes faster, to better meet the needs of their major customers. Integration with customers also allows manufacturers to deliver products faster and more reliably. Therefore, manufacturers should invest time and resources to integrate with their major customers.

What is the Role of Relationship Commitment in Customer Integration and Performance Improvement?

Our study is the first to examine the impact of relationship commitment on SCI. The results show that manufacturers' normative relationship commitment was positively related to the degree to which manufacturers are integrated with customers, while instrumental relationship commitment was not related. Thus, manufacturers should cultivate normative relationship commitment with their customers, in order to enhance integration. With normative relationship commitment, customers cooperate with manufacturers and thus share information and integrate inter-organizational processes and activities. In contrast, due to the short term and loose nature of instrumental relationship commitment, it does not have any significant influence on customer integration.

Normative relationship commitment was also positively related to manufacturers' customer service, however, instrumental relationship commitment was not related to it. This shows that relationship commitment can result in improved customer service performance, due to cooperative behaviors and reduced conflict between partners. There was no significant effect of instrumental relationship commitment on customer service. Therefore, we see that normative relationship commitment is much more effective than instrumental relationship commitment in enhancing manufacturers' customer service. As we discussed in the previous section, customer service is significantly related to financial performance. As a result, normative relationship commitment has a higher impact on manufacturers' financial performance than instrumental relationship commitment. This indicates that normative relationship commitment plays a very important role in improving relationship commitment to customers, in order to achieve better financial performance.

How Does Power Influence Relationship Commitment?

Our model shows that the customer power is significantly related to relationship commitment. Customers' expert and referent power were positively related to manufacturers' normative relationship commitment, but not to their instrumental relationship commitment. Customers' use of legitimate power was not significantly related to either type of relationship commitment. Expert power was the most important, among the five types of power, in its relationship to normative relationship commitment. Therefore, customers should strive to enhance their expert power by hiring knowledgeable people and managing their expertise and skills to influence their suppliers. The use of legitimate power, however, is not encouraged, because there is no significant relationship between it and either type of relationship commitment.

When customers use coercive power to influence manufacturers, the manufacturer's instrumental relationship commitment is enhanced, while its normative relationship commitment is reduced. Given the strong, positive impact of normative relationship commitment on customer integration and manufacturers' performance, customers should refrain from the use of coercive power. It is interesting that customers' use of reward power had a positive significant impact on both normative and instrumental relationship commitment. On one hand, customers' use of reward power was associated with manufacturers' instrumental relationship commitment. On the other hand, however, reward power was also associated with manufacturers' normative relationship commitment. Thus, it may be that reward power is used for different purposes in China.

Our model shows that customers should emphasize the use of non-mediated sources of power, to enhance normative relationship commitment. With increased normative relationship commitment, manufacturers will be able to serve their customers better in terms of flexibility and delivery, which leads to better financial performance. In contrast, the use of mediated sources of power by the customer will be ineffective or will produce negative effects on the manufacturer's relationship commitment and, thus, will not improve performance. Partners within the supply chain must understand the effect of different types of power, and should selectively exercise their power, in order to enhance relationship commitment and improve performance.

CONCLUSION

Our study proposes and validates a model of the relationship between power, relationship commitment, customer integration and performance in a supply chain. It shows that the use of expert and referent power are significantly related to normative relationship commitment, while legitimate power was not related to it, and all three types of non-mediated power were not related to instrumental relationship commitment. Coercive power was related to instrumental relationship commitment but negatively associated with normative relationship commitment, while the use of reward power was positively associated with both normative and instrumental relationship commitment. Furthermore, the model shows that expert power had the strongest impact on normative relationship commitment. This is the first empirical study to systematically examine the relationship between power and relationship commitment in a supply chain. These findings provide a guideline for managers in understanding power in supply chain relationships.

Our model demonstrated that normative relationship commitment is strongly related to customer integration and manufacturers' customer service performance in a supply chain, clearly showing the importance of managing supply chain relationships. When partners have the intrinsic desire to continue a relationship, due to congruence in values and norms, SCI can be accomplished more readily, and the resulting commitment can help enhance performance. However, instrumental relationship commitment is much less effective in enhancing SCI and operational performance. Therefore, companies should strive to improve normative relationship commitment.

Finally our model shows that customer service, in terms of delivery, flexibility and level of customer service, has a strong impact on financial performance. Our study provides empirical support for an increased emphasis on flexibility and delivery as competitive priorities in today's global competitive environment. This indicates that Chinese manufacturers which focus on these priorities will achieve better financial performance. Being on the receiving end of non-mediated power from the partner, enhancing normative relationship commitment and increasing the level of integration are also effective ways of improving financial performance.

In addition to ample implications for practicing managers, this study also makes significant contributions to the supply chain management and relationship management literature. We demonstrated the importance of SCI and normative relationship commitment in improving customer service. We empirically showed that customer service is very important in improving manufacturers' financial performance. We demonstrated how the use of different types of power influences different types of commitment. We also found that some of the relationships between power and relationship commitment in China were different from those reported by Brown, et al. (1995), based on studies using data from the U.S. While Brown, et al. (1995) reported that mediated power was negatively related to normative relationship commitment, we found that reward power was positively related to both normative and instrumental relationship commitment in China. We speculate that these differences might be caused by the differences in national culture between China and the U.S. Further studies are needed to examine cross-cultural differences in the relationship between power and relationship commitment, and this study opens up a new stream of research in this area. Finally, the instrument validated by this study can be used in future studies and will thus foster future research in this important area.

Although the study described in this chapter makes significant contributions to both academia and practice, there are several limitations which open up venues for further research. First, this study did not examine the impact of power asymmetry on the relationships between power, relationship commitment, SCI and performance, which may moderate some of these relationships (Brown, et al., 1995), and thus should be included in future studies. Related to this, the impact of industry should also be investigated. In some industries, the balance of power between manufacturers and customers might be different and, therefore, the relationship between power, relationship commitment and performance will be different. The most important competitive priorities may vary by industry, due to differences in customer requirements and preferences. In addition, we only used data from China to develop and test this model. Because culture may have a significant influence on the role of power and relationship commitment in inter-firm relationships, this study should be extended to examine the moderating effect of culture on the relationships focused upon in this study.

While power and relationship commitment were found to be related to SCI, many other factors, such as competitive hostility and environmental uncertainty, may also be related to SCI and the impact of SCI on performance. Future studies should seek more drivers of SCI and examine their impact. One potentially important factor to be considered is trust and how different types of trust influence SCI. This study only examined the power of the major customer, based on perceptual data from manufacturers. Future studies should collect the perspectives of both manufacturers and customers. Comparison of both perspectives may shed more light on the relationship between power and relationship commitment. Finally, to understand the entire supply chain, future studies should examine power and relationship commitment among suppliers, manufacturers and customers together. Comparison of how they are related to SCI and performance among all three parties will reveal more complex dynamic relationships among these variables.

APPENDIX CONSTRUCT MEASUREMENT

Financial Performance

FPERF1: Growth in sales.
FPERF2: Growth in profit.
FPERF3: Growth in market share.
FPERF4: Growth in ROI.
FPERF5: Growth in return on sales.

Customer Service

CS1: Our company can quickly modify products to meet our major customer's requirements.
CS2: Our company can quickly introduce new products into the markets.
CS3: Our company can quickly respond to changes in market demand.
CS4: Our company has an outstanding on-time delivery record to our major customer.
CS5: The lead time for fulfilling customer orders (the time which elapses between the receipt of customer's order and the delivery of the goods) is short.
CS6: Our company provides high level of customer service to our major customer.

Customer Integration

CI1: The level of linkage with major customer through information network.
CI2: The level of computerization for our major customer ordering.
CI3: The level of sharing of market information from our major customer.
CI4: The level of communication with our major customer.
CI5: The establishment of quick ordering system with our major customer.
CI6: Follow-up with our major customer for feedback.
CI7: The frequency of periodical contacts with our major customer.
CI8: Our major customer shares Point of Sales (PoS) information with us.
CI9: Our major customer shares demand forecast with us.
CI10: We share our available inventory with our major customer.
CI11: We share our production plan with our major customer.

Normative Relationship Commitment to Customer

NRC1: We feel that our major customer views us as being an important "team member", rather than our being just another supplier.
NRC2: We are proud to tell others that we are a supplier for this customer.
NRC3: Our attachment to this customer is primarily based on the similarity of our values and those of this customer.
NRC4: The reason we prefer this customer to others is because of what is stands for, its values.

NRC5: During the past year. Our company's values and those of the major customer have become more similar.
NRC6: What this customer stands for is important to our company.

Instrumental Relationship Commitment to Customer

IRC1: Unless we are rewarded for it in some way, we see no reason to expend extra effort on behalf of this customer.
IRC2: How hard we work for this major customer is directly linked to how much we are rewarded.
IRC3: Bargaining is necessary in order to obtain favorable terms of trade in dealing with this customer.

Customer's Use of Expert Power

EXP1: The people in the customer's organization knew what they are doing.
EXP2: We usually got good advice fro m our major customer.
EXP3: The customer had specially trained people who really knew what had to be done.
EXP4: Our major customer's business expertise made them likely to suggest the proper thing to do.

Customer's Use of Referent Power

REF1: We really admire the way our major customer runs their business, so we tried to follow their lead.
REF2: We generally wanted to operate our company very similar to the way we thought the major customer would.
REF3: Our company did what the customer wanted because we have very similar feelings about the way a business should be run.

Customer's Use of Legitimate Power

LEG1: It was our duty to do as the major customer requested.
LEG2: We had an obligation to do what the major customer wanted, even though it wasn't a part of the contract.
LEG3: Since they were the customer, we accepted their recommendations.
LEG4: The major customer had the right to expect us to go along with their request.

Customer's Use of Reward Power

REW1: IF we did not do what as the major customer asked, we would not have received very good treatment from them.
REW2: We felt that by going along with the major customer, we would have been favored on some other occasions.
REW3: By going along with the major customer's requests, we avoided some of the problems other suppliers face.
REW4: Our major customer often rewarded us to get our company to go along with their wishes.

Customer's Use of Coercive Power

COE1: The major customer's personnel would somehow get back at us if we did not do as they asked and they would have found out.

COE2: The major customer often hinted that they would take certain actions that would reduce our profits if we did not go along with their requests.

COE3: The major customer might have withdrawn certain needed services from us if we did not go along with them.

COE4: IF our company did not agree to their suggestions, the major customer could have made things more difficult for us.

Chapter 69
Firm-Specific Factors and the Degree of Innovation Openness

Valentina Lazzarotti

Raffaella Manzini
Carlo Cattaneo University, Italy

Luisa Pellegrini
University of Pisa, Italy

ABSTRACT

This chapter investigates the topic of how open innovation is actually implemented by companies, according to a conceptual approach in which open and closed models of innovation represent the two extremes of a continuum of different openness degrees; though, these are not the only two possible models. By means of a survey conducted among Italian manufacturing companies, this chapter sheds light on the many different ways in which companies open their innovation processes. Four main models emerge from the empirical study, which are investigated in depth in order to understand the relationship between a set of firm-specific factors (such as size, R&D intensity, sector of activity, company organization) and the specific open innovation model adopted by a company.

INTRODUCTION

The concept of "Open Innovation" (OI) is often studied supposing an artificial dichotomy between closed and open approaches, whilst the idea of exploring different degrees and types of openness in a sort of continuum seems to provide a more interesting avenue (Chesbrough, 2003b). Prior research has highlighted that open innovation may be pursued in different ways, which are identifiable in terms of organisational form of acquisition or commercialization, number and typologies of partners, phases of the innovation process that are actually open, the direction of opennes (inbound and/or outbound) and governance (hierarchical or flat).

Moreover, previous research has also attempted to study the relationships among different OI models and several contextual factors, driven by the idea that these factors could explain or,

DOI: 10.4018/978-1-4666-1945-6.ch069

at least, characterize the companies' choices in terms of degree of openness. Lastly, different OI models, defined according to this concept (i.e. degree of openness and models within their specific context), have been analysed in some preliminary work in terms of their performance (Lichtenthaler, 2008; 2009).

The objective of this chapter is thus threefold: first, to provide evidence in support of Chesbrough's (2003b) theoretical proposition that businesses may be located along an Open Innovation Continuum, second, through the use of extensive study, to identify any potential intermediate states between the extreme points of the Continuum - Open and Closed Innovators - and, third, to identify the contextual factors that affect the choices firms make along the Open Innovation Continuum.

In particular, for the identification of the potential intermediate states in the OI Continuum, we focalized on two variables representing the openness degree, which are not still deeply investigated: (1) the number and type of partners (partners variety) and (2) the number and type of phases of the innovation process open to external contributions in and/or out (innovation phase variety). It should be noted that we assume that the innovation process is composed of different phases: idea generation (identification of a technology opportunity through scouting, monitoring, market analysis, trends analysis); experimentation (from the idea to the prototype); engineering (transforming the prototype into an industrial project); manufacturing (defining and organising the "plant"); commercialisation (planning of commercialisation and promotional activities).

The choices in terms of OI will be investigated in terms of those contextual factors whose role is still controversial (Lichtenthaler, 2008), or otherwise it can be better understood in light of the concept of openness suggested here. Our investigation was carried out in Italy, where empirical evidence about OI is still poor. However, there are many pressures, arising from institutions, too, towards the establishment of collaborative models (Global Business Summit, 2010). Thus, investigating if, how and with what results companies work together becomes a relevant issue for both Italian scholars and practitioners.

We would also like to emphasize that our endeavour to identify any in-between states along the Open Innovation Continuum is the first attempt to research this topic and that the subject indeed requires further research in order to better characterise such intermediate states.

The following sections are divided into subtopics: a description of the pertinent literature (so as to better understand the research questions we posed), a description of the empirical study we carried out and the methodology used, the main research results, a discussion of the results, conclusions and future research.

THEORETICAL BACKGROUND

The Theoretical Framework and the Research Questions

Traditionally, large firms relied on internal research and development (R&D) to innovate and, in many industries, large internal R&D labs were a strategic asset and firms could internally discover, develop and commercialize technologies. This approach has been labelled the "closed innovation model" (Chesbrough, 2003a). Although it worked well for quite some time, the current innovation landscape has changed. Due to labour mobility, increasing R&D costs, abundant venture capital and widely dispersed knowledge across multiple public and private organizations and the need for specialisation in knowledge production, enterprises can no longer afford to innovate on their own, but rather need to engage in alternative innovation practices. In this regard, Open Innovation (OI) represents an important innovation practice that can help firms to innovate without having to rely only on their in-house strengths. Since Chesbrough published his book in 2003, the concept of "Open Innovation" has received a considerable amount of attention from practitioners and researchers. A large number of studies are adopting this term to describe the phenomenon where firms rely increasingly on external sources of innovation, which means that ideas, resources and individuals flow in and out of organizations (Chesbrough, 2003a). While contributions are still growing (Gassmann, 2006; Enkel et al., 2009; Enkel et al., 2010), the debate on innovation management is enriched by studies that critically examine the Open Innovation concept by exposing its weakness and limitations (Dahlander & Gann, 2007; Trott and Hartmann, 2009). In particular, the concept of Open Innovation is criticized because of the widespread view that the concept highlights an artificial dichotomy between closed and open approaches. On the other hand, the idea of exploring different degrees and types of openness in a sort of continuum (i.e. the openness degree concept) seems to provide a more interesting and richer avenue to investigate, (Chesbrough, 2003b; Dahlander & Gann, 2007). Indeed, this view allows for a deeper and more real investigation into company behaviour and into the particular nature and context of innovation sources (Chesbrough, 2003b; Gassmann, 2006; Dahlander & Gann, 2007).

In any case, the era of open innovation has begun and many firms are opening their innovation process to the outside world (Enkel et al., 2009). The way the innovation process can be opened has been studied in management literature from a variety of perspectives. Although the perspective that has received most of the attention in the literature is undoubtedly the direction of openness, other approaches have also been investigated. More specifically, these look at the number and types of partners, the kind of governance in the innovation networks, and the organisational forms chosen to define the links among partners (high vs. low integration level).

As regards the perspective connected with the "direction of openness", three models of open innovation can be observed: the inbound, exploration or outside-in process, the outbound, exploitation or inside-out process, and the coupled process (Keupp & Gassman, 2009; Lichtentaler, 2008; Enkel, et al., 2009). Thanks to the outside-in process, firms aim at enriching the company's own knowledge base through the integration of external knowledge sourcing, and hence increase their innovativeness (Enkel et al., 2009). Through the inside-out process, firms aim at earning profits by bringing ideas to market, selling IP, and multiplying technology by transferring ideas to the outside environment, in order to bring ideas to market faster than they could through internal development (Enkel et al., 2009). The coupled process combines the two abovementioned processes to simultaneously gain external knowledge and bring ideas to market.

As regards the perspective connected with the "types of partners" (Enkel et al., 2009), literature has highlighted the interactive character of the innovation process, suggesting that innovators use ideas and knowledge of external actors in their innovation processes: firms rely heavily on their interaction with lead users, suppliers, and a range of institutions inside the innovation system (von Hippel, 1988; Lundvall, 1992; Brown & Eisenhardt, 1995; Szulanski, 1996). With each innovation source, an organization can achieve different intensity levels of collaboration (Laursen & Salter 2006; Keupp & Gassman 2009). Hence, it is possible to define different open innovation models depending on both breadth (i.e., the number of sources used for innovation activities) and depth (i.e., the intensity of collaboration with each source).

As regards the perspective connected with the "kind of governance" in the innovation networks, there are two dimensions which need to be considered (Pisano & Verganti, 2008): openness, i.e. a large number of involved partners and hierarchy, i.e. the level of 'democracy' in decision making. On the basis of two such aspects, four open innovation models emerge: (1) the open/

hierarchical model, in which anyone can offer ideas but only one company defines the problem and chooses the solution; (2) the open/flat model, in which anyone can generate ideas, and no one has the authority to decide what is or is not a valid innovation; (3) the closed/hierarchical model, in which a company selects certain participants and decides which ideas are to be developed; (4) the closed/flat model, in which a selected group offers ideas, while making critical decisions together.

As regards the "organisational forms" chosen to define the links among partners (high vs. low integration level), there are four technology sourcing modes that firms can adopt: corporate Venture Capital investments, non-equity alliances, equity alliances and acquisitions. Each form carries with it different implications in terms of the investing company's reversibility and commitment (Chiesa & Manzini, 1998; van de Vrande et al., 2006). More precisely, corporate Venture Capital investments and non-equity alliances are reversible to some extent and involve a relatively low level of commitment from the investing company, while equity alliances and acquisitions require a high level of commitment and are hardly reversible.

In our opinion, all these contributions share two aspects: on one hand, they have a common interpretation of open innovation, while, on the other, they have a weakness.

Regarding common interpretation, all these contributions share the understanding that the open innovation models which the firms follow are not exclusively open or closed, but rather show varying degrees of openness: i.e. between the two pure models – open or closed, which represent the two extremes of a continuum – there are many shades of grey (Chesbrough, 2003b). Indeed, according to Dahlaner and Gann (2007), the dichotomy between open vs. closed is artificial and it is necessary to explore different degrees and types of openness: this can yield more insight in understanding openness.

With regards to weakness, the perspectives used in the previous contributions are not exhaustive in explaining the open innovation models followed by firms. In other words, the latest literature still does not fully explain in what ways the degree of openness can happen. Indeed, to the best of our knowledge, the literature does not address the question whether some firms conduct open innovation in many phases of their innovation funnel and if others focus only on a very few of them; if this is the case, we must consider which phases of the innovation funnel are open or closed.

Hence, literature does not help companies to find the right balance between closed and open phases of the innovation funnel. Neither is it clear if the phases of the innovation funnel that are permeable are open to many or just a few partners. With few exceptions, it is not even clear if the involved partners are different in terms of typologies or not. For instance, De Backer et al. (2008) analyzed such a problem and found that universities and government research institutes are generally considered to be an important source of knowledge transfer for the innovation activities of companies, especially regarding more upstream/research activities.

On the basis of these premises, our objective is to contribute to the literature which sustains that business reality is not based on pure open innovation, but on companies that invest simultaneously in closed as well as in open innovation activities (Enkel et al., 2009) throughout the innovation funnel with different partners. Hence, we will introduce a new perspective that considers both the number/typology of partners and the number/typology of phases, in order to understand if such a perspective can confirm the existence of different models of open innovation. Within this context we will try to answer the following specific research questions:

- Do different firm-specific factors characterize the models of open innovation?
- Do such different models show a different level of innovative performance?

Figure 1 depicts the constructs of our theoretical framework. The operationalisation of each construct is reported in detail in the Appendix (all questions were measured on a four-point Likert scale to indicate the frequency of use, with 1 = disagreement and 4 = agreement).

As explained in the introduction, the main objective of the chapter is to provide empirical evidence to the notion of OI as a continuum, that is to say that different OI models may exist. Before characterizing them by means of our empirical analysis, in the following we will analyze what the literature says about the relationships between some contextual factors (i.e. R&D intensity, size, type of industry, approach to innovation, company's objectives for collaboration, managerial-organizational actions supporting open innovation) and OI models and their performance, by highlighting areas that are lacking which justify our subsequent empirical analysis. First, an analysis of the relationships between the firm-specific factors and the open innovation models will be made. Then, an analysis of the impact of the open innovation models on innovative performance will follow. Specifically, what is lacking in the literature has been highlighted for each of the relationships studied.

The Firm-Specific Factors and Open innovation

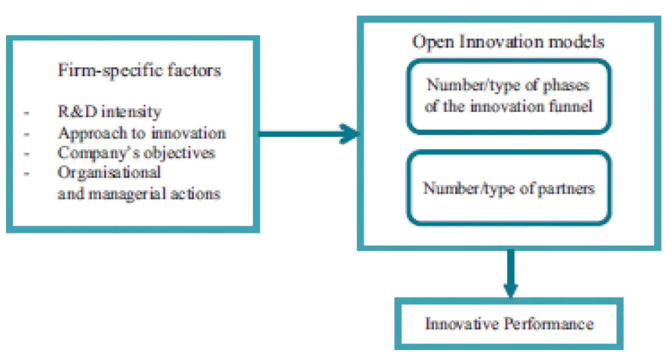
Relationship between R&D Intensity and Open Innovation Models

As regards the role played by R&D intensity, Lichtenthaler (2008), Lichtenthater and Ernst (2009), Calantone and Stanko (2007) and Sofka and Grimpe (2008) investigated this role from different viewpoints. Lichtenthaler (2008) and Lichtenthater and Ernst (2009) analysed the effect of R&D intensity and found that the greater the level of R&D intensity the greater the technological exploration. This provides support for the assumption that firms pursue external technology acquisition as a complement to internal R&D and not as a substitute (Cohen & Levinthal, 1990, Zahra & George, 2002).

Calantone and Stanko (2007) underpin that firms' exploration activities cannot occur frequently: therefore, given the high costs for developing specialized structures, firms are more likely to resort to outside expertise. Moreover, they state that firms performing a great deal of in-house exploratory research are likely to be led by this exploration away from their competencies, and will therefore be more likely to seek out outside expertise.

Sofka and Grimpe (2008) studied the effect of internal R&D investments on "breadth" (i.e. extent

Figure 1. Theoretical framework



of partner typology) and "depth" (i.e. intensity of collaboration for each partner) of research strategies. They hypothesize that internal R&D investments lead to deep research strategies rather than broad ones. With their survey, which involved firms from twelve European countries, they argue that firms building absorptive capacities through internal R&D have both broader and deeper research strategies. However, the effect on depth is stronger than the effect on breadth. In other words, committing internal resources to in-house labs and specialized scientists and engineers is therefore the primary path for innovation managers to achieve more depth in their search strategies.

Hence, on the basis of these contributions, the role played by R&D intensity is studied in relation to two of the abovementioned perspectives, through which it is possible to investigate how the innovation process can be opened: the perspective connected with the "direction of openness" and the perspective connected with the "types of partners". Thus, literature lacks the investigation of the role that R&D intensity plays with regards to the perspective offered in this chapter, which will consider both the variety of partners involved and the variety of stages in which companies collaborate.

Relationship between Size and Open Innovation Models

Size is one of the most investigated of the contextual factors and it is still a controversial subject.

On the one hand, empirical literature suggests that open innovation is mainly driven by larger companies. Empirical investigations show that size impacts on two variables representing the openness degree: the extent of both technology exploitation and exploration (Lichtenthaler, 2008; Lichtenthaler & Ernst, 2009). Indeed, as regards technology exploitation, larger companies seem to have a bigger technology portfolio than smaller companies and hence have wider technological knowledge that is potentially suitable for commercialization. As regards technology exploration, larger firms do not seem to be able to completely rely on internal activities due to the diversity of the technological knowledge that they use. In general, the fact that larger firms seem to drive the opening of the innovation process can be justified by the more systematic approach they have in their innovation processes (Lichtentaler, 2008) and the larger resources they possess with respect to small and medium enterprises (Lichtentaler, 2008; De Backer et al., 2008; van de Vrande et al., 2008). In addition, according to Lichtentaler (2008), it should be noted that the effect of size seems to be stronger in the case of technology commercialization than in technology exploration, in that commercialization is rather a newer phenomena than acquisition. As the external mode of technology exploitation has become a broader trend only in recent years, it is still driven by large pioneering firms, while the acquisition of external technology is distributed more evenly across firms of different sizes. Keupp and Gassman (2009) analyse the effect of size on two different variables representing the openness degree: the number of knowledge sources used for OI activities (i.e. the breath of OI) and the intensity of collaboration with each source (i.e. the depth of OI) and show that there is a positive and significant effect of firm size on both the breadth and the depth of OI.

On the other hand, some literature emphasises that especially small companies, often lacking resources and competence to innovate by themselves, would have great benefits from exploiting the OI model. In fact, SME are increasingly adopting OI practices (van deVrande et al., 2008).

Hence, on the basis of these contributions, it is possible to draw considerations similar to those regarding the role played by R&D intensity. Indeed, the role of size is studied in relation to the same two abovementioned perspectives: the perspective connected with the direction of openness and the perspective connected with the types of partners. In addition, its role is still controversial. As a consequence, it is possible to assert that literature lacks the investigation of the role that size plays with regard to the perspective offered in this chapter (number/typology of partners and number/typology of phases).

Relationship between Type of Industry and Open Innovation Models

Some authors investigate the impact that industry exerts on OI, interpreting industry as the typology of sector in which firms operate. Also in this case, literature is not unidirectional in that empirical findings show contrasting results. What's more, the same Lichtenthaler in different publications (Lichtenthaler, 2008 and Lichtenthaler & Ernst, 2009), while referring to the same sample, finds different results.

In fact, on the one hand, Lichtenthaler and Ernst (2009) show that a firm belonging to a particular industry does not produce any impact either on the external technology acquisition or on external technology exploitation. Similarly, Lichtenthaler (2008) states that his findings demonstrate the insignificant effect which industry differences have across the clusters. Thus, the openness of the innovation process does not seem to be determined principally by industry characteristics.

On the other hand, the studies by Gassman and Enkel (2004) and De Backer et al. (2008) demonstrate the opposite. More in particular, Gassman and Enkel (2004) state that the relative importance of internal and external sources varies across different industries. De Backer et al. (2008), although focusing on particular aspects, such as patent licensing, find important differences among industries, with chemical/drugs, electronic/electrical/semiconductors and machinery/equipment/computers as the industries where licensing deals take place more frequently than in others.

Relationship between Approach to Innovation and OI Models

A relevant concept investigated in the literature is that of "technology aggressiveness" (measured by three items, among them "the emphasis on radical innovation rather than incremental innovation")[1]. Lichtenthaler and Ernst (2009) find that technology aggressiveness is negatively related to the extent of external technology acquisition and is positively related to external technology exploitation, in that commercialization nurtures benefits in terms of setting industry standards, entering into new markets, and realizing learning effects.

In another publication, Lichtenthaler (2008) studies the implications connected with firms' emphasis on radical innovation and finds that the degree of openness seems to rise with the degree of emphasis on radical innovation, especially concerning the degree of external technology commercialization. There are two reasons for this: first, the opportunity to commercialize knowledge which, when not applied in the organization, turns out to be residual; second, the possibility to facilitate acceptance on the market and the creation of a standard. Lichtenthaler (2008) also finds that firms which emphasize radical innovation are obviously not able to develop all knowledge internally, but they have to strongly rely on complementary external sources and thus they use technology acquisition (Perrons et al., 2005).

Hence we can draw even more restrictive considerations than those regarding R&D intensity: technological aggressiveness is studied in the literature in relation only with the perspective connected with the direction of openness. If we add that this factor's role is still controversial, it emerges that new empirical investigation is needed to analyze the impact exerted by technological aggressiveness on OI models.

Company Collaboration Objectives and OI Models

The main reasons that push firms towards choices of open innovation are, on the one hand, the need to reduce innovation costs and business risks, and on the other, the need to extend skills, competences and creativity (Huang et al., 2009).

As regards the objective of diminishing costs and risks, Calantone and Stanko (2007) analyze outsourcing as a tool for increasing staffing efficiency measured in terms of employee sales efficiency. They infer that the decision to reduce the number of employees is related to the outsourcing of innovation in the short run but not over the long term. Gassmann and Enkel (2004) state that research-driven companies usually aim at reducing the R&D's fixed costs and sharing risk. Chiaroni, Chiesa and Frattini (2009) state that the reason for accessing external sources is the willingness to minimize risk by investing in technologies that are already proven in other applications.

Another main reason for firms to undertake R&D outsourcing includes accessing specialized skill sets and creativity, which exposes the internal development staff to new knowledge, technology, and organizational development processes (Catalone & Stanko, 2007; Chesbrough and Teece, 1996; Linder, 2004; Lynch, 2004), even if this strategy has drawbacks in terms of opening the market to new entrants (Porter, 1980) and exposing core competencies to imitation and substitution (Piachaud, 2005).

In comparison with the other firm-specific variables, the objectives of collaboration are studied in the literature even more restrictively; not only are they studied in relation to the perspective connected with the direction of openness, but also mainly in relation to one of the two directions, i.e. with the inbound process. Hence, for this firm-specific variable, too, there is a gap in the research literature which needs to be filled, that being an analysis of the impact exerted by collaboration objectives on the open innovation models.

Managerial-Organizational Actions Supporting Open Innovation and OI Models

Managerial-organisational actions allow open innovation to be pursued easily and more deeply, Some of these actions include the commitment of top management to promote the transition towards an open innovation approach (Vanhaverbeke, 2006; vandeMeer, 2007; Chiaroni et al., 2009, Pisano & Verganti, 2008); the need for a champion supporting the integration of external technology into an existing product development phase–gate process (Chesbrough, 2006; Chesbrough & Crowther, 2006); the exploitation of the personal relationship of the R&D managers for starting technological collaborations; the formal evaluation of collaboration objectives and risks, as well as the analysis and selection of the potential partners with a formal and explicit process (Sakkab, 2002; Huston & Sakkab, 2006). Although the works cited have shed light on how organizational and managerial factors facilitate the implementation of open models, we believe that enriching this line of inquiry with new empirical evidence is in any case quite important.

The Impact on Performance

The debate is still open on whether and how openness degree and contextual factors impact on innovative and economic performance. The results are still quite limited and contradictory, although very recent contributions (Chiang & Hung, 2010; Sofka & Grimpe, 2010) shed more light on the topic.

A widely accepted assumption is that the relations between openness degree and performance must be analyzed considering the moderator role of external environmental moderators (e.g. patent protection status: Lichtentaler, 2009; Slowinsky & Zerby, 2008; MacCormack & Iansiti, 2009). Indeed, regarding performance, it should be noted that the analysis of the company's financial performance is a complex topic due to the fact it can be explained only by considering a wide set of factors that can have contrasting effects.

Probably, the concept of innovative performance (Chiang & Hung, 2010; Sofka & Grimpe, 2010) is more understandable. The impact of open innovation models on innovative performance has been analysed in terms of a company's competence base, development costs, time to market and the level of innovation of new products/processes. Literature is unidirectional in showing the impact of the outside-in process on the access and integration of internal company capabilities with new and complementary knowledge of external firms (Gassmann and Enkel, 2004). Instead, literature results are not unidirectional as far as the reduction of development time is considered: for instance, on one hand, Gassmann and Enkel (2004) state that the benefits of co-operation are seen in an improvement in the competitive position and in risk minimisation, but not in a reduction of development time; on the other hand, according to Kolk and Püümann (2008) firms not concentrating on Open Innovation strategies fail, as rising development costs and shorter product life cycles make it increasingly difficult to justify investments in innovation. Other studies (e.g. Dahlaner & Gann, 2007) show that relationships with other actors help firms to increase the level of innovativeness.

In summary, as suggested by the literature listed above, certain relationships between the selected firm-specific variables and the openness degree are still controversial or lacking in depth. Below, we suggest improving the empirical evidence available by adopting a perspective based on number/typology of partners and the number/typology of phases, with particular reference to Italy, where partnerships are desired by many subjects, including institutional ones, though the issue is still poorly studied.

RESEARCH DESIGN AND METHODOLOGY

Survey Design

The empirical study has focused on companies located in Lombardy, a Northern Italian region; in 2008 the companies had applied for funding from the Chamber of Commerce to conduct innovative activities within different manufacturing sectors, including the mechanical and machinery sectors, as well as in sectors dealing with automotive, metallurgy, textiles, food, electronics, chemicals, pharmaceuticals, plastic, rubber, paper and paperboard, publishing and printing, wood and wood products (NACE rev.2 codes). This engagement in innovation by such companies, combined with the fact that Lombardy is marked by a particular propensity for innovation (if measured by the number of patents, Lombardy ranks first among the Italian regions according to the European Patent Office data for Italy elaborated by the Unioncamere Observatory of Patents and Brands, 2008) make them very interesting topics of innovation study. The data was collected by means of questionnaires distributed by email to participants. The advantages of such a method include low cost, completion at the respondent's convenience, absence of time constraints, guarantee of anonymity and reduction of interviewer bias (Forza, 2002). Its shortcomings, on the other hand, are represented by lower response rate as compared to other methods, longer completion times and greater effects due to the lack of both interviewer involvement and open-ended questions. The survey tool was conducted as a questionnaire whose items regarded company characteristics (sector, size), innovation strategy; organization for innovation; collaborations and innovative performance, as will be clarified in more detail below.

Before sending the questionnaire to the companies, a pilot test was conducted to assess the quality of the measure items. The items were tested by a group of senior managers and academics with working experience in innovation. They were asked to analyze the questionnaire in order to eliminate items not having strong content validity. After this stage, the resulting questionnaire was sent to the key informants of the companies that we identified as the R&D manager (if present in the company) or the company owner, if deeply involved in the definition of the company's innovation strategy (as is very common in Italian companies).

Statistical Analysis

Among the companies that have applied for funding (about 500) 99 firms have responded during a four-months period in 2009 (i.e. with a response rate equal to 20%). A general premise should be made as concerns company size (in terms of number of employees and revenues): except for few big subjects, the size of the studied companies can be classified as middle/small[2]. This imbalance can hardly be avoided because it is due to the intrinsic major sectoral composition in Lombardia, where the small size plays an important role. If, from the one hand, it is also found in non-respondents and thus it protects against the potential non-response bias, on the other hand it may prevent capture size differences when we will analyze firms characterized by different openness degrees. We must therefore bear in mind that this cannot make next comparisons between companies significant because of the intrinsic nature of the sample. However, this is the typical situation in Lombardia as well as in Italy. As clarified above in the theoretical background, we adopt the partner variety and the phase variety as relevant variables to represent and to investigate the degree of openness. Regarding their operationalization, we used subjective measures based on four-point Likert-type scales (1=strongly disagree; 4 = strongly agree) as given in the Appendix. In order to better specify the partner variety and the phase variety we introduced the variables: intensity of collaboration with partner and intensity of collaboration on phases that make up the innovation funnel (measures also based on the Likert-type scale). The study of correlations between these two variables allowed us to understand which are the most typical combination partner/phase and thus to characterize the innovation process in practice. To study firms' approaches to open innovation, we firstly carried out a cluster analysis ("complete linkage method", recommended when researcher wants to identify groups which are distinct from each other as much as possible; Barbaranelli, 2006) based on the partner variety and the phase variety. Secondly, concerning the firm-specific variables, with which we intended to describe the companies belonging to different clusters, we carried out the following procedure. Items of the questionnaire were defined on the basis of scales already used in previous works or coming from partial reworking of such scales (still Likert-type). Anyway, we applied to the gathered data an exploratory factor analysis (principal axis factoring as extraction method and promax rotation in the case of initially unclear solution) in order to delete weakly related items and to understand the factor structure and the measurement quality. An evaluation of the Eigenvalues and the Scree plot were used to identify the number of factors to retain. In addition, all factor loadings were above the acceptance level of 0.50 (Hair et al., 2006; Barbaranelli, 2006; Cheng and Shiu, 2008), thus indicating the unidimensionality of the various factors. These were saved as variables and employed in the subsequent analysis. The factors/firm-specific variables were the following (see the Appendix for detail):

Objectives of collaborations classified in two factors:

1. aims to extend skills, competences and creativity (three items, inspired by the work of Huang et al., 2009; Cronbach's α: 0,71);

2. aims to share risks and costs (two items, based on Calantone and Stanko, 2007; Cronbach's α: 0,84).

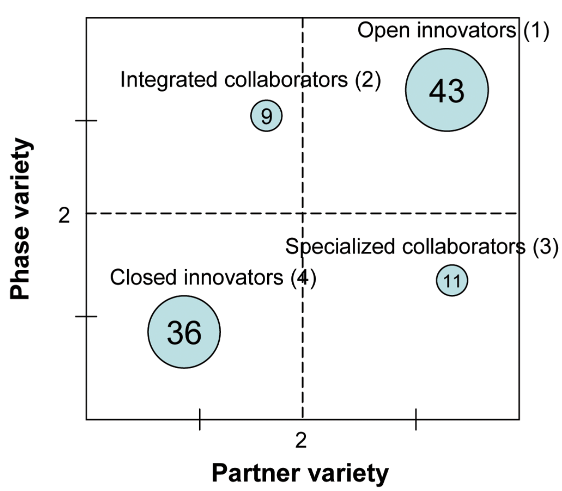
Approach to innovation: technological aggressiveness with emphasis on radical innovation (five items, inspired by Lichtenthaler and Ernst, 2009, that use suggestion by Brockoff and Pearson, 1992. We re-adapted the scale also on SURVEY TOOL 2.1 basis, a questionnaire sponsored by Industrial Research Institute, Cronbach's α: 0,71)

Organizational and managerial actions for open innovation (five items, scale based on SURVEY TOOL 2.1, Cronbach's α: 0,85)

Some other variables, not presented in Appendix, were measured directly (and eventually transformed in logarithmic scale to improve normality), such as:

- R&D intensity (i.e. percentage of R&D expenses/sales)
- Revenues (i.e. to operazionalize size)
- Number of employees (i.e. to operazionalize size)
- Indicators of company's performance (ROA – Return On Assets - and ROS – Return On Sales).

Figure 2. Results of cluster analysis



As concerns company's results, also a factor representing innovative performance was defined (five items reported in the Appendix, our scale based on Calantone et al. (2002); Cronbach's α: 0,82). After all, dummy variables were included for: the type of industry; the existence of organizational unit specifically devoted to support collaboration; the type of organizational structure used by companies for innovation activities (input-oriented, output-oriented, matrix; Chiesa, 2001).

Finally, as concerns data analysis, we applied the one-way variance analysis (i.e. ANOVA), in order to appreciate differences among clusters in terms of scale variables, and Chi-square test to compare the frequency on nominal variables.

RESULTS

Figure 2 illustrates the results of cluster analysis based on the partner variety and the phase variety.

This has resulted in a solution with four groups of firms. The decision on the number of clusters has been determined by the criterion that suggests of stopping the aggregation process at the stage that precedes the one with the highest increase in the coefficient of agglomeration (Barbaranelli, 2006). In the four-cluster solution, the variance inside clusters is about 21% whereas the variance among clusters is about 72% (F-tests sig. <.001). Despite the quite high correlation between partner variety and phase variety variables, which suggests that most firms adopt open or closed innovation approach on both dimensions, small intermediate clusters - 2 and 3 - exist (i.e. they open their innovation process more strongly in one direction rather than in the other) and thus they are worth to be analyzed although they only provide clues for further analysis.

Cluster 1 refers to the *open innovators*, companies that make up the largest group. From data about partner and phase variety variables (reported in Table 1), we found that these companies are really able to manage a wide set of technological relationships, that impact on the whole innovation funnel and involve a wide set of different partners. Although the open innovators strongly collaborate especially with the supplier in the engineering and experimentation phases[3], many other types of partners (particularly, firms operating in different sectors of activity, customers, universities, technical and scientific service companies, governmental institutions) are involved at different stages (especially in the idea generation, experimentation and engineering). An example is a medium-sized company from the machinery industry that conceptualizes and produces boilers for industrial use. Cluster 4 refers to the *closed innovators*, companies that form the second largest group. From data in Table 1, we realized that these companies access to external sources of knowledge only for a specific, single phase of the innovation funnel and typically in dyadic collaborations. The prevalent partners are in fact suppliers and customers, especially on the idea generation phase. Particularly little-used in the closed companies are the collaborations with universities and firms operating in different sectors of activity. A good example here is a small-sized textile company that has declared in some follow-up interviews, carried out after data-analysis stage, to follow a traditional innovation approach (i.e. internal research and development procedures "jealously preserved") by using the low-intensity contribution of its customers and suppliers on the idea generation phase. The companies in the smallest cluster 2 can be named *integrated collaborators*. Already found in the evidence emerged by a multiple case-study in a previous work (Lazzarotti & Manzini, 2009), these companies are the most similar to the closed ones: collaborations are with few types of partners (typically suppliers and customers), but instead of being tightly focused on one stage, they can be extended to the whole funnel. This means that the integrated collaborators "share" with their few trusted partners the whole process of innovation. An example is a small company in the electronics industry that produces and commercializes panels and electrical equipment: suppliers and customers, with whom the company has a longstanding relationship, support it through the whole process of innovation. Finally, companies in the other small cluster 4 can be classified as *specialized collaborators*. Already also emerged in our previous work, they form a group similar to open innovators regarding the variety of partners (suppliers, customers, universities, governmental institutions) but they concentrate their collaborations in a single/few points of the innovation funnel (typically the idea generation and the experimentation). From the follow-up interviews, these companies still seem a "bit behind the open", but it is a matter of time: with increasing confidence in partners, the cooperation will also increase by covering all the innovation process. An example here is a medium-sized company in the electronics industry that open to many partners (universities and governmental institutions as well as the traditional customers and suppliers) the idea generation phase.

To analyze differences across clusters, in particular the *open* and *closed* ones, one-way variance analysis (i.e. ANOVA) has been used for comparing means of scale variables (i.e. company's size expressed by revenues and number of employees, R&D intensity, approach to innovation, types of objectives, organizational and managerial actions for open innovation, performance expressed by innovative performance) and Chi-square test has been employed to compare the frequency on nominal variables (i.e. type of industry, existence of organizational units supporting collaborations). It must be said that the scarcity of observations on clusters *integrated* and *specialized* makes not applicable Chi-square tests as well as the results regarding scale variables are often not significant. Anyway, although the following evidence is useful above all to compare *open* and *closed* companies, some clues on other two clusters also emerge and thus, if interesting, they will be briefly presented in order to deepen them with next research.

Table 1. Information on the clusters and main differences (scale variables)

Variables	Sample (n=99)	Cluster 1 (n=43) Open	Cluster 2 (n=9) Integrated collaborator	Cluster 3 (n=11) Specialized collaborator	Cluster 4 (n=36) Closed	Significance (Anova test)
Partner and phase variables						
Partner variety	2.63	3.44	1.89	3.18	1.67	**.000**
Phase variety	2.61	3.49	3.11	1.82	1.67	**.000**
Intensity of collaboration with University and Research centres	1.38	1.59	1.16	1.36	1.18	**.005**
Intensity of collaboration with Technical and Scientific Service Companies	1.37	1.56	1.29	1.05	1.25	**.02**
Intensity of collaboration with Governmental institutions	1.11	1.20	1.00	1.18	1.01	**.03**
Intensity of collaboration with customers	1.70	1.77	1.56	1.80	1.61	.63
Intensity of collaboration with suppliers	1.93	2.12	1.80	1.87	1.74	.17
Intensity of collaboration with competitors	1.09	1.08	1.18	1.29	1.03	**.01**
Intensity of collaboration with firms operating in different sectors of activity	1.40	1.61	1.29	1.33	1.19	**.04**
Intensity of collaboration on Idea generation	1.51	1.62	1.38	1.52	1.39	.11
Intensity of collaboration on Experimentation	1.56	1.72	1.35	1.69	1.36	**.000**
Intensity of collaboration on Engineering	1.44	1.61	1.40	.1.32	1.29	**.002**
Intensity of collaboration on Manufacturing set up	1.34	1.49	1.13	1.26	1.22	**.002**
Intensity of collaboration on Commercialization	1.28	1.35	1.35	1.25	1.18	.23
Firm-specific contextual variables/factors						
Revenues (Log)	7.35	7.5	7.5	7.35	6.9	0.53
Employees (Log)	1.52	1.63	1.58	1.66	1.32	0.41

Variables	Sample (n=99)	Cluster 1 (n=43) Open	Cluster 2 (n=9) Integrated collaborator	Cluster 3 (n=11) Specialized collaborator	Cluster 4 (n=36) Closed	Significance (Anova test)
Performance						
Innovative performance	-0.04	0.30	0.08	0.29	-0.48	**.001**
ROS (Log)	0.73	0.76	0.80	0.65	0.70	0.89
ROA (Log)	0.78	0.78	0.69	0.75	0.81	0.94

Regarding *R&D intensity*, we found significant difference among open and closed clusters (see Table 1): the open companies invest more on average than the closed companies. This finding provides support for the assumption that firms consider open innovation as complementary with internal R&D and not a substitute (Lichtenthaler, 2008). This is consistent with the theory of absorptive capacity (Cohen & Levinthal, 1990, Zahra & George, 2002) in the sense that to be able to absorb from the outside, a company must have the appropriate skills and competences. This does not mean that the closed invests little, just it seems they invest less than open. As clues relatively to integrated and specialized clusters, interestingly the integrated shows the lowest average of R&D intensity whereas the specialist is more similar to the open one. Perhaps the integrated innovator invests internally less because it relies on a few trusted collaborators along the whole innovation process. In addition, in similar vein with previous absorptive capacity interpretation, Chi-square tests on internal organizational structure for innovation activities show that the input-oriented one (i.e. where people are organized according to their specific area of expertise, whose growth is continuously fed - Chiesa 2001) is typical for open innovators rather than for closed (for which an informal type of organization is prevalent). Indeed, the competence-building receives also a formally structured attention and thus it could suggest competence is considered a pre-requisite to openness.

As concerns *size* (see Table 1), we did not find significant differences among clusters. However, we reiterate that this may be due to the inherent imbalance of the investigated sample (i.e. high weight of medium-small sizes for companies) that reflects the Lombardia's and Italy's condition. But what perhaps we can say is that Italian companies, despite being small, are nevertheless brought to open up to outside sources, in keeping the stream of literature that argues that small firms behave like this (van de Vrande et al., 2008).

Groups do not seem different even for *type of industry* (see Table 2). As suggested by the follow-up interviews, the degree of open innovation seems to be mainly determined by the individual strategic choice of a company rather than by industry characteristics (for similar evidence, see Lichtenthaler, 2008).

As concerns *approach to innovation*, with emphasis on radical innovation rather than incremental innovation, we found that the open cluster has a higher mean (in the factor score resulting by factor analysis) than the closed and this difference is statistically significant. This is consistent with the literature and empirical evidence that suggest that companies, when focalized on radical innovations, must collaborate because they are not able to internally develop all relevant knowledge (Lichtenthaler, 2008; Perrons et al., 2005). "Relevant knowledge" that our data seem to suggest is coming from a higher degree of openness in term of wide partner variety and wide phase variety. Interestingly, the specialized, al-

Table 2. Information on open and closed and main differences (dummy variables)

Variables	Sample (n=99)	Cluster 1 (n=43) Open	Cluster 4 (n=36) Closed	Significance (Chi-square test)
Industry				
Mechanic/machinery	41%	46%	34%	0.29
Metallurgy	14%	12%	18%	0.38
Textile	8%	7%	9%	0.7
Food	4%	5%	3%	0.7
Electronics	7%	7%	6%	0.9
Chemical/pharmaceuticals	10%	14%	6%	0.42
Organizational context				
Organization input-oriented	44%	53%	33%	**.05**
Existence of organizational unit supporting collaboration	35%	47%	22%	**.02**

though very little, shows a mean higher than integrated, which might suggest that perhaps the partner variety is more relevant.

Regarding the *type of objectives* pushing companies to collaborate, open cluster shows higher mean (and statistical different) in the first-type goal "aim to extend skills, competences, creativity" with respect to closed companies. Very similar to each other (and in intermediate position between open and closed), the integrated and the specialized cluster. This finding suggests that companies look for competences and creativity by opening up in some way: to a wide variety of partners (even if on few phases), to a wide variety of phases (even if with few partners) or, at the highest level, in both directions. Similarly, the second-type goal of sharing risks and costs is related to the degree of openness in our conception. It is also interesting to note the prevalent objective in each cluster. Whereas in open cluster the main goal is the first, closed companies are pushed to open by the objective of sharing costs and risks.

As concerns the *organizational and managerial actions*, open cluster shows an average intensity on these tools statistically higher than closed (integrated and specialised still similar each other and in intermediate position between open and closed). As suggested by literature (Pisano & Verganti, 2008) these type of actions are necessary to ensure successful collaborations and this is confirmed by our evidence. Integrated and specialised have got a lower degree of openness (the integrated lower than the specialized) and probably a lower complexity in the collaborations. Thus, it is not necessary to introduce high-intensive managerial and organizational actions. Also a significant Chi-square test on the existence of an organizational unit supporting collaboration (see Table 2) gives evidence of the organizational and managerial differences between open and closed approaches.

Regarding *performance* (see Table 1) we obtained only some preliminary indications and mainly focus on innovative performance. Indeed, we believe that the analysis of overall company's performance is a complex topic due to the fact it can be "explained" only by considering a wide set of factors that can have opposite impacts. With this premise, we studied the differences between clusters only with an explorative purpose to define next steps of research and in terms of innovative performance (i.e. factor that is a combination of five items). We found that open cluster seems more performing than closed (and better than the sample average). Moreover, by studying correlations between innovative performance and partner variety, we found a high and significant relation. Particularly strong were the relations between the single item "The company's competence base was enlarged" and partner variety and "the level of innovativeness of new products/processes was improved" and still the partner variety, suggesting that the open is more innovative and that the innovativeness seems to be linked to the partner variety. Another clue for this type of interpretation is given by the specialist innovative performance: higher than integrated just in these two items. Anyway, it is important to keep in mind that they are only clues, not confirmed by the analysis of company's overall performance (measured by means of ROS and ROA), that is even greater in the closed than in the open cluster. Thus, further investigation on performance is surely required.

DISCUSSION

In this chapter, different models for open innovation are studied, by means of a survey conducted among 99 Italian manufacturing companies, with respect to two variables: the partner variety and the innovation phase variety. Although these two variables are highly correlated (.71; p<.001), intermediate cases (i.e. companies for which the two variables are different in their value, low or high) were found among companies. As a result, four different models for open innovation were found in the practice of companies: open innovators, specialised collaborators, integrated collaborators, closed innovators. The two extreme models – open and closed - are far more diffused (in coherence with the correlation found between the two variables), so the intermediate ones need a more dedicated analysis to confirm what is emerging here, that is difficult to generalise because of the limited number of companies included in these clusters. Open and closed innovators actually emerge from this analysis as two significantly different open innovation models, especially in terms of:

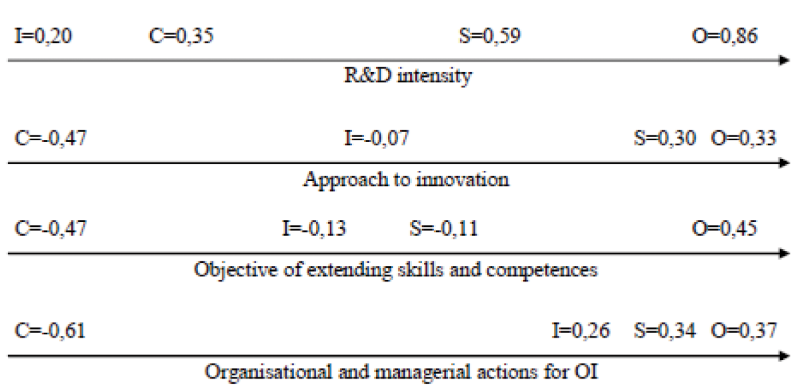
- **Approach to innovation:** open innovators are those who choose an aggressive technology and innovation strategy, in which they work to be technological leaders, to come first to the market with new products, to lead the technology evolution with superior know-how, to pursue even radical innovations. In other words, it can be argued that opening the innovation process to a wide variety of partners and all along the innovation funnel is conceived as part of an aggressive strategy;
- **R&D intensity:** open innovators invest more in R&D than closed, and this in some way confirms the difference in the strategy for the two clusters; aggressive innovators spend significantly more in R&D and, as part of their effort, they spend for opening up their innovation process. Another interesting explanation of this result refers to the need to invest in internal competences in order to be open, as the absorptive capacity of the company is critical to identify and exploit potential collaborations and exchanges with external partners. In perfect coherence with this result, there is evidence that an input-oriented organisational structure for the R&D activities, which maximises the absorptive capacity, is typical for open innovators rather than for closed;
- **Type of objectives:** in coherence with the two results above, open innovators, with respect to closed ones, mainly open their innovation process to achieve benefits related to internal competences, i.e. to deepen and integrate the knowledge base, to increase creativity and flexibility, to achieve excellence in knowledge production. On the other side, closed innovators are rather focused on reducing the costs and risks of innovation, by sharing them with external partners;

- **Organisational and managerial actions implemented to support openness:** open innovators have actually modified their organisational structure and management techniques, by introducing roles, routines and tools especially dedicated to the design, development and implementation of collaborations with external partners;
- **The results concerning the two "intermediate" models of open innovation,** i.e. specialised collaborators and integrated collaborators, are less robust, because of the limited number of companies found for these two clusters. As a consequence, only some tentative interpretation of the achieved results can be put forward. However, it is relevant to reflect on such results since they can represent the starting point for a future research aimed at verifying whether these two open innovation models can actually represent a valid alternative to open and closed models and, if so, in which specific context conditions. By making a synthesis of all results achieved for specialised and integrated collaborators, it seems that there is a sort of "continuum" in the openness of companies, in terms of the most relevant context conditions emerged in this study, as shown in Figure 3.

Figure 3 clearly shows that specialised and integrated collaborators can be really considered as "intermediate" models: the most significant variables that characterise the open and closed models, in fact, have values that are between the two extremes[4]. Integrated and specialised collaborators are thus viable options for companies that don't have a highly aggressive approach to innovation and that don't want to invest too much for opening up the innovation process. As a consequence, these companies have limited expectations in terms of benefits deriving from open innovation, but do not want to completely abandon the opportunity to access to external sources of knowledge and competencies. As an example, let's take a specialised collaborator, the electronic company cited above: the general manager wanted to spend a limited amount of resources on studying opportunities for opening the innovation process, but, at the same time, R&D managers clearly felt the need to integrate their knowledge with external contributions coming from other industries, universities, excellent research centres. As a consequence, they decided to open only the idea generation phase to a wide variety of partners.

Even in terms of performance the four models are different and a first tentative conclusion in this sense is that the degree of openness is posi-

Figure 3. Specialised and integrated collaborators between the two extreme models (C=closed innovators; I=integrated collaborators; S= specialised collaborators; O=open innovators)



tively correlated to the innovative performance: from closed innovators to open ones the level of innovative performance increases (in terms of new products and services, time to market, level of novelty, learning, costs for new products). But this does not seem to have an effect on the company's economic performance in the short term, as already discussed above. This result is in contrast with other studies (Lichtenthaler 2009), which found a positive correlation between the degree of openness (measured in terms of intensity of outbound licensing) and the economic performance (measured through ROS and ROI). In our opinion, the relation between performance and open innovation is very complex to be studied: performance is intrinsically a multi-dimensional concept (think, just to quote a well known framework, to the balanced scorecard concept), as well as the degree of openness. This can probably lead to many different measures for evaluating the relationship between openness and performance that certainly requires further in depth studies.

CONCLUSION AND FUTURE RESEARCH DIRECTIONS

Our area of research is related and contributes to innovation because collaborations and networks (in particular, technological collaboration), and the proper ways to manage them, are today largely recognized as means to improve, or at least to support, firms' innovation capabilities (Chesbrough, 2006). The study is conducted by means of a survey involving 99 Italian companies operating in manufacturing industries. Different models for open innovation are found in the practice of companies: open innovators, specialized collaborators, integrated collaborators, closed innovators. The two extreme models – open and closed - are far more diffused and actually emerge as two significantly different open innovation models, in terms of approach to innovation, R&D intensity, type of objectives, organizational and managerial actions implemented to support openness. The two intermediate models - specialized and the integrated collaborators - although in need of further empirical investigation, provide evidence in support of Chesbrough's (2003b) theoretical proposition that businesses may be located along an Open Innovation Continuum.

In conclusion, the chapter introduces a new perspective that integrates both the number/typology of partners and the number/typology of phases, in order to understand if such perspective can confirm the existence of different open innovation models. Moreover, it provides useful managerial implications because it suggests that OI is not an "on/off" choice, but it can be interpreted and adopted with different degrees (Chesbrough, 2003b), consistently with the company's specific context. Thus, intermediate open innovation models (i.e. integrated and specialized collaborators) are viable options for companies that do not have a highly aggressive approach to innovation and that do not want to invest too much for opening up the innovation process. As a consequence, these companies have limited expectations in terms of benefits deriving form open innovation, but do not want to completely abandon the opportunity to access to external sources of knowledge and competencies. We suggest that intermediate models for opening the innovation process can be a first relevant topic for future research; performance of open innovation can be a second one and, finally, a third one may concern the study of open innovation models in a dynamic perspective, i.e. analyzing the path followed by companies to open their innovation process (Chiaroni et al., 2009). Adopting a dynamic perspective, the different models found in this study may be interpreted as different steps in a long term path towards open innovation: starting from a closed innovation process, companies may gradually open to a very limited set of well known partners (suppliers and customers) in a integrated collaboration model, or may decide to open only a single phase of the innovation process to a wide variety of partners with a specialized collaborator approach. Some of the cases studied in a previous work (Lazzarotti & Manzini, 2009) seem to confirm this hypothesis. A future research with longitudinal case studies can probably improve the understanding of this dynamic path to open innovation.

Finally, it should be noted that the number of respondents is still very limited. Moreover, it is studied only the relationship between some firm-specific factors and the degree of openness (defined specifically in terms of partner variety and phase variety): a wider investigation is recommendable to include more contextual factors, i.e. external/environmental ones, or more variables that can help to define the openness degree.

KEY TERMS AND DEFINITIONS

Absorptive Capacity: The ability of a firm to recognize the value of new, external information, assimilate it, and apply it to commercial ends (Cohen & Levinthal, 1990).

Closed Innovation Model: In closed innovation model a company generates, develops and commercializes its own ideas. This philosophy of self-reliance dominated the R&D operations of many leading industrial corporations for most of the 20th century (Chesbrough, 2003b).

Inbound Open Innovation (*Outside-In Process*): Enriching the company's own knowledge base through the integration of suppliers, customers and external knowledge sourcing (Gassmann & Enkel, 2004).

Open Innovation: Firms rely increasingly on external sources of innovation, which means that ideas, resources and individuals flow in and out of organizations (Chesbrough, 2003a).

Open Innovation Continuum: Innovation models which the firms follow are not exclusively open or closed, but rather show varying degrees of openness. Between the two pure models - open or closed - there are many shades of grey and the dichotomy between open vs. closed is artificial (Chesbrough, 2003b; Dahlaner & Gann, 2007).

Outbound Open Innovation (*Inside-Out Process*): Earning profits by bringing ideas to market, selling IP and multiplying technology by transferring ideas to the outside environment (Gassmann & Enkel, 2004).

Technology Aggressiveness: Firms with aggressive technology strategies constantly developing new technologies that are superior to the technologies of their competitors. R&D activities of firms with aggressive technology strategies are usually highly specialized. Based on this specialization, the firms tend to focus on radical rather than incremental innovations (Brockhoff, & Pearson, 1992; Lichtenthaler & Ernst, 2009).

ENDNOTES

1. The other two items are: the specialization of the company's R&D activities and the high importance of development activities (the D part of R&D) relative to the firm's overall R&D activities (Lichtenthaler and Ernst, 2009).
2. We applied the criteria suggested by the EU (European Commission, 2005) for classifying firms on the basis of their size. Specifically, an autonomous company is classified as: (i) small, if the number of workers is < 50 and turnover is <= 10 million € or the annual balance sheet total is <= 10 million € (ii) medium, if the number of workers is between 50 and 250 and turnover is between 10 and 50 million € or the annual balance sheet total is between 10 and 43 million €; (iii) large, if the number of workers is > 250 and revenues > 50 million € or the annual balance sheet total is > 43 million €.
3. Data about correlations between intensity of collaboration with each typology of partner and each typology of phase are not reported in this chapter but they are available upon request.
4. Only R&D intensity is lowest in the case of integrated collaborators, but this is coherent with the fact that closed innovators need to invest a lot in R&D, since they have to develop internally all tangible and intangible resources needed for innovation.

APPENDIX

1. Partner variety: in the last five years you have collaborated with a wide variety of external actors
2. Phase variety: in the last five years you have collaborated on a wide variety of phases.
3. Intensity of collaboration with (each) partner: in the last five years you have collaborated very strongly with the following partner (University and Research centres, Technical and Scientific Service Companies, Governmental institutions, Customers, Suppliers, Competitors, Firms operating in different sectors of activity).
4. Intensity of collaboration on phase: in the last five years you have collaborated very strongly on the following phases (Idea generation, Experimentation, Engineering, Manufacturing set up, Commercialization).
5. Objectives of collaboration
    a. aims to extend skills, competences and creativity:
        i. Enlarge the company's competence base
        ii. Increase the flexibility of the internal organization
        iii. Stimulate creativity and idea generation capability
    b. aims to share risks and costs:
        i. Reduce or share the risks of innovation
        ii. Reduce or share the costs of innovation
6. Approach to innovation (technology aggressiveness)
    a. Investing for technological leadership
    b. Aggressive acquiring new business areas by means of innovation
    c. Influencing the industry structure and rules by means of products characteristics
    d. Trying to recruit the best researchers and experts available on the market
    e. Giving emphasis on radical rather than incremental innovation
7. Organizational and managerial actions for open innovation
    a. Top management is committed towards the maximization of the collaborations results
    b. Personal relationship of the R&D manager are exploited to start technological collaborations
    c. For each collaboration, there is a "champion" acting as a facilitator for the collaboration success
    d. The company formally evaluates the objectives and risks of the collaboration
    e. The company analyses and selects the potential partners with a formal and explicit process
8. Innovative performance
    a. The company's competence base was enlarged
    b. The average development costs of new products/processes was reduced
    c. The time to market of new products / processes was reduced
    d. The level of innovativeness of new products / processes was improved
    e. Sales volume and market acceptance of new products was improved

This work was previously published in Technological, Managerial and Organizational Core Competencies: Dynamic Innovation and Sustainable Development, edited by Farley Simon Nobre, David Walker and Robert J. Harris, pp. 167-190, copyright 2012 by Business Science Reference (an imprint of IGI Global).

Section 6
Managerial Impact

This section presents contemporary coverage of the social implications of Industrial Engineering, more specifically related to the corporate and managerial utilization of information sharing technologies and applications, and how these technologies can be extrapolated to be used in Industrial Engineering. Core ideas such as service delivery, gender evaluation, public participation, and other determinants that affect the intention to adopt technological innovations in Industrial Engineering are discussed. Equally as crucial, chapters within this section discuss how leaders can utilize Industrial Engineering applications to get the best outcomes from their shareholders and their customers.

Chapter 70
Offshoring Process:
A Comparative Investigation of Danish and Japanese Manufacturing Companies

Dmitrij Slepniov
Aalborg University, Denmark

Brian Vejrum Wæhrens
Aalborg University, Denmark

Hiroshi Katayama
Waseda University, Japan

ABSTRACT

The purpose of this chapter is to contribute to the knowledge on how production offshoring and international operations management vary across cultural contexts. The chapter attempts to shed light on how companies approach the process of offshoring in different cultural contexts. In order to achieve this objective, the authors employ a qualitative methodology and compare three Danish and three Japanese manufacturing companies. On the basis of this comparative investigation, the authors find that the parent companies from both contexts employ offshoring as a remedy for the challenges of globalisation. Yet there are clear differences in how offshoring is conducted in Denmark and Japan. The main differences are outlined in a framework and explained employing cultural variables. The findings lead to a number of propositions suggesting that the process of offshoring is not simply a uniform technical-rational calculation of the most efficient organisation of activities across national borders, but it is rather specific to the parent companies' national contexts.

INTRODUCTION

The IT-revolution, market liberalisation, market integration, innovative production technologies and numerous other factors related to globalisation have enabled many tasks to be performed at a distance. In order to utilise the best locations for discrete value-added activities, companies configure these activities on a global scale. As a result, growing numbers of production companies resemble dynamic, complex globally dispersed and interconnected webs of internal and external

DOI: 10.4018/978-1-4666-1945-6.ch070

relationships, rather than static and traditional co-located production systems.

In this chapter, the global dispersion of value-added activities is referred to as offshoring. This process arises through substituting overseas activities for domestic activities; as a rule, it also involves a re-configuration of the existing global operations set-up (Farrell, 2004; Pyndt & Pedersen, 2006; Lewin & Couto, 2007). Offshoring is closely interrelated with the management of global supply chain relationships. The nature of offshoring suggests that it inevitably leads to more complex and varying relationships amongst entities in globally stretched configurations of operations.

The topic of offshoring has received extensive attention in the literature. Since the 1960s, the international business (IB) literature has dealt with various aspects of why multinational corporations (MNCs) exist and how they organize the relationship between headquarters and international subsidiaries (e.g. Dunning, 1977; Bartlett & Ghoshal, 1986). The strategy literature has applied the lenses of transaction cost economics (TCE) (Williamson, 1975), resource-based view (RBV) (Barney, 1991) and core competencies (Hamel & Prahalad, 1990) to the analysis. The operations management (OM) literature has discussed the changing roles of manufacturing (e.g., Voss, 2005; Riis et al., 2007) and newly emerging manufacturing systems organised as global manufacturing networks (Ferdows, 1997; Shi & Gregory, 1998).

In spite of their variety, the theoretical approaches to the topic of offshoring have been predominantly rooted in the inherent economic logic. The factors and variables of offshoring have been treated as uniform and universal for a very broad spectrum of leading firms from the industrial triad of North America, Western Europe and Japan. This perspective is based on a basic assumption that, in order to remain competitive, these lead firms have to move parts of their operations activities to the low-cost regions of non-Japan Asia, Latin America and Eastern Europe (e.g., Quinn, 1999; Mol et al., 2005; McIvor, 2005; Kakabadse & Kakabadse, 2003). As vital and valid that this assumption might be, the issue of how the process of offshoring varies across the cultural context of these developed countries remains largely unexplored.

The research objective of this chapter is, therefore, to add to the existing literature by exploring whether and how offshoring process patterns depend on the cultural context of a dispatching organisation. We refer to the dispatching organisation as the parent company, located in the domestic base from which an offshoring initiative originates. The receiving organisation, on the other hand, is defined as the wholly owned subsidiary or third party facility in a foreign country to which operations activities are being relocated.

We recognize the importance of the receiving context and its fit with the dispatching context. However, this chapter primarily focuses on the dispatching organisation and the role of its cultural context. The underlying premise is that the initial offshoring decision, as well as the process that follows it, is influenced more by the dispatching organisation than by its differentiated partners and affiliates on the receiving side. The support for this premise can also be found in the literature. For example, Buckley (2009) argues that spatial distribution strategies make the role of parent organisations more important in the new global set-up than in conventional firms.

The objectives of the study are achieved by conducting a comparative investigation of Danish and Japanese companies. We identify a number of differences in the companies' offshoring journeys and discuss the role of the parent companies' cultural context which, among other factors, has influenced a particular approach to offshoring.

We pursue these arguments in the rest of the chapter. The following section introduces the concepts and theories employed in the investigation. Next, we introduce recent studies that outline the patterns of offshoring in Danish and Japanese companies. This is followed by six case studies from these countries. Finally, we present the analysis and discussion of offshoring processes in companies from the Danish and Japanese cultural contexts.

THEORETICAL BACKGROUND

Offshoring: Modes, Drivers and Impediments

Over the past decades, the world has become flat, as 'flat as the screen on which a business leader can host a meeting of his whole supply chain' (Friedman, 2005:7). In these 'flat' conditions operations are becoming increasingly dispersed geographically; growing numbers of companies of various sizes are turning to offshoring, in an attempt to increase their competitiveness on a global basis (Farrell, 2004; Mol et al., 2005). However, offshoring has been one of the most hotly debated research topics in recent years; there is no consensus in the literature about what is even meant by the term 'offshoring'. One reason for this is the complexity and multi-dimensionality of this phenomenon. It deals with international competitiveness and growing interdependence of firms from developed and developing countries; a large part of the offshoring debate touches upon the global labour market and its effects on jobs, wages and skills in various parts of the world; there is also a focus on how economics activities are organised across firm and country boundaries.

This chapter is concerned with the latter aspects of offshoring. As has been mentioned above, we define offshoring as the global dispersion of value-added activities. But even this definition of offshoring is not straightforward, and its meaning has changed over time. In its early years, offshoring as the global spread of production was examined mostly from the 'in-house' and foreign direct investment (FDI) perspectives. The first studies that contributed to understanding operations-related offshoring issues originating in the international business (IB) literature stream (e.g., Dunning, 1977; Bartlett & Ghoshal, 1986). Four different types of FDI were identified: market-seeking, efficiency-seeking, resource-seeking and strategic asset-seeking. These are related to location advantages of the national subsidiaries of the multinational enterprise (MNE), which was one of the primary research units in the IB literature. Back then, offshoring was viewed as a mean for international expansion through FDI and entering new markets by establishing new national subsidiaries.

Although the above perspective is conceptually clear and might have been adequate in the 1960-1980s, it hardly captures the complexity of how operations are likely to be organised today. In this new organisation, national subsidiary companies have been replaced by a series of discrete and dispersed value-added activities (Birkinshaw, 2003). Parent companies configure these activities on a global scale. From this perspective, offshoring can be defined as the relocation of an operations activity or an entire manufacturing facility to a foreign country (Cavusgil et al., 2008). We adopt this view on offshoring in the remainder of the chapter.

The relocation of activities can take place in two ways: (1) captive and (2) offshore outsourcing. The captive way of offshoring refers to the process of relocating company's activities overseas without giving up their ownership and direct control. In other words, captive offshoring occurs on an in-house or 'intrafirm' basis. Offshore outsourcing, on the other hand, can be viewed as a complete or partial discontinuation of in-house domestic or in-house international activities and, thus, refers to externally supplied or 'outsourced' activities.

Obviously, captive offshoring and offshore outsourcing do not represent the full spectrum of offshoring possibilities. They rather show two extreme scenarios, which can be further differentiated, in terms of both their contractual and location implications. Kotabe & Murray (2004) argue that in terms of contractual arrangements offshore outsourcing can further be split into arm's length relationships and strategic partnerships. From a location point of view, companies can relocate activities either to geographically distant countries or 'nearshore'. The Economist (2005) defines nearshoring as the business of moving activities 'to countries that are quite cheap and very close rather than very cheap and far away'.

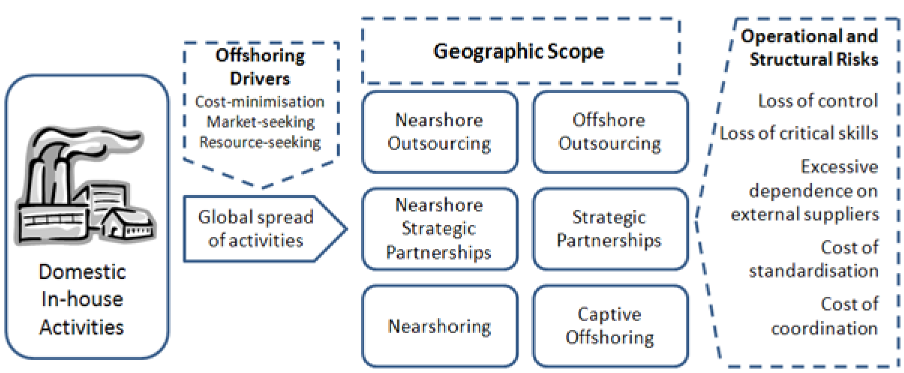
By configuring value-adding activities across the world, companies reap various benefits of offshoring. These benefits include getting access to cheaper factors of production, being close to important markets and getting access to knowledge and other strategic resources (Ferdows, 1997; Doh, 2005). If offshoring takes place in the offshore outsourcing way, the parent company may also benefit from the economies of specialisation and focus on the core competencies (Hamel & Prahalad, 1990). However, on the other hand, a number of factors also impede the trend towards offshoring. First of all, the cost of coordinating globally dispersed value-adding activities may be high (Kotabe & Murray, 2004). Next, offshoring of some activities, proprietary activities in particular, may lead to operational risks (e.g., quality-related) and structural risks (e.g., decreasing brand value) (Aron & Singh, 2005). In the case of offshore outsourcing, both the operational and structural risks are particularly severe. They may potentially lead to the loss of control over activities, loss of critical skills, declining innovation capability of the parent company, and excessive dependence on external suppliers (e.g., Kotabe, 1992; McIvor, 2005).

The choice of the offshoring mode also depends on which value-added activities are to be transferred overseas. While highly proprietary activities (e.g., R&D, design, branding) have the overall tendency to be concentrated at home, standardised activities (e.g., production) are more conductive to being geographically dispersed using the offshore outsourcing mode (Cavusgil et al., 2008).

Figure 1 builds on the reviewed literature and outlines the major offshoring modes, drivers and impediments briefly discussed in this section. The factors and variables of offshoring articulated here will be employed in the following parts of the chapter.

The literature also identifies a number of theoretical competing explanations for why and how companies offshore. Institutional theories (e.g., Greenwood & Hinings, 1996) emphasize congruence with shifting industry norms and shared logics. The transaction cost economics (TCE) approach (e.g., Williamson, 1975) focuses on intra-firm vs. inter-firm transactions costs and achieving the optimum level of internalization of activities. The resource-based view (RBV) (e.g., Barney, 1991) stresses the importance of firm-core-related resources and capabilities in sustaining a firm's competitive advantage. These explanations focus on the rational search for an optimal

Figure 1.



fit between performance objectives and operations resources. They also typically portray companies from developed countries as a homogeneous group 'renting' the cheaper capacity from overseas partners. However, we should not rush into making fast conclusions about uniformity and universality of the location and make-or-buy decisions of companies from the traditional industrial centres of North America, Western Europe and Japan.

Relating Offshoring Processes to Cultural Context

Westeney (2003), discussing how Japanese companies differ from US and European companies, outlines three sets of factors determining potential differences: 1) system-level factors related to history, dominant management ideologies, and investment regimes; 2) home country effects related to generic patterns of strategy institutionalised in the domestic business system; 3) firm-level factors related to a company's international experience.

The firm level factors are dynamic and tend to converge across companies from different countries over time. However, the inherent economic logic that any firm follows does not account for all aspects of its behaviour, and differing patterns still occur. Some of them may well be attributed to system-level factors, such as government policies. They may play an important role in shaping firms' offshoring patterns. However, the full assessment of the role of such factors can only be conducted working from a base in political economy and is beyond the scope of this chapter. Instead, we choose to focus on company's country of origin impacts in terms of national culture. Our reasoning for this choice is based on the argument that introducing the cultural dimension of offshoring will allow for probing non-rational and county-specific aspects of offshoring patterns, as they develop through a complex and evolutionary interplay of historical events and human agents.

The notion that the country of origin matters in various aspects of global business is generally accepted in the IB literature (e.g. Kogut & Singh, 1988). However, in the operations and supply chain management literature, the impact of national culture on offshoring has been somewhat peripheral to the discussion. A study by Voss and Blackmon (1998) represents one of the rare exceptions. It addresses cultural differences as a factor contributing to different operations strategy orientations between Japan and the West. Several other studies (e.g., Pagell et al., 2005; Ang & Inkepen, 2008) also call for employing cultural variables in dealing with various aspects of international operations management.

However, what is culture, and how can the issue of the possible cultural relativity of offshoring practices be approached? In the second half of the 20th century, many authors attempted to define culture (e.g. Kroeber & Parsons, 1958; Hofstede, 1983; Schein, 2004). In this chapter, we adopt Hofstede's (1983) cross-disciplinary definition of culture as the collective mental programming of people within a national culture, with consequences for beliefs, attitudes, and skills. Hofstede's (1983, 1984, 2001) dimensional approach to cross-cultural comparison includes five dimensions of national cultural variation: Collectivism vs. Individualism, Large vs. Small Power Distance, Strong vs. Weak Uncertainty Avoidance, Masculinity vs. Femininity, Long vs. Short-Term Orientation.

The approach for arriving at these dimensions, as well as the way of measuring them, is not immune to criticisms. McSweeney (2002), one of Hofstede's harshest critics, questions several aspects of Hofstede's approach. First, concerns are raised about the representativeness of the sample used in Hofstede's study, which was conducted over thirty years ago. The data were collected using a survey of professionals only from one location in each country and from employees of only one company (IBM). Next, according to McSweeney (2002), because the results of the survey show considerable variation within samples in individual countries, we can only resort to using average tendencies when comparing nations. Finally, exposing the limitations of the functionalist approach, the critics cast doubts about whether the five dimensions capture all the complexities of a national culture which is not always territorially bound. Hofstede (2001) counters many of these criticisms, but also admits that his 'world-scale dimensions cannot do justice to the profound meanings of local practices in the countries' (Hofstede, 2001:73).

Nevertheless, since the 1980s, when four out of five dimensions were introduced, the ideas of Hofstede have become an integral part of any major study dealing with culture. The number of societies covered in the Hofstede's research – more than 50 – includes similar as well as different ones. This number is large enough to describe the research as geocentric, rather than just ethnocentric or polycentric. Compared to other multidimensional classifications of culture we considered (e.g. Inkeles & Levinson, 1997), Hofstede's research also stands out as grasping the notion of culture in a manageable and suitable manner for international business and operations management. These factors determined the use of Hofstede's indices in our analysis. In the discussion part of the chapter, we link each of the five cultural dimensions to patterns of offshoring observed in the literature and practice in the contexts of two developed countries: Denmark and Japan.

Before we proceed, it is important to note that, despite our focus on national culture, we acknowledge that in a business context, culture can develop at different levels – national, organisational, professional. Our deliberate focus on national culture is based on the argument articulated in numerous studies on cross-cultural management that it is the national culture in which an organisation is embedded that has been found to be the main influence (Browaeys & Price, 2008).

In the following section, we compare offshoring trajectories in companies from the two countries. The question is: what link, if any, can be established between the offshoring strategies of companies and their cultural context?

COMPARISON OF OFFSHORING IN DENMARK AND JAPAN

Patterns Highlighted in the Literature

The contexts of Denmark and Japan offer a good opportunity for a comparative analysis. Apart from differences in size, both economies have some important similarities. Both countries enjoy the same high level of industrialisation and economic development, both have high labour costs, and the manufacturing sectors in both countries have traditionally been *first forte* of the their economies. So what is already known about offshoring patterns in Denmark and Japan?

First of all, neither of the two countries represents an exception to the growth in scale and scope of the offshoring phenomenon. Kimura and Ando (2005) suggest that Japanese firms have been increasingly capitalizing on the opportunities arising from offshoring of production activities. The geographic targets of Japanese offshoring initiatives as well as the logic behind these initiatives, has shifted over time. In 1980, North America was the primary destination for Japanese FDI. Access to market, tariff avoidance and yen-dollar exchange rates were among the major factors in the location of 'transplants' of Japanese companies to the U.S. in the period of 1970-1990 (Schroeder et al., 1992).

However, over time, the market entry motivation behind offshoring has been decreasing due to lower trade barriers. Katayama et al. (1999) point out that, since the 1990s, growing numbers of world-class Japanese industries have been increasingly shifting their operations to low-cost Asian countries, in order to deal with the challenges of maintaining competitiveness through getting access to cheaper labour and resources. During this period, Asia became one of the prime locations for the inflow of manufacturing investments by Japanese companies (Westney, 2003).

Hijzen et al. (2006) find that, despite widespread concerns that offshoring leads to a hollowing-out effect and job losses, the Japanese firms engaged in offshoring actually tend to strengthen their economic activities in Japan both in terms of output and employment. Westney (2003) finds that in many Japanese companies which were actively extending their production networks abroad in the 1990s, the export ratio fell very little or in some cases even rose considerably.

There is evidence to suggest that, in shifting their activities overseas, Japanese firms tend to chose captive offshoring as opposed to offshore outsourcing. Tomiura (2005) reports that only a small fraction, less than 3%, of Japanese manufacturing firms, outsource their production from independent suppliers (*dukuritsu kaisha*). According to The Economist (2007), relative lack of enthusiasm for engaging in the offshore outsourcing mode is partially due to the fact that in Japan, outsourcing decisions are seen as uncomfortable and undermining corporate pride.

Benito et al. (2002), studying internationalisation patterns of Scandinavian companies, Danish among them, find that companies from this region demonstrate a very high propensity to internationalise their operations. Statistics Denmark (2008) reported that 19% of all Danish companies (with 50 or more employees) sourced internationally. The most frequent destinations for offshoring in Danish companies were the new EU member states, as well as low-cost countries in South East Asia (Statistics Denmark, 2008). The same study found that captive offshoring and offshore outsourcing were equally important types of offshoring by Danish companies. Some research points out that Danish firms tend to reduce their domestic operations especially with regard to labour-intensive jobs. For example, according to Pyndt and Pedersen (2006), 80% of all textile-related jobs in Denmark were lost as a consequence of offshoring of labour-intensive activities to low-cost regions. In general, in the latest wave of offshoring, efficiency seeking is seen by Danish companies as the main driver for shifting activities abroad (Statistics Denmark, 2008)

Jenster et al.'s (2006) study analyzed offshoring trends in Europe. It found that, in terms of jobs loses to offshoring, Denmark is two to three times more severely affected than the European Union average. However, it is important to note that synergetic and dynamic effects of offshoring also result in an increase in knowledge-intensive job creation in Denmark (Jenster et al., 2006; Statistics Denmark, 2008). Although these findings demonstrate ambiguity about the impact of offshoring on the Danish labour market, one thing seems certain - Danish companies take a rather aggressive approach to offshoring and downsize their domestic base.

Table 1 summarizes the major features of offshoring patterns, distilled from the reviewed studies focusing on offshoring by Danish and Japanese companies.

To enrich the empirical base for our investigation, in the following we present cases of three Japanese and three Danish companies. The case descriptions together with the material discussed above, form the basis for the analysis which follows the case studies section.

Case Examples from Denmark and Japan

Methodology

The case study, one of several strategies for doing qualitative research, has been chosen for this investigation for several reasons. First, case studies can describe, enlighten and explain real-life phenomena that are too complex for strategies requiring tightly structured designs or pre-specified data sets. On the other hand, case studies do not have to be ethnographic or participatory action research based. They are 'defined by interest in individual cases, not by methods of enquiry'

Table 1. Differing patterns of offshoring in Danish and Japanese companies

	Offshoring Drivers	*Offshoring Mode*	*Offshoring Effects*
Japan	Market-seeking Cost-minimisation Resource-seeking Currency exchange rate fluctuations	Mixed, but predominantly captive and strategic partnerships	Domestic core intact or enhanced
Denmark	Cost-minimisation Market-seeking Resource-seeking	Mixed, but with high degree of offshore outsourcing	Domestic core downsized (especially in labour-intensive activities)

(Stake, 2003:134). Second, instrumentally, the case study strategy is well equipped for furthering understanding of particular contemporary issues or concepts which have not been deeply investigated so far (Eisenhardt, 1989; Voss et al. 2002; Yin, 2009). Third, according to Yin (2009), case studies are generally preferred for answering 'how' and 'why' questions about a contemporary phenomenon, over events in which the investigator has little or no control.

Our research objective satisfies all these conditions (i.e., the type of questions, phenomenon under investigation and controllability) and thus is well suited for the case study strategy. The study is concerned with how the process of offshoring varies across cultural contexts. As we established, studies focusing on cultural variables in the context of offshoring process are scarce and the cultural relativity of offshoring is still at the understanding and discovery stage. As far as the controllability issue is concerned, case studies again emerge as the preferred method for this study. On the one hand, we had sufficient access to the actual phenomenon through company visits and interviews with managers involved in offshoring initiatives. On the other hand, the control we had over the events in the cases was not sufficient for applying other methods, such as a participatory action research.

Six exploratory case studies (three representing the Danish context and three – the Japanese context) were selected randomly on the basis of possessing two key attributes: 1) a long-standing involvement in offshoring initiatives; 2) a strong need for closeness to markets. The latter criterion was introduced in order to control for the market-proximity factor on the firm level. Considerations about the access to potential data, including commitment of interviewees, and availability of documents, were also taken into account.

The offshoring process in all six companies started prior to our involvement in the cases. Therefore, many events relevant to the study had to be captured in retrospect. The data collection was conducted following a formal research protocol. However, the nature of case study research is rather iterative and unfolding (Strauss, 1987; Pettigrew, 1990). It was almost impossible to routinize the data collection because the specific information was often not readily available. In these instances, alternative leads had to be pursued.

The data collected for the case study was organised in a database. Table 2 outlines two main elements of the database indicating which data were collected and how.

Documents and archival records, as the sources of evidence, formed a significant amount of the case studies database. They had several strengths: could be reviewed repeatedly, provided broad coverage of time and events, and contained exact spelling of names and references. All the collected documents and records were extensively studied prior and after the site visits and interviews.

Interviews constituted another source of evidence. The interviews were conducted as in-depth

Table 2. Value of the five dimensions for Denmark and Japan

Country	Individualism/ Collectivism		Power Distance		Uncertainty Avoidance		Masculinity/ Femininity		Long/Short Term Or.	
	Index	Rank	Index	Rank	Index	Rank	Index	Rank	Index	Rank
Denmark	74	9	18	51	23	51	16	50	46	10
Japan	46	22-23	54	33	92	7	95	1	80	4

Source: Hofstede (2001)

guided conversations. Respondents were asked to give detailed accounts of their companies' offshoring initiatives. The focus was put on chronology of events, major drivers, location decisions, decision making authority, and areas of organisation affected by offshoring. Moreover, the respondents were asked about how the initiative had affected their job and its task environment. The interview data had its challenges and weaknesses. This source of evidence is not immune to biases, poor recollection of events and inaccuracies. To minimize the impact of these weaknesses, the interview data were triangulated with the documents and records we collected.

All these data combined were used to build the case narratives presented below. Within-case and more general cross-case analyses enabled us to identify patterns of offshoring, which we compare with those identified in the literature and later discussed in relation to the pre-selected cultural dimensions.

Case A: Cautious Offshoring Expansion with Retaining Manufacturing Competencies

Company A is a Japanese company, which develops and produces bearings as well as other friction control products, for a wide variety of industries. Currently it has approximately 1500 employees worldwide. 1100 of them are based in Japan, where the company's headquarters and its five manufacturing sites are located. The company also operates four wholly owned manufacturing sites overseas in the USA, China, Thailand and Czech Republic. It also has a wide network of differentiated affiliates, mainly involved in sales and distribution.

The company's production offshoring journey started in 1986 with the establishment of manufacturing facilities in the USA. In 1988, this was followed by establishing a subsidiary in Germany, where production of some components for the automotive industry started in 1991. These investments were made in order to be close to key customers and to reduce the negative impact of the strong yen on the company's export prices.

The offshoring initiative got a big boost during the last decade. However, the motivation for offshoring has changed. The recent offshoring moves were largely cost-minimisation driven. In this period, several manufacturing sites were opened in the low-cost locations. In 1998, the company started its manufacturing activities in Shanghai, China. In 2002, a sales office and manufacturing facilities were established in Thailand. In 2005, the company's European manufacturing base was transfered from Germany to the Czech Republic. The same year, activities in China were expanded and a new site in Suzhou was established.

Implications of the latest offshoring initiatives for the domestic base were very limited. To some extent, this can be explained by a low level of connectivity between plants. In such fragmented system, the domestic base remains shielded from the changes happening in the company's global operations set-up. However, it is also part of the company's strategy to preserve a strong domestic base, which is perceived as paramount to maintaining a long-term competitive advantage. In 2002-

2008 at all its Japanese facilities, the company implemented a new production system, based on the Toyota Production System (TPS) principles. This was done to ensure that manufacturing in Japan remained competitive and was retained as one of the company's core competencies. Thus, the company approaches its overseas facilities as a complement, rather than a substitute, to its domestic production. It remains persistently committed to retaining its manufacturing competences in-house in its domestic base. The same approach is taken towards the development function. Although some development activities take place in the company's facilities in the USA, they are tightly controlled from Japan. There are no plans to replicate or intensify technology development in other parts of the world.

Case B: Emphasising Ownership and Consolidating Mission Critical Activities at Home

Case B is a Japanese company specialising in measurement, control and automation technologies and equipment. The company's main production facilities are located in Japan, the US and China, with workforce of approximately 5500 employees. Its overseas affiliates and subsidiaries, focusing mainly on sales and customer support, are located in 11 other countries. The company prioritises full ownership of its subsidiaries, at home as well as overseas, and sees this as a central means for reinforcing its business sustainability.

Traditionally, the company's international links were limited to collaboration with an American partner, which had an equity stake in the case company for several decades. However, in 1990, this equity stake was considerably reduced. In the 1990s, the company started a gradual expansion of its presence in Asia. In spite of unfavourable economic conditions in the region at the time, the company opened sales and customer support offices in Thailand, Indonesia, Philippines, Singapore, Korea, Malaysia, and Taiwan. In 2001, the company also established a manufacturing base in Europe as a result of a 12-year journey, which started in 1989 with the opening of a sales office in Belgium.

The facilities in Europe were established primarily with the objective to improve access to the market there. However, in addition to market-seeking, in the 1990s, the company also started looking for low-cost manufacturing locations. In 1992, the company established its first joint-venture in China, where a new manufacturing plant was opened in 1995. Over a number of years, these facilities, which currently are 100% owned by the company, played a number of roles. First, the Chinese site was used as a server for the south-east Asian market, demanding less sophisticated lower-cost products. Second, by supplying precision die-cast components to the Japanese plants, the facilities in China played a crucial role in the company's steps towards strengthening the cost-competitiveness of its production at the domestic base in Japan. In 2008, similar roles were assigned to newly opened wholly owned facilities in Vietnam. As was the case with other overseas facilities, the operations in Vietnam were a result of a carefully planned 3 year initiative. It started with opening a representative office in the country and later was followed by a gradually increasing commitment to this location.

In the end of the 1990s, a new International Business Division was set up in the company's headquarters in Tokyo. The division was established in order to centralise all the affiliates' activities and provide a global overview of overseas operations. The role of the division increased considerably in 2002, when the company terminated its long-term equity alliance with the American partner after gradually reducing the partner's stake in the business for a number of years. Since then, the Tokyo headquarters has become responsible for the coordination and development of sales and operations worldwide. Previously, this activity was largely the prerogative of the American partner.

The company sees itself as a technology-oriented manufacturer. In 2007, its R&D function, previously scattered across its operating base, was consolidated at the company's new technology centre near Tokyo. Concentrating research, product development and engineering at the domestic base was a strategic step, providing 'one-stop' solutions in a close proximity to the main Japanese manufacturing sites.

Case C: Preserving Strategic Competences in the Domestic Base

Case C is a Tokyo-based manufacturer of industrial instruments and control systems. It currently employs approximately 5000 people. Close to 50% of the company's sales are generated outside its home market, in 32 countries from all over the world. This has been achieved through consistent long-term efforts in global business expansion.

As early as the 1970s, the first production facilities outside Japan were established in Singapore. In 1986, the company started operations in China. In the following years, the number of new overseas production plants gradually increased. In 2007, the company was operating 14 plants in 9 different countries including high-cost countries, such as the US, the Netherlands, Singapore and Germany, as well as low-cost countries, such as China, Korea, Brazil, Indonesia, and India. Its presence in the high-cost countries was crucial for having better visibility and access to strategic markets, whereas, the plants in low-cost countries represented the company's attempt to enhance production capabilities in low-cost destinations and ensure a low-cost supply to the Japanese facilities.

The strategy of the company was not only to keep as much production in Japan as possible, but also to preserve its core development capabilities in the domestic base. The first R&D centres were opened outside Japan, in Singapore and India. These new centres, in total employing 85 people, played a more peripheral support role to the main R&D function, with 1000 engineers located in Japan. The centre in Singapore was supposed to develop better links with customers, particularly outside Japan. The idea of the new centre was also to practice a style of communication and thought-process that engineers based in Japan could gradually learn from. The mission of the team of engineers in India was somewhat similar to that of the Singapore office, i.e. to improve the link with overseas customers. The engineers in India were trained to speak and even to think in Japanese, so they could communicate effectively with colleagues in Japan. The company started training its Indian team 10 years before the office was open, so they could contribute more to product development projects led by engineers in Japan.

Case D: Aggressive Offshoring Cycle - from Production to Competence Centre Overseas

Company D is a Danish company, which develops and produces acoustics and mechanics components for the telecommunication industry. It is known for its high quality standards and is on the forefront of innovation in the industry. The company has approximately 4000 employees worldwide, of which 75 are based at its headquarters in Denmark. It operates R&D and sales facilities in the USA and the Netherlands, as well as five wholly owned production sites in Poland, China, and Vietnam.

In the past 5-7 years, the company experienced a period of enormous intensity of offshoring. In 2001-2002, company's production in the Netherlands was relocated to Poland. In 2005, the bulk of production was moved from Poland to Vietnam. The Polish site was transformed into pre-production and R&D centre.

In the period of 1999-2006, the company transitioned from lead production in Denmark to lead production in China, through a number of intermediate steps. In 1999, a customer service centre was established in China to serve the rising Asian market. In 2000, full scale production was transferred from Denmark to China. This move was mainly based on cost considerations. The market was in a slump, and the company believed that the transfer would lead to an increased focus on cost. A secondary driver, but increasingly important, was emergence of the local market in China. At that time, all product and process development, along with some ramp-up activities, were retained in Denmark. However, by 2006, after realizing that having two parallel sites was counterproductive, all production activities were relocated from Denmark to China. The production set-up in China was very different from the Danish one. In particular, production processes in China were more manual work based, while only quality sensitive processes were automated.

Moving production to China affected all other functions of the company. In 2005, a small R&D department was established in Shanghai, to support ramp-up activities and indigenous development activities in China. In 2006, it was decided to give the Chinese production site the role of competence centre for production, thus recognising that production competence was no longer primarily based in Denmark. The proximity to suppliers of key components played an important role in this decision, and a new purchasing department was established in China. It took over all operational and tactical tasks from the Danish parent company, which preserved only the authority over the strategic purchasing decisions.

In the end of 2006, a new production site in Vietnam was opened. The main motivation for establishing the new facilities was related to lower labour costs. Production at the new site primarily complements production at the Chinese facilities, where lead production continues to take place.

Case E: Outsourcing Initiative with an Ambitious Scale and Timeline

Company E is a Danish producer of products characterised by high seasonality and exposure to fashion trend fluctuations. The company employs approximately 4000 employees worldwide. It had traditionally been committed to its operations in Denmark. For a number of years, it had also operated its own production sites in Switzerland and the United States. However, in 2004, its perspective on global operations changed considerably. Its emphasis switched from in-house production to outsourcing in low-cost countries: Mexico, Hungary and the Czech Republic.
