List of Contributors

Table of Contents

Volume I

Section 1
Fundamental Concepts and Theories

This section serves as a foundation for this exhaustive reference tool by addressing underlying principles essential to the understanding of Industrial Engineering. Chapters found within these pages provide an excellent framework in which to position Industrial Engineering within the field of information science and technology. Insight regarding the critical incorporation of global measures into Industrial Engineering is addressed, while crucial stumbling blocks of this field are explored. With 10 chapters comprising this foundational section, the reader can learn and chose from a compendium of expert research on the elemental theories underscoring the Industrial Engineering discipline.

Section 2
Development and Design Methodologies

This section provides in-depth coverage of conceptual architecture frameworks to provide the reader with a comprehensive understanding of the emerging developments within the field of Industrial Engineering. Research fundamentals imperative to the understanding of developmental processes within Industrial Engineering are offered. From broad examinations to specific discussions on methodology, the research found within this section spans the discipline while offering detailed, specific discussions. From basic designs to abstract development, these chapters serve to expand the reaches of development and design technologies within the Industrial Engineering community. This section includes 14 contributions from researchers throughout the world on the topic of Industrial Engineering.

Section 3
Tools and Technologies

This section presents an extensive coverage of various tools and technologies available in the field of Industrial Engineering that practitioners and academicians alike can utilize to develop different techniques. These chapters enlighten readers about fundamental research on the many tools facilitating the burgeoning field of Industrial Engineering. It is through these rigorously researched chapters that the reader is provided with countless examples of the up-and-coming tools and technologies emerging from the field of Industrial Engineering. With 14 chapters, this section offers a broad treatment of some of the many tools and technologies within the Industrial Engineering field.

Volume II

Section 4
Utilization and Application

This section discusses a variety of applications and opportunities available that can be considered by practitioners in developing viable and effective Industrial Engineering programs and processes. This section includes 14 chapters that review topics from case studies in Cyprus to best practices in Africa and ongoing research in the United States. Further chapters discuss Industrial Engineering in a variety of settings (air travel, education, gaming, etc.). Contributions included in this section provide excellent coverage of today's IT community and how research into Industrial Engineering is impacting the social fabric of our present-day global village.

Section 6
Managerial Impact

This section presents contemporary coverage of the social implications of Industrial Engineering, more specifically related to the corporate and managerial utilization of information sharing technologies and applications, and how these technologies can be extrapolated to be used in Industrial Engineering. Core ideas such as service delivery, gender evaluation, public participation, and other determinants that affect the intention to adopt technological innovations in Industrial Engineering are discussed. Equally as crucial, chapters within this section discuss how leaders can utilize Industrial Engineering applications to get the best outcomes from their shareholders and their customers.

Volume III

Section 7
Critical Issues

This section contains 13 chapters, giving a wide variety of perspectives on Industrial Engineering and its implications. Such perspectives include reading in privacy, gender, ethics, and several more. The section also discusses new ethical considerations within social constructivism and gender gaps. Within the chapters, the reader is presented with an in-depth analysis of the most current and relevant issues within this growing field of study. Crucial questions are addressed and alternatives offered, and topics discussed such as creative regions in Europe, ethos as an enabler of organizational knowledge creation, and design of manufacturing cells based on graph theory.

Preface

The constantly changing landscape of Industrial Engineering makes it challenging for experts and practitioners to stay informed of the field's most up-to-date research. That is why Information Science Reference is pleased to offer this three-volume reference collection that will empower students, researchers, and academicians with a strong understanding of critical issues within Industrial Engineering by providing both broad and detailed perspectives on cutting-edge theories and developments. This reference is designed to act as a single reference source on conceptual, methodological, technical, and managerial issues, as well as provide insight into emerging trends and future opportunities within the discipline.

Industrial Engineering: Concepts, Methodologies, Tools and Applications is organized into eight distinct sections that provide comprehensive coverage of important topics. The sections are: (1) Fundamental Concepts and Theories, (2) Development and Design Methodologies, (3) Tools and Technologies, (4) Utilization and Application, (5) Organizational and Social Implications, (6) Managerial Impact, (7) Critical Issues, and (8) Emerging Trends. The following paragraphs provide a summary of what to expect from this invaluable reference tool.

Section 1, **Fundamental Concepts and Theories**, serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of Industrial Engineering. Introducing the book is "*Defining, Teaching, and Assessing Engineering Design Skills*" by Nikos J. Mourtos, a great foundation laying the groundwork for the basic concepts and theories that will be discussed throughout the rest of the book. Another chapter of note in Section 1 is titled "*Integrating 'Designerly' Ways with Engineering Science*" by Ian de Vere and Gavin Melles, which discusses the novel techniques of adding aspects of design science into the stricter roles of engineering practices. Section 1 concludes, and leads into the following portion of the book with a nice segue chapter, "*Tracing the Implementation of Non-Functional Requirements*," by Stephan Bode and Matthias Riebisch. Where Section 1 leaves off with fundamental concepts, Section 2 discusses architectures and frameworks in place for Industrial Engineering.

Section 2, **Development and Design Methodologies**, presents in-depth coverage of the conceptual design and architecture of Industrial Engineering, focusing on aspects including parametric design, service design, fuzzy logic, control modeling, supply chain systems, and many more topics. Opening the section is "*Learning Parametric Designing*" by Marc Aurel Schnabel. This section is vital for developers and practitioners who want to measure and track the progress of Industrial Engineering on a through the multiple lens of parametric design. Through case studies, this section lays excellent groundwork for later sections that will get into present and future applications for Industrial Engineering, including, of note: "*Decision Support Framework for the Selection of a Layout Type*" by Jannes Slomp and Jos A.C. Bokhorst, and "*Internal Supply Chain Integration*" by Virpi Turkulainen. The section concludes with an excellent work by Mousumi Debnath and Mukeshwar Pandey, titled "*Enhancing Engineering Education Learning Outcomes Using Project-Based Learning*."

Section 3, **Tools and Technologies**, presents extensive coverage of the various tools and technologies used in the implementation of Industrial Engineering. Section 3 begins where Section 2 left off, though this section describes more concrete tools at place in the modeling, planning, and applications of Industrial Engineering. The first chapter, "*Semantic Technologies in Motion*," by Ricardo Colomo-Palacios, lays a framework for the types of works that can be found in this section, a perfect resource for practitioners looking for the fundamentals of the types of semantic technologies currently in practice in Industrial Engineering. Section 3 is full of excellent chapters like this one, including such titles as "*Optimization and Mathematical Programming to Design and Planning Issues in Cellular Manufacturing Systems under Uncertain Situations*," "*Multi-Modal Assembly-Support System for Cellular Manufacturing*," and "*An Estimation of Distribution Algorithm for Part Cell Formation Problem*" to name a few. Where Section 3 described specific tools and technologies at the disposal of practitioners, Section 4 describes successes, failures, best practices, and different applications of the tools and frameworks discussed in previous sections.

Section 4, **Utilization and Application**, describes how the broad range of Industrial Engineering efforts has been utilized and offers insight on and important lessons for their applications and impact. Section 4 includes the widest range of topics because it describes case studies, research, methodologies, frameworks, architectures, theory, analysis, and guides for implementation. Topics range from serios games, enterprise resource planning, and crisis management, to air travel development and design. The first chapter in the section is titled "*Using Serious Games for Collecting and Modeling Human Procurement Decisions in a Supply Chain Context*," which was written by Souleiman Naciri, Min-Jung Yoo, and Rémy Glardon. The breadth of topics covered in the chapter is also reflected in the diversity of its authors, from countries all over the globe, including Germany, Slovenia, Norway, Hong Kong, Malaysia, Brazil, Cyprus, Turkey, the United States, and more. Section 4 concludes with an excellent view of a case study in a new program, "*UB1-HIT Dual Master's Programme,*" by David Chen, Bruno Vallespir, Jean-Paul Bourrieres, and Thecle Alix.

Section 5, **Organizational and Social Implications**, includes chapters discussing the organizational and social impact of Industrial Engineering. The section opens with "*Process Innovation with Ambient Intelligence (AmI) Technologies in Manufacturing SMEs*" by Kathryn J. Hayes and Ross Chapman. Where Section 4 focused on the broad, many applications of Industrial Engineering technology, Section 5 focuses exclusively on how these technologies affect human lives, either through the way they interact with each other, or through how they affect behavioral/workplace situations. Other interesting chapters of note in Section 5 include "*Group Decision Making for Advanced Manufacturing Technology Selection Using the Choquet Integral*" by Cengiz Kahraman, Selçuk Çebi, and Ihsan Kaya, and "*Direct Building Manufacturing of Homes with Digital Fabrication*" by Lawrence Sass. Section 5 concludes with a fascinating study of a new development in Industrial Engineering, in "*Firm-Specific Factors and the Degree of Innovation Openness*" by Valentina Lazzarotti, Raffaella Manzini, and Luisa Pellegrini.

Section 6, **Managerial Impact**, presents focused coverage of Industrial Engineering as it relates to effective uses of offshoring, network marketing, knowledge management, e-government, knowledge dissemination, and many more utilities. This section serves as a vital resource for developers who want to utilize the latest research to bolster the capabilities and functionalities of their processes. The section begins with "*Offshoring Process*," a great look into whether or not offshoring practices could help a given business, alongside best practices and some new trends in the field. The 13 chapters in this section offer unmistakable value to managers looking to implement new strategies that work at larger bureaucratic levels. The section concludes with "*Research Profiles*" by Gretchen Jordan, Jonathon Mote, and Jerald Hage. Where Section 6 leaves off, section seven picks up with a focus on some of the more content-theoretical material of this compendium.

Section 7, **Critical Issues**, presents coverage of academic and research perspectives on Industrial Engineering tools and applications. The section begins with "*Cultural Models and Variations*" by Yongjiang Shi and Zheng Liu. Other issues covered in detail in Section 7 include design paradigns, knowledge dynamics, layout structuring, design ethos, and much more. The section concludes with "*Engineer-to-Order*" by Ephrem Eyob and Richard Addo-Tenkorang, a great transitional chapter between Sections 7 and 8 because it examines an important trend going into the future of the field. The last chapter manages to show a theoretical look into future and potential technologies, a topic covered in more detail in Section 8.

Section 8, **Emerging Trends**, highlights areas for future research within the field of Industrial Engineering, opening with "*Advanced Technologies for Transient Faults Detection and Compensation*" by Matteo Sonza Reorda, Luca Sterpone, and Massimo Violante. Section 8 contains chapters that look at what might happen in the coming years that can extend the already staggering amount of applications for Industrial Engineering. Other chapters of note include "*Embedded RFID Solutions Challenges for Product Design and Development*" and "*Green Computing as an Ecological Aid in Industry*." The final chapter of the book looks at an emerging field within Industrial Engineering, in the excellent contribution, "*Zero-Downtime Reconfiguration of Distributed Control Logic in Industrial Automation and Control*" by Thomas Strasser and Alois Zoitl.

Although the primary organization of the contents in this multi-volume work is based on its eight sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. Furthermore to ensure that the scholar, researcher, and educator have access to the entire contents of this multi volume set as well as additional coverage that could not be included in the print version of this publication, the publisher will provide unlimited multi-user electronic access to the online aggregated database of this collection for the life of the edition, free of charge when a library purchases a print copy. This aggregated database provides far more contents than what can be included in the print version, in addition to continual updates. This unlimited access, coupled with the continuous updates to the database ensures that the most current research is accessible to knowledge seekers.

As a comprehensive collection of research on the latest findings related to using technology to providing various services, *Industrial Engineering: Concepts, Methodologies, Tools and Applications*, provides researchers, administrators and all audiences with a complete understanding of the development of applications and concepts in Industrial Engineering. Given the vast number of issues concerning usage, failure, success, policies, strategies, and applications of Industrial Engineering in countries around the world, *Industrial Engineering: Concepts, Methodologies, Tools and Applications* addresses the demand for a resource that encompasses the most pertinent research in technologies being employed to globally bolster the knowledge and applications of Industrial Engineering.

Section 1
Fundamental Concepts and Theories

This section serves as a foundation for this exhaustive reference tool by addressing underlying principles essential to the understanding of Industrial Engineering. Chapters found within these pages provide an excellent framework in which to position Industrial Engineering within the field of information science and technology. Insight regarding the critical incorporation of global measures into Industrial Engineering is addressed, while crucial stumbling blocks of this field are explored. With 10 chapters comprising this foundational section, the reader can learn and chose from a compendium of expert research on the elemental theories underscoring the Industrial Engineering discipline.

Chapter 1
Defining, Teaching, and Assessing Engineering Design Skills

Nikos J. Mourtos
San Jose State University, USA

ABSTRACT

The paper discusses a systematic approach for defining, teaching, and assessing engineering design skills. Although the examples presented in the paper are from the field of aerospace engineering, the principles apply to engineering design in general. What makes the teaching of engineering design particularly challenging is that the necessary skills and attributes are both technical and non-technical and come from the cognitive as well as the affective domains. Each set of skills requires a different approach to teach and assess. Implementing a variety of approaches for a number of years at SJSU has shown that it is just as necessary to teach affective skills, as it is to teach cognitive skills. As one might expect, each set of skills presents its own challenges.

INTRODUCTION

Design is the heart of engineering practice. In fact, many engineering experts consider design as being synonymous with engineering. Yet engineering schools have come under increasing criticism after World War II because they have overemphasized analytical approaches and engineering science at the expense of hands-on, design skills (Seely, 1999; Petrosky, 2000). As the editor of Machine Design put it, *schools are being charged with not responding to industry needs for hands-on design talent, but instead are grinding out legions of research scientists* (Curry, 1991).

In response to this criticism and to increase student retention, many engineering schools, including SJSU, introduce design at the freshman level to excite students about engineering. Freshman design also helps students put into perspective the entire curriculum, by viewing each subject as

DOI: 10.4018/978-1-4666-1945-6.ch001

a necessary tool in the design process. Design is also globally dispersed in a variety of junior and senior level courses in the form of mini design projects and is finally experienced in a more realistic setting in a two-semester, senior design capstone experience.

The paper first attempts to provide a comprehensive definition of design skills. Subsequently, it presents a model for curriculum design that addresses these skills. Lastly, it presents ideas for assessing student competence in design. What makes teaching engineering design particularly challenging is that the necessary skills and attributes are technical as well as non-technical, and come from the cognitive as well as the affective domains. For example, the ability to define "real world" problems in practical (engineering) terms, to investigate and evaluate prior solutions, and to develop constraints and criteria for evaluation are technical skills, while the ability to communicate the results of a design, to work in teams, and decide on the best course of action when a decision has ethical implications are non-technical skills. Most technical skills are cognitive, however, there are several skills from the affective domain as well, such as the willingness to spend time reading, gathering information and defining the problem, and the willingness to risk and cope with ambiguity, to welcome change and manage stress. All these skills, technical and non-technical, cognitive and affective are essential for engineers, yet each requires a different approach to teach and assess.

DEFINING ENGINEERING DESIGN SKILLS

What is Engineering?

To define the skills necessary for design engineers we need to start with the definition of engineering itself. Nicolai (1988) defines engineering as *the design of a commodity for the benefit of mankind.* Obviously, the word *design* is key to the definition of engineering. Engineers design things in their attempt to solve everyday problems and improve the quality of our lives. As Theodore Von Karman put it: *A scientist discovers that which exists. An engineer creates that which never was*.

What is Design?

The next step in our search for design skills is to define design itself.

"Design is a process through which one creates and transforms ideas and concepts into a product that satisfies certain requirements and constraints."

Design requirements are usually technical and describe the performance expectations of the product, as specified by the customer or a perceived need. For example, a new passenger airplane may have mission requirements such as:

- A range of 3,000 km (i.e., the distance it will be able to fly without refueling).
- A payload of 100 passengers (i.e., the number of passengers along with their luggage it will be able to carry).
- A flight speed of 750 km/hr at a cruise altitude of 10 km.
- A takeoff field length of 1,500 m at standard sea level conditions.

The performance requirements specified by an airline (the customer), however, are not the only technical requirements that a passenger airplane must meet. To be certified, the plane must also satisfy additional airworthiness requirements. For example, FAR 25.121 part(b), refers to the ability of the plane to climb with one engine inoperative and requires that:

- In the takeoff configuration with the landing gear fully retracted but without ground effect the airplane must be able to maintain

> a steady climb gradient of at least 2.4% for two-engine airplanes, 2.7% for three-engine airplanes, and 3% for four-engine airplanes at a climb speed that is also specified and known as V2 (Flightsim Aviation Zone, 2010).

Such airworthiness requirements often prove to be more challenging than the original performance requirements specified by the customer. Additional design requirements, not specified by the customer, are not unique to aerospace engineering. For example, civil and architectural engineers must satisfy building code requirements, usually set by cities or countries.

The definition of design also mentions constraints. Constraints are sometimes difficult to distinguish from requirements. They may be viewed as limitations stated in regards to materials, cost, environmental factors, etc. For example, the Hughes H-4 Hercules aircraft, the largest flying boat ever built, was made out of wood because of wartime restrictions on the use of aluminum (Wikipedia, 2011). Another example is the noise standards for transport aircraft (Flightsim Aviation Zone, 2010).

In summary, design engineers must satisfy technical requirements, as specified by the customer and possibly additional technical requirements related to safety. Furthermore they must be concerned with the broader impact of their designs to individuals, the society, and the environment. This has become increasingly more important in our interconnected, globalized world.

Pink (2005) adds yet another challenge to engineering design, one that relates to aesthetics. He argues that because of the 'abundance' of products we have come to expect in the 21st century, the lower manufacturing cost in many countries, and the fact that many engineering tasks can now be automated, *it is no longer enough to create a product that's reasonably priced and adequately functional. It must also be beautiful, unique, and meaningful.* This requirement adds a new dimension to engineering design, a dimension that has much in common with the creative arts.

The Engineering Design Process

The next step in our search for design skills is to look at the engineering design process. Figure 1 is an attempt to illustrate this iterative process, as it takes place in our brain (Nicolai, 1998).

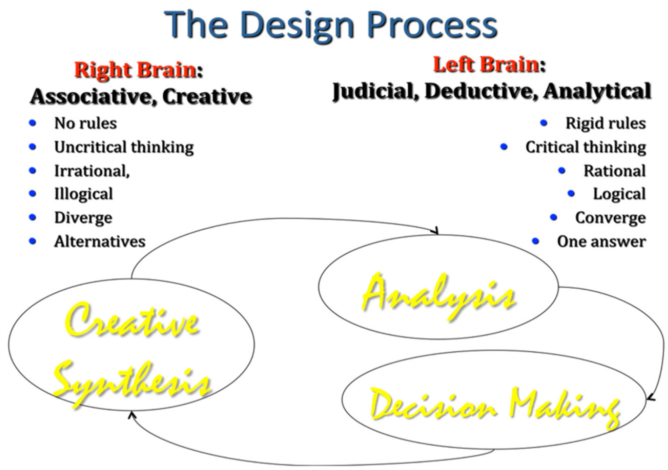
Design begins with brainstorming of ideas. This takes place in the right (creative) part of the brain. There are virtually no rules in generating these ideas. In fact, it is desirable to come up with as many ideas as possible and allow for "wild" ideas as well as conventional ones. While brainstorming, the right brain tends to be holistic, intuitive, and highly nonlinear (i.e., it jumps around). It sees things in their context as well as metaphorically, recognizes patterns, focuses on relationships between the various parts and cares about aesthetics.

Subsequently, each idea is evaluated in the left (analytical) part of the brain under very rigid rules. The left brain acts as a filter on the ideas generated, deciding which ones are viable under the current rules and which ones are not. The left brain tends to be logical, sequential, computer-like. It sees things literally and focuses on categories.

As Figure 1 illustrates, the design process involves an iterative cycling through a sequence that involves creative, imaginative exploration, objective analytical evaluation, and finally making a decision. It is this context, known also as convergent–divergent thinking (Nicolai, 1998), in which one should look for the skills and attributes necessary for a good design engineer.

But there is more to the iterative nature of engineering design than the interchange between the right and the left brain illustrated in Figure 1; iteration is also necessary because of the open-ended nature of design. It is simply not possible to follow a linear, step-by-step process to arrive at a single answer or a unique product that meets our need. First of all, design requires numerous

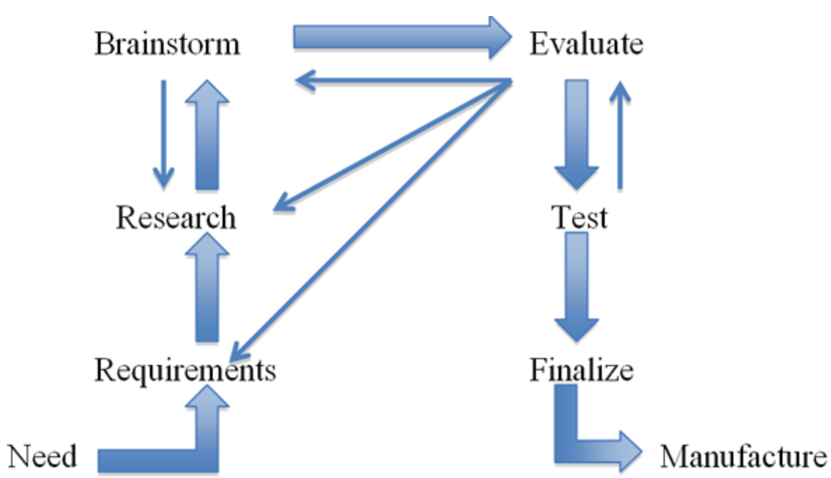
Figure 1. The engineering design process: an iteration between creative synthesis and analytical evaluation (adapted from Nicolai, 1998)



assumptions because there are always so many unknowns. Some of these assumptions may be proven wrong down the road, requiring us to go back, make changes, and repeat our calculations, hence the need for iteration. The non-unique nature of design becomes obvious when one looks at the multitude of products available in the market to address a given need.

Figure 2 illustrates the engineering design process. Engineering design begins with identifying a need. This need is articulated in terms of specific technical requirements that the product must meet. Following this design specification engineers research existing solutions to the problem before proposing any new ones. Brainstorming is the most creative part in the design process. The members of the design team who brainstorm typically bring various perspectives and expertise to the problem. The goal is to create as many ideas as possible, including unusual and wild ones. To achieve this goal, participants are not allowed to criticize any ideas put forth. Rather, to create synergy, they

Figure 2. The engineering design process: From identifying a need to production



are encouraged to build on others' ideas. After brainstorming the group selects two or three of these ideas to move forward with evaluation. Each proposed concept is analyzed systematically using appropriate engineering science in an effort to prove its feasibility and functionality. Hopefully, at least one of these concepts will prove feasible through analysis. A model is then built for actual testing. The tests will hopefully validate one of the proposed concepts, at which point the design is finalized and goes into production.

Design also requires compromise because requirements often conflict with each other. For example, to provide comfort for airplane passengers one needs a large cross-sectional area. But a large cross-sectional area results in greater drag and compromised fuel efficiency, especially at high speeds. A successful aircraft designer must decide where to draw the line between these two conflicting requirements.

Skills and Attributes of Design Engineers

Clearly, engineering design is a very complex process and as such, it requires several, very different from each other, sets of skills. These are briefly discussed in the following sub-sections.

Analytical Skills

The right-hand side of Figure 1 attests to the need for traditional engineering analytical skills: solid fundamentals in mathematics, physical science (e.g., physics, chemistry, etc.), and engineering science (e.g., fluid mechanics, thermodynamics, dynamics, etc.). The need for such skills has been articulated in the desired attributes of a global engineer (The Boeing Company & Rensselaer Polytechnic Institute, 1997), as well as in ABET EC 2000, Outcome 3a (Engineering Accreditation Commission):

"A good grasp of engineering science fundamentals, including: mechanics and dynamics, mathematics (including statistics), physical and life sciences, and information science/technology

An ability to apply knowledge of mathematics, science, and engineering"

Open-Ended Problem Solving Skills

Design skills build upon open-ended problem solving skills. Outcome 3e of ABET EC 2000 (Engineering Accreditation Commission) highlights the need for such skills when it states that engineering graduates must be able to *identify* and *formulate* engineering problems in addition to being able to solve such problems.

Students who are open-ended problem solvers exhibit the attributes listed below (Woods, 1997). Mourtos, Okamoto, and Rhee (2004) classified these attributes according to the various levels of Bloom's taxonomy of educational objectives in the cognitive and the affective domains (Bloom, 1984; Bloom, Karthwohl, & Massia, 1984):

a. Are willing to spend time reading, gathering information and defining the problem (Affective)
b. Use a process, as well as a variety of tactics and heuristics to tackle problems (Cognitive)
c. Monitor their problem-solving process and reflect upon its effectiveness (Affective and Cognitive)
d. Emphasize accuracy rather than speed (Affective and Cognitive)
e. Write down ideas and create charts / figures, while solving a problem (Affective and Cognitive)
f. Are organized and systematic (Affective)
g. Are flexible (keep options open, can view a situation from different perspectives / points of view) (Affective)
h. Draw on the pertinent subject knowledge and objectively and critically assess the quality,

accuracy, and pertinence of that knowledge / data (Cognitive)

i. Are willing to risk and cope with ambiguity, welcoming change and managing stress (Affective)

j. Use an overall approach that emphasizes fundamentals rather than trying to combine various memorized sample solutions (Cognitive)

It is interesting to note that the need for flexibility (attribute g) is also established as a desired attribute for a global engineer in a context much broader than engineering problem solving (The Boeing Company & Rensselaer Polytechnic Institute, 1997):

"Flexibility: the ability and willingness to adapt to rapid and/or major change."

The observation that some of these attributes are associated with the affective domain suggests that engineering design is not all about cognitive skills; it is also about acquiring the right attitudes. Although it is not difficult to illustrate the need for such skills in class, their assessment is more challenging and requires special rubrics. Mourtos (2010) presents an example of a set of rubrics developed to assess open-ended problem solving skills.

A View for Total Engineering

Design engineers must be generalists and acquire a basic understanding of a variety of subjects, from within as well as outside their major – in fact, even from outside of engineering – to develop a view for total engineering. This need has been expressed in three desired attributes for a global engineer (The Boeing Company & Rensselaer Polytechnic Institute, 1997):

- *A good understanding of the design and manufacturing process (i.e., understands engineering and industrial perspective)*
- *A multidisciplinary, systems perspective, along with a product focus*
- *An awareness of the boundaries of one's knowledge, along with an appreciation for other areas of knowledge and their interrelatedness with one's own expertise*

For example, an aircraft designer must have a good understanding of the basic aeronautical engineering disciplines: aerodynamics, propulsion, structures and materials, stability and control, performance, weight and balance. In addition, he/she must develop an understanding of how each part is manufactured and how its design and manufacturing affects the acquisition and operation cost of the airplane.

The example illustrates the multidisciplinary nature of engineering design. Clearly, being an expert in one of the fields involved and inadequate in one or more of the rest, will not work well for a design engineer. Furthermore, engineers must take into consideration a variety of constraints when they design a new product. Some of these constraints are technical; some are non-technical. This expectation is stated in Outcome 3c of ABET EC 2000 (Engineering Accreditation Commission):

"Engineering graduates must have an ability to design a system, component, or process to meet desired needs within realistic constraints such as economic, environmental, social, political, ethical, health and safety, manufacturability, and sustainability."

The importance of taking into consideration non-technical constraints (e.g., social, political, ethical, safety) is further reinforced in other ABET outcomes as well, where engineering graduates are expected to have:

"3f: an understanding of professional and ethical responsibility.

3h: the broad education necessary to understand the impact of engineering solutions in a global, economic, environmental, and societal context.

3j: a knowledge of contemporary issues"

- *A basic understanding of the context in which engineering is practiced, including: customer and societal needs and concerns, economics and finance, the environment and its protection, the history of technology and society*
- *High ethical standards (honesty, sense of personal and social responsibility, fairness, etc.)*

In summary, the design engineer must develop an aptitude for systems thinking and maintain sight of the big picture, which is often influenced by technical as well as non-technical factors. Clearly, it is very difficult to quantify a set of specific skills to describe the ideal design engineer. Nevertheless, in an effort to facilitate the teaching and assessment of these design skills, the BSAE Program at SJSU adapted the following set of performance criteria:

Aerospace engineering graduates must be able to:

a. Research, evaluate, and compare aerospace vehicles designed for similar missions.
b. Follow a prescribed process to develop the conceptual / preliminary design of an aerospace vehicle.
c. Develop economic, environmental, social, political, ethical, health and safety, manufacturability, and sustainability constraints and ensure that the vehicle they design meets these constraints.
d. Select an appropriate configuration for an aerospace vehicle with a specified mission.
e. Develop and compare alternative configurations for an aerospace vehicle, considering trade-offs and appropriate figures of merit.
f. Apply aerospace engineering principles (ex. aerodynamics, structures, flight mechanics, propulsion, stability and control) to design the various vehicle subsystems.
g. Develop final specifications for an aerospace vehicle.

Ability to Use Design Tools

Freehand Drawing and Visualization

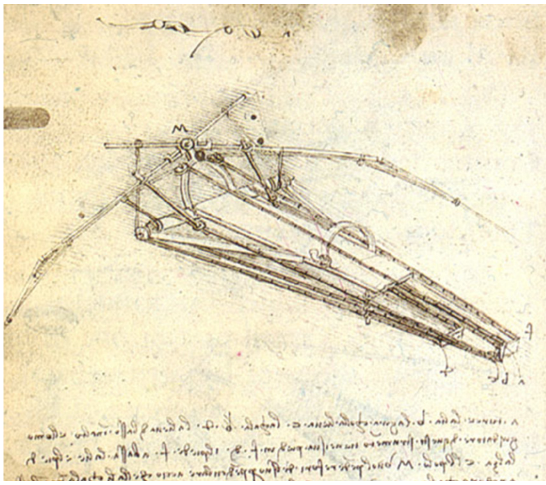
Drawing is the ability to translate a mental image into a visually recognizable form. Eventually any design drawing is rendered as a Computer–Aided Drawing (CAD) with the help of appropriate software. However, CAD is not the best medium when a creative design engineer wants to convey an idea of "how things work" to nontechnical people. Freehand pictorial drawing is most easily and universally understood. Furthermore, a freehand drawing can be a very effective and quick way to communicate ideas in three-dimensions when concepts evolve quickly, as is the case during the early stages of design (e.g., brainstorming), at which point it is not worth investing time and effort in a CAD.

Leonardo da Vinci (1452 – 1519) was one of the earliest engineers who demonstrated mastery in freehand drawing, making it possible for us today to visualize how his inventions worked and appreciate his genius (Figure 3). Freehand drawing is a right-brain activity because it is free of technical symbols and it is closely associated with our ability to visualize things in three dimensions, an indispensable design skill.

Computer–Aided Drawing and Computer–Aided Design

Unlike freehand drawing with its artistic flavor, engineering drawing is a precise discipline based

Figure 3. Design for flying by Leonardo da Vinci (the drawings of Leonardo da Vinci)



on the principles of orthographic projection. In contrast to freehand drawing, engineering drawing emphasizes accuracy, something that has been greatly enhanced by the use of modern computers and graphic capabilities. Today a CAD is much more than a computer generated engineering drawing; it involves an extensive database detailing the attributes of an object and allows it to be rotated, sectioned, and viewed from any angle. This capability is indispensable in the design of complex engineering equipment, such as an airplane, because engineers can now superposition the various subsystems and immediately see potential conflicts. CAD has led to Computer-Aided Manufacturing (CAM), where the machines that manufacture the various components receive their operating instructions directly from the database in the computer.

Kinematics

A design engineer needs skills in kinematics since the various parts of an engineering product move, rotate and may also expand / retract or fold. An understanding of kinematics (e.g., selecting the proper mechanism and visualizing its operation) allows the design engineer to evaluate what will work and what will not work. For example, in the design of an airplane landing gear, the designer must be able to visualize how the gear will fold and retract in its proper space and make sure that it will not conflict with other components in the process.

The skills described in this section fall under Outcome 3k of ABET EC 2000, which states that *engineering graduates must have an ability to use the techniques, skills, and modern engineering tools necessary for engineering practice.*

Interpersonal, Communication, and Team Skills

Interpersonal and Team Skills

Archimedes designed his screw pump (Wikipedia, 2007) alone. This was not uncommon in the ancient world. Similarly, Leonardo da Vinci designed his engineering devices, such as the one shown in Figure 3, alone. Today, working alone to design an engineering product is, for the most part, a thing of the past unless, of course, the product is a very simple one. The complexity of modern engineering products requires engineers to work in teams; in fact, sometimes several teams must work together. For example, in the design of a new transport, it is typical to have a team of engineers for each of the disciplines mentioned above (aerodynamics, controls, manufacturing, etc.). These teams work closely together to meet the same set of mission and airworthiness requirements, while at the same time making sure there are no conflicts between the various airplane sub-systems.

Hence, although earlier we expressed the need for design engineers to be generalists, so they can appreciate the multidisciplinary requirements that come into play in the design of a new product, it is not possible for an individual to have enough expertise in each and every one of the technical areas to adequately perform the detail design of all the subsystems, not to mention the analysis of the impact of a new product in a global, economic, environmental, and societal context.

Outcome 3d of ABET EC 2000 states that *engineering graduates must have an ability to function on multidisciplinary teams*. In today's multicultural world, this outcome also implies an ability to collaborate with people from different cultures, abilities, and backgrounds. This is further elaborated in the following four desired attributes for a global engineer (The Boeing Company & Rensselaer Polytechnic Institute, 1997):

- *An awareness of and strong appreciation for other cultures and their diversity, their distinctiveness, and their inherent value.*
- *A strong commitment to team work, including extensive experience with and understanding of team dynamics.*
- *An ability to think both critically and creatively, in both independent and cooperative modes.*
- *An ability to impart knowledge to others.*

The following performance criteria have been chosen to assess this outcome in the BSAE Program at SJSU:

Students working in teams are expected to:

- Be committed to the team and the project; be dependable, faithful, and reliable. Attend all meetings, arrive on time or early, and come prepared and ready to work.
- Exhibit leadership by taking initiative, making suggestions, providing focus. Be creative, bring energy and excitement to the team, and have a "can do" attitude; spark creativity in others.
- Gladly accept responsibility for work and get it done; exhibit a spirit of excellence.
- Demonstrate abilities the team needs and make the most of these abilities by giving fully to the team.
- Communicate clearly with team members when speaking and writing. Understand the direction of the team.
- Bring a positive attitude to the team, encourage others, seek consensus, and bring out the best in others.

Communication Skills

Design requires clear and effective communication not only between team members, but also between the team and third parties (management, customers, etc.). Communication usually takes two forms, oral and written and can be informal, such as between team members or formal, such as when the team presents information to third parties. All four types are crucial for the success of a project. Needless to say, good verbal communication requires not only ability to express one's ideas clearly but also the ability to listen carefully and understand ideas and concerns expressed by others. The need to communicate effectively is outlined in Outcome 3g of ABET EC 2000. In the BSAE Program at SJSU the following performance criteria were selected to express the skills embedded in this outcome:

Ability to:

a. Produce well-organized reports, following guidelines.
b. Use clear, correct language and terminology while describing experiments, projects or solutions to engineering problems.
c. Describe accurately in a few paragraphs a project / experiment performed, the procedure used, and the most important results (abstracts, summaries).
d. Use appropriate graphs and tables following published engineering standards to present results.

It is interesting to note that the desired attribute for a global engineer relating to communication skills, includes *listening* but also *graphic* skills as part of the list (The Boeing Company & Rensselaer Polytechnic Institute, 1997):

"Good communication skills, including written, verbal, graphic, and listening."

Although graphic skills were discussed earlier in the topic of freehand drawing and CAD, the term graphic here includes the ability to prepare engineering graphs that illustrate for example, parametric studies pertinent to a particular design. One thing that becomes obvious in this discussion is that the skills and attributes necessary for competent engineering design are so integrated that in some cases it is not even possible to draw clear distinctive lines between them.

CURRICULUM AND COURSE DESIGN FOR TEACHING ENGINEERING DESIGN SKILLS

Like any set of skills, design skills must be introduced early in the curriculum, practiced often, and culminate in a realistic design experience if students are to achieve the level of mastery prescribed in ABET EC 2000 and expected in industry. The following subsections describe how design skills are introduced at the freshman level, dispersed throughout the BSAE curriculum, and culminate in a senior design capstone sequence. The Project-Based Learning (PBL) pedagogical model is used in all the courses where design is taught and students work in teams for all design projects. Non-traditional ways of assessing design skills are also discussed.

First-Year Design

At SJSU engineering design is first taught in our Introduction to Engineering course (E10). E10 is a one-semester, two-hour lecture/three-hour laboratory course for freshmen, required by all engineering majors. Engineering design is taught through hands-on projects (PBL) as well as through case studies in engineering failures, which also bring up the subject of engineering ethics. For each project, students work in teams to research, brainstorm, design, build, test, and finally demonstrate a device in class (Mourtos & Furman, 2002). Typically, students participate in two or three projects during the semester. This course design followed well-established research, which shows that first-year design courses help attract and retain engineering students (Ercolano, 1996).

E10 students report significant gains in their understanding of design and ethics, design report writing and briefing skills (Mourtos & Furman, 2002). They report slightly lower gains in open-ended problem solving skills, including estimation and mathematical modeling. On the other hand, they report low gains in team skills. This was due to the fact that team skills were not taught explicitly at the time of the assessment. Despite a significant amount of time spent working in teams, students needed more guidance and coaching on skills like conflict resolution, task delegation, decision making, etc.). These skills are now taught more explicitly.

In addition to student self-reporting, authentic assessment data from course instructors show that engineering freshmen perform fairly well in their design assignments.

Design Globally Dispersed-Teaching and Assessment of Open-Ended Problem Solving Skills

In the BSAE Program design is dispersed throughout the curriculum, so students have an opportunity to practice design in a variety of subjects. Student design practice begins with open-ended problems to help them develop the related skills and attributes described earlier. For example, to help students develop:

a. A habit of doing research before attempting to solve a problem: an extensive literature review is required for all open-ended problems and design projects.

b. Competency in the use of a process, as well as specific tactics and heuristics to solve a problem: a problem-solving methodology is taught and required to use in the solution of all open-ended problems.

c. An ability to monitor their progress following a problem-solving process: students write a reflection on the effectiveness of their problem-solving process and identify their strengths and weaknesses.

d. A value system in which accuracy is more important than speed: students are given sufficient time to tackle problems, whether in class (exams) or outside of class, and their grading depends heavily on the accuracy of their calculations.

e. A habit of writing down ideas and creating sketches, charts, and figures while solving a problem: students are graded not only on their final answer but also on how well they integrate such features in their solution of problems.

f. An organized and systematic way of approaching problems: students are expected to document in their solutions every step of the problem-solving methodology they are required to follow.

g. An open mindedness and flexibility when solving problems: students are required to consider, analyze, discuss, and present multiple approaches and solutions to a problem.

h. A risk-taking attitude when solving problems: innovative approaches are encouraged; students are not penalized for presenting such solutions, even when the final outcome is not the best.

i. An ability to use an overall approach that emphasizes fundamentals rather than combining memorized solutions as well as an ability to cope with ambiguity and manage the stress: open-ended problems are practiced in all upper division courses.

Design was originally introduced through projects in several junior level aerospace engineering courses. For example, in aerodynamics (AE162), students designed an airfoil for an ultralight aircraft and a wing for a high subsonic transport, both of which had to meet very specific requirements. Similarly, in propulsion (AE167) students designed a compressor and a turbine and they subsequently matched them for placement in a jet engine with specific thrust requirements.

In an effort to address the compartmentalization of traditional engineering curricula this approach was modified in 2005. In each of the junior fall and spring semesters, students now define their own design project that involves applications from at least two courses, taken concurrently in the particular semester (Mourtos, Papadopoulos, & Agrawal, 2006). For example, one project involved the design of a ramjet inlet and required integration of compressible flow (AE164) and propulsion principles (AE167). Another, more ambitious project involved the design of a flexible wing for high maneuverability and required integration of principles from aerospace structures (AE114), aerodynamics (AE162), flight mechanics (AE165), and computational fluid dynamics (AE169).

This project-based integration of the curriculum offers students an opportunity to appreciate the integrative nature of aerospace engineering design on a smaller scale, before they delve into a much more demanding senior design experience.

Senior Design Capstone Experience

In their senior year, aerospace engineering students may specialize in aircraft (AE171A&B) or spacecraft (AE172A&B) design. Both course sequences involve the conceptual and preliminary design of an aerospace vehicle. Depending on the project, the experience may also include the detail design and manufacturing of the vehicle. Although only one of these course sequences is required, a few students choose to take both in lieu of technical electives.

Teaching and Assessment of Team Skills

As anyone who has ever worked in a team knows, team skills are not acquired automatically simply by working in a team; they need to be taught explicitly, practiced regularly, and assessed periodically, just like any other set of skills. Although team skills are now taught in E10 and assessed in every course that involves a team project or experiment, it is in the senior design course sequence that these skills are formally taught and assessed. As the course meets once a week for two and a half hours, the first 15 to 30 minutes are dedicated to building an understanding of how effective teams work. At the beginning of the year, after teams are formed, students engage in various team-building activities. Lessons from these activities are discussed in class. Subsequently, in each class meeting students present and discuss one of the 17 laws of teamwork (Maxwell, 2001). Finally, at the end of each semester students submit a team member report card, in which they evaluate the performance of their teammates as well as their own, using the performance criteria for effective teamwork defined earlier and which are shown also in Table 1. These peer reviews are taken into consideration when assigning individual course grades.

Table 1. Team member report card

Project Title:					
	Criteria	Filled out by:			
		Member 2	Member 3	Member 4	Self
1	*Quality of Technical Work:* Work is correct, clear, complete, and relevant to the problem. Equations, graphs, and notes are clear and intelligible.				
2	*Commitment to Team / Project:* Attends all meetings. Arrives on time or early. Prepared. Ready to work. Dependable, faithful, reliable.				
3	*Leadership:* Takes initiative, makes suggestions, provides focus. Creative. Brings energy and excitement to the team. Has a "can do" attitude. Sparks creativity in others.				
4	*Responsibility:* Gladly accepts work and gets it done. Spirit of excellence.				
5	Has abilities the team needs. Makes the most of these abilities. Gives fully, doesn't hold back.				
6	Communication: Communicates clearly when he/she speaks and when she/he writes. Understands the team's direction.				
7	*Personality:* Positive attitude, encourages others, seeks consensus. Brings out the best in others.				
	Average score				

Grading scale:

5 – Always, 4 – Most of the time, 3 – Sometimes, 2 – Rarely, 1 – Never

Keep in mind that if you award high scores to everyone, regardless of their contribution, team members who have worked unduly hard or provided extraordinary leadership will go unrecognized, as will those at the other end of the scale who need your corrective feedback.

Please write below and on the back of this form one (**minimum**) or more paragraphs about the work of **each member** of your team, including your own. These narratives should amplify the ratings you gave in the table, by (a) identifying the strengths and weaknesses of each individual and (b) suggesting ways in which his / her work can be more effective. Also, evaluate the team as a whole. Feel free to attach additional pages.

Assessment of Total Engineering Skills

Many student teams choose to participate in the SAE (Society for Automotive Engineering) Aero-Design or the AIAA (American Institute for Aeronautics and Astronautics) Design/Build/Fly competitions. In addition to the conceptual and preliminary design, these teams carry out the detail design of their airplane, which they proceed to build and test. Clearly, these competitions give students an opportunity to go beyond a design on paper and experience challenges related to manufacturability and cost. Often engineering professionals from the aerospace industry mentor students in their designs. Participation in design competitions offers unique learning experiences through interactions with students, faculty, and engineers from educational institutions and companies around the country (US) and the world. Both the SAE and the AIAA competitions attract student teams from universities around the world. Furthermore, it provides unique opportunities for authentic assessment of student design skills by engineering professionals. In addition to the engagement factor, which in itself enhances the students' learning experience in engineering design (Mourtos, 2003), the flight competition itself provides the ultimate test for their designs.

Assessment of Technical Communication Skills

Although students must pass a technical writing course (E100W) and have several design and lab reports evaluated in previous courses, it is again the senior design capstone experience that offers opportunities for more realistic assessment of technical communication skills. For example, students who participate in design competitions have their design reports and drawings evaluated by a team of professional engineers, from whom they receive a score sheet and written feedback. Teams also present their design orally and receive a separate evaluation of their presentation. This kind of feedback naturally adds to any comments given by the course instructor throughout the year. In fact, in many cases it carries a greater weight.

In addition to participating in design competitions, students are encouraged to submit and present papers to conferences (e.g., Johnson et al., 2009; Casas et al., 2008). Whether a student conference or a professional conference, participation provides similar benefits in terms of evaluating student written and oral communication skills.

Safety, Ethics, and Liability Issues

Safety, ethics, and liability issues are addressed in the course through aerospace case studies involving accidents. Students research background information for each case, make a class presentation, and argue about the various issues in class. A written report is also required. Students in general engage in these discussions and perform fairly well in their written assignments not only because safety, ethics, and liability provide an interesting dimension to aerospace vehicle design but also because these assignments are the only ones addressing ABET Outcome 3f in the BSAE Curriculum, and as such, they have been designated as "gateway" assignments. Hence, students must receive a score of 70% or better in these assignments to pass the course, regardless of their performance in the technical aspects of their design.

Economic, Environmental, Societal, and Global Impact

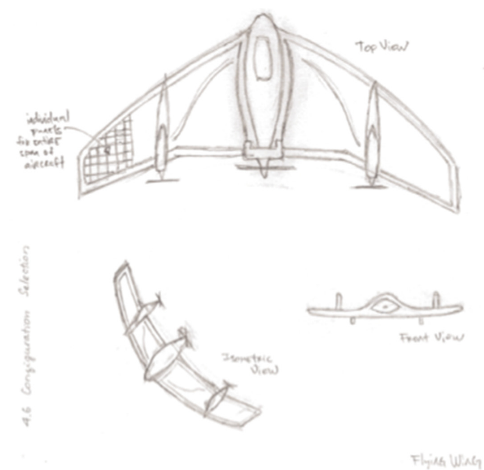
Students discuss in one of their reports the impact of their designs in an economic, environmental, societal, and global context. For example, a team that designed a solar-powered UAV performed a simple analysis on the environmental impact of their airplane by estimating the emissions from a small internal combustion engine with comparable power. They also discussed operating cost taking into consideration the replacement cost of their expensive solar panels every time their UAV crashed. On the other hand, it is not always possible to find interesting and realistic social, political and other types of constraints for all airplanes that students choose to design. Nevertheless, it is important that students develop at least a basic understanding of such issues as well as ways to properly research them before attempting to address them.

To develop such an understanding of these issues as they relate to aircraft design, students perform an additional individual assignment by selecting and researching a topic of interest to them. For example, two very interesting topics selected by students were the impact of airplanes on cultural integration and the contribution of jet aircraft contrails on global warming. Students are required to find at least five references related to their topic, at least two of which must be technical journal articles, conference papers or technical reports. For the rest of their references students may use newspaper or magazine articles and the worldwide web. Students study these references and prepare a two-page paper summarizing the key points of their research and a ten-minute presentation for our class. In their presentation students must include two key questions related to their issue, as a way to facilitate class discussion.

Graphic Communication Skills

To introduce students to freehand drawing a collaboration has been established with the SJSU School of Art and Design. A team of students from the graduate class Artists Teaching Art Seminar (Art 276) visits the aircraft design class to offer a three-hour workshop on freehand drawing, which includes contour drawing, gesture drawing, and perspective. Both groups of students have been very positive about their experience; the art students because they are given an opportunity to practice their teaching skills in a realistic setting; the aircraft design students because they get an opportunity to express themselves creatively

Figure 4. Example of a free-hand drawing in the early design stages



within the context of a very demanding engineering course. An example of a free-hand drawing illustrating a possible configuration for a small solar-powered UAV is shown in Figure 4.

Engineering students tend to be very capable with computer programs, including those used in design. For example, a student produced an artist's concept of his proposed very large, luxury airship, as a way of helping his audience visualize the level of comfort and luxury afforded in this kind of vehicle and provide a contrast with the interior one finds in most airlines today (Figure 5).

Naturally, three-view CAD drawings are expected from students in all final design reports. Students are introduced to CAD early in their curriculum with a required freshman-level course in Design & Graphics (ME20). In addition, Computer Aided Design (ME165) is a popular technical elective for many students.

REQUIRED SKILLS FOR FACULTY WHO TEACH ENGINEERING DESIGN

An additional challenge in teaching design is the competence level, as far as design skills are concerned, of the faculty who teach design courses.

Figure 5. Example of an artist's concept drawing for the interior of a very large, luxury airship

To provide a thorough analysis of this issue is beyond the scope of this article, however, it is worth mentioning two very distinct reasons, which contribute to this challenge:

a. A successful completion of a Ph.D. degree, required for a faculty position at most engineering schools, entails primarily development of analytical (left brain), research skills. On the other hand, as we have seen, design requires both analytical and creative skills.
b. To earn tenure and promotion in an academic setting engineering faculty are required to perform research, publish in refereed journals, and seek external funding. To maximize their chances for success under this kind of pressure, engineering faculty continue the same line of research they did in graduate school. After all, the venues available for publishing design work or seeking funding to do such work are limited compared with traditional areas of engineering research.

Hence, faculty members who are asked to teach a design course, often find themselves unprepared. One way to address this deficiency is to require engineering faculty to undergo some training in engineering design before teaching a design course. There are many workshops on design for faculty members as well as for engineers who work in industry, sponsored by professional societies, universities, and engineering companies. Professional societies also offer summer fellowships for engineering faculty willing to spend a summer in industry working alongside design engineers. Another way to address this issue is to hire adjunct faculty with current design experience from industry to teach design courses. This solution, however, poses its own problems.

a. While some engineering schools are strategically located in areas where adjunct faculty with design experience are available, not every engineering school is blessed with proximity to engineering companies that may provide such faculty. This issue can be addressed in creative ways. For example, to accommodate an adjunct faculty member who teaches a design course at SJSU, a blended course has been scheduled: traditional (face-to-face) and online. The instructor flies from another state every other week and spends three hours with the students. In between, the course is conducted online using appropriate software.
b. Teaching any subject including design requires not only expertise in the subject matter but also appropriate pedagogical

knowledge (Mourtos, 2007). Unfortunately, most engineering faculty do not possess such knowledge, as it is not a requirement in their job description. This is true for full-time as well as part-time faculty. Our experience at SJSU has shown that both full-time and adjunct faculty have opportunities to develop pedagogical knowledge through experience and reflection by teaching a variety of courses over time as well as through optional pedagogical training available at most universities. As a result, some – certainly not all – of the faculty do develop appropriate pedagogical content knowledge over time and become effective teachers.

CONCLUSION

An attempt has been made to provide a comprehensive list of skills, technical and non-technical, for design engineers. These skills include analytical, open-ended problem solving, a view for total engineering, interpersonal and team skills, communication skills, as well as fluency with modern tools and techniques used in engineering design. In addition to these skills, design engineers must develop certain attributes, such as curiosity to learn new things and explore new ideas, self-confidence in making design decisions, taking risks by trying new concepts, thinking out-of-the-box, and persistence to keep trying when things don't work.

The paper presented course and curriculum design from the BSAE Program at SJSU that addresses these skills and attributes and touched briefly on the challenge of engineering faculty competence in design skills and pedagogy. Some of the elements in this curriculum were introduced several years ago, have been assessed extensively and indicate that students indeed acquire an adequate level of competence in some of these skills. Some of these elements, such as the teaching of freehand drawing through the collaboration with the College of Arts and Design, were introduced only recently and have not yet been assessed. In any case, the attributes of a design engineer, as described above, are difficult to measure and will require the development of special rubrics.

Chapter 2
Why Get Your Engineering Programme Accredited?

Peter Goodhew
University of Liverpool, UK

ABSTRACT

In many countries engineering degree programmes can be submitted for accreditation by a professional body and/or graduate engineers can be certified or registered. Where this is available most academic institutions feel that they must offer accredited engineering programmes. The author suggests that these processes are at best ineffective (they do not achieve their aims) and at worst they are destructive of creativity, innovation and confidence in the academic community. The author argues that such processes (including any internal certification within the Conceive-Design-Implement-Operate, i.e., CDIO Initiative) should be abandoned completely. The author proposes alternative ways of maintaining the quality of engineering design and manufacture, which place the responsibility where it properly lies – with the manufacturer or contractor. This is a polemic piece, not a referenced review of accreditation.

INTRODUCTION

In many countries undergraduate engineering programmes can be submitted to a national body for *accreditation*. Graduates from accredited programmes are eligible, often with an additional requirement for relevant work experience, for registration as a professional engineer. In the UK this accreditation is overseen by the Engineering Council via UK-Spec. and opens the way to C.Eng, I.Eng or Eng Tech qualifications. In the USA ABET serves a similar function, while in Australia the appropriate body is Engineers Australia. In all cases the programme, its students, and sometimes its graduates, are scrutinised by a committee of professional engineers before accreditation is awarded for a fixed period such as five years. The accreditation process involves substantial paperwork and usually a one or two day visitation, so is quite costly both for the educational institution and the professional body. I argue in this article that this considerable effort does not represent good value for money and in some cases may have a negative effect on the quality of engineering education.

DOI: 10.4018/978-1-4666-1945-6.ch002

THE CASE AGAINST ACCREDITATION

Did the accreditation of professional engineering programmes prevent the disastrous crash of the Airbus 330, flight AF 447, in June 2009? Equally, is it responsible for the fact that the Eiffel tower has remained standing for 120 years? Or that my iPhone is so brilliant? No, no and no. So what is accreditation supposed to be for? At the highest level I presume that the intention is to ensure and enhance the quality and safety of engineered products throughout the world. At a more mundane (and self-interested) national level it might be intended to enable the world-wide transferability, and thus profitability, of a nation's engineering industry by ensuring the international credibility and employability of its engineers.

These seem to be laudable objectives, but delivery of them is several steps away from the accreditation of university programmes. The logic is presumably that the employers of professional engineers must have confidence, via external testimony, in their skills and their fitness to practice. This confidence is engendered by their status as professional (*chartered* in UK parlance, *registered* in other jurisdictions) engineers, part of the qualification for which is that, at some time in the past, they graduated from an *accredited* degree programme. These engineers also have to demonstrate some appropriate experience in employment and the membership of a professional body.

I find the whole system of accreditation unsatisfactory in two ways: It does not deliver the intended outcome (and so is ineffectual) and, additionally, it can damage our education system and thus our students and graduates.

First, the charge that it is ineffectual: Engineered products are conceived, designed, made and operated (CDIO-ed) by engineers employed by large or small companies. Some, but certainly not all, of these engineers may be chartered. They will usually have earned their chartered status by virtue of the work undertaken in their first few years of employment, backed up by the degree they were awarded several years ago. Since receiving their chartered status they will have been encouraged to undertake continuous professional development, but this will not have been checked. A fifty-year-old chartered engineer is thus operating on the basis of a validation process twenty years ago and a degree awarded about 25 to 30 years ago. The accreditation of this degree, so long ago, has almost no relevance for the engineering practices in use today. Indeed if the degree was typical of those awarded 25 years ago it will have contained a significant amount of engineering science and very few tests of engineering aptitude or attitude (which is of course why we have the CDIO *movement*). The fitness to practice of an individual engineer will in reality depend on what they have done, seen and learned during their working life, which is almost independent of the content of their first degree. Indeed the technical content of a degree in one engineering discipline may have almost no overlap with the content of another engineering discipline so it is hard to argue that subject content has anything to do with being, or thinking like, an engineer.

Furthermore an engineer employed today may be working in an area unrelated to their original area of study. This is very likely for bioengineers, nanoengineers, environmental engineers, nuclear engineers and others working in interdisciplinary areas. Their original degree would either have been un-accredited or the accreditation would relate to a different disciplinary area. How can this in any way validate or assure the quality of their current work?

A third issue is the effectiveness of the quality assurance provided by chartered status. I have already asserted that there are almost no checks on the continued professional development of chartered engineers, but equally there are almost no cases of the de-registration of rogue chartered engineers (and even if there were, they would certainly – like doctors – be de-registered after they had committed a grave misjudgment or offence, not before).

So the accreditation of programmes is certainly ineffectual, but it is also damaging to the education process. University departments of Engineering spend a great deal of time preparing for accreditation visits, and tuning their degree programmes to fit the perceived requirements of their professional bodies. They do this not to improve their programmes (most programme leaders do not believe that the comments of accreditors will achieve this) but because of the fear that they will no longer be able to compete in the marketplace for students if they are not accredited. This fear is probably misplaced, but no department has the courage to put it to the test. Accreditation panels almost always feel that they should make some critical (framed as *helpful*) comments but these usually reflect the prejudices of individual panel members, who are rarely experts in higher education and frequently elderly and tending to be out of date. (I have resolved never to accept another invitation to sit on an accreditation panel now I have reached 65.) The damage to the system is that the threat of accreditation makes our engineering departments more conservative, less willing to change or innovate, as well as taking time and money which would be better spent on the education of their students. It also reinforces (unhelpfully) the audit culture which has over-run our universities in the last twenty years (at least in the UK).

It would be unreasonable to criticise the existing system of accreditation without making some attempt to suggest what might replace it to provide the assurance of quality demanded by society. My suggestion is that the responsibility for the safety and quality of products (from multi-billion tunnels to five-penny toys) should remain where it legally is – with the manufacturer or major contractor. These businesses should assure themselves that their workers are appropriately skilled and work to appropriate safety and ethical standards. To achieve this they might need to strengthen their recruitment procedures to include a real assessment of candidates' current abilities and skill sets. They would also want, as many do, to ensure periodically that their employees are up to date. They might wish to buy in the necessary training expertise, perhaps even from a local university, but they will not be much helped by a past accreditation. The proof of the quality of training, and of initial education, will be demonstrated by the performance of the employee – supervised and checked by experienced colleagues – not by their possession of a yellowing piece of paper.

I notice that I have not mentioned professional bodies. What might their role be? Certainly not as accreditors, but perhaps as honest brokers between employers and trainers and educators, or as forums for discussion (but not regulation) of best practice. In which case perhaps there should be an upper age limit for service on any committee or as an officer – shall we say 50 – and those in their dotage (like me) should only speak when asked.

CONCLUSION

The arguments I have advanced here also apply to the certification of undergraduate programmes as, *CDIO-compliant*. Such a scheme would cost effort (and almost certainly money) to implement, it would cost even more to police (so this would be unlikely to happen) and would still offer no assurance of the quality of an engineering graduate. A further particular argument which applies to CDIO members is that (unlike many other engineering teaching departments) they have already shown their commitment to improving engineering education and are thus the least likely programmes to need the additional discipline offered by certification process. So I strongly suggest that we do not bother.

Chapter 3
Quality and Environmental Management Systems in the Fashion Supply Chain

Chris K. Y. Lo
The Hong Kong Polytechnic University, Hong Kong

ABSTRACT

Consumers and stakeholders have rising concerns over product quality and environmental issues, and therefore, quality and environmental management have become important topics for today's fashion products manufacturers. This chapter presents some empirical evidence of the adoption of quality management systems (QMS) and environmental management systems (EMS) and their impact on fashion and textiles related firms' supply chain efficiency. Although both management systems are commonly adopted in the manufacturing industries and becoming a passport to business, their actual impacts specifically on the fashion supply chain have not been explored. By investigating the adoption of ISO 9000 (a quality management system) and ISO 14000 (an environmental management system) in the U.S. fashion and textiles firms, we estimate their impact on manufacturers' supply chain performance. Based on 284 publicly listed fashion and textiles manufacturing firms in the U.S., we find that fashion and textiles firms operating cycle time had shortened by 15.12 days in a five-year period. In the cross-sectional analysis, the results show that early adopters of ISO 9000 and high-tech textiles related firms obtained more supply chain benefits. We only find mixed results of the impact of ISO 14000 on supply chain performance.

BACKGROUND

The quality of textiles products at each stage in the fashion supply chain is essential for the success of a fashion product. The quality level delivered to the final customer is the result of quality management practices of each link in the fashion supply chain, thus each actor is responsible for their own quality issues (Romano & Vinelli, 2001). This is because the quality of the final product that reaches the customers is clearly the results of a chain of successive, inter-linked phases: spinning, weaving, apparel and distribution, and thus quality management in supply chain are particularly

DOI: 10.4018/978-1-4666-1945-6.ch003

relevant in the fashion and textiles industries (Romano & Vinelli, 2001).

Quality management is defined as an integrated approach to achieve and sustain high quality output, focusing on the maintenance and continuous improvement of processes and defect prevention at all levels and in all functions of the organization to meet or exceed customer expectation (Flynn, Schroeder, & Sakakibara, 1994). The customer expectations on the quality of a product, however, are not just its physical attributes and workmanship. According to ISO 9000, quality is defined as customer expectations over actual performance (ISO, 2004). Consumers' expectations on fashion products, nowadays, also include its environmental attributes, for instance, use of sustainable materials and control of environmental impacts during the manufacturing processes, etc. Therefore, both quality and environmental management have become important focuses for today's fashion and textiles manufacturers. International buyers of major brands often use quality management system (QMS) and environmental management systems (EMS) as a major tool to select capable fashion and textiles suppliers (Boiral, 2003; Boiral & Sala, 1998), to ensure their products and raw materials could meet customers' expectations on quality and environmental aspects.

To respond to the call for management systems in various industries, International Organization for Standardization (ISO) has developed ISO 9000 in 1987 and ISO 14000 in 1996, which are generic QMS and EMS for worldwide applications. The number of ISO 9000 certified firms has been increasing persistently since its introduction some 20 years ago. According to recent statistics (ISO, 2009), almost one million of firms or business divisions in 175 countries have adopted ISO 9000. In the past five years, almost 800,000 firms or business units have adopted ISO 9000, representing an increase of almost 570%. For ISO 14000, it has been adopted by 188,815 firms or business divisions in 155 countries (ISO, 2009). From 2006 to 2008, almost 60,000 firms or business units have adopted ISO 14000, representing an increase of about 47% (ISO, 2009). Multinational enterprises (MNEs) with operations in more than one country are widely recognized as key agents in the diffusion of ISO certifications across national borders.

The diffusion of ISO 9000 in the fashion and textiles industries is particularly pronounced. In the early 1990s, European Committee for Standardization (Committee European pour Normalization - CEN) developed importing regulations for use by the European Union (EU) countries. CEN requires manufacturing firms that are importing products into the European market to comply with ISO 9000 standard. Import of fashion and textiles products to EU countries are under this regulation. The requirement of ISO 9000 was then followed by major MNEs, which use the ISO-based criteria to certify their own suppliers and have developed their internal quality management systems according to the ISO guidelines (Guler, Guillen, & Macpherson, 2002). Many suppliers to MNEs subsequently required their upstream suppliers or business partners to be ISO certified, leading to the widespread diffusion of the standard in global supply chain.

ISO 14000 follows the global diffusion pattern of ISO 9000, and it has become the most widely adopted EMS in the world (Corbett & Kirsch, 2001). It is a set of management processes and procedures requiring firms to identify, measure, and control their environmental impacts (Bansal & Hunter, 2003). With the aim of improving the environmental performance of a firm, compliance with the standard is audited and certified by an independent, third-party certification body (Jiang & Bansal, 2003). The initial version of ISO 14000 was a consolidation of various elements in BS 7750, a British environmental management standard, and European's Environmental Management and Audit Scheme (EMAS).

Regulations of different countries towards the adoption of ISO 14000 also affect the diffusion of this standard. European countries and some Asian countries, such as Japan (Bansal & Roth, 2000) and Singapore (Quazi, Khoo, Tan, & Wong, 2001), provide favourable legislative environment for firms to adopt EMS, while the U.S. comparatively provides less favourable legislative environment (Kollman & Prakash, 2001, 2002). The regulatory environment within a country affect the costs and perceived benefits of ISO 14000 adoption (Delmas, 2002). Jennings and Zandbergen (1995) maintained that the larger the pressure from the environment, the faster the diffusion of EMS.

Due to globalization, the environmental law and regulations are not just affecting the firms within a particular country, but also affecting firms which import and export goods to other countries. Christmann and Taylor (2001) found that if the polluting firms in developing countries export a large proportion of their output to developed countries, they would be more likely to adopt ISO 14000, despite they may be tempted by lax environmental regulations in developing countries.

Although the original objective of ISO 14000 is quite different from ISO 9000's, they shared the same management framework and both diffuse along the global supply chain. In the literature, some scholars investigated on the interactions between ISO 9000 and ISO 14000. Corbett & Kirsch (2001) found that ISO 9000 appears as an important factor explaining diffusion of ISO 14000, suggesting that the motivation, such as attracting potential customers, behind the two have significantly overlap. Pan (2003) also found that there is a strong linkage between the motivations of implementing ISO 9000 and ISO 14000 and their perceived benefits of adoption. Albuquerque, Bronnenberg, & Corbett (2007) further investigated the global diffusion patterns of ISO 9000 and ISO 14000, and they found that both certifications diffuse across countries primarily by geography. In addition, the adoption experience of ISO 9000 could also help certified firms to effectively implement ISO 14000, as the two systems are very similar in terms of implementation requirements (Poksinska, Dahlgaard, & Eklund, 2003).

LITERATURE REVIEW OF QMS AND EMS ADOPTION IN THE FASHION SUPPLY CHAIN

In fashion and textiles literature, researchers mainly focus on the usefulness of QMS and EMS in supplier selection process. Buyers use management certification (e.g., ISO 9000 and ISO 14000) as an instrument to determine whether the supplier is capable to follow industry's standards (Motwani, Youssef, Kathawala, & Futch, 1999; Teng & Jaramillo, 2005; Thaver & Wilcock, 2006). Teng and Jaramillo (2005) developed a model for evaluation of supplier in the fashion supply chain. They proposed five performance clusters to evaluate textiles supplier performance, which are delivery, flexibility, cost, reliability, and quality. They suggested using QMS certifications as the evidence for quality performance evaluation. The suppliers would receive a higher score in the evaluation model, if they are ISO 9000 certified.

There are only a few anecdote cases that discussed the impact of QMS on the fashion supply chain. Sarkar (1998) found that a textiles mill in India obtained higher customer satisfaction through increased employee involvement and product quality improvement due to ISO 9000 adoption. Romano and Vinelli (2001) conducted a case study of the Marzotto Group, one of the most important Italian textiles and apparel manufactures, about its relationships with both upstream and downstream suppliers. They found that quality management system is the "glue" that makes the supply network to operate as a "whole system". Adanur and Allen (1995) conducted the first industry survey of ISO 9000 in the U.S. textiles industry, and they found that the certified firms experienced decrease in production time and product returns. The certified firms also reported fewer raw material rejections from ISO 9000 certified suppliers. A recent study shows that the adoption of ISO 9000 can improve the adopting firms' supply chain efficiency in the general manufacturing industries in the U.S. (Lo, Yeung, & Cheng, 2009), suggesting that the adoption of QMS might help the certified firms to become a more efficient node in their supply chain.

The implementation of QMS are often under the pressure of major customers, thus small- and medium-sized textiles manufacturers have no choice but to comply with customer requirements on these certification. They might pursuit ISO 9000 without genius knowledge about QMS. Allen and Oakland (1988, 1991a, 1991b) found that small textiles firms lack correct knowledge about QMS compared to large firms, in three survey studies of 183 textiles firms. They concluded that there is a distinct lack of good quality management practices within in the British textiles industry. Fatima and Ahmed (2010) studied the ISO 9000 certified firms in Pakistan's bedwear textiles industry. They found that 60% of the firms offered poor training, 70% had poorly defined quality policy and objectives, and 70% had ineffective internal audit. Their findings show that despite the high adoption rate of ISO 9000 in the industry, there is lack of real implementation of QMS, and ISO 9000 is merely a passport into export markets. Fashion and textiles manufacturers in developing countries have self-regulation pressures to adopt QMS for gaining legitimacy from the MNEs of developed countries (Christmann & Taylor, 2001).

In the operation management (OM) literature, there are some critics on EMS's benefits in firm operations. The critics believe that environmental initiatives often transfer the cost previously bored by the society back to the firms (McGuire, Sundgren, & Schneeweis, 1988). The increased liability and environmental obligations would also lead to a negative impact on firms' operational performance and its flexibility in production (i.e. limited choices of environmental friendly dyes and fabrics, which are often more expensive). Therefore, textiles firms' operations managers would hesitate to adopt EMS in their production. On the other hand, the advocate of EMS believe that the ISO 14000 could improve environmental performance, which eventually improved firms' performance through cost-saving and revenue gain pathways (Klassen & McLaughlin, 1996).

In fact, the perceived benefits of EMS in fashion supply chain are quite direct. The dying process in textiles processing could produce huge amount of emissions that would lead to fine and high restoration cost. The impact of EMS is especially important for the wet processing of natural fibres, which are water, energy and pollution intensive (Ren, 2000). Managing the environmental impact through a systematic process would help the firms to reduce water and energy consumption, as well as to avoid serious pollution incidents. Therefore, EMS adoption is particularly relevant to fashion and textiles related firms. However, compared to ISO 9000, the number of empirical works that focused on the EMS adoption in the fashion supply chain is very limited. There are only a few survey studies discussed about the sustainability of the fashion supply chain.. For example, Fresner (1998) conducted a case study of an Austrian textiles mill and found that the adoption of ISO 9000 helped to reduce solid waste and then pursuit ISO 14000 for further improvement in productivity. Brito et al. (2008) found that the adoption of ISO 14000 in Europe fashion and textiles industries would improve customer services and cost optimization for the adopting firms, and eventually improve the overall performance of the whole supply chain. However, both studies mentioned above did not provide objective evidence of such impact. To explore how QMS and EMS affect fashion and textiles firms' supply chain efficiency, more empirical evidence is needed.

HYPOTHESIS DEVELOPMENT

Supply chain efficiency could refer to lead-time performance, delivery promptness and inventory level (Kojima, Nakashima, & Ohno, 2008). If the members of a fashion supply chain could deliver their products to their down stream customers in shorter period, the performance of the overall supply chain performance is improved. The well-known Supply Chain Operations Reference (SCOR) model suggested that firms' operating cycle time is an important indicator to measure supply chain efficiency (Stewart, 1995, 1997). To measure supply chain efficiency for a particular firm, accounting-based performance indicators, namely 1) inventory days, 2) accounts receivable days, and 3) operating cycle time can be used (Lo, et al., 2009). We discuss how ISO 9000 and ISO14000 could possibly affect the supply chain efficiency of adopting firms as follows.

ISO 9000 requires the adopting firm to ensure that product quality is constantly measured and appropriate corrective actions are taken whenever defects occur. These actions must be undertaken through a well-defined management system that monitors the potential quality problems continuously. Therefore, the defect rate of the fashion products should decrease and defects should be detected and corrected early in the production processes, and less scrap and rework need to be handled in the manufacturing processes (Naveh & Marcus, 2005). Therefore, the overall time required turning raw material into fashion and textiles products that fulfil customer order should be shortened (i.e. lower inventory days).

ISO 14000 adoption could also lead to lower inventory days, as it requires organizations to implement pollution prevention procedures to avoid environmental spills, crises, and liabilities that might incur huge effort in restoration (Bansal & Hunter, 2003; Brio, Fernandez, Junquera, & Vazquez, 2001). Therefore, ISO 14000 certified firms could face less frequent mandatory pollution restoration that could seriously disrupt their operations. ISO 14000 certified firms are also perceived as less risky than their non-certified counterparts, less frequent environmental inspections from customers and regulators are required (Potoski & Prakash, 2005), leading to further shortening of inventory days. Therefore, we hypothesize that the time required to convert raw materials into textiles products (i.e., inventory days) is shorter after ISO 9000 or ISO 14000 implementation. As the initial objectives and its impact on supply chain are different between ISO 9000 and ISO 14000, we develop two parallel hypotheses to estimate their impact on supply chain performance independently.

H1a: *The adoption of QMS leads to lower inventory days.*

H1b: *The adoption of EMS leads to lower inventory days.*

The perceived benefits of ISO 9000 are not just confined to improving product quality, but also enhancing customer services (Buttle, 1997). If ISO 9000 implementation can improve product quality and customer services, the customer orders fulfilment time should be shorter. Moreover, if there were any quality problem of the fashion products, payment would be postponed as defective fashion products are returned to rework. Customers may not pay for the products until the reworked products being delivered and met their quality requirements. As a result, the time between product delivery and customer payment (i.e. accounts receivable days) should be shorter for firms with higher product and service quality for the ISO 9000 certified firms (Lo, et al., 2009).

By taking proactive measures to prevent environmental crises, an ISO 14000 certified firm are able to prevent mistaken use of hazardous materials, and violation of environmental regulatory requirements in the customer's market, which might results in large-scale product recall. Once a product recall is needed, the accounts receivable days will be significantly affected (i.e. longer). Besides, as customers are more favourable toward environmentally friendly products and organizations, ISO 14000 adoption can establish a positive corporate image and trust from customers in the long run (Bansal & Hunter, 2003). Therefore, such firms have the potential to bargain for more favourable payment terms from customers who trusted and loyal to them (i.e., customers are willing to pay earlier). This hypothesis can be tested by measuring the accounts receivable days.

H2a: *The adoption of QMS leads to lower accounts receivable days.*
H2b: *The adoption of EMS leads to lower accounts receivable days.*

In the fashion supply chain, operating cycle time consists of manufacturing time (the time required to turn raw materials into products), delivery time (the time required to deliver products from the manufacturer to customers), and payment fulfilment time (the time required for customers to pay for their accepted products). The total time incurred in the above processes is known as operating cycle or "cash-to-cash cycle" (Eskew & Jensen, 1996). Therefore, we hypothesize that operating cycle time should be shorter after the implementation of ISO 9000 and ISO 14000.

H3a: *The adoption of QMS leads to a shorter operating cycle.*
H3b: *The adoption of EMS leads to a shorter operating cycle.*

METHODOLOGY AND DATA COLLECTION

In this research, we focus on fashion and textiles related firms in the manufacturing industry (SIC code 2000-3999). All firms under the industry that contains keywords such as "Fashion", "Textiles", "Dye", "Apparels" and "Fabrics", were included in our sample. To generate our sample, we identified ISO 9000 and ISO 14000 certified firms and their years of certification from registration data of *Quality Digest* and *Who's Registered,* which are online registration databases. Since each firm could have multiple plants/sites certified, we follow the practice of previous research (e.g., Corbett, Montes-Sancho, & Kirsch, 2005; Naveh & Marcus, 2005) by focusing on the first certification. It is because this is the only time period representing the change from a non-certified to a certified firm status. Additional certifications after the first certification only mean continuous improvements. After compiling the data from the online databases and from Standard and Poor's financial database - COMPUSTAT, we found that 284 ISO 9000 certified and 61 ISO 14000 certified publicly listed fashion or textiles manufacturing firms in the U.S.

We define the year of formal ISO certification as the certification year (year 0). To measure the abnormal change in performance over a long-term period (event window), we should start by defining the base year, when there is no prior impact from the preparation of ISO certification on the sample firms. To pass the certification audit, the average preparation time is 6-18 months prior to registration (Corbett, et al., 2005). Therefore, year -2 should be taken as the base year. As we only focus on the first certification, we can assume that there is no impact from ISO implementation on all the sample firms during the base year (year -2). ISO requires a third-party audit to verify that it has been effectively implemented, so a strong impact of ISO on performance should appear in the certification year when the firm passed the audit. The performance of certified firms should also experience the impact years after ISO certification. Therefore, we set the event period in this research at year -2 as the base year and measure the changes over the next five years (year -1, year 0, year 1, year 2, and year 3).

To estimate the abnormal changes in supply chain performance within the event window, we compare the actual performance with the expected performance of the sample firms, which is based on the changes in performance of control firms (Barber & Lyon, 1996). The selection of control firms should be based on a combination of three criteria: pre-event performance, industry, and firm size (Barber and Lyon, 1996). First, matching on pre-event performance can avoid the mean reversion problem of accounting data and control the impact of other factors on firms' performance (Barber & Lyon, 1996). Second, industry economic status could account for up to 20% of the changes in financial performance (McGahan & Porter, 1997). Moreover, environmental issues and the impact of EMS are industry-specific (Russo & Fouts, 1997), so we must control industry type in matching sample and control firms. Third, previous studies have suggested that operating performance varies by size (e.g., Fama & French, 1995). We thus match sample and control pairs based on the three matching criteria.

We generate the sample-control pairs and regard these pairs as the *performance-industry-matched* group. The first step is to match each sample firm to a portfolio of control firms based on at least a two-digit SIC code and 90%-110% of performance in year -2. In Step 2, if there are some firms have no control firm is matched in step 1, we use at least a one-digit SIC code and 90%-110% of performance to match for control firms. If no control firm is matched in the Step 2, we use only the 90%-110% of performance as the matching criterion.

In our sample, there are 248 ISO 9000 certified firms, of which 58 are ISO 14000 certified. We discard 57 firms that did not have financial information (Operating cycle) in year -2. In the remaining 191 fashion and textiles related firms, 154 firms are matched in Step 1 (80.6%). five firms are matched in Step 2. No firm is matched in Step 3. We matched 159 sample firms with at least one control firm in year -2. The financial information presented in Table 1, the number of sample and control matched pairs gradually decrease from the ending period year 1 to year 3, due to lack of financial information in either sample firms or control firms.

For another group of matching, i.e., *performance-industry-size-matched*, we further control the firm size. We use the 50%-200% range of total assets for controlling the firm size. In other words, we match the sample and control firms with at least a two-digit SIC code, 50-200% firm size (in terms of total assets), and 90%-110% prior certification performance in year -2 (Step 1). In the case where a sample firm cannot match any control firm in Step 1, we relax the industry-matching criterion to at least a one-digit SIC code, while keeping the other matching criteria unchanged (Step 2). If no control firm is matched in Step 2, we use only the 50%-200% of firm size and 90%-110% of performance as the criteria (Step 3). The reason for taking the prescribed steps to create two control groups is to try to match most of the firms without compromising on the tightness of the matches on performance (Hendricks & Singhal, 2008).

Measurements of Indicators

We measure the fashion and textiles firms' supply chain efficiency by measuring the inventory days, accounts receivable days, and operating cycle time. For the calculation of inventory days, we first divide the cost of goods sold by average inventory. We then divide the 365 days by inventory turnover ratio for the Inventory days. The unit of inventory days is in terms of day (see Formula 1). For accounts receivable days, similarly, we first calculate the accounts receivable turnover by dividing the credit sales by average accounts receivable. We then use 365 days over accounts receivable turnover to estimate the number of accounts receivable days (see Formula 2). The overall operating cycle is the summation of inventory days and accounts receivable days, and it represents the time required to turn the raw materials to cash from customers. The corresponding formulas as follows:

Letting IT be inventory turnover ratio, given by

$$IT = \frac{COGS}{Avg.Inv.},$$

Table 1. Abnormal operating cycles of sample firms for the ISO 9000 adoption in three-year period (year -2 to year 1), four-year period (year -2 to year 2), and five-year period (year -2 to year 3), based on performance-industry-matched and performance-industry-size-matched matching. $p < 0.1$; $p < 0.05$**; $p < 0.01$*** for one-tailed tests; [a] in percentage*

Where

COGS = cost of goods sold,
Avg.Inv. = average inventory balance,

We have

$$I = \frac{365}{IT}. \qquad (1)$$

Similarly, letting *ART* be the accounts receivable turnover ratio, given by

$$ART = \frac{CS}{Avg.AR},$$

Where

CS = credit sales,
Avg. AR = average accounts receivable balance,

We have

$$AR = \frac{365}{ART}. \qquad (2)$$

$$OC = I + AR \qquad (3)$$

Where

OC = operating cycle,
I = number of inventory days,
AR = number of accounts receivable days.

We estimate abnormal supply chain efficiency (i.e., inventory days, accounts receivable days, and operating cycle time) within the event window as the difference between sample post-event performance (i.e., actual performance in year 1, year 2 and year 3) and expected performance (in year 1, year 2 and year 3). We estimate expected performance as the sum of sample pre-event performance (i.e., in year -2) and change in the median performance of control firms in that period (i.e., from year -2 to year 1, year 2 and year 3). The formulas are as follows:

$AP_{(t+j)} = PS_{(t+j)} - EP_{(t+j)}$,

$EP_{(t+j)} = PS_{(t+i)} + (PC_{(t+j)} - PC_{(t+i)})$,

Where

AP – abnormal performance,
EP – expected performance,
PS – performance of sample firms,
PC – median performance of control firms,
t – year of ISO 9000 / ISO 14000 certification,
i – starting year of comparison (i = -2),
j – ending year of comparison (j = 1, 2, or 3).

We obtain the performance data from the COMPUSTAT database. Since the first ISO 9000 (ISO 14000) certification was awarded in 1990 (1996) and we need performance data at least two years before certification (year -2) and three years after certification (year 3) for analysis, we obtain performance data covering the period 1988 to 2008.

We conduct the Wilcoxon signed-rank (WSR) test to examine the median abnormal performance. We also carry out the Sign test to determine if the percentage of positive abnormal performance is significantly higher (i.e., higher than 50%). To check for consistency, we further conduct the parametric *t*-test on the mean abnormal performance to ensure that our findings are robust. Table 1 and Table 2 present the results of ISO 9000 and ISO 14000 on supply chain efficiency respectively.

RESULTS

We begin our discussion by examining abnormal supply chain efficiency on ISO 9000 certified textiles and textiles related firms. The cumula-

tive results of three-year to five-year (from year -2 to year 1, year 2 and year 3) changes provide a clearer picture on the long term impact of ISO 9000 adoption on firms' supply chain efficiency in the fashion supply chain. For the results of the *performance-industry-matched* group from the year prior to ISO 9000 implementation (year -2) to the year of post-certification (year 1), the median (mean) cumulative changes in operating cycle is -13.24 days (-18.44 days), which is significant at the 1% (1%) level. More than half of the sample firms (63%) experience a shorter operating cycle, which is significantly higher than 50% ($p < 0.01$). The median (mean) abnormal change in inventory days is -10.31 days (-14.00 days), which is significant at the 1% (1%) level, with over 62% of the sample firms shortened their inventory days. The median (mean) abnormal change in accounts receivable days is -1.05 days (-9.95 days), which is significant at the 5% (5%) level. More than half of the sample firms (51%) experiencing a shorter accounts receivable days.

For the results of *performance-industry-matched* group from year -2 to year 2, the median (mean) cumulative changes in operating cycle is -14.13 days (-11.59 days), which is significant at the 1% (1%) level. About 63% of sample firms experience a shorter operating cycle, which is significantly higher than 50% ($p < 0.01$). The median (mean) abnormal change in inventory days is -9.69 days (-11.00 days), which is significant at the 1% (1%) level, with over 63% of the sample firms shortened their inventory days. The median (mean) abnormal change in accounts receivable days is -1.56 days (-1.78 days). More than half of the sample firms (54%) experiencing a shorter accounts receivable days.

For the results of *performance-industry-matched* group from year -2 to year 3, the median (mean) cumulative changes in operating cycle is -15.12 days (-17.24 days), which is significant at the 1% (1%) level. About 67% of sample firms experience a shorter operating cycle, which is significantly higher than 50% ($p < 0.01$). The median (mean) abnormal change in inventory days is -9.47 days (-14.48 days), which is significant at the 1% (1%) level, with over 65% of the sample firms shortened their inventory days. The median (mean) abnormal change in accounts receivable days is -4.32 days (-7.56 days). More than half of the sample firms (61%) experiencing a shorter accounts receivable days.

The results of abnormal supply chain performance are similar between the *performance-industry-matched* group and the *performance-industry-size-matched* group, except for the accounts receivable days results. In both matching groups, the impacts of ISO 9000 on operating cycle and inventory days are statistically significant. Hypotheses H1a and H3a are supported. However, the abnormal impact of ISO 9000 on accounts receivable days is not statistically significant in the *performance-industry-size-matched* group. This mixed results suggest that accounts receivable days is sensitive to firm size; hypothesis H2a is only partially supported.

The overall results are robust between the three-year, four-year and five-year cumulative results, revealing that the impact of ISO 9000 on supply chain performance is long lasting in fashion and textiles industries. The length of shorten operating cycle is longer in the period from year -2 to year +3, which means the impact of ISO 9000 is long lasting. The certified textiles related firms improve their supply chain efficiency continuously in the five-year period.

Table 2 presents the results of ISO 14000 matching groups. The *performance-industry-matched* group from the year -2 to year 1, the median (mean) cumulative changes in operating cycle is -11.15 days (-13.36 days), which is significant at the 5% (5%) level. More than half of the sample firms (64%) experience a shorter operating cycle, which is significantly higher than 50% ($p < 0.05$). The median (mean) abnormal change in inventory days is -4.86 days (-6.36 days), which is significant at the 5% (5%) level, with over 64% of the sample firms shortened their inventory days.

The median (mean) abnormal change in accounts receivable days is -2.54 days (-15.45 days), which is significant at the 5% (5%) level. More than half of the sample firms (62%) experiencing a shorter accounts receivable days.

The abnormal median changes of all three supply chain performance indicators are negative in the four-year (from year -2 to year 2) and five-year periods (from year -2 to year 3). However, they are not statistically significant in nearly all the statistical tests. Such results suggest that the impact of ISO 14000 on fashion and textiles related firms' supply chain efficiency is temporary. This impact diminished after year 1. We could not found significant impact of ISO 14000 on the three indicators in the *performance-industry-size-matched* group. These mixed results suggest that hypotheses 1b, 2b and 3b are not supported. The adoption of ISO 14000 only has some short-term impact on supply chain efficiency but it is not enduring. We will discuss these findings in the discussion section.

MODERATING FACTORS OF ISO 9000 ADOPTION IN THE FASHION SUPPLY CHAIN

We try to provide a deeper understanding on the association between ISO 9000 adoption and the improvement in operating cycle. We only focus on ISO 9000 because we reveal no significant change on operating cycle from ISO 14000 adoption in the previous section. We construct a regression model to study how firm-level characteristics affect the impact of ISO 9000 on abnormal operating cycle over the five-year event period (from year -2 to year 3). We use firm size, and original financial performance of the ISO 9000 certified firms as the control factors. The abnormal performance in operating cycle of ISO 9000 certified firms could be more positive for larger firms. Larger firms normally have more resources for hiring external consultants, providing additional training, and dedicating additional manpower to facilitate the implementation process of ISO 9000. We use firms' total assets to represent the firm size.

We also control the financial performance of the firm because firms that are more profitable are more efficient in operations. As ISO 9000 adoption calls for improvement in a firm's operational efficiency, firms that are more efficient may be able to implement the system more effectively than less efficient firms. Firms that are more profitable could also have more resources for ISO 9000 implementation. We estimate the financial performance of a firm as the firm's ROA in year 3.

We include three independent variables into the regression model, which are labour intensity, R&D intensity, and time of ISO 9000 adoption. The arguments and predictions of the three indicators are as follows:

Independent variables:

1. *Labour intensity:* The abnormal changes in operating cycle could be more positive (shortened length of operating cycle) in more labour intensive firms. It is because these firms might have higher need in standardizing their operation procedure to ensure the production processes is smooth. The calculation of labour intensity is the number of employee over firm's total assets.
2. *R&D intensity*: Industries with higher R&D intensity would normally mean that they face more rapid technological and product changes. There are thus more opportunities for new product development for high-technology textiles firms. This allows them to implement efficient process designs to a greater extent. Therefore, the positive impact of ISO 9000 on abnormal operating cycle could be higher in firms with higher levels of R&D intensity. We measure R&D intensity as R&D expenses over sales.
3. *Time of ISO 9000 adoption*: According to the institutional theory, early adoptions of organizational innovations are motivated by

technical and economic needs (DiMaggio & Powell, 1983), while later adopters respond to the growing social legitimacy of the innovations as taken-for-granted organizational structure improvements (Westphal, Gulati, & Shortell, 1997). ISO 9000 is a well-recognized example of institutionalized management practice (Guler, et al., 2002). Therefore, we predict that early adopter of ISO 9000 could have larger improvement in operating cycle than the later ones, as the formers are motivated by technical benefits of ISO 9000.

Table 3 presents the cross-sectional regression results. We use the abnormal performance in operating cycle of the *performance-industry-matched* group for analysis. For this model, the *F*-value is 2.89, which is significant at the 1% level. The adjusted R^2 values is 8.0%, which is comparable to those observed in previous studies that attempted to use cross-sectional regression models to explain abnormal performance (e.g., Hendricks & Singhal, 2008).

We find that firm size and firm labour intensity do not moderate the association between ISO 9000 adoption and abnormal operating cycle. Fashion and textiles firms' ROA is negatively related ($p < 0.01$) to abnormal operating cycle. It means textiles firms that are more profitable can further shortened their operating cycle time from ISO 9000 adoption. The coefficient of R&D intensity is negatively and statistically significant at the 1% level ($p < 0.01$). It means that high technology fashion and textiles firms could benefit more from the reduction of operating cycle time after ISO 9000 adoption. The coefficient of time of adoption is positive and statistically significant at the 5% level. Late adopters of ISO 9000 obtain less abnormal benefit from ISO 9000 adoption (i.e. they have longer abnormal operating cycle compared to early adopters). It shows that the institutionalization of ISO 9000 in general manufacturing industries also appear in the fashion supply chain.

DISCUSSION AND SUMMARY

This study provides empirical evidence on the impact of QMS and EMS adoption on firms' supply chain performance in the fashion supply chain. Based on the 248 ISO 9000 and 61 14000 certified publicly-listed fashion or textiles related

firms in the U.S., we find that ISO 9000 adoption has a statistically significant positive impact on operating cycle, inventory days and accounts receivable days. Depending on the methods used to estimate abnormal performance, the median abnormal improvement in operating cycle ranges from 7.18 days to 15.12 days shorter than non-certified firms over a five-year period. In other words, the certified firms save up to 15.12 days to turn raw materials into cash payment from their customers. This suggests that the certified fashions or textiles firms become a more efficient node in the fashion supply chain.

The median improvement in inventory days ranges from 5.46 days to 7.18 days over a five-year period. The results show that the improvement in inventory days is the major reason of the overall improvement in operating cycle. QMS certified firms in the fashion supply chain are more efficient in their production process and inventory management, resulting a shorter inventory days compared to non-certified competitors.

The median improvement in accounts receivable days of *performance-industry-matched* group is 4.32 days. The magnitudes of abnormal changes in accounts receivable days are generally smaller than the changes in inventory days. There are also mixed results of abnormal changes in accounts receivable days between the two matching groups, which mean the impact of ISO 9000 is less significant on this indicator. The possible reason is that accounts receivable days is sensitive to firm size, therefore, the impact of ISO 9000 on it was taken away after firm size had been controlled.

In the cross-sectional analysis, we find that high-tech firms could achieve better supply chain performance than low-tech firms in the fashion supply chain. These high-tech firms in the fashion supply chain are the firms with advanced manufacturing techniques and technology. The results show that the adoption of ISO 9000 could help these firms to further improve their utilization of technological resources and thus improve their supply chain operations. The late adopters of ISO 9000 in the fashion supply chain obtain much less supply chain benefits than the early adopters do. The coefficient is about 2.9, which means the abnormal operating cycle is 2.9 days longer for every one-year delay in adoption. This result supports the institutional explanation of ISO 9000 adoption in the operation management literature, suggesting that the late adopters are not driven by the technical efficiency of a management practice. Another possible explanation is that there are less inefficient non-certified firms in the industry in the later years, therefore the comparative improvement in supply chain efficiency become much less significant.

Why EMS has Just Limited Impact on Firms' Supply Chain Efficiency?

We also investigated that the abnormal changes in operating cycle, inventory days, and accounts receivable days in ISO 14000 certified firms in the fashion supply chain. However, such change is not long lasting (only in year -2 to year 1 period) and only appears in the *performance-industry-matched* group. One possible reason is that some ISO 14000 certified firms sample have already ISO 9000 certified prior the adoption of ISO 14000. Therefore, the incremental benefits from ISO 14000 are smaller than their first ISO 9000 certification. It is also possible that there are only limited number of ISO 14000 firms in our sample to reveal any statistical significance of ISO 14000 impact. In addition, a previous study showed that ISO 9000 is partly driven by bilateral trade relationships in the supply chain, while ISO 14000 is by culture (Albuquerque, et al., 2007), it could be the reason why ISO 9000 could show more benefits in supply chain efficiency comparatively. Although both certifications are being used as supplier selection tools, only ISO 9000 shows strong and significant impact on firms' supply chain performance. The results suggested that the adoption of QMS is likely to be the primary "glue" that makes the nodes in the fashion supply chain works more closely with each other and thus the whole supply chain could become more efficient.

Managerial Implications to Fashion and Textiles Manufacturers

Fashion and textiles firms, which have not obtained ISO 9000, should consider such adoption. It is obvious that ISO 9000 adoption is necessary for improving firms' supply chain efficiency. Our cross-sectional analysis results further suggest that labour intensity is not a moderating factor of ISO 9000 impact on supply chain efficiency. It means that it works not only labour intensive textiles firms (which are very common in textiles industry), but also highly automated textiles firms. For textiles firms with higher R&D intensity, which often have faster new product development and shorter product life cycles, could benefit more from being certified by ISO 9000. In other words, firms that have already adopted ISO 9000 can further improve their supply chain efficiency, by implementing a corporate strategy with higher R&D investment for new products. The late adopters of ISO 9000 should also pay attention to the motivation in obtaining this certification. If the motivation is largely institutional (i.e. by responding to customer requirement), instead of improving firms' operational efficiency, such firms received much less supply chain benefits.

Although we could not reveal a consistent and long-term impact from the ISO 14000 adoption on supply chain performance in this study, we could not rule out the possibility that there are other potential benefits for being certified by ISO 14000. Given the large amount of pollutant emissions and high level of energy and water consumptions during textiles manufacturing processes, the benefits of ISO 14000 might be more on firms' cost efficiency. Therefore, the results should not be interpreted as the lack of usefulness of ISO 14000. Besides, the impact of ISO 14000 on firms' supply chain efficiency on other manufacturing industries might be exists. The mixed results of ISO 14000 in this study should not be implied that ISO 14000 has no impact to general manufacturing industries.

LIMITATIONS AND FUTURE RESEARCH

This study is the first exploratory empirical work focuses on the QMS and EMS adoption in the fashion supply chain and its impact of supply chain performance. There are some limitations should be addressed in future research. First, this study has only included the fashion and textiles related firms in manufacturing industries. However, fashion retailers are also key players in the fashion supply chain. They might have dominating negotiation power over their suppliers in the supply chain. The power between the buyer-supplier relationships may have strong moderating effects on the abnormal performance. Second, we only included all the publicly listed textiles related firms in the fashion supply chain of the U.S. However, most fashion supply chains involve significant number of suppliers from developing countries (e.g., China and India). The impact of ISO 9000 on the textiles firms from developing countries might not be the same as the firms in the U.S. The textiles firms in developing countries might adopt the standard not because of its technical efficiency, but for the legitimacy from its customers in developed countries. Therefore, a replication of the current study under developing countries context could provide the complete picture of the impact of QMS and EMS in the fashion supply chain. Finally, this study only explored the impact of QMS and EMS on supply chain performance. Further studies should be made with the focus on firms' profitability and cost efficiency, to provide additional evidence of the usefulness of these certifications in the fashion supply chain.

KEY TERMS AND DEFINITIONS

Accounts Receivable Days: It is an average number of days a firms needed to receive payments from their customers.

Accounts Receivable Turnover: It is the ratio of the number of times that accounts receivable is collected in one year.

Inventory Days: It is the average number of days goods remain in inventory before being sold to customers.

Inventory Turnover: It is the ratio showing how many times a firm's inventory is sold and replaced in one year.

ISO 14000: An environmental management system developed by ISO in 1996, and its latest version is ISO 14000:2004

ISO 9000: A quality management system developed by ISO in 1987, and its latest version is ISO 9000:2008.

Operating Cycle: It is the time required from turning raw materials into products to customers pay for their accepted products, it is also called cash-to-cash cycle.

Chapter 4

People-Focused Knowledge Sharing Initiatives in Medium-High and High Technology Companies:

Organizational Facilitating Conditions and Impact on Innovation and Business Competitiveness

Nekane Aramburu
University of Deusto, Spain

Josune Sáenz
University of Deusto, Spain

ABSTRACT

The aim of this chapter is to analyse the organizational conditions that foster the development of different people-focused knowledge sharing initiatives in medium-high and high technology companies, as well as the degree of influence of those initiatives on the ideation stage of innovation processes. Finally, considering that successful innovation is the one that helps to improve business competitiveness, the degree of influence of this innovation capability dimension on company performance is examined. For these relationships to be tested, an empirical study has been carried out among medium-high and high technology Spanish manufacturing firms with more than 50 employees and which carry out R&D activities. To this end, a questionnaire has been designed and submitted to the CEOs of the companies making up the target population of the research. Structural equation modelling (SEM) based on partial least squares (PLS) has then been applied in order to test the main hypotheses of the research.

DOI: 10.4018/978-1-4666-1945-6.ch004

INTRODUCTION

Since the last decade, the study of knowledge has been one of the most important topics in the management arena (Nonaka, 1991; Nonaka & Takeuchi, 1995; Davenport & Prusak, 1998). Indeed, we are supposed to live in a "knowledge economy", where intangible assets – and knowledge in particular – are the key sources for value creation (Brooking, 1996; Edvinsson & Malone, 1997; Stewart, 1997).

This idea is clearly reinforced by the existing relationship between knowledge creation and innovation (Nonaka, 1991; Nonaka & Takeuchi, 1995). In today's economy, innovation is one of the main driving forces behind business competitiveness (Drucker, 1988; Shapiro & Varian, 1998; Sveiby, 1997). Along these lines, it is generally assumed that innovation depends on the accumulation and development of relevant knowledge of a wide variety (Fischer, 2001).

For new knowledge to be created, knowledge sharing between individuals is the key (Nonaka, 1991; Nonaka & Takeuchi, 1995; Nonaka, von Krogh & Voelpel, 2006). As a consequence, the study of different mechanisms and initiatives which could facilitate knowledge sharing represents an extremely relevant research topic. Many of these mechanisms take advantage of information and communication technologies (i.e. they are "IT-based" – Dalkir, 2005; Davenport, 2007) whereas, in other cases, personal interaction between individuals is the key (i.e. "people-focused" knowledge management; Wiig, 2004). A review of early literature on knowledge management gives clear proof of the prevalence of information technology (IT) focused research in this domain (Swan, Robertson & Nevell, 2001).

Taking this into consideration, the focus of this chapter will be on people-focused knowledge sharing (i.e. the type of knowledge sharing which involves personal or "face-to-face" interaction). In particular, the organizational conditions that foster the development of different people-focused knowledge sharing initiatives (e.g. communities of practice, coaching, mentoring, employee functional rotation and other initiatives for knowledge sharing with external stakeholders) will be analysed, as well as the degree of influence of those initiatives on the ideation stage of innovation processes. Finally, considering that successful innovation is the one that helps to improve business competitiveness, the degree of influence of this innovation capability dimension on company performance will be examined. In other words, it is assumed that business competitiveness is related to superior performance (Cantwell, 2005).

Given their special focus on innovation, their extremely high knowledge intensity, and the degree of complexity of the knowledge being dealt with, medium-high and high technology companies will be under scrutiny in this research. As a result, these companies will be provided with a basic framework in order to shape their knowledge management strategies and in order to enhance their capability for generating new ideas and developing successful innovation.

THEORETICAL FOUNDATIONS

The Concept and Nature of Knowledge

A single definition of "knowledge" does not exist, but it is quite common to approach this concept by starting out from the hierarchical distinction between *data*, *information* and *knowledge* highlighted by Davenport and Prusak in 1998. According to these authors, *data* is a set of discrete, objective facts about events; *information* is a message, usually in the form of a document or audible or visible communication; and *knowledge* is a fluid mix of framed experiences, values, contextual information and expert insight that provides a framework for evaluating and incorporating new experiences and information.

Usually, a distinction is made between *tacit* and *explicit* knowledge. The concept of *tacit knowledge* was first coined by the philosopher Michael Polanyi in 1966, but it is thanks to the seminal works by Nonaka in 1991 and Nonaka and Takeuchi in 1995 that it has become extremely popular in management literature as well. However, the meaning attributed by Nonaka to this concept differs from the one attributed by Polany (Allee, 2003). For the latter, the tacit dimension of knowledge refers to innate intelligence, perception and capacities for reasoning, whereas for Nonaka, *tacit knowledge* is the type of knowledge which is personal, context-specific and, therefore, hard to formalize and communicate. Conversely, *explicit or codified knowledge* refers to knowledge that is transmittable in formal, systematic language (Nonaka & Takeuchi, 1995). Hence, according to this perception, tacit knowledge tends to reside within the head of knowers, whereas explicit knowledge is usually contained within tangible or concrete media (Dalkir, 2005).

In Nonaka's view, tacit and explicit knowledge are not totally separate, but mutually complementary entities: human knowledge is created and expanded through social interaction between tacit and explicit knowledge. This interaction is called "knowledge conversion" and there are four types of it: from tacit to tacit (socialization); from tacit to explicit (externalization); from explicit to explicit (combination); and from explicit to tacit (internalization). Therefore, the possibility exists of transforming one type of knowledge (tacit or explicit) into the other. However, if the concept of tacit knowledge were the one advocated by Polanyi, such a possibility would not exist. As Allee (2003) points out, for Polanyi, tacit knowledge could never be made explicit. For him, when knowledge is shared, there is an articulated or explicit communication and an unspoken tacit communication going on at the same time.

In any case, Nonaka's point of view is the most widespread one in the knowledge management literature today. According to him, the tacit/explicit interaction is continuous and dynamic and is shaped by shifts between the different modes of knowledge conversion, which gives rise to a "knowledge creation spiral". As previously mentioned, *socialization* involves the conversion of tacit knowledge into a tacit one. This only can be achieved by a process of experience sharing. As a result of this, a set of shared mental models and technical skills will be obtained. In *externalization*, tacit knowledge is articulated into explicit concepts, using metaphors, analogies, hypotheses or models. This is triggered by dialogue or collective reflection. On the other hand, *combination* involves systemizing concepts into a knowledge system, which implies using different bodies of explicit knowledge. Documents, meetings, conversations or computerized communication networks could be used to this end. Finally, *internalization* is closely related to the idea of "learning by doing", and it means embodying explicit knowledge into (a) tacit one. "For explicit knowledge to become tacit, it helps if the knowledge is verbalized or diagrammed into documents, manuals or oral stories" (Nonaka & Takeuchi, 1995, p. 69).

As can be seen, in all the previously-mentioned processes knowledge sharing is involved, which means this is a critical aspect in enlarging organizational knowledge. In other words, the knowledge that the organization possesses cannot be amplified if the knowledge possessed by individuals is not shared. This shows us the social nature of knowledge. For this reason, different authors have been interested in the study of knowledge sharing mechanisms in organizations (Nahapiet & Ghoshal, 1998; Nonaka, Toyama & Byosière, 2003). In the next section, we are going to take a closer look at this issue.

Knowledge Sharing

As previously mentioned, in order to make knowledge sharing happen within and among organizations, several *ad hoc* mechanisms and initiatives have been proposed. Some of them are IT-based (email; on-line discussion forums and/or blogs; intranets; extranets; groupware tools; and on-line knowledge repositories), whereas in other cases, personal interaction between individuals is the key (communities of practice, coaching, mentoring, and employee functional rotation, to name but a few).

Early literature on knowledge management shows a clear prevalence of the information technology perspective. In a survey reported by Swan, Robertson & Newell in 2001, it was proven that the dominant discourse in this domain was not related to the role of people in organizations, but to technologies that facilitate the acquisition, codification and exploitation of knowledge. However, although IT-based practices could help in the exchange and assimilation of explicit knowledge (i.e. internalization and combination processes), they leave aside "social construction" (Berger & Luckmann, 1966) and the organizational learning processes underlying socialization. As Allee points out (2003), "in all types of knowledge work, even where technology is very helpful, people require conversation, experimentation and experiences shared with other people who do what they do" (p. 113).

In this chapter, the focus will be on this second perspective: that is, on social interaction-based (i.e. people-focused) knowledge sharing. In particular, the following knowledge sharing initiatives will be considered: communities of practice, coaching and mentoring, employee functional rotation and meeting events and/or workshops in order to promote reflection as well as knowledge and experience sharing with external agents.

Among the previously-mentioned mechanisms, communities of practice are of special relevance (Dalkir, 2005; Saint-Onge & Wallace, 2003). They refer to a group or network of individuals who share a concern, a set of problems or a passion about a topic, and who deepen their knowledge and expertise in this area by interacting with each other on an ongoing basis (Wenger, McDermott & Snyder, 2002). Along these lines, "the critical component of a community lies in the sharing of common work problems between members, a membership that sees the clear benefits of sharing knowledge among themselves" (Dalkir, 2005, p.123).Therefore, communities of practice are a vehicle for increasing knowledge creation as well as for expanding the extent and accelerating the speed at which knowledge is exchanged across the organization (Saint-Onge & Wallace, 2003, p.12).

On the other hand, coaching, mentoring and employee functional rotation facilitate learning and socialization processes across the organization as well. In particular, they are used to allow the transmission of knowledge that is grounded on experience (i.e. tacit knowledge). According to action learning theory (Revans, 1983), individuals learn through experience within a social context. This type of experience-grounded learning is quite difficult to transmit to others because of its tacit nature. For this reason, a social context is needed to allow this transmission. As work-based learning theory maintains (Raelin, 2000), individuals learn in their work environment, which constitutes the immediate social context in which they gain experience. In this context, individuals not only gain experience, but also share it with others. Hence, socialization processes (i.e. tacit knowledge sharing) take place.

Finally, the mobilization of external knowledge held by outside stakeholders is also an essential aspect for knowledge creation to occur (Nonaka & Takeuchi, 1995; Almeida, Anupama & Grant, 2003). In other words, the exchange of knowledge with external agents is a key element for creating new knowledge. As Maznevski & Athanassiou (2007) point out, "the scope and breadth of knowledge available from outside sources is generally much greater than that available from inside sources" (p. 69). Therefore, meeting events and/or workshops in order to promote reflection as well as knowledge and experience sharing with external agents constitute other relevant social interaction-based mechanisms to enable knowledge sharing and subsequent knowledge creation to take place.

On the other hand, for knowledge sharing to occur, specific spaces should be created within the organization, where knowledge exchange among people would be facilitated. These particular spaces are what Nonaka *et alter* called "ba" (Nonaka, Reinmoeller & Senoo, 1998). According to these authors, the ba is the physical and/or virtual space where knowledge exchange and generation take place. As stated by Nonaka, Toyama & Hirata (2008), it is "an existential place where participants share contexts and create new meanings through interactions"(p.34).

More precisely, the *physical ba* refers to those organizational conditions which can promote or, on the contrary, hinder the exchange of knowledge. In particular, organizational design and technological infrastructure are included within this category (Nonaka & Takeuchi, 1995). On the other hand, *the virtual ba* (i.e. the mental space for knowledge sharing) is linked to organizational culture or the set of shared values assumed by the members of the organization. Sharing a specific set of values generates a collective mental space which facilitates mutual understanding among people and, hence, mutual interaction and knowledge sharing.

In this research, the influence of different organizational conditions (i.e. ba components) on people-based knowledge sharing is analysed.

Knowledge Sharing and its Relationship with Knowledge Creation and Innovation

Since the seminal works by Nonaka in 1991, and Nonaka & Takeuchi in 1995, the concept of innovation has been closely related to that of "knowledge creation". Along these lines, it is generally assumed that the process of innovation consists of an ongoing pursuit of harnessing new and unique knowledge (Subramaniam & Youndt, 2005).

According to Nonaka, von Krogh and Voelpel (2006), knowledge creation involves a continuous process through which one overcomes the individual boundaries and constraints imposed by information and past learning by acquiring a new context, a new view of the world and new knowledge. By interacting and sharing tacit and explicit knowledge with others, the individual enhances the capacity to define a situation or problem, and apply his or her knowledge so as to act and specifically solve the problem. In the case of organizational knowledge creation, this means making available and amplifying the knowledge created by individuals as well as crystallizing and connecting it with the organization's knowledge system (Nonaka & Takeuchi, 1995; Nonaka, von Krogh & Voelpel, 2006). Therefore, knowledge sharing and diffusion are both essential in order to create new knowledge and produce innovation (Dalkir, 2005).

On the other hand, innovation is a dynamic capability (i.e. a capability which allows the company to create, extend or modify its resource base – Helfat *et alter*, 2007) with multiple dimensions. The first one is that of ideation (Davila, Epstein & Shelton, 2006), which involves new idea generation and selection. Selected new ideas should then be put into practice (Van de Ven & Angle, 2000). This brings us to the execution phase. In this phase, managing innovation projects effectively should be combined with the ability to fit them into budgeted costs and deadlines (i.e. timeliness and cost efficiency). Finally, all the aforementioned dimensions should lead to value creation.

Considering that the generation and selection of new ideas is the first step in order to achieve successful innovation and that this is something not specifically addressed by previous research (which in many cases assesses innovation capability in terms of the outcomes it produces, instead of measuring the capability itself), in this chapter the focus will be on the ideation phase of innovation processes and on value creation. In particular, the impact of people-focused knowledge sharing initiatives on the generation of new ideas will be examined, as well as the impact of the latter on firm performance.

DEVELOPING A RESEARCH MODEL FOR ANALYSING THE INFLUENCE OF ORGANIZATIONAL CONDITIONS ON PEOPLE-FOCUSED KNOWLEDGE SHARING AND THE IMPACT OF THE LATTER ON THE GENERATION OF NEW IDEAS AND ON COMPANY PERFORMANCE

In this section, a research model will be proposed in order to analyse the degree of influence of different organizational dimensions (i.e. organizational design, organizational culture and information and communication technology infrastructure) on the degree of success of different people-focused knowledge sharing initiatives and their impact on the generation of new ideas and company performance.

This model will allow us to answer the following questions:

- Are all organizational dimensions considered equally important in order to support people-focused knowledge sharing initiatives?
- What is the degree of influence of those initiatives when it comes to enhancing the generation of new ideas and, therefore, the innovation capability of firms?
- What is the degree of relevance of this dimension (i.e. ideation) in successful innovation (i.e. in the improvement of business competitiveness)?

The answers to these questions will provide companies with important clues so as to shape their knowledge management and innovation strategies.

As regards the different knowledge sharing catalysts considered, the first one is organizational design. This refers to the type of organizational structure in place within the company, to the communication channels (both vertical and horizontal) that link different organizational units and teams, and to the physical design of the workplace.

As regards organizational structure, Nonaka and Takeuchi (1995), and Nonaka, Toyama and Byosière (2003) advocate the fact that certain types of structure facilitate knowledge sharing and knowledge creation processes more than others (i.e. they are more "learning supportive"). In particular, they defend the hypertext type of organization as the most suitable one in order to foster knowledge sharing and creation.

Likewise, communication channels could play a substantial role in fostering knowledge sharing and subsequent knowledge creation. As Kalla (2005) points out, knowledge sharing is a function of integrated internal communications. Hence, it is assumed that vertical and horizontal communication channels act as catalysts for knowledge sharing.

Finally, physical design of the workplace is the last element making up organizational design that could promote or, on the contrary, hinder the knowledge sharing processes. According to Nonaka, Schamer and Toyama (2001), "the single most important factor shaping the quality of knowledge is the quality of place" (p. 233).

In accordance with the prominent role that, from a theoretical point of view, organizational design could play in knowledge sharing, the following hypothesis has been formulated:

H1: Organizational design acts as a catalyst for knowledge sharing that takes place through different people-focused initiatives.

Organizational culture is the second organizational dimension considered that, according to literature, could have a significant influence on knowledge sharing. As Dalkir (2005) points out, "corporate culture is a key component in ensuring that critical knowledge and information flow within an organization" (p. 185). In particular, the creation of an organizational culture based on trust and commitment on the part of individuals is essential (Argyris, 1990; Argyris & Schön, 1978, 1996; Allee, 2003; Friedman, Lipshitz & Overmeer, 2003; Wiig, 2004). All this gives rise to the second research hypothesis:

H2: Organizational culture is a catalyst for knowledge sharing that takes place through different people-focused initiatives.

Finally, information and communication technologies can also contribute to a great extent to knowledge sharing (Davenport, 2007). According to Allee (2003), "there must be a technology infrastructure in place that really supports the right kind of conversations and connections" (p.89). In particular, the existence of specific technological tools that foster the capturing and storing of knowledge, as well as the connection between individuals and groups(,) may be very helpful (Dalkir, 2005). Therefore, the following hypothesis has been formulated:

H3: Information and communication technologies facilitate knowledge sharing that takes place through different people-focused initiatives.

Additionally, and considering the theoretical foundations explained in previous sections, the following hypotheses have been formulated:

H4: People-focused knowledge sharing initiatives have a positive impact on the generation of new ideas.

H5: Managing the generation of new ideas effectively improves business competitiveness.

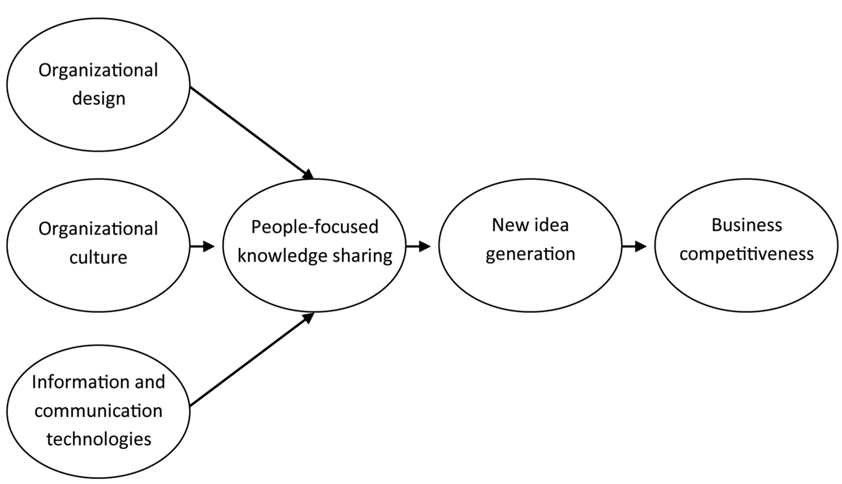
Figure 1 summarizes the model proposed.

TESTING THE RESEARCH MODEL

Research Method

The research model previously outlined has been tested in a sample of Spanish firms. In particular, the population subject to study was made up of medium-high and high technology Spanish manufacturing firms with over 50 employees and which carry out R&D activities. The companies making up the target population were identified thanks to the use of the SABI data base ("Sistema de Análisis de Balances Ibéricos" / System of Iberian Balance Sheet Analysis), which contains the registered annual accounts of over 190,000

Figure 1. Research model



Spanish companies, selecting only those firms which had included their expenses on R&D in their balance sheet.

In order to gather information about the relevant variables of the research, a questionnaire was designed and submitted to the CEOs of the companies making up the target population by the end of the year 2006 and the beginning of the year 2007. 75 answers out 446 were obtained, which means an average response rate of 17%.

The sample size obtained is large enough to carry out a statistical study based on structural equation modelling (partial least squares approach) by means of PLS-Graph software (Chin & Frye, 2003). According to the complexity level of the model to be tested, the minimum sample size required was calculated, and this was made up of 40 firms.

Structural equation modelling (SEM) constitutes a second generation of multivariate analysis which combines multiple regression concerns (by examining dependency relationships) and factor analysis (by representing unobserved variables by means of multiple observed measures), in order to estimate a set of dependency relationships which are all simultaneously interrelated.

When applying SEM, two approaches can be used: the covariance-based approach and the partial least squares (PLS) approach. In the first case, the aim is to minimize the difference between the sample covariances and those predicted by the model. This approach is mainly used for confirmatory analysis. In the second case, however, the aim is to obtain determinate values of the latent variables for predictive purposes. This approach is very useful for exploratory research, as is the case in this chapter (Wold, 1985).

A PLS model is analysed and interpreted in two stages: firstly, the assessment of the reliability and validity of the measurement model and secondly, the assessment of the structural model. This sequence ensures that the constructs' measures are valid and reliable before attempting to draw conclusions regarding relationships among constructs (Barclay *et al.*, 1995).

In the next section, the measurement model is presented in more detail.

Constructs and Measures

The exogenous constructs of the research are those related to the different organizational enablers considered. The first one within this category is *Organizational design*. This construct is made up of four formative indicators which give rise to the existence of an organizational design which favours organizational learning and knowledge sharing. The first indicator refers to the type of organizational structure in place. For the purposes of this research, organizational structures have been classified into three different categories: level 1 learning supportive (i.e. the least learning supportive) organizational structures (that is, functional, divisional or matrix-type structures with no process- or project-based axis); level 2 learning supportive organizational structures (that is, process-based structures or matrix-type structures with a process-based axis); and level 3 learning supportive (i.e. the most learning supportive) organizational structures (that is, project-based structures or matrix-type structures with a project-based axis). The second and third indicators refer to the extent to which vertical and horizontal communication channels allow the flow of ideas, initiatives and points of view in an agile and fluid way, whereas the last one measures the extent to which the physical design of the work environment favours communication and dialogue among all the members of the company. These last three indicators have been measured by means of 1 to 7 Likert scales.

Organizational culture is the second exogenous construct of the research. As has been explained in the theoretical framework, this is linked to the degree of presence within the company of different values and attitudes which are related to a culture of knowledge sharing. The degree of presence of the aforementioned values and attitudes (trust, transparency, open mentality, mistakes considered as learning opportunities, and cooperation and mutual help) has been measured by means of 1 to 7 Likert scales. All the indicators considered are reflective in nature, as they show the type of organizational culture in place within the company.

Finally, *Information and communication technologies* encompass three reflective indicators that show the extent to which the company is equipped with ICT systems which facilitate knowledge sharing and permanent connection with different agents. In particular, these indicators refer to the extent to which ICT systems in place facilitate the storage of organizational knowledge and its easy access by the members of the company; to the extent to which they allow permanent connection among all members of the organization; and to the extent to which they facilitate continued action and joint work with external agents. All of these indicators have been measured by means of 1 to 7 Likert scales.

On the other hand, *People-focused knowledge sharing* is the first endogenous construct of the research. In this case, the degree of use of different mechanisms in order to promote social interaction among individuals has been measured (Wiig, 2004): communities of practice and/or meetings by field of interest; coaching and/or mentoring; employee functional rotation; and meeting events and/or workshops in order to promote reflection as well as knowledge and experience sharing with external agents. All of these indicators have been measured by means of 1 to 7 Likert scales and are formative in nature: that is, the use of the different initiatives mentioned gives rise to the existence of knowledge sharing (i.e. the latent variable being studied).

New idea generation is then the second endogenous construct of the research. In this case, the following items have been checked, all of them referring to the last 5 years: whether the company has been able to identify numerous opportunities for incremental/radical improvement; whether the firm has been able to identify many alternative and new uses for already existing technologies; whether the new idea generation process has been managed in a conscious and effective way; and whether the company has been able to clearly distinguish which of the new opportunities identified had a greater potential for development. Once more, these indicators have been measured by means of 1 to 7 Likert scales and, in this case, they are reflective in nature: that is, they reflect the effectiveness of the new idea generation process.

To bring the presentation of the measurement model to a close, only the *Business competitiveness* construct remains to be explained. With a 5 year scope and using again 1 to 7 Likert scales, the following reflective measures have been chosen: whether incremental/radical innovation projects carried out have shown expected results; whether innovation outcomes have had a very positive impact on the company's income statement; whether innovation outcomes have had a very positive impact on the company's competitive position; and whether innovation outcomes have allowed the company to grow and improve its market share.

MEASUREMENT MODEL EVALUATION

Following the sequence previously described in the method section, an analysis of the results obtained should begin with the evaluation of the measurement model. This assessment differs depending on the nature of the construct under scrutiny. In the case of constructs made up of reflective indicators (i.e. when the measures observed are the consequence of the latent variable and, therefore, should be highly correlated), individual item reliability, construct reliability, convergent validity, and discriminant validity should be checked. However, in the case of constructs made up of formative indicators (i.e. when the measures observed give rise to the existence of the latent variable), multicolinearity problems should be explored.

As regards the reflective constructs of the model (the ones related to organizational culture, information and communication technologies, new idea generation and business competitiveness) all the tests carried out have shown satisfactory results. Indicator loadings (individual item reliability) are greater than 0.7, with a single exception: the one referring to the extent to which the firm has been able to identify many alternative and new uses for already existing technologies, whose loading is 0.6791. Given that the aforementioned value is not too far from the right limit, the decision has been made to keep the indicator in the model.

On the other hand, composite reliability (which measures construct reliability) is higher than 0.8 in all cases; average variance extracted (which measures convergent validity) is greater than 0.5 in all constructs; and discriminant validity is excellent too. As regards formative constructs (i.e. the rest of the constructs of the model), multicolinearity problems have not been identified.

Once the quality of the measurement model has been guaranteed by means of the previously-mentioned tests, the quality of the structural model should then be assessed. This refers to the strength of the research hypotheses and to the amount of variance explained (R^2) in the case of endogenous constructs, as well as to an analysis of the predictive power achieved.

STRUCTURAL MODEL EVALUATION

In order to assess the research hypotheses, path coefficient levels should be examined, as well as their degree of significance, by means of bootstrapping techniques. Tables 1, 2 and 3 summarize the results obtained. In these tables, we can also see the contribution of each exogenous construct to the amount of variance explained (which has been obtained by multiplying correlation and path coefficients), as well as the predictive power achieved. The latter has been confirmed by means of a Stone Geiser test, where cross-validated redundancy (Q^2) must be higher than 0 in order to consider that the model has predictive power for that specific construct.

According to the figures contained in Table 1, we can conclude that the three organizational factors considered (organizational design, orga-

Table 1. Structural model evaluation – Impact of organizational conditions on people-focused knowledge sharing

	Organiza-tional design	Organiza-tional culture	ICT systems	Total amount of variance explained	Predictive power Q^2
Path	0.241*	0.334***	0.248**		
Correlation	0.521	0.544	0.450		
R^2	**12.56%**	**18.17%**	**11.16%**	**41.89%**	**0.0853**

Notes***p<0.001, **p<0.01, *p<0.05 (based on t_{499}, one-tailed test).

Table 2. Structural model evaluation – Impact of people-focused knowledge sharing on the generation of new ideas

Path coefficient	Total amount of variance explained R^2	Predictive power Q^2
0.637***	40.56%	0.1396

Notes***p<0.001 (based on t_{499}, one-tailed test).

Table 3. Structural model evaluation – Impact of the effectiveness of the new idea generation process on business competitiveness

Path coefficient	Total amount of variance explained R^2	Predictive power Q^2
0.630***	39.69%	0.1384

Notes***$p<0.001$ (based on t_{499}, one-tailed test).

nizational culture and information and communication technologies) contribute to a great extent to the knowledge sharing which takes place through different people-focused initiatives in medium-high and high technology firms (amount of variance explained: 42%). Indeed, all path coefficients are statistically significant and, hence, hypotheses 1, 2 and 3 are clearly supported.

As regards the degree of relevance of each explanatory factor in order to enhance this type of knowledge sharing, the most relevant one is organizational culture (contribution to the amount of variance explained: 18%), followed by organizational design (13%) and by information and communication technologies (11%).

On the other hand, people-focused knowledge sharing proves to be extremely important in order to enhance the generation of new ideas in medium-high and high technology firms. As can be seen in Table 2, this type of knowledge sharing is able to explain 41% of the variance in the case of the new idea generation construct and, accordingly, the path coefficient linking both constructs (people-focused knowledge sharing and ideation) is extremely significant. Therefore, hypothesis 4 is clearly supported.

Finally, Table 3 shows that good performance at the ideation stage accounts for 40% of total innovation performance (i.e. business competitiveness improvement). Once more, the path coefficient linking both constructs (ideation and business competitiveness) is statistically significant and, hence, hypothesis 5 is clearly supported.

As a conclusion, people-focused knowledge sharing is of high relevance even in a type of company where technology (and, therefore, IT-based knowledge sharing) is supposed to be at the forefront. This reinforces the relevance of the social dimension of knowledge and the need to facilitate conversation, experimentation and experience sharing among people.

Once the strength of the research hypotheses and the predictive power of the model have been examined, for those explanatory constructs made up of formative indicators (i.e. organizational design and people-focused knowledge sharing), it would be interesting to see the degree of relevance of each specific element making up the construct. For this to be done, indicator weights should be examined. Technically speaking, an analysis of the aforementioned weights should be carried out within the measurement model evaluation section. However, from an intuitive point of view, it seems more logical to know the degree of relevance of the construct as a whole first and, once this has been established, to study the degree of relevance of the specific elements making up the construct in depth. In the case of reflective variables, this analysis does not make any sense, as all the indicators of the construct should be highly correlated and, therefore, their degree of influence should be very similar.

Table 4 shows us the degree of relevance of each specific item making up organizational design, whereas Table 5 does the same thing for people-focused knowledge sharing initiatives.

As can be seen in Table 4, and as far as organizational design is concerned, physical design of the workplace is clearly the most influential item within this construct when it comes to supporting people-focused knowledge sharing. The agility and fluidity of vertical and horizontal com-

Table 4. Organizational design – Ranking of indicators according to their weight

Elements	Weights
Physical design of the workplace	0.5974
Vertical communication channels	0.4610
Horizontal communication channels	0.2922
Organizational structure	0.0081

Table 5. People-focused knowledge sharing – Ranking of indicators according to their weight

Elements	Weights
Communities of practice	0.5786
Employee functional rotation	0.4280
External networking	0.2182
Coaching and/or mentoring	0.1740

munication channels is quite important too, specially in the case of the vertical ones. On the contrary, the type of organizational structure in place is a completely unimportant issue. This is a surprising and unexpected result. In fact, according to theory and previous empirical studies carried out in other geographical settings, organizational structure constitutes a very relevant organizational dimension in order to enhance knowledge sharing. At least this is the case for the Japanese companies studied by Nonaka and Takeuchi in 1995.

As regards people-focused knowledge sharing, communities of practice appear to be the most relevant mechanism in order to enhance the generation of new ideas within medium-high and high technology firms, followed quite closely by employee functional rotation. On the other hand, coaching and/or mentoring as well as the development of different initiatives in order to facilitate knowledge and experience sharing with other stakeholders occupy a more secondary position.

CONCLUSION AND PRACTICAL IMPLICATIONS

The research carried out shows that organizational conditions (i.e. organizational design, organizational culture and information and communication technologies) are extremely important catalysts when it comes to enhancing people-focused knowledge sharing in medium-high and high technology firms. Moreover, this type of knowledge sharing proves to be essential in order to facilitate the generation of new ideas, which is an extremely important dimension of the innovation capability of firms in order to guarantee success in this domain (i.e. in order to improve business competitiveness).

This is a very interesting conclusion of the research. Considering that the companies analysed are technology(-)intensive, it could be thought *a priori* that IT-based knowledge sharing would be the prevalent one or at least that it could "eclipse" social interaction-based knowledge sharing. Nevertheless, the research shows that people-based knowledge sharing is really important in these companies and that this is an essential ingredient for fostering the generation of new ideas.

From a practical point of view, the results obtained provide companies with a useful insight in order to prioritize their knowledge management efforts. In the case of the firms under study (medium-high and high technology firms), developing and nurturing communities of practice as well as supporting employee functional rotation seem to be the best initiatives in order to facilitate the generation of new ideas and the development of innovation. Therefore, communities of practice constitute a very important mechanism when it comes to fostering creativity and to increasing the innovation capability of firms. For this reason, communities of practice should be considered seriously as a key instrument in the implementation process of innovation strategies in medium-high and high technology firms.

On the other hand, and as regards the organizational conditions considered in the research, taking care of the physical design of the workplace and of the agility and fluidity of vertical and horizontal communication channels constitute the two main aspects to be managed within organizational design, together with organizational culture and information and communication technologies.

FUTURE RESEARCH PATHS

The research carried out has shed some light on the influence of different organizational enablers on social interaction-based knowledge sharing in medium-high and high technology companies, and on the influence of the latter on the ideation stage of innovation processes. Moreover, it has shown the relevance of this innovation capability dimension in the final success of innovation processes. Nevertheless, different aspects remain still uncovered, paving the way for future research.

For instance, another organizational factor that could significantly influence knowledge sharing is the assessment and reward system implemented in the organization. In order to foster knowledge sharing it is crucial that this system supports an organizational culture based on trust and commitment on the part of individuals (Allee, 2003). If the reward system is exclusively geared towards individual achievement, it could be difficult to find any incentive to share knowledge with others, as this could slow down personal performance. In the same way, leadership style (participative vs. authoritarian) could also support or, on the contrary, hinder knowledge sharing. Finally, the existence of an explicit knowledge management strategy and the implementation of specific control/assessment tools in this domain could help to a great extent to improve the degree of success of the knowledge sharing initiatives implemented by the company. Therefore, the research model should be enlarged in order to encompass these elements too.

On the other hand, it would be interesting to analyse the influence of this type of knowledge sharing mechanisms in other dimensions of the innovation capability of firms, such as innovation project management.

Additionally, the research carried out could be complemented with the inclusion of different contingent variables, such as company size or industry type. Only manufacturing firms have been studied so far, leaving aside service companies. It would be interesting to see whether service firms ask for different knowledge sharing catalysts compared to manufacturing companies, and whether the knowledge sharing mechanisms employed have a different impact on the innovation capability of firms. The research could be extended to encompass low-tech companies too.

Finally, it should be verified whether the results obtained can be generalized in other geographical settings, or whether substantial differences exist according to geographical location.

KEY TERMS AND DEFINITIONS

Ba: It refers to the physical and/or mental space where knowledge generation and exchange take place.

Communities of Practice (Cop's): "Groups of people who share a concern, a set of problems, or a passion about a topic, and who deepen their understanding and knowledge of this area by interacting on an ongoing basis" (Wenger *et alter*, 2002, p. 4).

ICT-Based Knowledge Sharing: It refers to the processes of knowledge exchange which take place through the use of information and communication technologies (ICT).

Knowledge Sharing: It refers to knowledge exchange processes which take place both among people from the same organization and from different ones.

Knowledge Sharing Enablers: It refers to the set of organizational conditions (organizational design, culture, technological infrastructure and management systems in place) which facilitate the exchange of knowledge (i.e. knowledge sharing).

Knowledge Management: It refers to the management of knowledge acquisition, creation, transmission, storage and retrieval processes.

People-Based Knowledge Sharing: It refers to knowledge exchange processes which take place by means of social/direct interaction among people.

Chapter 5
Integrating 'Designerly' Ways with Engineering Science:
A Catalyst for Change within Product Design and Development

Ian de Vere
Swinburne University of Technology, Australia

Gavin Melles
Swinburne University of Technology, Australia

ABSTRACT

The fields of design and engineering both contribute to product design and development. Increasingly design teams require an integrated approach in environments where mutual understanding and respect replace traditional professional rivalries. These new synergies both enhance communication and understanding between designers and engineers and lead engineering into new areas of professional activity. Engineers are integral to the product development process, but change in product development and manufacturing requires new responsibilities; design engineers must assume a greater role to achieve successful product realisation. However, to be effective engineers must develop new skills; creative design ability, understanding of societal and environmental impacts and a human-centred approach. These themes, not typically addressed by engineering curricula are evident in a new approach to engineering education - product design engineering. This chapter addresses issues confronting product design and development and examines the emergence of this new engineering professional in response.

DOI: 10.4018/978-1-4666-1945-6.ch005

INTRODUCTION

Product design and development (PDD) responsibilities have changed. There is greater focus on sustainable design, socially responsible design and design for need. Opportunities exist for design teams to make a positive commitment to the welfare of global communities whilst advancing technologies that support sustainable development. It is no longer appropriate for designers and engineers to serve solely the interests of business; instead PDD teams must understand the potential for design to make a greater contribution to lives and society.

As the roles and responsibilities of product design and development teams are reformed, so too are their professional composition. The single discipline purity of the traditional industrial design consultancy has evolved into an interdisciplinary team, where designers and design engineers collaborate harmoniously to provide an extended palette of services. Product design teams require an integrated and collaborative approach in environments of understanding and mutual appreciation. The product design and development process is enhanced by these new synergies between engineers and designers, as is the progression of the engineering designer into new areas of professional activity.

Whilst design engineers have always been an integral part of the product development process, their roles have traditionally been confined to working within constraints and defined parameters to achieve closure to the product realisation stage. However, emerging trends in manufacturing and revised professional responsibilities require design engineers to have a greater role in product design and development, particularly in the conceptual design and embodiment stages. Yet to be effective, they require an extensive palette of new skills; creative design ability, a thorough understanding of the societal and environmental impacts of their professional activities and a human-centred and responsible approach. These attributes are not characteristic outcomes of traditional engineering curricula, but are evident in product design engineering courses.

This new engineering discipline results from the integration of two traditionally disparate professions; mechanical engineering and industrial design. It responds to the need for interdisciplinary professionals and a greater participation in design teams by engineers conversant, indeed accomplished, in the product design and development process. These new engineering pedagogies support the changing role of the engineering designer and are catalysts for significant change in product design and development through greater team synergy, interdisciplinary understanding and communication. "Times of great flux call for those who can cross disciplines, who can see and understand the big picture." (Akay, 2003)

BACKGROUND

It has been observed that the boundaries between the design and engineering can inhibit both innovation and successful product realisation, particularly in the product design and development milieu. "These two mindsets often clash as one seeks to broaden the scope of the problem, while the other is working to achieve closure." (Fry, 2006)

In Engineering Design Methods: Strategies for Product Design, Nigel Cross notes that "the increasing competition for consumer markets and the growing awareness of the importance of design for the market has led to reinforcement of the view that successful design can only be accomplished by an integration of the skills of both engineering and industrial designers." (Cross, 2000)

This trend is evident both in the traditional industrial design consultancy and in the manufacturing sector where there is increased demand for engineers who can operate effectively in a variety of environments within global multidisciplinary teams. Engineers, particularly those in product design and development, are now expected to creative, flexible and adaptable, responsible and human-centred designers. "In this evolving world, a new kind of engineer is needed, one who can think broadly across disciplines and consider the human dimensions that are at the heart of every design challenge." (Grasso & Martinelli, 2007)

Conflict between disciplines has been common in product design and development, where differing professional approaches can destabilise the progression of design ideals. A long-standing cultural conflict exists between designers and engineers, one that can be traced to the foundation of their approach to problem solving and design. Fry (2006) defines industrial designers as "looking for new contexts and opportunities for innovation" whilst engineers "predominately work to define a set of parameters and target values up front that would define a specific, successful solution within a narrow range."

It is important to acknowledge that the approach of engineers to design activity results from the attitudinal emphasis of their education. Many engineering curricula offer limited exposure to the design process and often graduates are inexperienced in open-ended problem solving and fearful of the uncertainty of the design process. Engineers trained only in the 'science' and 'methods' of engineering are often hesitant to engage in intuitive or creative processes that may lead to an unexpected outcome.

This absence of cohesion between engineers and designers can lead to misunderstanding, a lack of appreciation, and subsequently, professional distrust and discord within the PDD team. Professional disparity between engineers and designers can result in inefficiencies in the PDD process and can be detrimental to successful product realisation. To facilitate developments in product design and development, the disparities between the professions must be addressed through engineering educational programs that seek to emphasise design, encourage creativity and innovation, resulting in improved cross-disciplinary communication, understanding and mutual appreciation.

We need "a new generation of adaptable, flexible, well rounded and innovative professionals" (Stouffer, Russell, & Oliva, 2004). However innovation and creativity does not readily emerge from typical engineering process. To be creative one needs to seek the unexpected through a process of divergent thinking. Unfortunately engineering design and industrial design follow differing methods; "convergence is at the core of the engineering process...divergence is at the core of the industrial design process" (Fry, 2006) It is therefore apparent that to develop creative engineers, their educational experience must not only include rational applications of science, but also experience in open-ended problem solving and familiarity with what Cross describes as 'designerly ways'. (Cross, 2001)

'Designerly ways' suggests a way of thinking that is common in designers, but which differs significantly from those with a techno-scientific approach, such as engineers. Cross observed that scientists problem-solve by analysis, whereas designers problem-solve by synthesis. This constructive and often intuitive approach uses non-verbal thought and communication, translates abstract requirements into concrete objects and contributes to the solution-focussed approach designers take to solving ill-defined problems. Engineering education can learn much from design pedagogy if engineers are to develop creative problem solving skills early through education, rather than later in the workplace.

The engineering profession must progress from the role of technical service provider, to a profession that leads change through understanding of the human, environmental, societal and cultural challenges and the consequences of professional activity.

ISSUES CONFRONTING PRODUCT DESIGN AND DEVELOPMENT

Design is a fundamental building block of innovation and a critical enabler of competitive advantage. Product design is essential in addressing the challenges that modern societies face in the 21st Century; whether it be enabling the delivery of technological, scientific and medical advances, mobilising public opinion, empowering communities, or simply improving the experience of a product. (Design Victoria, 2008)

However there are many challenges facing the product design and development industry as we move into the 21st century. These range from the decline of local manufacturing and the impact of a global economic downturn, to new opportunities afforded by emerging markets, the integration of new disciplines and the redefinition of existing professional responsibilities. Sustainable practice and socially responsible design will continue redefine the landscape and the PDD industry must take responsibility for its activities and show leadership as drivers of change and innovation.

The fortunes and growth potential of the product design industry are too closely allied to the manufacturing sector, an area of recent considerable upheaval and changing alliances. The transfer to offshore manufacturing has had unprecedented impact in the design sectors of many countries, as have the competitive forces of a global economy and the reduction in Government protection of local industries. Many product design environments have witnessed a rationalisation of product lines, a reduction of local content and a shift in outsourcing towards ‘design and supply’ contracts.

In response product designers must take responsibility for their destiny through business diversification, entrepreneurship and the creation of new opportunities through flexible and adaptable approaches. PDD must reduce its reliance on the manufacturing sector (as a sole source of revenue); in turn this will lead to greater diversification of services into new sectors, including interdisciplinary activities which are solution, rather than market focussed.

Socially responsible design initiatives and sustainable solutions are imperative and offer PDD teams a diversity of new opportunities. This will need to be complimented by design-led initiatives as PDD teams redefine and create new avenues of activity, and respond to societal needs on a global basis.

“A new economy is evolving and it needs products and services that have been designed to eliminate environmental impacts.” Kel Dummet, Sustainability Victoria (Design Victoria, 2008)

As the manufacturing industries adjust to a changing economic and social environment, new markets are emerging with diversified consumer behaviour and expectation. It is therefore essential that PDD teams develop interdisciplinary attributes that successfully integrate design, engineering, management and marketing in a flexible milieu of understanding and respect, with a high level of creativity and consideration for environmental, societal, cultural and economic demands.

Typically, poor product design decisions can adversely affect manufacturing costs, assembly schematics, quality control, product to market lead-times and overall product success. This can be addressed through consideration of manufacturing issues earlier in the PDD process, in particular design for assembly, with user-centred design addressing not only the end user, but also production, transportation, and where appropriate, installation personnel. This early integration of manufacturing consideration into the design process can be facilitated by the inclusion of design-skilled engineers into PDD, bringing production concern to the forefront of product embodiment decisions.

Product design is at a turning point, one which will redefine the industry and allow significant societal contribution to be made through new directions of activity. The key issues facing the PDD industry; sustainability, social responsibility, design for need, global distribution of design and manufacturing processes, new and emerging markets and shifting economic power will be the focus of the next generation of product designers, who must be sufficiently informed and skilled to lead the inevitable reform of industry practice.

In Australia, the Design Victoria report "Five Years On: Victoria's Design Sector 2003-2008", (through a survey of 340 design service providers and 1253 businesses) identifies design as making an essential contribution of economic growth, yet also identifies that graduates lack appropriate skills including business acumen and production and manufacturing knowledge. (Design Victoria, 2008) This trend is apparent in both the design and engineering sectors. Typically design curricula have become generic and holistic whilst engineering curricula continues to focus on the science rather than preparing graduates for engineering practice. Clearly the challenges faced by industry must be met firstly by the educational community through revised, industry relevant and progressive curricula: industry reform should be led by the next generation of designers and engineers.

So how do we define the roles and responsibilities of future PDD teams and what will be the challenges they face and the contributions they make? Firstly we must anticipate the impact of trends in product design and development, respond to the emergence of new technologies and constraints, and most importantly we must involve engineering education in the conversation. We cannot hope to foresee all of the challenges that our graduates will face throughout their careers; however we can prepare them for significant change through educational programs that deliver flexible, adaptable and responsible engineers who are lifelong learners and creative problem solvers.

Tertiary education should be the foundation of improved and redefined professional outcomes for product design. New paradigms such as product design engineering (discussed later in this chapter) are catalysts for significant change and directly respond to industry needs and societal demands. The integration of disparate disciplines (industrial design and mechanical engineering) facilitates greater professional synergies, and thus, efficiencies in the product design and development process. It is essential that all PDD team participants, particularly the engineers, are fully engaged and cognisant in all aspects of the product's 'function-aesthetic-experience' and demonstrate an eagerness for innovation. The challenges of future product design and development will be greatly facilitated through teams which include these 'integralists' (Eekels, 1987) who can articulate the overall product vision in an collaborative environment devoid of traditional professional rivalry.

The product design engineering discipline emerges from industry-informed curricula which develop well prepared, highly skilled and adaptable practitioners vital to the security and future competitiveness of the PDD industry.

DEFINING THE ROLE OF ENGINEERING IN PRODUCT DESIGN

What is the role of this new discipline, the product design engineer, in the PDD process? Before we address this, it is important to define the roles of engineers and industrial designers and examine disparate claims regarding who 'owns' the process.

Ulrich and Eppinger in their definitive text "Product Design and Development" (Ulrich & Eppinger, 2004), devote a chapter to Industrial Design (ID) where they define the role of ID in the PDD process. In addition, they endeavour to quantify the effectiveness and utilisation of industrial designers and the timing of their involvement in the development process. They state that "typically, ID is incorporated into the product development process during the later phases for a technology-driven product and throughout the entire product development process for a user driven product." They also declare that the ID process is a "subprocess of the product development process" and that "the technical nature of the problems that confront engineers in their design activities typically demands more development effort than do the issues considered by ID".

The reader may discern two things from the position taken by Ulrich and Eppinger. Firstly, that the product design process is not directed from a design perspective and secondly, that ID is a non-technical and potentially optional phase of PDD which is not integral to product development. With their statements, they are reinforcing a position not uncommon in production engineering circles, but one which devalues not only the contribution that industrial designers make to product design and development, but also the potential for designers to contribute significantly to product forecasting and planning.

With due respect to Ulrich and Eppinger, whose writings on PDD are exemplary and extremely valuable to students and practitioners seeking to develop a thorough and 'validate-able' PDD process, the industrial design profession may wish to present an alternate stance.

The early involvement of designers greatly informs the product design and development process and can actually drive technology development through earlier consideration of user needs and more appropriate and targeted product specification. Indeed it is essential that the early stages of all projects (regardless of whether it is for user or technology led products), involve those personnel with a human-centred focus and a divergent thinking approach.

It has been our professional experience that all too frequently Industrial Design input is integrated far too late in the project, often at a convergent stage of development, where the product's technical specification has been established. This limits the scope and potential of the product and forces the industrial designers to adapt and package often unsuitable or inappropriate technology and components that have been developed for poorly defined user needs. The impact of the designer's understanding of market, expertise in socially responsible design (SRD), sustainable design, ergonomics, user needs, product interaction, aesthetics and product differentiation combined with their intrinsic quest for creative solutions and innovation cannot be underestimated in product scoping and planning.

Accordingly, design practitioners must be central to the product planning process, not introduced retrospectively when parameters are pre-defined and existing constraints restrict innovation. This can be addressed in two ways, with the establishment of a collaborative team comprising both industrial designers and engineers early in the product planning stages, or with the inclusion of a new type of engineering professional; the product design engineer.

These new engineering professionals though the integration of 'designerly ways' into the practice of engineering are well placed to drive a user-centred and creative design philosophy in the planning stages of PDD, particularly in technology driven products where typically industrial designers may not be included in the discussion.

New Directions for Engineering

It is apparent that as product design and development evolves to meet new challenges that its engineers will require:

- improved design emphasis (including sketching ability),
- a creative approach,
- a socially responsible design philosophy,
- an emphasis on sustainable product design and manufacture and
- advanced open-ended problem solving ability

An Emphasis on Design: Integration of Designerly Ways

Most engineering faculties have been reticent to incorporate any significant design course components, at least until the final or capstone years. Faculties prefer to build a solid foundation of engineering science, but without supporting design activities that provide opportunities for this knowledge to be applied. "We do not teach the language of design, preferring instead the language of mathematics". (Dym, 1999) This view is supported by a perusal of typical engineering curricula that finds that negligible design projects and a notable absence of divergent thinking or creativity agenda.

Design has always been fundamental to the practice of engineering, and thus should be a key constituent in engineering education. Unless design and creative skills are a focus of learning activity, graduate engineers will continue to be technically competent, but will not prepared for the practice of engineering or the challenges they will face professionally. Both Fox and Cross have identified that there is 'an educational justification for design' as a means to develop cognitive skills and real-world problem solving abilities. (Fox, 1981) (Cross, 2001)

Yet it appears most engineering curricula continue to focus on the theory-based science model, denying students the learning opportunities afforded by design projects, particularly in the application of engineering science to real world practice. Design needs to move from the periphery to a central role in engineering education if we are to graduate innovative and adaptable engineers, and enable more valuable engineering input in the PDD process.

"One of the consequences of design-focused education is that students learn that they are applying knowledge in differing forms to serve different ends, which means that they can become fluent translators of engineering languages." (Dym, 1999)

Fostering Creativity

It appears that many in engineering faculties do not value creativity or do not readily acknowledge its importance in engineering practice. This despite many calls for a focus on fostering creativity. "Creativity is the essence of engineering. Yet creativity is neither explicitly taught nor promoted in the engineering curriculum." (Santamarina, 2002)

Creativity is frequently misunderstood, and is often viewed with an element of mistrust, especially by those outside the design community. This is due to creativity being viewed as resulting from 'ex nihlo' (something from nothing), rather than from less confronting processes involving structured problems and expected or predefined solutions. However teaching engineers that creativity involves "a non-linear, unstructured and flexible approach to solving problems and generating ideas" (Pappas, 2002) can facilitate acceptance and willingness. Engineering students must become comfortable with the creative process, if they are to embrace unexpected outcomes and pursue innovative solutions. "Making the strange familiar – accepting creativity as a desirable mindset and attribute of engineers – is a tangible and realisable goal." (Stouffer et al., 2004)

So what is creativity and why is it important in an engineering educational context?

Creativity emerges from a divergent thinking process that allows the designer unconstrained exploration, the use of intuition and reflection to respond to a problem with a solution-focussed approach. Creativity seeks to generate new, unique and unexpected solutions.

"Creativity is of paramount importance in engineering for it endows one with insight and discipline to seek out and address problems from the boundaries of different engineering disciplines" (Ghosh, 1993)

Creativity involves having unusual ideas, tolerating the unconventional and seeing unexpected implications. (Cropley & Cropley, 2000) This can be rather challenging for engineering students who are more comfortable working within defined parameters and tackling constrained (rather than open-ended) problems, and who typically, have a tendency to fixate on prior solutions. "Students must be aware that instruction in creative thinking will not provide the certainty offered them in most engineering tasks. Creative thinking is a more ambiguous endeavour than most engineers are used to or skilled in...there are no right answers" (Pappas, 2002).

Yet without a creative methodology, the potential for engineers to contribute to the PDD process is limited and innovative engineering solutions are less likely. Creativity results from a flexible and open approach to problem solving, an approach dependent on confidence and a willingness to take risks and trust intuitive ideas. Typically, these attributes have not been developed through the engineer's education, but have been gained through extensive industry experience. To better prepare graduates for the demand of industry and to enable more innovative engineering practice, we must foster creativity in students. To achieve this, curricula must facilitate significant experience of design problems, in an environment that appreciates unexpected solutions, tolerates failure and nurtures students through the framing and resolution of ill-defined problems.

Initial attempts at fostering creativity focussed on teaching specific techniques, for example Osborn's brainstorming. However this ignored the non cognitive aspects of creativity including motivation and self confidence (Cropley & Cropley, 2000), which are integral to student engagement in the creative process. Engineering education must focus on developing problem solving skills, in particular, to reduce anxiety about unexpected solutions, develop confidence in the student's creative potential, and instil a desire for seeking creative and innovative solutions. It is no longer sufficient for students to be engaged in simple problem solving activities; experience in the 'practice of engineering' must occur through experiential learning projects that allow science to be applied to real world problems.

The Importance of Sketching

There is significant research that links sketching to creativity, yet many engineering curricula fail to develop the sketching skills essential for design conceptualisation and communication and resultantly limit the ability of engineering graduates to explore design possibilities. Sketching enables abstract idea development and is not just a documentation and communication process; rather it facilitates the creative process through contextual citing of the design intent. Without sketching ability, many engineers struggle to find the unintended consequences that stimulate the design exploratory process in what Schon and Wiggins (1992) called the 'reflective conversation with the situation'.

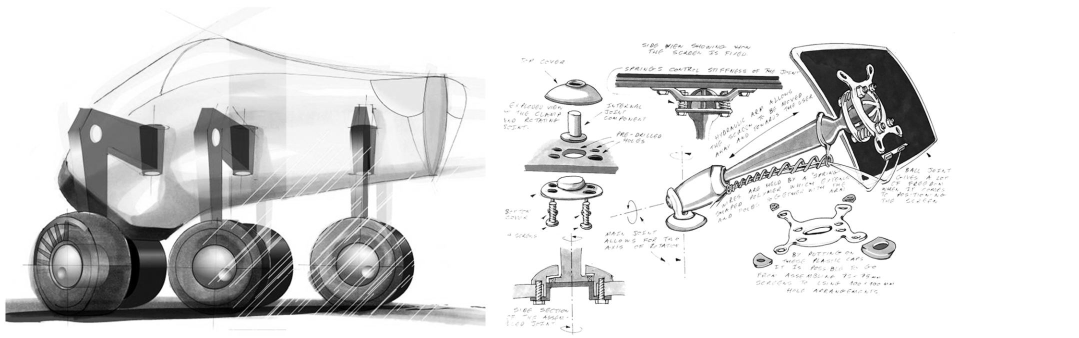
"It appears that the very design process is limited by the ability to use graphics as a cognitive extension. This implies the need for training... not only in the standard drafting skills, but additionally in the ability to represent concepts that are more abstract and best represented as sketches" (Ullman, Wood, & Craig, 1990)

Sketching is fluent, flexible and inaccurate and because sketches are 'rough' there is less reluctance to discard them in favour of alternative designs. Sketches are fast, implicit, inexact and abstract, require minimal commitment and serve both analysis and simulation requirements. (Lipson & Shpitalni, 2000) Goldschmidt in his definition of sketching dialectics, refers to a dialogue between reflective criticism ('seeing that') and analogical reasoning and reinterpretation of the sketch ('seeing as'). (Goldschmidt, 1991)

Most importantly, sketches allow the designer and engineer the opportunity to explore as many concepts as possible before moving into the detailed design stage. That sketching is integral to the creativity process, is reinforced by studies of industrial design students which compared skilled and unskilled sketchers (Verstijnen & Hennessey, 1998) who found that those with sketching ability were advantaged by externalisation of mental imagery.

Yet many engineering faculties rely solely on CAD for design, neglecting the possibilities that sketching offer in developing creative solutions. As sketching facilitates "the creative shift to

Figure 1. Differing roles of conceptual sketching: Exploration of form (left) and abstraction of technical details (right)



new alternatives" (Goel, 1995) it is imperative that engineering students are competent sketchers, capable of articulating unformed ideas and design intent.

SOCIALLY RESPONSIBILITY DESIGN (SRD)

It is imperative that engineering serve the community in a socially responsible, sustainable and culturally sensitive manner. "Because of the intrinsic connection of engineering design with values, the engineer as designer shall not only be answerable for his/her engineering capabilities, but also and always for his/her ethical conceptions and behaviour as a moral person." (Eekels, 1994) Not only do product design teams need to be aware of the consequences of their professional actions, they must also be cognisant of the opportunities afforded them to lead positive change.

Designing for our complex societies requires anticipation of future needs and cultural sensitivity, but there exists a greater need, that of those at the base of the pyramid (the other 90%). Product design teams must address the societal needs of developing nations through designs that are indeed life supporting, sustainable and empowering. Urgent action is required in many critical areas including clean drinking water, sanitation, renewable energy, and healthcare and disease prevention.

A new engineering conscience is needed, one that emboldens 'design for need' over the material needs of first world consumers and repositions product design and development not as a functionary of business, but as the leader of change for greater social good. Engineering education is well positioned to make a significant contribution to determining attitudinal change amongst the student cohort and thus developing social conscience and sustainable and ethical practice in its graduates. The next generation of engineers can contribute to appropriate product design and development through responsible, ethical and culturally and environmentally sensitive design practice.

The engineering profession must progress from the role of technical service provider, to a profession that leads change through understanding of the human, environmental, societal and cultural challenges and the consequences of professional activity. This can only be achieved through a systematic and thorough grounding in the principles of socially responsible design (SRD) combined with opportunities to apply sound engineering practice to real world problems throughout the educational journey.

Sustainability

The UN has estimated that 80 percent of all product-related environmental impacts are determined during the product design stage. If issues of resource depletion, energy usage, material reuse and recycling, environmental degradation and climate change are to be addressed in sufficient time, environmental and social considerations need to be integrated early into the education of design engineers. Our responsibility as educators cannot be just to our students; we must be answerable to societies in general for the consequences of our graduates' professional behaviour. Our engineering graduates need not just awareness of the issues, but an embedded ethical philosophy and the tools to effect reform through sustainable design and product engineering.

The decade 2005-2014 has been declared the United Nations 'Decade of Education in Sustainable Development'. This initiative aims to "encourage changes in behaviour that will create a more sustainable future in terms of environmental integrity, economic viability and a just society for present and future generations." We must respond to this call through a targeted program that teaches not only awareness, but also the tools to affect behavioural change and to lead reform in design practice and manufacturing. The next generation of product designers and design engineers must direct initiatives to address the challenges faced by the manufacturing sector. Energy and material consumption and carbon emissions must be reduced, environmental degradation must be halted and alternative technologies developed. But most importantly the needs and aspirations of those currently outside the first world consumer societies must be addressed; not only are they the unwilling participants in relentless and unsustainable development, they also lack the basic elements that constitute a safe, healthy and equitable existence.

"Sustainability cannot be conducted on the sidelines. It can only be achieved through a paradigm shift which results in sustainability becoming part of everyday life, directing the way in which communities and individuals make decisions that contribute to the development of broad social goals." (Hammer, 2007) Engineering and design educators are ideally placed to make a positive contribution to reducing the impact of product manufacture and life cycle through the development of pedagogy that facilitates this paradigm shift.

Many of these goals can be addressed through innovative curricula that inform, encourage and require design project outcomes that include sustainable manufacturing processes and material selection, life cycle analysis (cradle to grave), design for assembly and disassembly and a holistic approach to product design that questions not only the impact of the product but also the 'need' for the product to exist at all. Designers and engineers must be taught to question established practice and to be sufficiently confident to make strategic calls that may defy established practice in search of a more sustainable product solution. "Designers have responsibility over the choices they make in design processes." (Papanek, 1985) Sustainable design practice must merge as an entrenched design methodology that is at the core of all professional activity. This will require attitudinal change and will require product design teams to serve not only their immediate stakeholders (clients and customers), but also the needs of global societies, including those outside their own market.

Sustainable design addresses the 'triple bottom line', a reporting framework that considers ecological and social aspects, in addition to the traditional financial measures. These goals demand that corporate responsibility be to its stakeholders not just its shareholders; consequently anyone who is influenced or affected, either directly or indirectly, must be considered. Appropriate design, fair trade initiatives, reduced ecological footprints and true accountability must be paramount in the minds of product design teams if we are to reduce the negative impact of our activities in product design and manufacturing. Victor Papenek famously declared that "there are professions more harmful than industrial design, but few of them." (Papanek, 1985) In response, product design and development teams must take the initiative to secure a sustainable lifestyle for future generations through well considered and responsible design and engineering practice; the role of engineering education is to provide the knowledge, aptitude and attitude required to lead this paradigm shift.

Problem Solving: 'Wicked' and Open-Ended Problems

It is evident that the 21st century design engineer will be confronted with ill-defined problems; design problems that will not be solved solely through the appliance of engineering science. These 'wicked' problems (Rittel & Webber, 1973) will require a new engineering approach, one that incorporates divergent thinking, creative and intuitive processes, and a willingness to embrace unexpected solutions; a designers approach to problem solving.

As discussed earlier, design is a divergent activity, whereas engineering thinking is mostly convergent. It is no surprise that mechanical engineering students struggle with open-ended problem solving when compared with design students. Most engineers are more comfortable with constrained problems, where the parameters are set and the outcome is, if not immediately apparent, determined by constraints afforded by material and processes. By contrast designers 'live' for the creative moment: they thrive on the pressure of uncertainty, exult in the quest for uniqueness and triumph with innovative solutions.

Design is an intensely personal pursuit where one makes a commitment to the problem that involves significant personal vulnerability and a willingness to face uncertainty and failure head-on. It has been said that a designer is only as good as his/her last design, as such designers must constantly expose themself to intense scrutiny as their outcomes are measured against unforgiving criteria, and judged by a market often driven purely by economic rationalism. Successful design practice requires a degree of self examination and confidence in the face of critical scrutiny that is not required by other professions; in design mere competency is insufficient.

However, many of the problems facing design engineers in product design environments will also be poorly defined and their first challenge will be problem definition; this will need experience and confidence when faced with uncertainty. Students need a learning process of construction and confrontation rather than memorisation. Project-based learning allows students to define and analyse the problem, develop alternative strategies to problem solving and to build, enhance and practice their expertise. But not all project-based learning will afford intense exploration and challenge students to work without constraints or parameters, as will an open-ended problem.

Open ended design problems "force students to think creatively and ultimately foster in them an appreciation for developing creative solutions." (Ghosh, 1993) This requires students to tolerate the unusual, unconventional and unexpected, and to become comfortable with divergent thinking processes. Open-ended problems require problem finding, evaluation, definition and resolution skills together with ideational fluency. They take students away from a problem 'solving' role into a position of exploration and synthesis that enforces a more holistic reasoning approach with critical analysis and creative expression. Experience with ill-defined design problems (that are not amenable to the techniques of science and engineering), is invaluable in engineering education. Students must develop flexible and divergent dichotomies and eliminate any tendency to fixate on prior solutions; this will require a new approach to the teaching of engineering design.

To address ill-defined problems, engineers must be confident seeking solutions outside their traditional fields of expertise, and comfortable using intuition to solve problems, rather than relying on solely on mathematical and scientific solutions.

The Emergence of a New Engineering Discipline within PDD

Industry trends indicate that role and responsibilities of the engineering designer in product design and development have changed from technical resolution to a more central role in the planning and design process. Design engineers are often engaged in creative 'front end' design activities (typically the domain of industrial designers) in addition to systems engineering and manufacturing resolution roles. "Current trends in technology and our increasingly complex society and workplace require engineers to have a wider variety of skills and a broader understanding of engineering as a discipline if they are to be successful." (Pappas, 2002)

Unfortunately it appears that traditional engineering curricula has not responded to the repositioning of engineering in PDD environments, and continues to focus on the 'theory' rather than the 'practice' of engineering, neglecting the development of design and creativity in students. "Historically, engineering curricula have been based largely on an 'engineering science' model." (Dym, et al, 2005) However, curriculum developments, particularly during the last decade, have led to the emergence of new engineering pedagogy that support integrated design environments. These new educational models show evidence of an attitudinal shift that leans "toward a more explicit recognition of design as a distinguishing feature of engineering practice and a motivating factor in the learning of engineering." (Dym, 1999)

Product design engineering (PDE) has created a new style of engineering designer; creative, flexible and adaptable, sustainable, ethical and responsible. Product design engineering whilst a relatively new engineering discipline, is gaining support with global distribution of curricula. These pioneering curricula integrate the traditionally disparate disciplines of industrial design and mechanical engineering to develop a creative 'next generation' engineer more adapt at the changing roles of product design and development.

Swinburne University of Technology PDE graduates have already made a significant impact in local product design and development. From observation of (and discussions with) leading industrial design consultancies in Melbourne, Australia, it is apparent that the product design engineering model is leading a trend in product design and development team constitution, with these interdisciplinary professionals defining a new approach to product design and breaking down traditional professional rivalries.

All of the major consultancies (and most companies in the manufacturing sector) are employing PDE graduates as they provide extended services to their clients and engage in brand building, global manufacturing and sustainable design solutions. Upon investigation, it appears that in the three leading industrial design consultancies examined closely, Swinburne product design engineers represented approximately 20-30 percent of the design staff, the balance being industrial designers. This is a significant achievement for a single course that has only seven years of graduates and that is lacking in public awareness as a distinct design discipline.

Ensuing conversations revealed that when employing a graduate, consultancy directors are more inclined towards employing a product design engineer for a traditional ID role, on the basis of their greater technical ability. It is felt that product design engineers 'reflected the industrial design graduates of previous generations', were more industry ready and could make a valuable contribution immediately upon employment. By contrast most ID graduates lacked technical ability and an understanding of professional practice, as a result of an education process less rigorous and more generic in nature. In consultancies whose activities were defined as approximately 20 percent front end creative, 60 percent detail design and 20 percent project management, the PDE's were a better investment with several consultancy directors declaring that they prefer product design engineers when hiring junior staff.

It was said that ID graduates were still slightly better at purely conceptual front-end design and that at present the most preferred employee was an industrial designer with 5-10 years industry experience; although this may change as PDE graduates reach professional maturity.

CASE STUDY—THE SWINBURNE PRODUCT DESIGN ENGINEERING CURRICULA: A CATALYST FOR CHANGE

Overview

Product design engineering represents a different approach to the teaching of engineering. It is an exemplary example of interdisciplinary education that not only develops a creative and human centred engineer, but understands the need for a more integrated approach to product embodiment. Without neglecting the science of engineering, it seeks to develop graduates who utilise the intuitive creativity of the design practitioner, united with sound engineering design method, to create a new approach to product design and development.

This educational paradigm is evident across a range of educational institutions worldwide as engineering faculties seek to address shortcomings in traditional curricula; in particular the notable absence of embedded design activities and negligible fostering of creativity. There are many models emerging either through targeted product design activities in mechanical engineering curricula (e.g. the product design major at Stanford), double degree courses or fully integrated programs such as the PDE courses offered in the United Kingdom, Europe and Australia. But all of these courses address the identification by Dym, Pappas, Akay, Santamarina and others, that engineering education needs reform if we are to develop engineers who are 'creative thinkers'.

It is important to clarify that the product design engineering paradigm discussed here is the product of fully accredited engineering courses with an engineering qualification (e.g. BEng, MEng) outcome and should not be confused with variations of the industrial design paradigm; PDE graduates are a new category of engineering designer.

However this new engineering curricula is not the only educational response to develop greater synergies between engineering and industrial design. The industrial design engineering (IDE) programs prevalent in Europe and the UK respond to the same industry requirements but through an expansion of industrial design curricula to incorporate engineering content.

Product design engineers are capable of operating with distinction in both professions, they utilise the divergent, reflective approach of designers, but engineer with the disciplined thoroughness and scientific method of engineers. More importantly, their integrated approach to product design incorporates a level of engineering proficiency not evident in industrial design, and their engineering methods benefit from the creative, flexible and human centred approach of the designer. This allows a valuable contribution to the PDD environment as they design from the 'inside out'; firstly engineering the functionality and then designing the user experience.

Product design engineers with their interdisciplinary attributes utilise intuitive creativity with sound engineering design method, to develop innovative solutions to complex, ill-defined problems. This results in a more proactive role in product design and development as these new engineers engage in initial problem framing activities, share responsibilities with industrial designers, and produce user-centred design solutions.

Background to PDE

Product Design Engineering originated as a new engineering discipline in Glasgow, Scotland in the late 1980s as a changing manufacturing environment demanded a professional fluent in both engineering and design. The first product design engineering course resulted from collaboration between Glasgow School of Art, (Industrial Design at the School of Design) and the University of Glasgow, Department of Mechanical Engineering and was soon followed by similar pedagogy at the University of Strathclyde. It intended to alleviate the gulf between the design and engineering professions and address disparate technical and cultural issues. It also aimed to introduce many of the educational topics raised by Donald Schön in 'Educating the Reflective Practitioner' including reflection-in-action and joint experimentation on open-ended problems. This new engineering curriculum integrated the design and engineering disciplines to create one model of reflective practicum (Green & Kennedy, 2001) with "design a continuous thread running through the teaching", an attribute preferred by the Institution of Mechanical Engineers, in the Grant Report, The Formation of Mechanical Engineers: Present and Future Needs.(IME, 1985)0

The importance of this interdisciplinary educational approach is evidenced by the emergence of similar pedagogy within the last decade, particularly in the United Kingdom and Western Europe (PDE is now offered by least twenty-five Universities worldwide), and the success of the Swinburne University of Technology PDE program in Melbourne, Australia, established in 1997. As industry enthusiastically embrace these 'new' engineering graduates, these innovative curricula appear to be feasible alternatives to traditional methods for teaching engineering, particularly in areas where design skills, creativity and problem solving ability are valued professionally.

The intent of the product design engineering curriculum is best described by a sample of course mission statements from institutions offering this new curriculum, as follows:

"There are increasing pressures, both from existing and emerging world marketplaces, for products which not only respond to the needs of function, user and society, but which can be brought to market ever more rapidly through state-of-the-art development and manufacturing processes. Industries which develop, manufacture and market today's products need high calibre graduates equipped to handle these processes with management skill and creative drive, and the PDE programme develops graduates with these skills." (Glasgow School of Art, 2009)

"The Product Design major concerns itself with the conception and design of products, services and experiences for the benefit of society. The program teaches a design process that encourages creativity, craftsmanship and personal expression and emphasises brainstorming and need finding to discover latent or un-served human need." (Stanford University, 2009)

"This course bridges the worlds of design and engineering, producing true hybrid professionals who will move immediately into companies as design engineers and product development specialists. This rare degree format has proved to be highly regarded by industries worldwide for producing valuable employees." (Brunel University, 2009)

From these course descriptors, it is apparent that, regardless of the country or institution, the product design engineering paradigm intends to develop a creative and human-centred design approach to the practice of engineering within the PDD environment.

This new engineering curricula is dependent on a number of distinct and crucial elements which are integrated throughout all areas of the learning process. These include:

- interdisciplinary education and skill integration
- an emphasis on design – integration of designerly ways
- the fostering of creativity
- sketching
- social responsible design
- sustainability

- experience of 'wicked' and open-ended problems
- experiential project based learning

Project Based Learning: Learning from Design

"Innovation requires creativity. The easiest vehicle for promoting creativity and for developing the student's decision making ability is the design project." (Eekels, 1987)

Developing product design aptitude requires experience; opportunities to learn, to explore, to experiment and to fail. Traditional engineering pedagogy, reliant on a theory-based scientific model does not offer many such learning opportunities. Students are not required to apply their newfound knowledge to the design of product solutions for real world problems; it is more likely that students will be tested on their science through examination and through solution-focused problem solving activities that lead to predetermined outcomes. This leads not to creative and innovative engineering practitioners, but rather, to pragmatic and inflexible professionals who readily fixate on the security of known solutions.

On the other hand, a design curriculum is 'learning in action' where students learn theory, and develop creativity and design experience through project-based or experiential learning processes. Students are encouraged, indeed required, to explore the limits of their imagination, to push the boundaries of technology, processes and materials: to investigate the possibilities and extend their own potential. Project based learning affords opportunities for the application of the known, the science of engineering to be applied to the unknown, often resulting in an unexpected solution. The joy of teaching design projects is that every brief will result in unique and innovative designs from each and every student; there are no correct or incorrect answers, only creative and unexpected solutions.

Project based learning is constructive, participatory and problem driven; an exemplary pedagogical model of 'learning by doing' and the most effective way to educate creative engineers for product design and development.

Creativity and Innovation

Felder (Felder, 1987) notes that creativity can be fostered through exercises that focus on:

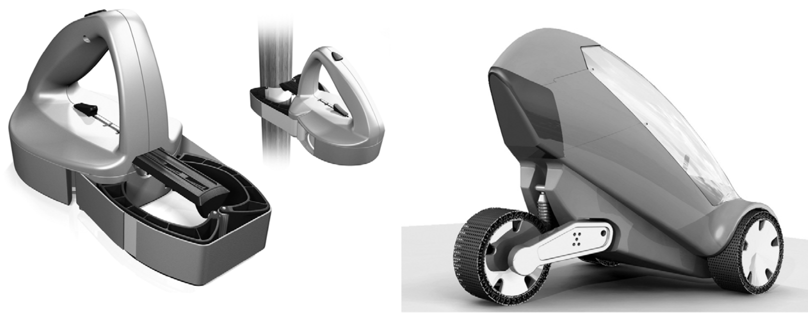
- ideational fluency
- poorly defined and open ended problems requiring divergent thinking
- synthesis of material outside normal boundaries
- evaluation – technical decisions vs. social and ethical considerations
- problem finding and definition (not just problem solving)

This model is intrinsic to the PDE educational approach where creativity and innovation are emphasised. Engineering education that focuses on problem solving results in graduates who can resolve a technical issue, but who are not solution focussed. Product design innovation does not result from solving a problem; it emerges from a creative, explorative and reflective process that expects only the best, a unique and creative solution.

Sketching

The product design engineering pedagogy through its integration of engineering with 'designerly ways' ensures that these new engineers are fluent at creative exploration and critical reflection and can 'handle different levels of abstraction simultaneously." (Cross, 2000) This is achieved through the requirement for aptitude in perspective sketching, which is taught from the first semester, and developed continuously throughout the four year undergraduate program. Students are required to utilise sketching in all stages of a design proj-

Figure 2. Innovative product solutions (Device to apply chemically-impregnated tape to grapevines to eradicate environmental contamination (left) Shared ownership urban 2020 vehicle concept utilising a sustainable propulsion system (right))



ect; beginning with initial conceptualisation, then concept development (Figure 3) and progressing to detail design and technical resolution (Figure 4).

In the PDE curriculum, perspective sketching and rendering are integrated into the learning process at all levels of the course experience and students are expected to become fluent communicators of form and function through non-digital drawing media.

Socially Responsibility

To address these goals, the Swinburne product design engineering program has established several strategic relationships with humanitarian aid agencies with the view to providing proficient design and engineering services in areas of desperate need, whilst providing students an opportunity for real world learning and experience in design for good. Product design projects have been conducted addressing scenarios provided by World Vision (a leading humanitarian aid agency) (Figure 6) and liaison with Engineers without Borders has been established to engage in long term infrastructure building activities.

Final year 'capstone' projects are required to address a social need through a product outcome. Students are encouraged to collaborate closely with partners from aid agencies, medical research organisations, disability support organisations and education and healthcare specialists to provide product solutions to real world needs (Figure 5). Such projects have developed an ethical and responsible approach to the practice of engineer-

Figure 3. Socially responsible designs. (Mobility aid/shopping trolley for elderly users (left), Ceramic pressurized sterilization unit for Nepal designed for local production (right))

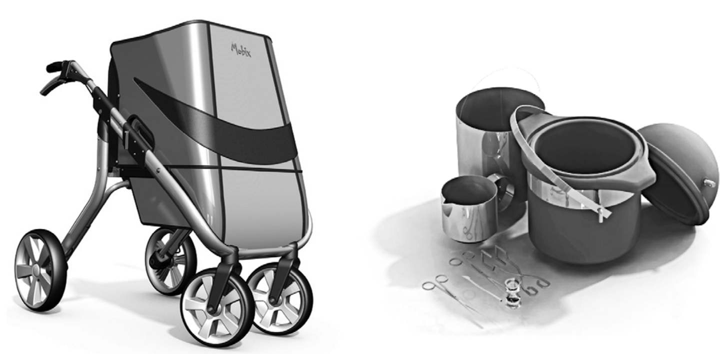


Figure 4. 2nd year project work – sustainable electronic products. (Solar-powered soil analysis device (left); Hand-powered communication/ banking access device for remote communities (right))

ing design amongst the student cohort, and many altruistic endeavours post-graduation.

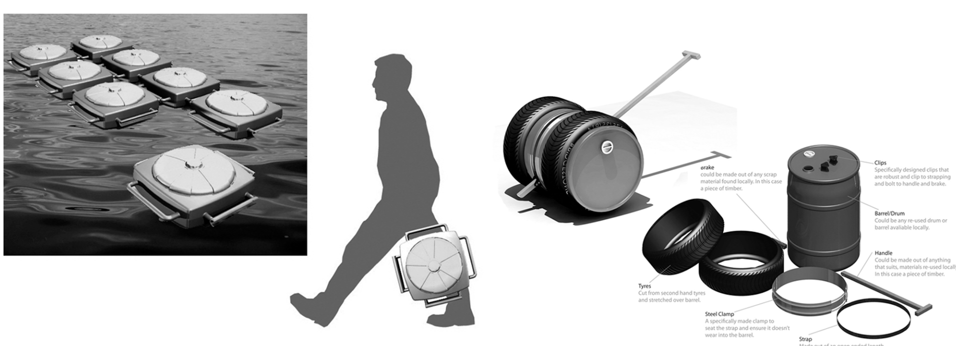
Sustainability

The product design engineering program focuses on sustainable design from the second year where the students are introduced to the principles of sustainability, the importance of life cycle analysis (cradle to grave), and ethical and eco-design methods. Students examine the impact of e-waste and the WEEE directive and then utilise environmental design tools to develop environmentally sustainable electronic devices (Figures 7 and 8). Eco-design is integrated from the early conceptual stages to ensure appropriate and well considered designs; band-aid solutions and products without a 'sustainable purpose' or genuine need are not accepted. Design outcomes must adhere to the "Ten Golden Rules of Eco-Design" (Luttropp & Lagerstedt, 2006), life cycle analysis (using Eco-Indicator and other software) and 'end of life' scenarios must be considered.

Open Ended Problems

It is important that students are set open–ended challenges where they must address a real world scenario without clear definition of potential outcomes. A typical project might be the design of a water transportation device to enable remote communities to convey water across either rug-

Figure 5. Open-ended problem solving exercise: water transportation for remote communities (Modular water transportation system for use in flooded landscapes (left); Water transportation system utilising readily available discarded materials (right))



ged or flooded terrain (Figures 9 and 10). These 'wicked' problems have numerous potential outcomes and are not constrained by known entities such as materials or manufacturing processes. Instead the students must consider the user and environment, define the problem and then design the product solution.

These projects are invaluable tools to develop creativity, and as students become familiar with uncertainty and confident in their design ability, true innovation emerges.

Future Trends in PDD: A Changing Environment

Industry trends indicate that product design and development will increasingly require an interdisciplinary professional capable of operating with distinction in both design and engineering roles. It is already apparent that successful design results from teams that integrate the skills of both engineering and industrial designers through non-combative collaboration built on mutual respect.

The challenges of the next few decades are immense; design teams must lead behavioural change through well considered, appropriate and sustainable products that meet the future needs of all stakeholders, not just their clients and customers. Confronting climate change inflicted by environmental degradation, reducing the impact of products throughout their life cycles, and enhancing the health, life expectancy and aspirations of those at the base of the pyramid will require real innovation in product design and development. This innovation will not occur naturally, a paradigm shift is required; one that will challenge expected conventions in PDD and revolutionise product design and manufacturing activities.

Advances in solid freeform fabrication (SFF) or rapid manufacturing (RM) have the potential to dramatically reshape the existing manufacturing sector. New design protocols and working methodologies will be developed to maximise the potential of these emerging manufacturing processes. The advent of rapid manufacturing will profoundly impact existing global manufacturing systems and may precipitate a move to local, or even customer production, using SFF technologies. As components and products are freed from the constraints of traditional manufacturing processes, fresh and innovative product architecture will emerge: we are at the dawn of a new product vernacular. Without the restrictions of centralised manufacture, transport and storage considerations will no longer critical as localised 'just in time' or 'buy and make' production of 'end use parts' will drive new directions in product design.

The implications of RM for the developing world are immense; previously unheralded access to products and services will drive rapid societal change. The removal of transportation from the product supply chain would dramatically reduce costs and aid in greenhouse gas reduction and fossil fuel consumption. Manufacturing processes not reliant on immense tooling and infrastructure costs will allow product design teams' far greater freedom to explore product potential and even to customise products for individual markets and/or customers. With this emerging technology, the traditional shackles of design for manufacturing will be removed or at least will be much less constraining, and this will revolutionise the product design and development environment.

The existing system of product manufacture, which has its origins in the Industrial Revolution, will be rapidly transformed and these changes may have similar socio-economic consequences and cultural impact, to that of mechanisation in the late 18th century.

This new environment will see the emergence of a new creative PDD professional; adaptable flexible, multilingual in the languages of engineering and design, responsible and culturally sensitive. The product design engineering paradigm which integrates engineering and design to develop an interdisciplinary professional, aims to produce graduates for these challenging and uncertain times; design engineers who are well equipped to adapt quickly to shifting environments and new methodology, in the pursuit of socially responsible and sustainable product innovation.

CONCLUSION

This chapter has dealt with the challenges facing product design and development teams in the near and immediate future. PDD needs to respond to existing and emerging challenges with a new paradigm that incorporates fresh approaches to practice that respond to global societal and environmental needs, empower individuals and cultures and embrace emerging technologies that will impact significantly on established protocols and the definition of professional disciplines.

The role of engineers in the product design and development process is shifting and will continue to be redefined as technological, environmental and societal considerations impact on professional practice. It is felt that these challenges are best addressed with a complex and multi-skilled practitioner, who bridges traditionally rival professions and facilitates a new era of collaboration, understanding and respect. Both the engineering and design professions need redefinition, a paradigm shift to address the rapidly changing climate with which we are faced. Engineers have always been integral to the PDD process, but their roles are shifting and the importance of their contribution in the near future, should not be underestimated.

The product design and development process can be enhanced by innovative engineers, but often is hampered by inflexibility, poor understanding of user needs and cultural insensitivity. The PDD environment will be the beneficiary of a more enlightened (and less rigid) approach to engineering education that seeks to impart skills that result in responsible practice and creative outcomes. And both society and environment will benefit from an engineer who is creative, innovative, adaptable and responsible; who can contribute to appropriate product design through new professional synergies and guide attitudinal change.

The role of engineering education in appropriate product design and development cannot be underestimated. Educators have a responsibility to global communities to produce engineering graduates with embedded ethical and creative philosophies who are well prepared and eager to make a significant contribution to environmental and societal issues. Early indications are that the product design engineering paradigm (emerging in direct response to the needs of industry) contributes to future global needs through a new engineering pedagogy that imbues its students with a strong understanding of the importance of their future contributions to society and the impact of appropriate professional behaviour.

The world is expectant of product design and development to address the future needs of our societies and environments. This will require new skills, enhanced communications and new synergies between stakeholders. The next generation of engineers, properly prepared, can direct the product design and development process confidently in new strategic directions.

KEY TERMS AND DEFINITIONS

Base of the Pyramid (BoP) - the other 90%: The base of the pyramid refers to the largest but poorest socio-economic groups; the four billion people who survive on less than $2 per day. These groups are not only isolated from the affluent materialistic lifestyles of first world Western populations, but are adversely affected by our development, manufacturing and quest for diminishing resources, and are the earliest victims of environmental degradation. Central to assisting those at the BoP are the principles of understanding, empowerment and respect, participatory development, mutual value and co-creation. Many of 'the other 90%' lack access to clean drinking water (1.1 billion), adequate sanitation (1.4 billion), healthcare and education. There exists many opportunities for design to contribute to improving the life expectancy and aspirations of those in need, through socially responsible design.

Creativity: A process that involves generation of new ideas and concepts; resulting in unique, innovative approaches and solutions. Creativity is an essential element of design thinking and depends on confidence to explore the unfamiliar, tolerate the unexpected and encourage the unknown. Creativity is an expressive and personal process that involves divergent thinking, exploration and reflection and at times relies on intuitive action.

Open-Ended Problems: Facilitate the development of creative problem solving skills. They are typically ill-defined problems that do not have an obvious single correct answer, and require a unique solution that emerges from a creative process. Open ended problems often require intuitive responses from students and the acceptance of the unexpected, which can cause discomfort for those with underdeveloped critical thinking or creative ability. It is critical that designers and engineers experience many of these 'wicked' problems throughout their education in order to develop problem framing skills, confidence in divergent thinking, and lose the tendency to fixate on prior solutions.

Pedagogy: Refers to strategies of teaching or principles and methods of instruction, sometimes referred to as 'the art of teaching'. It is effectively an array of teaching strategies that support the learning experience, through a well considered approach to curriculum development that empowers the teacher, student and learning experience. In this chapter, pedagogy is used as a broad descriptive term when describing the teaching strategies and curricula of the product design engineering paradigm.

Product Design Engineering (PDE): Product design engineering is an educational pedagogy and professional engineering paradigm, which seeks to integrate two disparate and traditionally rival professions; mechanical engineering and industrial design. Product design engineers are a new breed' of design engineer, interdisciplinary, creative and human centred, and highly skilled in the product design and development arena.

Project Based Learning (PjBL): An experiential learning process that involves the use of classroom projects to stimulate deep learning through enquiry and experimentation. In the context of design education it involves the students undertaking a design process in response to a detailed brief usually in a way that replicates real world professional practice. Project bases learning requires students to engage in design activities including conceptualisation, reflection, problem solving and exploration of possible solutions and detail resolution. The learning process is defined partly by the final artefact (design) and the success of the methods applied. In the context of teaching engineering design, PjBL allows students to integrate scientific knowledge into a solution-focussed approach encouraging 'learning through doing' which entails increased knowledge retention, and facilitates development of skills in the 'practice' of engineering' rather than relying on memorisation of theory.

Rapid Manufacture (RM): Rapid Manufacture utilises processes originally known as rapid prototyping (RP) and employs solid free-form fabrication (SFF) to deliver three dimensional components. It is an additive fabrication method that utilises sequential delivery of material and/or energy to specified areas to construct a particular form, layer by layer. As this technology evolves, increasingly complex forms are possible, including shapes and assemblies not achievable through traditional fabrication processes. This 'next level' technology has the potential to revolutionise manufacturing with particular regard to localised or even customer manufacture through advanced '3D-printing' processes.

Socially Responsible Design (SRD): The use of design to address social, environmental, economic issues and focuses on a move to move beyond first world consumer demands towards a more holistic and responsible approach to product design that embraces ethical, cultural and humanitarian values; simply termed 'design for good' or 'design for need'. SRD responds to all stakeholders (not just clients and customers) and examines the consequences of design activity and the potential for design to contribute positively to societal aspirations and expectations, health and lifestyle.

Sustainable Design: Sustainable design addresses the 'triple bottom line', addressing the principles of economic, social and environmental sustainability. It aims to counter negative impacts of products throughout their lifecycle with 'cradle-to-grave' philosophy that employ low impact materials and processes, and considers energy usage, embedded energy, design for disassembly to facilitate reuse or recycling, resource renewability, bio-mimicry and design impact measures (such as life cycle analysis). Sustainable design aims to support development "that meets the needs of the present without compromising the ability of future generations to meet their own needs." (United Nations, 1987)

Chapter 6
E-Learning for SMEs:
Challenges, Potential and Impact

Asbjorn Rolstadas
Norwegian University of Science and Technology, Norway

Bjorn Andersen
Norwegian University of Science and Technology, Norway

Manuel Fradinho
Cyntelix, the Netherlands

ABSTRACT

SMEs have a special need to be able to collect knowhow from the global community and implement this as competence in the enterprise. E-Learning is an approach for competence development that can assist SMEs in creating a learning organization. There are different approaches to E-Learning. Amongst the most powerful ones is the application of serious games. The PRIME project conducted experiments with serious games in project business and in manufacturing. This has resulted in a set of guidelines for successful implementation of games in an organization. It is necessary to allow a learning curve and put emphasis on the social context to obtain effective learning. For delivery of E-Learning the hybrid learning model is recommended. SMEs are advised to develop E-Learning in cooperation with academic institutions, and to use real life cases and problems for assignments. Delivery should be based on proven technology when used in SMEs.

INTRODUCTION

The extended enterprise is being implemented worldwide using different e-business technology. To be on the competitive arena today requires cutting-edge competence not only on the products supplied, but also in all aspects of business operation and competence development. ICT is in this respect an extremely powerful tool enabling enterprises to work globally and allowing creation of supply chains, enterprise networks, and learning communities. For SMEs this represents a challenge. SMEs have limited resources to drive this technology, but are at the same time dependent on access to the same technology. There is a special need to be able to collect knowhow from the global community and implement this as competence in the enterprise.

DOI: 10.4018/978-1-4666-1945-6.ch006

E-Learning is an approach for competence development that can assist SMEs in creating a learning organization. E-Learning allows learning at the time, place, and pace decided by the learner. It enables tailoring of learning content to the needs of the user and facilitates collaborative learning and access to expert teachers wherever they might be. Recent research from previous and on-going EU-projects (GEM, PRIME, and TARGET) has been able to demonstrate some of the power of E-Learning, or more correctly "technology-enhanced learning". Some key research findings from these projects will be presented together with a case study on practical implementations of E-Learning solutions in industry.

The GEM project developed a framework of a curriculum for manufacturing strategy. The project included a study of different delivery methods. The PRIME project used serious games to train middle management in decision making. It was tested through demonstrators for repetitive manufacturing and for project based business. The TARGET project is ongoing and is studying different learning approaches based on concepts for technology-enhanced learning (TEL).

The objectives of this chapter is to discuss different E-Learning approaches that are relevant for SMEs based on research findings from the mentioned projects and to develop an agenda for future research for competence development in SMEs using advanced ICT. It indirectly explore how SMEs can exploit E-Business by discussing how innovative E-Learning approaches can be used to facilitate transfer of knowledge and building of experience. This new knowledge and experience can in turn be leveraged by SMEs to develop and experiment with E-Business strategies.

E-LEARNING BACKGROUND

There exists a number of questionnaire-based evaluation approaches for E-Learning (Sage, 2002, U.S.I.G., 2003, Carliner, 2002, Hughes, 2003). They indicate four essential areas for evaluation (Schwesig, Rolstadås, and Thoben, 2005):

- E-Learning content - the preparation and the selection of content
- E-Learning approach - the instructional approach of the E-Learning course
- E-Learning delivery mechanism - the actual design of the learning environment
- Overall assessment- general questions, strengths and weaknesses, suggestions for improvement for the course

In this context, we will focus on E-Learning approach and delivery mechanisms.

E-Learning Approaches

Most SMEs are, in terms of organizational structure, fairly simply designed, with few departments or units. On the other hand, this means that typically employees are involved in more than one function or discipline required to run the company. In such integrated areas, decisions are taken that have a crucial influence on the competitiveness and profitability of a company. These decisions relate to questions like various strategic management tasks, product portfolio, product program, competitor strength, competition parameters, market segmentation, project planning, innovation management, process management, etc.

These integrated areas all require competences that go beyond the narrow technical competences that can be acquired easily and affordably through traditional courses or training. As complexity and dynamics in the internal and external specialization and collaborations increase, the need for training and competence development increases as well. In terms of competence development, organizations therefore have concrete needs that are not met well by traditional learning approaches:

- Reduce the time it takes an employee to acquire the necessary competences to do

their job in the most efficient and effective manner;
- Change the learning context rapidly and in response to the real world;
- Facilitate knowledge sharing within an organization;
- Support a soft failure environment where mistakes have no impact on the real world, thus promoting a willingness to engage in measured risk taking, focused on achieving a high level of polished performance in the real world

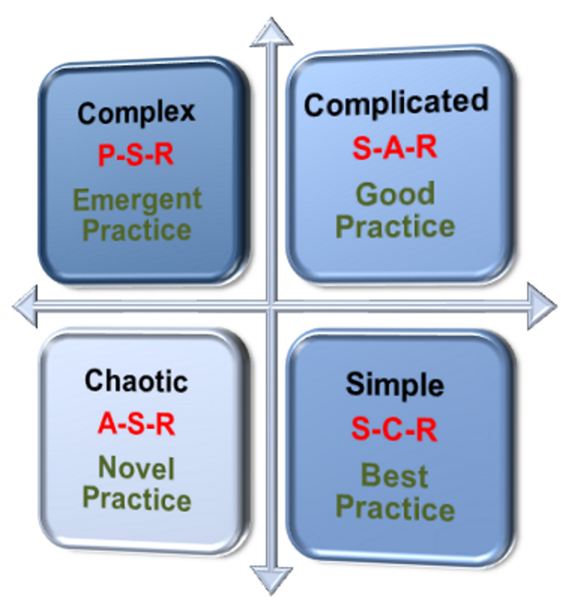
The above are a response to market pressures, but society itself has also gone through changes as a result of the advances of technology. For example, the way people scan reading material has changed significantly due to the World Wide Web, thus having a significant impact on marketing strategies (Meyer, Chall, Onofrey, and Rose, 1998). With E-Learning it is no different and already there are signs that E-Learning needs to take account of the enhanced abilities of the so-called gamer generation, such as differences in cognitive processes when compared to non-gamers, which can give gamers a competitive edge in fast-changing market situations such as arise in economic downturns (Herring and Job, 2008). This has implications for organizations that need to change work environments and business practices to face new challenges. In this light games can be seen as the most recent element in E-Learning offering new and different approaches to organizations in their effort to upgrade and enhance competences.

Traditionally, problems have been seen as complicated challenges that should be solved through breaking them down into smaller and smaller chunks. Seen from the solution perspective, the solutions then emerge by solving the problems related to the smaller chunks. Largely, this reflects an analytical way of thinking. In such regimes, learning and training are also related to the smaller chunks. By training the competences behind the smaller chunks the person gradually becomes able to meet the challenges.

We experience that most modern problems are more frequently complex rather than complicated. Complex problems are messier and more ambiguous in nature; they are more connected to other and often very different problems; more likely to react in unpredictable non-linear ways; and more likely to produce unintended consequences. Most organizations have been designed to deal with a complicated rather than a complex world. Hierarchical and silo structures are perfectly designed to break problems down into more manageable fragments. They are not, however, so effective in handling high levels of complexity. For this reason many institutions and companies are now struggling to adapt to a more complex world.

The Cynefin (the word has a Welsh origin and is pronounced *kun-ev'rin*) framework proposes an association between the nature of context of problems and appropriate responses (Snowdon & Boone, 2007). The Cynefin framework consists of five domains (see Figure 1 for an adapted version):

Figure 1. The Cynefin Framework



- Simple, in which the relationship between cause and effect is obvious and the appropriate approach is to Sense – Categorize – Respond
- Complicated, in which the relationship between cause and effect requires analysis or some other form of investigation and/or the application of expert knowledge, and the appropriate approach is Sense – Analyze – Respond
- Complex, in which the relationship between cause and effect can only be perceived in retrospect, but not in advance, and the appropriate approach is Probe – Sense – Respond
- Chaotic, in which there is no relationship between cause and effect at systems level, and the appropriate approach is to Act – Sense – Respond
- Disorder – in which it is unclear what type of causality exists. Disorder is in the centre of the framework. Here people will revert to their own comfort zone and choose the approach related hereto.

Each domain of the Cynefin framework represents different levels of expected achieved practice. In the simple domain, we can expect "Best Practice". In the complicated domain, we can expect "Good Practice". In the complex domain, we can expect "Emergent Practice", and in the chaotic domain, we can expect "Novel Practice".

These expectations relate to the nature of the problems. Heavily process-oriented situations, such as loan payment processing, are often simple contexts. Directives are straightforward, decisions can be easily delegated, and functions can be automated. As problems become complicated, they tend to require assistance from specialists: A car owner may know that something is wrong with his car because the engine is knocking, but he has to take it to a mechanic to diagnose the problem.

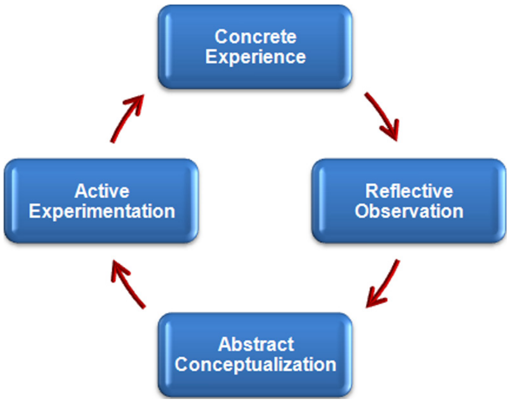
When problems become complex, the clear pattern between cause and effect disappears. We can understand why things happen only in retrospect. Instructive patterns, however, can emerge if the leader conducts experiments that are safe to fail. That is why, instead of attempting to impose a course of action, we must patiently allow the path forward to reveal itself. We need to probe first, then sense, and then respond. There is a scene in the film Apollo 13 where the astronauts encounter a crisis that moves the situation into a complex domain. A group of experts is put in a room with a mishmash of materials – bits of plastic and odds and ends that mirror the resources available to the astronauts in the flight. The team is told: This is what you have; find a solution or the astronauts will die. None of those experts knew a priori what would work. Instead, they had to let a solution emerge from the materials at hand.

In the chaotic context, searching for right answers would be pointless: The relationships between cause and effect are impossible to determine because they shift constantly, and no manageable patterns exist – only turbulence. Here we must first act to establish order, then sense where stability is present and from where it is absent, and then respond by working to transform the situation from chaos to complexity, where the identification of emerging patterns can both help prevent future crises and discern new opportunities.

The analytical learning and competence building approach that has proven efficient when dealing with simple and complicated problems proves inefficient when confronted with complex problems. In short the "probe" element is missing in traditional approaches, and the "sense" element appears to be very different when dealing with complex problems compared to complicated and simple problems.

The probe and sense elements seem to be crucial when dealing with complex problems. This is supported by a number of research results published in the past 30 years. In 1984 David Kolb published his book title "Experimental Learning" (Kolb, 1984). His claim is that we are learning by cyclic patterns of four types of activities: Concrete

Figure 2. David Kolb's learning circle



experience, reflective observation, abstract conceptualization, and active experimentation (see Figure 2). According to Kolb it does not matter where we start - the important requirement for real learning is that one goes through the full cycle.

Though Kolb's work is aiming at the individual level there are several contributions supporting that a similar pattern is valid at the organizational level. Dorothy Leonard argues that: "The primary activities spawning organizational learning are experimentation and prototyping" (Leonard-Barton, 1995) and Argyris and Schön (1978) have introduced the notion of single-loop and double-loop learning which includes active experimentation.

Donald Schön has been studying how professionals are working very differently from novices. His point is that when people have reached a certain level of professionalism it will change their working style and they become "reflecting practitioners" (Schön, 1983). The reflective practitioner is in a constant process of thinking, reflecting, acting, and building experience – very much in line with the learning process as described by Kolb. This process is efficient for the professional person but due to the amount of tacit knowledge it is often difficult to articulate and share the results with others (Polanyi, 1967). Physical models or other model representations seem to be the most efficient means to facilitate this sharing (and learning) process (Schrage, 2000).

In his book, Serious Play, Michael Schrage (2000) praises many aspects of prototyping for speeding up processes etc. and mentions examples of great breakthroughs made by new prototyping tools. The following extracts provide exemplary viewpoints from the book:

- When talented musicians improvise, you don't look inside their minds; you listen to what they play. When talented innovators innovate, you don't listen to the specs they quote. You look at the models they've created.
- The challenge of converting uncertainty into manageable risks or opportunities explains why serious play is often the most rational behavior for innovators.
- Serious play is about improvising with the unanticipated in ways that create new value.
- Prototypes engage the organization's thinking in the explicit. They externalize thought and spark conversation.
- Prototypes force confrontation with the tyranny of trade-offs.
- The conventional wisdom that "innovation processes" drive prototype development is misleading. Empirical observations of organizations with effective innovation cultures confirm just the opposite: changes in prototypes and simulations drive the innovation process.
- Prototypes are machine tools for producing choice.
- Most companies have formal prototyping processes and informal prototyping cultures.

Schrage (2000) argues against the common assumption that "great teams make prototypes" and suggests that instead one should realize that "prototypes make great teams". The making of great teams goes beyond the individual team, but helps create teams out of people with different backgrounds by creating "shared space". Shared space is the common ground where people can meet on even terms and objectively discuss matters.

Obviously, physical and mental prototypes provide opportunities to probe and sense. They invite for questioning and challenging of conventional wisdom (March, 2006) and thereby learning and competence development can be supported.

One of the most promising, future oriented concepts of E-Learning is the use of serious games. (This concept will be described more detailed in a later section.) The game culture has been studied by Oliveira, Andersen, Oliveira, and Rolstadås (2006). They assessed the culture and its impact using a questionnaire consisting of 48 questions. The results of the survey demonstrate that the gamer generation is not as prominent in Europe as in the United States, but present nonetheless. The managers, who experienced an upbringing with the influence of digital games, demonstrated an advantage over those that did not share the same background. Throughout all the statements aimed at capturing a respondent's thoughts and motivation on particular topics, the gamers revealed an edge and advantage over those without gaming experience.

Delivery Mechanisms

Delivery of E-Learning relies heavily on Internet-based technologies (Rolstadås, 2002; Lefrere, 2007). Technology, the fast outdating of knowledge and training, the desire for just-in-time training delivery, and the continuous hunt for cost-effective methods to meet learning requirements have redefined the processes of design, development, and delivery of training and education (Urdan and Weggen, 2000). Several terms have been used to characterize the new methods of E-Learning including: technology-enhanced learning, distributed learning, online learning, and web-based learning. Many educational organizations are experimenting with E-Learning, using intranets, websites, and multimedia solutions, and a great deal has been written about the issues and problems encountered in these attempts (Hall & Snider, 2000; Urdan & Weggen, 2000; Berge, 1998). However, by giving careful consideration to the design and implementation of E-Learning, successful courses that take full advantage of the benefits enabled by the technology can be created.

Delivery of E-Learning content can be synchronous or asynchronous. The alternate use of video, audio, pictures, text, (interactive) animations, quizzes and chat, and discussion boards should assure that both styles can be covered (Rolstadås and Hussein, 2002). Whatever the choice of learning communication, the learning success heavily depends on the actual form of mediation. According to Dale (1969), passive learning activities like reading texts or watching a demonstration result in the fact that just 10% (reading) or 30% (watching) of the content is remembered afterwards. Active involvement within the learning process, like participating in a discussion, leads to the fact that the learners can remember about 70% of the related content afterwards (Dale, 1969). Accordingly, content needs to be delivered on the basis of active learning. In order to assure the appropriate employment of the mentioned design elements and the application of active learning elements, design guidelines have been used explaining the correct use of pictures and texts, (interactive) animations, quizzes, chat/messaging video, and audio. Kommers, Grabinger, and Dunlap (1996) present a number of design elements such as pictures and text, animations, quizzes, chats, messaging, video, audio, games, and laboratories that can bring maximum benefit to the learner.

A powerful concept for delivery is based on the concept of the hybrid learning published by Rolstadås and Hussein (2002). They claim that this type of mixed instructional delivery has proved to be an effective tool for enhancing the learning value for the workforce. Applying this approach may also lead to significant reduction in learning time. The hybrid solution is well suited for large organizations distributed over a large geographic area. Thus, the target group may be characterized by diverse social, cultural, and academic background. Therefore, it is important that the model enables multiple learning styles.

According to Rolstadås and Hussein (2002), the hybrid model must contain the following properties:

- Create an environment for learning that addresses multiple learning styles
- Ensure active participation and to focus on accommodating the learners' former experiences
- Enable the learners to build personal and possibly social networks
- Use information and communication technology for designing the content in order to enrich the learning experience
- Restrict the use of on-campus delivery whenever high level of interactivity between the learners themselves is required or between the learners and the content
- Availability in the form of an updated support system that assists the learners on the academic, technical, and administrative level
- Learners should be motivated and self-disciplined and using education in order to achieve clear goals.

The hybrid model is based on a mixture of on-campus plenary learning sessions (face to face), self paced learning using rich media through virtual classroom, and collaborative group work using collaborative ICT tools included in the virtual classroom.

IMPROVING BUSINESS DECISION CAPABILITY USING SERIOUS GAMES

The knowledge-based economy has redefined the rules of economic development with continual and ever-more rapid industrial and social changes. Enterprises have realized that knowledge workers are a key to a company's productivity, competitive edge, and ability to adapt to changes in markets and customers. A highly educated, well-trained, and adaptable workforce is a key element in competitiveness, productivity, and the growth of employment, thus life-long learning (Aspin and Chapman, 2000) anywhere and anytime has become a fundamental strategy of the knowledge-based organisations. This is corroborated by the report of the Task Force on Employment, chaired by Wim Kok (2004), and the Spring European Council of 2004 stressed that Europe must invest more, and more effectively, in its human capital. These recommendations are clearly guiding the revised Lisbon Knowledge Society initiative, the i2010 Strategy. However, tailoring effective E-Learning frameworks within organizations is highly challenging and its promises have not been highly successful in addressing the challenge of supporting life-long learning of knowledge workers. Within SMEs, the challenges of deploying successfully an E-Learning framework are exacerbated due to their focus on immediate business survival.

As pointed out by Romiszowski (2004), the failure of E-Learning can be associated to some common mistakes, which are rooted in the focus on the technology itself rather than on the impact of technology in the context of human-activity systems (i.e., education and training systems). A promising technological innovation in E-Learning platforms is the use of digital games, which according to Prensky (2001) introduces play into the learning process, an essential missing factor in traditional technology-enhanced learning (TEL) platforms since learning is more than education.

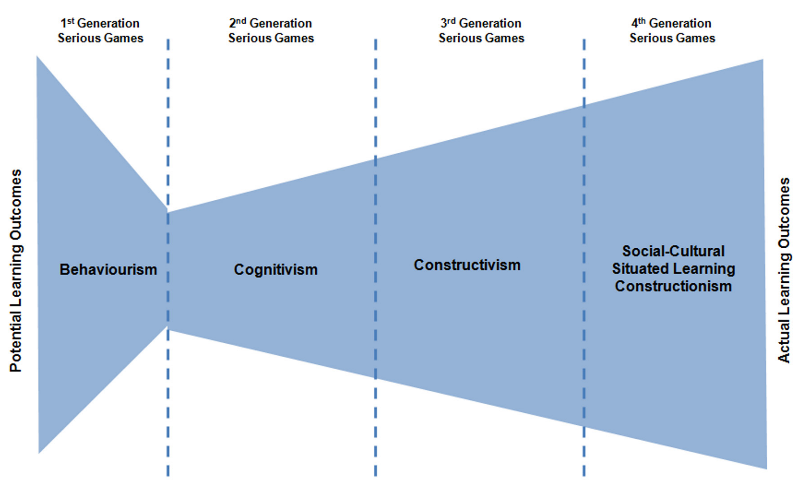
In fact, the most common term currently in use is serious games, where the flow engagement of digital games is merged with concrete learning outcomes. Although only recently have serious games gained more prominence in mainstream learning environments, one may consider that a total of 3 generations have taken place with a 4th generation emerging (Figure 3).

The first generation focused on learners acquiring designated behaviors through conditioning and reinforcements. The approach is only interested in directly observable behavior based on stimuli and response. The learning theory does not take into account that learners are different from one another and assumes that a learner acquires a skill provided it is practiced enough times. This led to the second generation where the focus shifts from the behavior to the learner and their internal cognitive constructs to represent knowledge. However, the feasibility of knowing precisely the learner's cognitive processes is limited. The third generation relies on constructivism, which still focuses on the learner, but from the outside. In this case, the learners build and constructs their knowledge by interacting with the environment and each learner acquires the knowledge in their own way. Finally, the current generation of serious games is based on situated learning where constructivism is complemented by social processes that are necessary for learners to externalize knowledge.

PRIME Case Description

Providing Real Integration in a Multi-disciplinary Environment (PRIME) is a serious game on the borderline between the 3rd and 4th generation, but exploiting some of the key strengths of cognitivism. The PRIME serious game was the result of a European IST project (FP6-016542), that aims to give business professionals in strategic manufacturing a learning environment where they can experiment with new ideas and learn the effects of their decision making. The PRIME serious game consists of a Virtual Business Environment (VBE) that defines the global business reality where users are responsible for the management of a single Business Unit (enterprise). A crucial characteristic, if not the strongest contributing factor, to learning is the feedback capability available to the learner. In addition, emotions (fun) are also connected to learning, where "people learn in direct proportion to the amount of fun they are having" (Rose and Nicholl, 1997). The

Figure 3. The four generations of serious games according to their driving learning theories

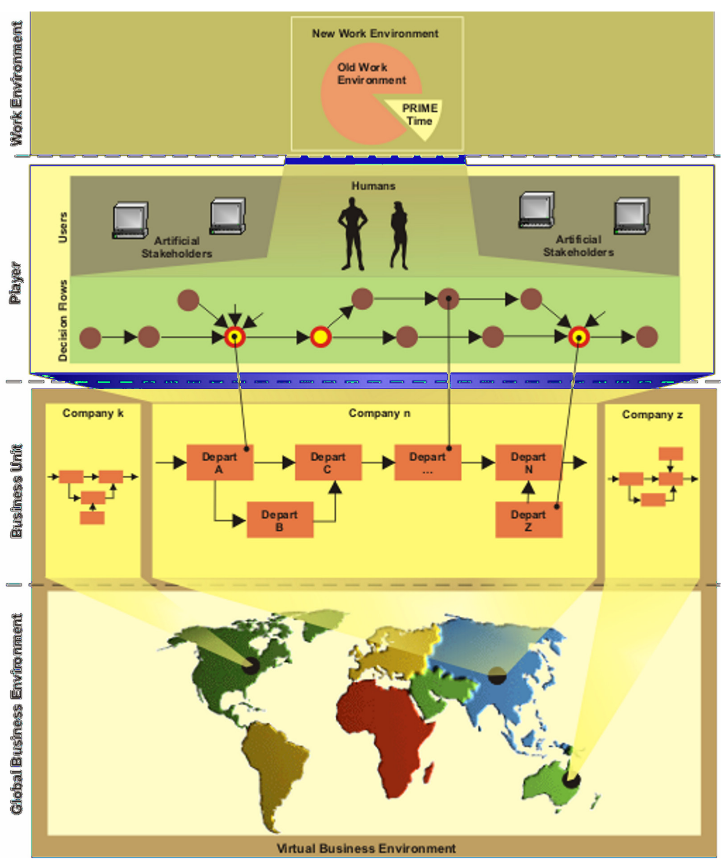


VBE provides real-time feedback to all the user's interactions and being a serious game, it focuses on providing a fun and engaging environment for users. The management breakdown of a business unit is based on eight functional units: Production, Product Development, Sales, Human Resources, Strategic Marketing, Distribution, Finance and Information Systems. Associated to each functional unit is a set of operation processes that are based on an input-transformation-output model.

The block diagram of Figure 4 corresponds to the PRIME conceptual model, illustrating the interplay of the global business environment and the different business units, each controlled by either a human player or an artificial stakeholder (agent).

The heart of the PRIME Concept Model is the set of Decision Flows where each flow consists of a linked graph of strategic decisions, which have far-reaching consequences for an organization and typically involve the commitment of vast resources. The decisions play out over long time frames and have significant opportunity costs. Strategic decisions often must be made under conditions of substantial uncertainty, particularly when complex policy objectives must be reformulated in the face of a dynamic, sometimes volatile strategic environment. Initial assumptions about the environment and other players may be incorrect or incomplete. The Decision Flows were shaped by applying a methodology based on Critical Incident Technique (CIT) (Flanagan, 1954) to capture the decisions supported by the PRIME Serious Game, which can be aggregated together in the following main categories: Logistics, Product Innovation and R&D, Sales and

Figure 4. PRIME Conceptual Model



Strategic Marketing, Production, and Finance. In essence, the Decision Flows define the game play of the PRIME serious game, which is an innovative approach to defining a serious game.

The implementation of the VBE relies on a hierarchical simulation model (Duin, Oliveira, and Saffarpour, 2007), which relies on a set of well-defined Key Performance Indicators (KPIs), such as throughput, defect rate, turnover, number of sold products, etc, which are derived from the underlying measures of the simulation model. KPIs describe how the operation process is performing. An initial set of KPIs is given to the user based on the ENAPS Framework (ENAPS Consortium, 2001). The supporting simulation model is extensible, thus it is permissible for an end-user to add more KPIs.

The PRIME Serious Game is based on two game modes:

- **Corporate**. The corporate mode provides an overview of the organization and the necessary information to support high-level strategic decisions. By default, the mode is dominated by the geographical global view. This view only exists in Corporate Mode and the player may extract information on geography, demographics, macro-economics and political systems.
- **Site**. The site mode provides fine granular detail, it is necessary for the player to switch from corporate mode into Site Mode to make localized strategic decisions.

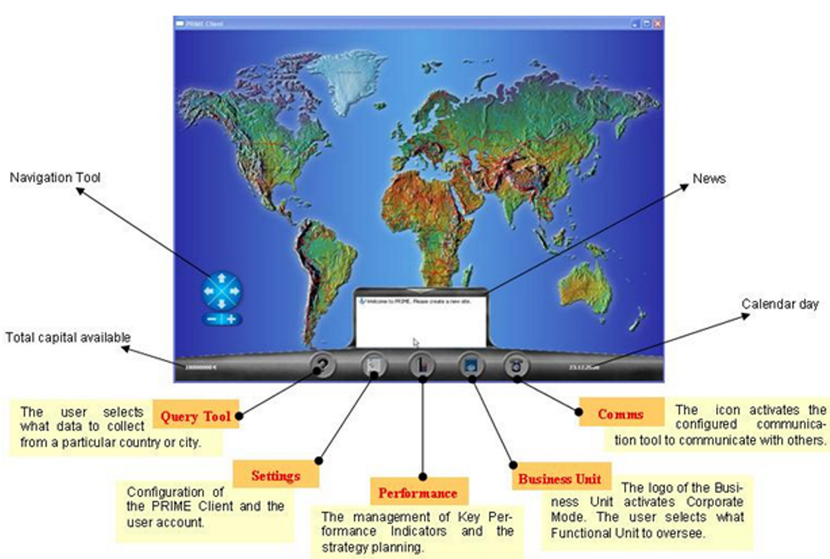
The image of Figure 5 shows an example of PRIME in corporate mode. It is extracted from the prototype corresponding to the final release version of the software, which again is corresponding to a fully working prototype.

Evaluation

The PRIME serious game was evaluated in six end-user companies, from different industrial sectors and with different characteristics:

- Fiat (automotive)
- IAI (aerospace)
- Intracom (telecommunications)
- Kesz (construction)

Figure 5. PRIME in corporate mode



- Lego (toy industry)
- Siemens (software)

The resulting population sample from the 6 end-user companies involved in the evaluation process yielded a total of 50 participants with different gaming experience, which revealed to be detrimental in tackling the learning curve associated to the PRIME serious game. 20% of the participants were players; 50% were seldom players; and 30 were not players. In average they spent 14 hours on PRIME.

The adopted evaluation methodology consisted of three phases:

- **Preparation**: This phase lasted two to three weeks and participants were encouraged to experiment with the PRIME serious game. This was necessary to tackle the learning curve and was done with the support of a moderator located locally within the organization. An underlying aim of PRIME is to facilitate the transfer of experience gained in the serious game to the real world, thus encouraging the building of the learner's repertoire. Consequently, the participant has two forms of preparation: guided-play and free-play. In the former, the participant interacted with the PRIME serious game based on tutorials that are well structured with clear aims for each case. In the case of free-play, the participant has no support or structure to their gaming sessions. During this phase, the participant was requested to log (Training Log) their opinions, difficulties, problems encountered and time spent playing the game.
- **Assessment**. At the end of the preparation phase, the participant was sufficiently familiarized with the PRIME serious game to focus on the learning process rather than any particular issue related to gameplay or game mechanics. The learner was challenged with a crafted "mission" where certain business objectives needed to be achieved within a given business context. During the process, evaluation data was collated in the form of semi-structured interviews, questionnaires, and quantitative data resulting from in-game performance indicators. The collated data forms part of the participant's Mission Log.
- **Analysis**. All the collated data from the two previous phases was analyzed and processed to distil lessons learnt and validate the PRIME serious games.

Only a small minority of participants were mainly players (around 20%), which has an impact on the evaluation data results since there was a correlation between the gaming experience and leveraging the learning curve associated to the PRIME serious game. For the assessment phase, the participants played a crafted mission that included:

- Sales Forecasts
- Project Management
- Product Development
- Production Management
- Logistic Management

Results

Even with a period of one month, the evaluation process could not measure the success of transference of experience into the real world. Consequently, the evaluation focused on usability and user friendliness with some exploration of its potential for achieving learning outcomes.

Since the PRIME serious game was a prototype, it was plagued with some development teething issues that were eventually sorted. The great majority of the learners (66% of the participants) experienced minor problems, but these would not affect their experience. A total of 14% never experienced problems whilst 18% manifested difficulties with the PRIME serious game. However, it should be noted that those experiencing most difficulties were also those individuals who did not have any previous gaming experience. Therefore when confronted with an open system that enabled emergent outcomes, an inexperienced learner would not understand how to proceed. Unlike a behaviorist approach where a learner has a well-defined path, in our case a constructivist approach was taken where there are no clear objectives, but the learner learns by doing. This problem was more self-evident in the Assessment phase where the learner was confronted with a mission with clear objectives, but the non-gamers had serious difficulty in proceeding without the assistance of the moderator. However, after the learner had built their own internal mental model of the process, they would gradually know how to engage and interact with the PRIME serious game.

Another factor to take into account is the fact that PRIME is a serious game on strategic global manufacturing involving management, which is a very complex and interdisciplinary topic. Consequently, PRIME touches most of the aspects of the life of a company, which depending on the size of the enterprise involves the management by a large team of people with different expertise, studies, and competences. Within the population sample, none of the industrial companies were small enough to have a single individual with all the necessary expertise to manage their organization, but neither was this the objective as one design requirement was the alignment of stakeholders by carrying out role reversal.

In addition to the semi-structured interviews and questionnaires, the participants were encouraged to provide comments and feedback in written form, which were important in identifying improvements in the PRIME serious game.

All learners clearly demonstrated, and reported, to enjoy the experience of being engaged with PRIME for learning. However, it was also reported that PRIME was more beneficial when engaged with a group of learners rather than in isolation. For this reason PRIME is located on the borderline between the 3rd and 4th generation of serious games according to Figure 3.

With regards to learning, it was not feasible to have an in-depth assessment that measured the transfer from serious game playing to real-life. However, 76% of the learners reported to acquired new knowledge and gained new understanding that they otherwise didn't have. For this reason, it is not surprising that more than 80% of the learners understood the potential of PRIME as a learning delivery mechanism for global strategic manufacturing.

Recommendations

From the analysis carried out, some guidelines for the improvement of PRIME and serious games in general emerged:

1. As with most sophisticated software, irrespective of how much effort is invested into improving usability, there will always be a learning curve that needs to be tackled by learners. An effective tool to support the leaner is the use of interactive tutorials, in the absence of these; video tutorials are also useful albeit less effective.
2. Learning is more effective in a social and situated context.
3. There is a need for single user experiences where a mission is tailored to very specific tasks. This is the particular case of highly engineered processes, which resemble almost an algorithm that the learner is required to follow. These cases bring the learner a significant return on their time.
4. Learners are partial to simpler missions that require short period of time to be experienced. However, learners recognise that their utility might be limited.
5. A serious game, such as PRIME, would benefit from linking to actual learning objects that provide the theoretical background, thus enabling the learner to have deeper under-

standing of what would be best decisions to make.

6. In the case of PRIME, each session should have a pre-briefing and debriefing to align the learner to what is the purpose of the mission and facilitate the externalization process.

STRATEGIES FOR CORPORATE LEARNING IN SMES

Corporate learning means learning organized by an enterprise – in this case SMEs. The SME sets up the learning objectives and defines the main structure in cooperation with an academic institution. The courses are tailor-made to the enterprise although a part of each course always is generic and therefore applicable independent of a company or even an industrial sector. Examples and cases used are normally based on real data from the enterprises, and assignments address problems the enterprise encounters. Solutions to assignments can be based on company procedures, systems, and governing documentation.

We will describe a case showing an E-Learning approach. Even though the case is from a large company, the approach may be applied also to SMEs. Next some of the challenges experiences in implementing and operating E-Learning will be discussed, and at the end some recommendations are given.

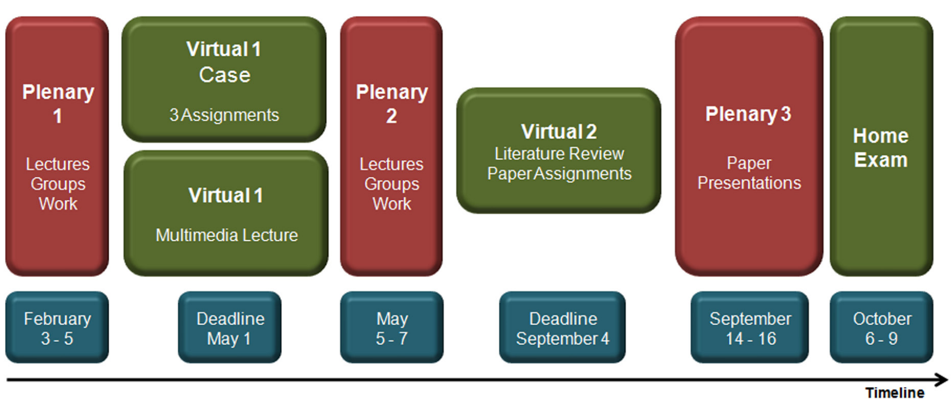
Case Description

The case is a real course developed and delivered in cooperation with a company and a university. The university cooperates with two other universities in different countries bringing a global dimension into the education.

Figure 6 shows an outline of the approach selected in the case. The course was used for training experienced project managers. Participation in each course is limited to 24 persons in order to provide the best possible learning environment. The participants all have more than 10 years of industrial experience from managing projects. Therefore the approach selected is discussion-oriented and highly interactive. The participants learn from each other, and the role of the teacher is more that of a moderator than a lecturer. The teachers are selected both from the company and the cooperating university.

As can be seen the selected approach is based on the hybrid model. There are three plenary sessions, each with three full days of face-to-face learning. The first two plenary sessions contain lectures and substantial group work and discussions. For each day, there are defined learning objectives. An electronic classroom is used for

Figure 6. E-Learning approach used in case



distributing handouts and reading material as well as for discussions amongst the participants and between participants and professors. The third plenary is different, as the participants will present the papers they have written in the virtual 2 assignment. Ample time is allowed to discuss each paper. This stimulates learning from each other and has proved very effective.

The first virtual session is split into two. The first part contains a case description. This is delivered using documents, slide shows, video clips, and interviews with actual stakeholders. From the case, each participant then gets three assignments that they will answer individually. The second virtual session is to write a paper according to normal academic standards. However, there is one important exception. The paper does not need to contain an original research contribution. It will be based on a problem from the company and take the form of a literature survey to find a solution to the problem or a recommendation for the company. This forces the learning to look into literature and discuss findings and alternative solutions. The problem has a "problem owner" in the company. This person serves as a mentor to the learner in addition to the supervision given by the professor. The learners work in groups of about three persons for this assignment. The paper is graded and the participants receive a certificate from the university. As already indicated, the group will have to present the results at the last plenary session.

After the third plenary session, there is a home exam to be answered individually. The exam is published in the virtual classroom and is open for three days. It represents about 6 hours of work, allowing the participant some flexibility in scheduling his or her work. All aids are permitted. The exam has the form of a case description with a number of assignments based on the case. The exam is graded and a certificate is issued by the university.

At the bottom of Figure 6, a typical timeline is indicated. The course is run once every year, and is now into its fourth year.

Challenges

The authors have been engaged in a number of E-Learning courses for different customers and using different approaches. The authors have also studied a number of E-Learning courses available on the web. There are many different solutions, ranging from simple courses presenting a number of slides and running quizzes to advanced multimedia applications.

Some of the most important challenges in developing a successful solution for an SME are discussed below.

The first challenge is to create a stimulating learning environment. This means that the learner is inspired to go on seeking more and more knowledge. A prerequisite for this is that the learning environment is interactive and that the delivery methods applied varies. It is also important that the participant is continuously challenged. The level of education must be adapted to needs of the learner. It should not be too easy or too difficult, and there must be reasonable progress.

Progress of the learner is in itself a challenge. All experience shows that learning is postponed until the very last moment. At the same time research shows that learning is a process maturing over time. It is thus important to break any course into a number of sessions, and to use deadlines and tests to enforce a reasonable progress.

Although progress must be enforced, it should not be so strict that the learner is not allowed any flexibility with respect to time and place for learning. People attending courses delivered through their employer will always have to attend to their normal job in addition. Even though they may use some time for learning during work hours, all experience show that they will have to spend some of their free time for learning as well. For them to succeed and keep up motivation, they should have flexibility to fit learning into their social life in a good way.

For the supplier of the course it is a challenge to respond to the service level demanded from the learner. Using electronic classrooms, one can easily see that questions from participants come in evenings after small children's bedtime and during the weekends. For the teacher it is a challenge to always be available when the participant needs help.

Also technology may represent a challenge. Pure technical questions connected to ICT platforms, security and firewalls may be solved, but requires attention and should not be underestimated. The use of media must also be carefully considered. Video is not always the best solution. The "talking head" may appear boring and reading an article may actually result in better learning. Interactive approaches, such as using serious games, have proved very effective.

Recommendations

For an SME starting to use E-Learning for developing their competence, the authors would like to offer the following recommendations:

1. Develop the courses in cooperation with an academic partner, but make sure the learning objectives are defined by the company.
2. Use hybrid learning based on asynchronous learning for the virtual sessions. Plenary sessions are extremely important for the participants to socialize and to stimulate learning from each other.
3. Base assignments and cases on realistic data from the company.
4. Involve the most qualified people from the company in lecturing practical approaches and company policies. Let the academic partner handle the generic aspects and the theory and try to put company practice into a global generic perspective.
5. Select proven technology for the delivery methods. Such courses are not the battleground for experimenting with cutting edge solutions and for training the employees in learning technology rather than learning content.
6. Provide adequate information on the selected approach to the participants before the first plenary session so that they can enter the learning arena well prepared.

FUTURE RESEARCH DIRECTIONS

In light of the challenges outlined earlier in this chapter, some topics for future research in the area of E-Learning can be identified:

- How to design E-Learning/technology-enhanced learning platforms that are at the same time cost effective in developing and implementing while providing tailored learning for the individual users. This is both a pedagogical and technical problem that is yet unsolved. The pedagogical issues will most likely have to be researched through exploring theories about learning models and concepts that attempt to identify learning needs of individuals (e.g., threshold concept (Meyer and Land, 2003). Technically, tailored learning can probably be realized through the use of mechanisms like serious games with tailored game scenarios, artificial mentors that aid the learners, etc. None of these issues have yet been sufficiently researched to be implemented in mature E-Learning environments.
- Learning progress measurement is another topic that is inherently difficult, but required to develop personalized and tailored learning situations. Determining the slope of the learning curve and presenting the learner with material, situations, and game scenarios that strike the required

balance between a sufficient level of difficulty to both motivate and not scare off and a suitable engagement factor to keep the learner's interest necessitates the ability to measure how the learner performs in various learning situations. Beyond learning quizzes and game scores, very little exists in terms of progress measurement approaches that can be put to use. Future research must look into aspects like cognitive load theory (Sweller, 2005), psycho-physiological measurements, and game scoring principles aimed at uncovering skills and understanding.

- While electronic learning systems have been designed almost exclusively for individual learning processes, i.e., where single learners obtain material, read, solve problems, etc. using their computers, there seems to be a much higher learning potential if at least part of the learning process can be integrated into a larger community of learners. Theories like learning communities (Wenger, 1999) and knowledge ecology (Qvortrup, 2006) have approached this issue from a social sciences perspective, but very little research has been done in terms of how such theories can be exploited to make E-Learning environments more effective. The strength of various on-line forums shows some of the potential, but we have yet to learn how to stimulate such powerful forums in E-Learning applications.

CONCLUSION

Most SMEs are in terms of organizational structure fairly simply designed, with few departments or units. On the other hand, this means that typically, employees are involved in more than one function or discipline required to run the company. In such integrated areas, decisions are taken that have a crucial influence on the competitiveness and profitability of a company. It is therefore mandatory to find adequate learning processes for these organizations to take up new ideas. E-Learning can help in this respect by:

- Reducing the time it takes an employee to acquire the necessary competences
- Changing the learning context rapidly and in response to the real world
- Facilitating knowledge sharing within the organization
- Supporting a soft failure environment where mistakes have no impact on the real world.

One of the most promising, future-oriented concepts of E-Learning is the use of serious games. Studies have shown that gamers have an edge and advantage over those without gaming experience. By introducing games as a tool in the learning process, changing of behaviour and mindset are stimulated and the organization may gradually be transformed into a learning organization.

The PRIME project has experimented with serious games for project business and on-going manufacturing. The project revealed some recommended guidelines for introducing games as learning tools into an organization:

- Irrespective of how much effort is invested into improving usability, there will always be a learning curve that needs to be tackled by learners. An effective tool to support the leaner is the use of interactive tutorials.
- Learning is more effective in a social and situated context.
- There is a need for single user experiences where a mission is tailored to very specific tasks.
- Learners are partial to simpler missions that require short period of time to be experienced.

- A serious game would benefit from linking to actual learning objects that provide the theoretical background.
- Each session should have a pre-briefing and debriefing to align the learner to what is the purpose of the mission and facilitate the externalization process.

For the delivery of E-Learning content, the concept of hybrid learning is recommended. A successful implementation should follow the following guidelines:

- Develop the courses in cooperation with an academic partner.
- Use hybrid learning based on asynchronous learning for the virtual sessions.
- Base assignments and cases on realistic data from the company.
- Involve the most qualified people from the company in lecturing practical issues.
- Select proven technology for the delivery methods.
- Provide adequate information on the selected approach to the participants before the first plenary session.

There is a need for further research in three directions:

- Design of cost effective technology-enhanced learning platforms that provides tailored learning for the individual users.
- Learning progress measurement.
- Integration of the learner process into larger communities of learners.

Chapter 7
Categorization of Losses across Supply Chains:
Cases of Manufacturing Firms

Priyanka Singh

ICICI Lombard, India

ABSTRACT

Supply chain loss can occur during transit and storage, leading to unnecessary inefficiencies. The literature details much of the traditional losses, albeit descriptively and for developed economies. Through several case studies conducted on the Indian manufacturers and retailers, this case study discusses the losses specific to supply chains operating in developing economies that are difficult to control and prevent even with contemporary enabling technologies such as RFID. This chapter also suggests some possible measures to counter such losses, so as to increase the efficiency and enhance the resilience of the supply chain. An understanding of these losses and their possible mitigation through improved flows, reduced inventory, and reduced manpower, can equip firms for better supply chain risk and productivity management.

INTRODUCTION

Losses are quite common during transit and can occur due to various reasons including theft, tampering and spillage. The type of loss also depends upon the nature of product. Bulk products are more prone to losses than packaged products.

DOI: 10.4018/978-1-4666-1945-6.ch007

Similarly, the type of transport used also determines the losses that would occur in the supply chain. Traditionally, firms allow some tolerance limit for such losses. However, any loss during the supply chain is still a loss. This is truer with increased competition and emphasis on all around cost-cutting. Lets us consider the example of coal transport. If there are 100 trucks supplying coal to a steel plant everyday and each truck can deliver 10 tonnes of coal. A tolerance limit of 1% means there would be a loss of 10 ton of coal every day. Considering the prevailing price of $50 per ton of coal, the total loss would be around $500 everyday and $0.15 million in terms of annual cost. This is a crude estimate.

Different supply chains are prone to different types of losses. For example, supply chains of perishable goods are prone to losses due to perishability of food products. Bulk products are prone to adulteration with lower quality bulk material as well as theft and spillage. Packaged goods are prone to damage during transit and sometimes intentional tampering is done, such as in crockery so that it will be sold at substantially lower prices.

Here, two case studies are reported which were conducted to identify these supply chain losses.

CASE 1: LOSSES IN SUPPLY CHAIN OF BULK PRODUCTS: COAL

The Indian energy sector is largely dependent on coal as the prime source of energy. After the Indian independence, a great need of coal production was felt in first five year plan. In 1951 a working party for the coal industry was setup, which suggested the amalgamation of small and fragmented producing units. This led to the idea of a unified coal sector [1]. Coal is an essential ingredient in various industries such as steel industry, thermal power plants, hydro-electric power plants, manufacturing industry, and cement industry.

Coal Mining in India

In the pre-nationalized era coal mining was controlled by private owners, and suffered from their lack of interest in scientific methods, unhealthy mining practices and sole motive of profiting. The miner lived in sub standard conditions as well. In 1956, the National Coal Development Corporation was formed with 11 collieries with the task of exploring new coalfields and expediting development of new coal mines[1]. The objective of nationalization was the conservation of the scarce coal resources, particularly coking coal. Later the name of NCDC was changed to Coal India Limited (CIL). Coal India Limited is a Schedule ‘A’ ‘Navratna’ Public Sector Undertaking under Ministry of Coal, Government of India, with Headquarters in Kolkata, West Bengal1. CIL is the single largest coal producing company in the world and the largest corporate employer in the country with manpower of 409,332 (as on 1 July 2009). With proven coal reserves of 105.82 Billion Tonnes out of total reserves of 267 Billion Tonnes (as on 1 April 2009) Coal India plays a pivotal role in Indian energy scenario. The Mission of Coal India Limited is to produce the planned quantity of coal, efficiently and economically with due regard to safety, conservation and quality[2]. Coal India is a holding company with seven wholly owned coal producing subsidiary companies and one mine planning & Consultancy Company. It encompasses the whole gamut of identification of coal reserves, detailed exploration followed by design and implementation and optimizing operations for coal extraction in its mines[2]. The producing companies are Eastern Coalfields Limited (ECL), Sanctoria, West Bengal; Bharat Coking Coal Limited (BCCL), Dhanbad, Jharkhand; Central Coalfields Limited (CCL), Ranchi, Jharkhand; South Eastern Coalfields Limited (SECL), Chattisgarh; Western Coalfields Limited (WCL), Nagpur, Maharashtra; Northern Coalfields Limited (NCL), Singrauli, Madhya Pradesh; and Mahanadi Coalfields Limtied (MCL), Sambalpur, Orissa; The consultancy company is Central Mine Planning and Design Institute Limited (CMPDIL), Ranchi, Jharkhand. North Eastern Coalfields (NEC) a small coal producing unit operating in Margherita, Assam is under direct operational control of CIL.

Types of Coal

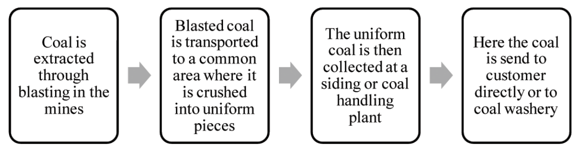
There are various types of coal and coking coal is considered the best variety of coal in India. These coals, when heated in the absence of air, form coherent beads, free from volatiles, with strong and porous mass, called coke. There is also semi-coking coal which when heated in the absence of air form coherent beads not strong enough to be directly fed into the blast furnace. Such coals are blended with coking coal in adequate proportion to make coke. The third variety NLW coking coal is not used in metallurgical industries and is also not acceptable for washing in coal washeries because of its high ash content. This coal is used for power utilities and non-core sector consumers. The coal with high ash content is washed in coal washeries. The washing process reduces the ash content of coal the coal becomes suitable for being used in steel and other industries. The coal without coking properties is known as non-coking coal. The byproducts of coal washing and beneficiation process are called middling and can still be used for various purposes. After removing clean coal and middling from the coal beneficiation processes the leftover is thrown away as rejects. CIL coke/ LTC coke is a smokeless, environment friendly product of coke oven plants.

The gradation of non-coking coal is based on Useful Heat Value (UHV), the gradation of coking coal is based on ash content and for semi coking / weakly coking coal it is based on ash plus moisture content, as in vogue as per notification3. The various grades of coal are listed in Table 1.

The suitability of coal for any particular use depends upon its grade. Table 2 shows the suitability of coal for any particular use.

Mining and Loading of Coal

The process of mining is simple but in practice it is very-very complex. The coal is extracted through blasting and the blasted coal is transported to a crusher, where it is crushed into uniform pieces. The amount of coal transported is crudely recorded in terms of the no. of trips made to the crusher by the truck / dumper and the capacity of the dumper. The coal is then collected at a siding or a coal handling plant. Here the coal is weighted at the weigh bridge and its weight is recorded. The amount of coal received from the mine (no. of trips x capacity of truck / dumper) is then matched with the quantity recorded at weighment bridge.



If impurity content in coal is more than the desired amount than this coal is sent to Coal Washing Plant. The main purpose of this plant is to remove impurity. Once this impurity is removed they are sent to siding. Siding is a place usually near railway stations, where coal from the mine is collected. To avoid any kind of dust disposition, water is spread over the coal. Here also different types of losses occur. If coal is transported to government sector or public sectors, sometimes inferior quality coal is added to require quality at the agreed rate.

From siding coal is transported to different customers and industries through train or truck. When coal is being dispatched, representatives of buyer and seller are present at the delivery point to make sure that the agreed quantity is being dispatched. From here the coal is send to the customer. The major customers of coal include Cement industry, Fertilizer and chemical industries, Steel industry, and Thermal power stations.

Several losses take place during this process. Before the weight is recorded, the losses are basically due to spillage during transportation and minor theft by the miners themselves. Major losses occur due to theft conducted by authorities themselves. Suppose the coal is transported by a truck / dumper from the blasting site to the hopper. If a truck / dumper of 35 tonnes capacity make 10

Table 1. Coal gradation and types

GRADES OF COKING COAL	
Grade	**Ash Content**
Steel Grade –I	Not exceeding 15%
Steel Grade -II	Exceeding 15% but not exceeding 18%
Washery Grade -I	Exceeding 18% but not exceeding 21%
Washery Grade -II	Exceeding 21% but not exceeding 24%
Washery Grade -III	Exceeding 24% but not exceeding 28%
Washery Grade -IV	Exceeding 28% but not exceeding 35%

GRADES OF NON-COKING COAL			
Grade	**Useful Heat Value (UHV) (Kcal/Kg) UHV= 8900-138(A+M)**	**Corresponding Ash% + Moisture % at (60% RH & 40^{O} C)**	**Gross Calorific Value GCV (Kcal/ Kg) (at 5% moisture level)**
A	Exceeding 6200	Not exceeding 19.5	6454
B	5600 to 6200	19.6 to 23.8	6049 to 6454
C	4940 to 5600	23.9 to 28.6	5597 to 6049
D	4200 to 4940	28.7 to 34.0	5089 to 5597
E	3360 to 4200	34.1 to 40.0	4324 to 5089
F	2400 to 3360	40.1 to 47.0	3865 to 4324
G	1300 to 2400	47.1 to 55.0	3113 to 3865

GRADES OF SEMI-COKING AND WEAKLY COKING COAL	
Grade	**Ash + Moisture Content**
Semi coking grade –I	Not exceeding 19%
Semi coking grade –II	Exceeding 19% but not exceeding 24%

GRADES OF NEC COAL		
Grades	**UHV (Kcal/Kg)**	**Corresponding Ash% + Moisture %age**
A	6200-6299	18.85 – 19.57
B	5600 – 6199	19.58 – 23.91

trips then the total quantity transported should be 350 tonnes. If these trucks are overloaded beyond their maximum capacity then the quantity transported would be more than 350 tonnes although the recorded total will still be 350 tonnes. This extra tonnage transported can now be stolen or sold to third party without one being charged for theft.

Theft can also be conducted by the dumper operators who may dump the coal in a different area rather than the stipulated place. Truck drivers either dump some portion of coal (which they carry for transporting of coal) in their area or they use it as mode of making payment to those where they take their meal.

Even at the dispatch locations, the nexus with the security guards and other related people increases the possibility of theft. A truck of coal would cost around Rs. 75000 to the company and if a company loses 10 trucks every month, then such loss would account to Rs. 10 million in annual costs. The total cost due to pilferage is very high to a firm thereby warranting adoption of a

Table 2. Types of coal and their industry use

Industry	Types of coal required
Cokeries/ coke oven plants	Coking and semi-coking coal
Steel making	Coking and semi-coking coal, direct feed and washed; blendable coal; low ash% ASSAM and Ranigunj coal
Sponge iron industry	Non-coking coal of high Initial Deformation Temperature
Domestic fuel making	Semi-coking and non-coking coal; Middlings & rejects of Washeries
Special Smokeless fuel	Semi-coking coal of index 8-10
Power sector	Non coking-coal; middlings of coking coal washeries; washed coal of non-coking coal washeries
Cement sector	Non-coking coal; middlings of coking coal washeries
Steel casting	Non-coking coal
Domestic use, Hotel and Restaurants	Non-coking coal; CIL coke/LTC coke

suitable technology that can improve supply chain visibility. RFID can help reduce theft at the point of dispatch by automating the security operations. Only those trucks that have RFID readers would be allowed to go inside the mines and come out of the mine thus preventing unauthorized entry and exit of trucks.

Transportation of Coal

Coal industries mainly use railways and roadways for transporting coal within the county. India also exports coal in negligible amount through waterways. India's transport sector is large and diverse; it caters to the needs of 1.1 billion people. In 2007, the sector contributed about 5.5 percent to the nation's GDP, with road transportation contributing the lion's share. Good physical connectivity in the urban and rural areas is essential for economic growth. Since the early 1990s, India's growing economy has witnessed a rise in demand for transport infrastructure and services. However, the sector has not been able to keep pace with rising demand and is proving to be a drag on the economy. Major improvements in the sector are required to support the country's continued economic growth and to reduce poverty[4].

Generally bulk products within the country are transported using railways or roadways. Indian Railways is one of the largest railways under single management. It carries some 17 million passengers and 2 million tonnes of freight a day in year 2007 and is one of the world's largest employers[4]. The railways play a leading role in carrying passengers and cargo across India's vast territory. However, most of its major corridors have capacity constraint requiring capacity enhancement plans. Railways provide special types of Bogies for transporting specific material. Steel rods, bars and blooms are generally transported on the chassis of a bogie. Coal is transported in open bogies with hopper. Grains etc. are transported in closed bogies. For transporting petroleum products, the bogies are designed in cylindrical shape. Railways also conduct container transport across the country. Railways are generally preferred for long distance transportation. Indian Railways also provide facility for captive siding where companies can load / unload products transported to their dispatch / unload section.

For short distance, roadways are dominant mode of transportation. They carry almost 90 percent of the country's passenger traffic and 65 percent of its freight. The density of India's highway network -- at 0.66 km of highway per square kilometer of land – is similar to that of the United States (0.65) and much greater than China's (0.16) or Brazil's (0.20)[4]. However, most highways in India are narrow and congested with poor surface quality, and 40 percent of India's villages do not have access to all-weather roads.

Transportation provides mobility to heavy and bulky raw material to basic industries like iron and steel. It leads to economic prosperity and infrastructural development of any economy. Core industries like iron and steel, coal industry, cement industry etc depends heavily on various means of transportation for acquiring its raw material and for making its finished goods available in the market.

Losses during Transportation of Coal from Coal Handling Plant and Coal Washery

The coal being transported to the customer is prone to several types of losses such as theft, spillage and adulteration. These losses are mentioned below:

Spillage

Spillage is one of the major causes of loss during transportation although the loss through spillage is negligible. Because of poor road conditions, potholed roads, speed breakers, narrow pathways etc. the losses take place. However, many-a-times the drivers are quite cautious to not allow such spillage to take place. This allows them to steal the coal and mark it as a loss due to spillage.

Pilferage of Goods / Materials during Transit

Most manufacturing firms in India receive goods in bulk form their raw material suppliers. These materials may include materials such as coal, ore, sand, bricks and petrol / diesel. Firms account for 2-3% of received material as loss during transit and consider this loss as normal. However, the transporters and transport operators take advantage of this allowance to conduct pilferage activities along the route from supplier to customer. Even this 2-3% loss could cost a firm millions of Rupees lost. For example, for a truck of coal transporting 30 tons of coal, pilferage of 1 ton of coal would amount to around 3% of loss. One ton of coal costs around Rs. 1500 to the firm. A firm receiving 30 trucks per day of coal will have to bear around Rs. 45000 everyday and around 1.5 million rupees annually. RFID technology coupled with GPRS technology thus holds a great potential for these firms, but even with RFID it is not easy to contain pilferage of goods during transit. This is because transport operators are known to cause damage to such tracking equipment and show erratic behavior when they are tracked along the supply chain. Moreover, even if their location is tracked, their nexus with naxalites, police and local junta make the task of tracking more difficult for the firm.

Theft and Nexus

This is perhaps the biggest cause of loss during transportation. Truck drivers dump some portion of coal (usually this is equal to the 3-4% tolerance limit of loss allowed during transportation) in their area and use it as a mode of making payment to the highway restaurants where they take meal. Sometimes truck drivers form nexus with people who help them to steal coal during transportation.

Sarda Energy and Minerals Limited, Siltara, Raipur (India) took steps to reduce such coal loss by covering the truck with tarpaulin and sealing it with 50-70 lead seals. A broken lead seals is an indication of tampering done with the sealing and a possible adulteration or theft, although it is likely that the seal may broke during transportation itself. Each seal costs around Rs. 10 thus costing the company Rs. 700 per truck per trip as well as 0.5-1.0 hr taken to seal each truck. The seals have reportedly reduced theft to 0.1%.

Another way to know whether theft has taken place is by recording the total transportation time and comparing it with average transportation time. If the total transportation time is exceedingly large as compared to average transportation time then it is a likely indication of theft.

Adulteration

Adulteration refers to mixing or adding of inferior quality or sub-standard material with the actual product. This happens in the case of coal also. Sometimes stone (usually bigger in size and black in colour) are added to coal to increase its weight. This generally happens when coal is supplied to government sectors. Sometimes, truck drivers replace coal with equivalent quantity of water so as to take care of discrepancy during weighment. These can however be easily revealed through chemical analysis of coal sample.

CASE 2: LOSSES IN SUPPLY CHAIN FOR MANUFACTURED GOODS: STEEL

Simplex Group of Industries is one of the leading Indian manufacturers of varied and diversified Engineering products, Castings and Equipments for all core industrial segments for over 40 years. With such a diversified Engineering experience and technical know-how – coupled with state of the art Design, Manufacturing and NDT facilities, Simplex is now synonyms with quality products worldwide. Simplex Group of Industries has six plants situated in and around Bhilai, Chhattisgarh and Madhya Pradesh. Simplex, as a multifaceted organization, has also acquired a prestigious branding in the heavy industry segment as an Equipment builder, Technology supplier and a Turnkey contractor. With the backing of more than 3000 strong and experienced professional workforce of highly skilled workmen and Engineers including 350 no. of advanced and sophisticated machine tools, meeting customer demands with quality and timely deliveries has become a culture in Simplex. With a well established network of offices in all metropolitan cities and resident representatives in all industrial segments, we are indeed growing by the day[5].

Simplex Castings engaged in manufacture of Heavy Engineering Castings in various grades (as cast supply, machined & assembled condition), for core industrial sector (both Domestic & Global level) like Steel, Power (Thermal, Hydel, Wind), Rail, Road, Mines, Cement, Oil, Defence, Sugar, Construction Earth Moving and other specialized areas. Simplex also contributes to industrial development with its highly experienced and professional staff. Given below is their manufacturing capacity[5].

Manufacturing Facilities at Simplex Castings

Grey Cast Iron Castings: Single piece weight from 05 Kgs. To 32000 Kgs.
Ductile / S.G Iron Castings: Single piece weight from 05 Kgs. To 15000 Kgs.
Cast Steel Castings: Single piece weight from 10 Kgs. To 27000 Kgs.
Stainless Steel Castings: Single piece weight from 350 Kgs. To 12000 Kgs

Other facilities include:

Pattern making: Fully equipped with wood working machines pattern shop with experienced pattern makers.
Heat Treatment: In-house facilities for stress relieving, normalizing, quenching etc. to achieve the properties of castings as per technical delivery conditions.
Machining: Equipped with 300 sophisticated machine tools comprising of Horizontal and Vertical Boring Machines, Milling Machines, CNC Lathe, Radial Drilling Machines, Plano Millers and Tool Planners.
Testing Facilities: At Simplex Castings foundries are equipped with versatile chemical and

physical Dye Penetrating Ultrasonic testing and all destructive and non-destructive facilities including spectrometers, microscope with cameras, cobalt 60 source for radiography, hydrogen analyzer for steel etc.

Basic Design and Detailing Facilities: For carrying out detailed design work, Simplex comprises full-fledged Design Department with CAD facilities, scanners and plotters where we design equipment with minimum possible weight.

Quality Standards: The products of Simplex Castings are accepted by inspection agencies like AAR, LLOYDS, RITES, RDSO, SGS, BUREAU VERITAS and other such international inspection agencies.

The product range at Simplex Castings include unalloyed plain carbon steel casting, alloy steel casting, 1.5% mn steel casting, hi-tensile steel casting, corrosion steel casting, ductile steel casting in d-2 grade, ductile iron, stainless steel casting, cast iron, heat-resistant cast iron, Ni-resistant cast iron.

Supply Chain at Simplex Castings

Raw Materials

In steel casting the two major raw materials are Sponge Iron and Steel Scrap. The sponge iron costs around Rs. 14 per Kg (App. $0.30 per Kg) and the major suppliers are Raipur Alloys, Jindal steel, Monnet Ispat and Topworth Steel. The sponge iron is transported through trucks capable of 24 tons capacity. Steel scrap costs around Rs. 18 per Kg (App. $0.40 per Kg). The major suppliers of steel scrap are Bhilai Steel Plant and Rourkela Steel Plant which transport the scrap via truck capable of carrying 16-18 tons. Some steel scrap is also imported from South Africa and Middle East using waterways to Vishakapatnam Port. From Visakhapatnam the steel scrap is transport by railways and roadways. Around 50-60 Kgs of steel scrap is stolen every week or two.

Steel Casting Process

Figure 2 shows the steel casting process at Simplex Casting.

Marketing and Supply Network of Simplex Castings

Besides its full fledged Marketing Office at all the four metropolitan cities of India, Simplex Castings have representation in all major Industrial Sectors (both National & International level) too. Today Simplex is a rising International Star with a rapidly growing Export Market and a commitment that places customer above all else. Simplex exports castings in as *cast & finish machined condition* to countries like U.S.A., Japan, France, Italy, Australia, and Egypt. Presently their export constitutes 30% of their annual turnover.

Losses during Transportation

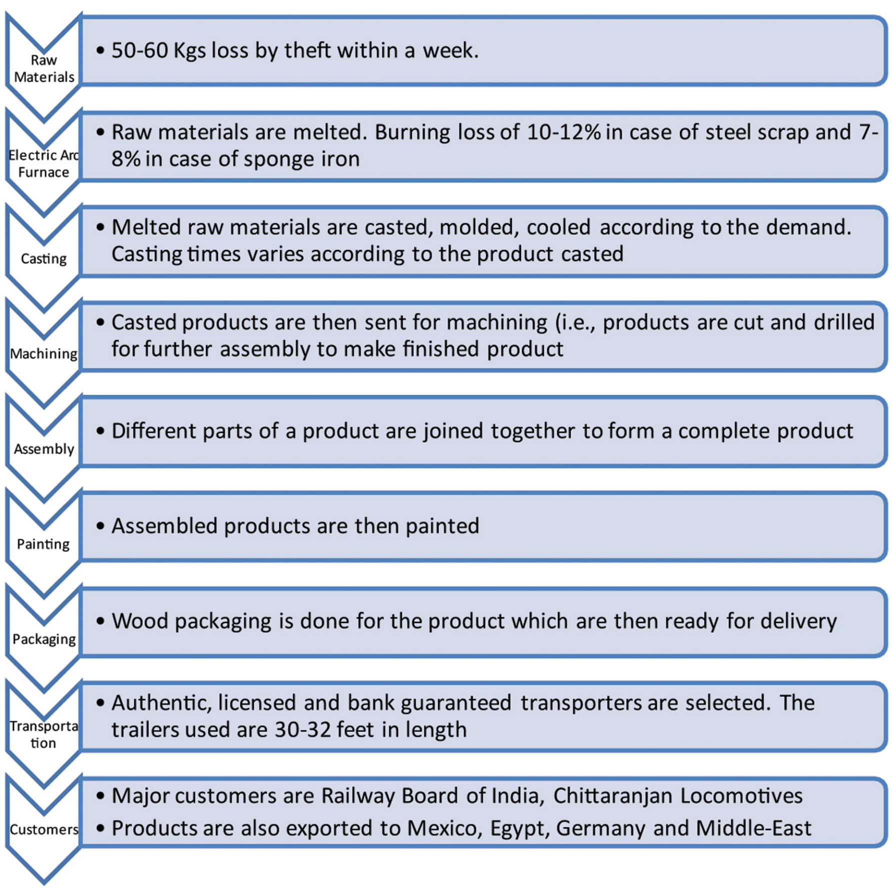
Both direct and indirect losses occur due to supply chain. If there is a delay in supply of raw materials, the production has an adverse effect which in turn affects dispatch of finished products. Delay in transportation also occurs due to strikes and accidents.

Theft usually occurs for small accessories while transportation. It is difficult to steal products that are bigger in size. The accessories that are included with these bigger products are however prone to theft. Moreover, it is difficult to trace the theft of these accessories.

If there is a delay in the time given by customers for delivery of goods LD (Late Delivery) has to be paid by the company which is 0.5% of the total value of the product which is calculated on per month basis. Company has to bear any kind of loss due to accidents while transportation, though the goods are insured but are not 100%, so again there is loss of manpower, energy, raw materials. Due to delay in delivery of products, there is also delay in payment.

Figure 1. Processes at Simplex Castings

Figure 2. Supply chain and steel casting process at Simplex Castings



Another difficulty lies is difficulty in tracking the movement of goods as there is no proper tracking method. Companies are now introducing Global Positioning System on transportation vehicles for tracking them during transportation.

Interference Problem with Steel

RFID tags are vulnerable to interference with steel. Some companies have suggested placing tags by sticking it to the end point of the steel. However, the rugged conditions of manufacturing plant render this possibility useless. Tags must be suitable for bearing wear and tear and hence must be placed snuggly on the bloom. Many RFID vendors have designed tags for steel equipment and these can be used on a trial basis for tagging blooms. These tags can be fitted to the blooms using a screw. However, blooms required for rail mill and plate mill cannot be tagged as they are re-heated / re-melted for further processing.

Reading Distance

In steel plants, at least 6-8 meter distance is required for placing RFID readers. RFID tags can comply with this distance, however, they are costly as compared to ordinary tags and a single tag can cost up to around Rs. 60-100.

CONCLUSION

The current cases discusses about the losses during transportation of bulk products (Coal) and bulky products, namely, steel casts. In case of bulky products, there are only a few reports of theft during the transportation of these products because they are very bulky in nature. The losses commonly occur in such supply chains due to delay in transportation, accidents and strikes. In case of bulk products, however, theft is quite common. The unholy nexus among local people and truck operators is a major cause of losses across supply chains. The remedial measures involve acceptance of Global Positioning System along with RFID technology. Through this technology people can be tracked and if there is unnecessary delay in the Supply Chain they can be questioned. But still there is a long way to go in preventing theft across the supply chain.

ABSTRACT

The focus of manufacturing planning and control has gradually expanded from (in-house) production activities towards all manufacturing and logistic activities in the supply chain. Planning of in-house operations is still very important, but the trends towards increased use of outsourcing and mass customisation require that customers and suppliers are able to exchange information frequently to cut down costs and lead time while quickly adapting their manufacturing and logistics operations to market/customer requirements. Many vendors offer systems to plan and control in-house operations, whereas only a few large vendors (such as Oracle, SAP and I2) offer supply chain planning systems. This limits the ability for SMEs to exploit the supply chain planning options. This chapter discuss current supply chain planning solutions and presents a more simple and adaptive concept to be used in both SMEs and larger enterprises. The research presented in this chapter is funded by the EU Union via the EmpoSME, ValuePole projects, and by the Research Council of Norway via the SFI Norman project.

INTRODUCTION

Most manufacturing companies face strong competition and continuous changes in market and customer requirements. Planning are frequently affected by the actions of suppliers and customers in their supply networks such as changes to orders that are already in production or re-planning caused by lack of materials or resources. Often, decisions have to be made without having a complete, real time overview of possible options and associated consequences. The result is typically excess inventories, too long lead times, too low customer satisfaction and poor resource utilisation.

DOI: 10.4018/978-1-4666-1945-6.ch008

Supply networks are dynamic and hard to define, and a single company is often part of several different supply networks simultaneously. An increasing level of customisation combined with demands for high quality, low costs, short and precise delivery times, and high flexibility represents a significant challenge to managing operations in networks.

Although these challenges will apply to companies of all sizes, they are particularly true for SMEs due to the following characteristics:

- The network are typically non-hierarchical
- They have limited staff available for specialist roles in planning and decision making
- They have limited resources available to invest in Advanced Planning Systems
- They require flexible tools which let them exploit the advantage of typically being flexible and easier to manage than larger enterprises

Observation shows that information exchange is often limited to order placements without any kind of information visibility or other communication between network partners. Thus network effects of individual decisions are often not possible to neither intercept nor predict. This implies that planning and control at any network partner is currently executed with incomplete information about status among the other network partners and without the possibility to see the full consequences of decisions being made. Additionally, the planning and control task will vary with regards to scope and complexity challenging the traditional planning and control approaches, and existing methodologies, tools and knowledge.

The paper briefly discusses three major areas for manufacturing in non-hierarchical networks. After this a more simple and adaptive alternative approach to existing APS solutions is presented, and finally the approach is positioned in a broader perspective titled "Work Bench Concept" to be used in both SMEs and larger enterprises.

COLLABORATION IN NON-HIERARCHICAL NETWORKS

Typical for SMEs is that they operate in non-hierarchical networks, characterised by power being distributed among members, and the absence of one or several dominant actors that dictate plans or impose a centralised planning perspective (Harland et al., 2001). In such networks each member participates in multiple supply chains and all members are more or less equal in status and therefore no member has the power to dictate the others (Jagdev and Thoben, 2001). The core part of each network might form what could be titled as a Virtual Enterprise to share skills or core competencies and resources in order to better respond to business opportunities.

Coordination and collaboration between the companies is vital in such networks. Collaboration refers to the activities and environment related to the "joint planning and execution of supply chain activities" (Ayers, 2006), and is therefore an essential element in planning activities in a network perspective. Collaboration is using cooperative efforts in order to meet mutual goals, exchanging information, developing improvement in partnership (Ayers, 2006). A manufacturing network is fully coordinated when all decisions are aligned to accomplish global system objectives (Sahin and Robinson 2002); of course when this occurs decisions have already crossed the company's boundaries, meeting articulated and complex contexts (Danese et al., 2004). Several collaborative models for coordination networks activities have been developed. The aim of models such as collaborative planning, forecasting and replenishment (CPFR), vendor managed inventory (VMI) and automated replenishment programs (ARP) is to achieve seamless inter-organisational interfaces by specifying control principles and operations models for the flow of materials and information (Holweg et al., 2005).

Collaboration in the network is decentralised and each actor performs individual planning, with the aim of optimising operations in a local perspective. Companies in non-hierarchical networks face challenges that make collaboration difficult. Firstly, the networks themselves are dynamic and hard to define, and a single company is often part of several different manufacturing networks simultaneously. The focal company and other network members frequently face situations with conflicting interest and trade-off situations. A typical scenario is when orders from different networks compete for scarce resources and deadlines and delivery times are short. Frequently, these requirements cannot be fulfilled because there is a lack of information about the current state of the production and network processes. In addition, customers might request changes to orders that are already in production, making it difficult to make quick decisions based on a complete, real time overview of possible options and associated consequences. Secondly, products are becoming more and more sophisticated and intelligent, with service and value added elements embedded in the products themselves. Further, with an increasing level of customisation, and demands for high quality, low costs, short and precise delivery times, and high flexibility, the management of the operations in the networks represents a significant challenge.

Other examples of E-Business Impacts on Supply Chain Integration and Business Processes are seen in Table 1.

One would imagine that the main improvements from implementing information exchange solutions would be a reduction of resources to enter/update information in the ERP-system, but experiences from Electrolux in Australia shows that even more time is released from (not) answering all kind of order related questions on the phone, not only in the administration but also in the production.

MANUFACTURING PLANNING AND CONTROL

The essential task of *manufacturing planning and control* is to efficiently manage the flow of materi-

Table 1. Examples of E-Business Impacts on Supply Chain Integration and Business Processes (Lee & Whang, 2001)

	Business Processes			
Dimensions of SC Integration	*Procurement*	*Order Fulfilment*	*Product Design*	*Post-Sales Support*
Information Integration	Supplier information sharing	Information sharing across the supply chain	Design data sharing, product change plan sharing	Customer usage data linkages
Planning Synchro-nisation	Co-ordinated replenishment	Collaborative planning and co-ordination, demand and supply management	Synchronised new product introduction and rollover plans	Service supply chain planning co-ordination
Workflow Co-ordination	Paperless procurement, auctions, auto replenishment, auto payment	Workflow automation with contract manu-facturers or logistics providers, replenishment services.	Product change management automation, collaborative design	Auto replenishment of consumables
New Business Models	Market exchanges, auctions, secondary markets	Click-and-mortar models, supply chain restructuring, market intelligence & demand management	Mass customisation, new service offerings	Remote sensing & diagnosis, auto-test, downloadable upgrades
Monitoring and Measurement	Contract agreement compliance monitoring	Logistics tracking, order monitoring	Project monitoring	Performance measurement and tracking

als, the utilisation of people and equipment and to respond to customer requirements by utilising the capacity of suppliers and internal resources to meet customer demand (Vollmann et al., 2005). *Planning* across non-hierarchical networks is a complicated and complex task due to conflicting objectives and continuously changing demand. In such a case, the planning and scheduling issues will have to face the challenge of coordinating systems that do not fully share all relevant information between companies (Alvarez, 2007).

Distributed planning in non-hierarchical networks has to be performed in a setting where relevant information from several IT systems are integrated and up to date, and can be accessed in real time from anywhere in the network. This information visibility depends on the exchange of critical data required for the efficient management and control of the flow of products, services and related information between members in the network (Handsfield and Nichols, 2002). Each node should ideally be able to see the real time situation in the network, downstream as well as upstream, from boardroom to shop floor, enabled by *automatic data acquisition*. Although *information visibility* and *system integration* are regarded as keys for enabling collaboration, very few networks have successfully achieved this (Quinn, 2003).

The dominating techniques and systems for planning and control (e.g. Enterprise Resource Planning - ERP, Manufacturing Execution Systems - MES) do not support the need for a network perspective. They have a single-company focus and mainly support centralized production and planning and control (Alvarez, 2007). This makes network planning difficult and inefficient. This amplifies the need for supply chains to rely on flexible, adaptable and responsive planning and *decision support tools* across the entire network (Özbayrak, 2006).

ADVANCED PLANNING AND SCHEDULING

Advanced Planning and Scheduling (APS) systems introduced the benefits of constraint-based planning and optimization to the business world and enabled companies to optimize plans according to financial and other strategic objectives. APS seeks to find feasible, near optimal plans unlike traditional Enterprise Resource Planning (ERP) systems (Stadtler & Kilger, 2005). APS takes into account constraints at enterprise level as well as at plant level. Materials and capacity issues are considered simultaneously, and manufacturing, distribution, and transportation issues are integrated. Many ERP and APS systems make it possible to include suppliers and customers in the planning procedure and thereby optimize a whole supply chain on a real-time basis (Wortmann, 1998; Vollmann et al., 2004; Kennerly & Neely, 2001).

Therefore, APS does not substitute but supplement existing ERP systems. The ERP system handles the basic activities and transactions such as customer orders and accounting whereas the APS system focus on the operational activities related to decision-making, planning, scheduling and control of a supply chain and related management activities, which are not explicitly well covered in ERP systems. APS has the capability to simulate different scenarios for decision support, to plan and to schedule on-line as well as off-line. Planning and scheduling is by nature a proactive process, which can initiate an event in another area of the business or at partners based on the workflow control.

APS is the most comprehensive system for supply chain planning and control today. Although APS aims at automating and computerizing the planning processes by use of simulation and optimization, the decision-making is still made by planners with insight in the particular supply chain and know how on the system constraints but likewise important: a feeling for feasibility of created plans. Thus, APS aim to bridge the gap between the supply chain complexity and the day-to-day operative decisions. This requires, however, that planners are able to model and setup decision rules for the planning and optimization.

According to Petroni (2002) there are several problems involved in using planning software such as high complexity, lack of training and knowledge among managers and personnel, low-data accuracy, and lack of support from the software vendor. Early adopters of APS report significant reductions in cycle time, resource and inventory load (OM Control, 2001; Schell, 2002; Hess, 2002). A study by Funk (2001) however, showed that only 20% of the APS installations investigated were successful (based on a threshold of achieving 70% of projected gain to become a success).

In spite of the supply chain functionality, most APS implementations are limited to a single organization or a single manufacturing site. A few cases can be found in literature on successful supply chain implementations. Gupta et al. (2002), for example, describe a decision support system which helps Pfizer to plan their distribution network. Another study from the Vita Group show an increase in delivery accuracy from 79 up to 99% while reducing lead time from 5-7 days to zero and reducing the planning resources by 30% (Works Management, 2008).

THE WORK BENCH CONCEPT

As pointed out by the US National Institute of Standards and Technology, the 20th century, competitive advantage was defined by the production and labour capabilities of individual original equipment manufacturers (OEMs). In the mid 90s, OEMs sought to reduce those costs by distributing those capabilities across a global supply chain. Competitive advantage is now seen as the combined capabilities of the suppliers that make up the OEMs' supply chain. Therefore, the only way to improve competitive advantage is to improve those combined capabilities through better integration – that is information exchange across the supply chain. The challenge is to develop and demonstrate an open, standards-based, testing and integration infrastructure that enables the automated exchange of information across the supply chain. This infrastructure will provide the foundation for new types of collaboration and management and it will help propel both OEMs and SMEs to a better competitive position in the global marketplace.

The Work Bench Concept is an alternative approach to enable such an infrastructure supporting supply chain planning where decentralised planning decisions are made with regards to individual company operations – but with a network perspective. The main functionality is to operate and manage existing SMEs manufacturing networks. The work bench comprises components for integration of information systems, visualisation of the planning and production situation, communication to enable cooperative decision making under uncertainty, optimisation of plans and simulation of the decisions, network diagnostics and performance monitoring among others. This involves a number of challenges such as providing members access to network-wide real time information (Wang and Wei, 2007), enable visualisation of the available information (Boyson et al., 2003), secure the interaction between advanced ICT based decision support tools and human decision making (Barthélemy et al., 2002), and creating a coordinated and collaborative environment (Deek et al., 2003) for planning and decision making. The state of the art, major challenges and identified requirements are listed in Table 2.

In the following section a supply chain planning approach to solve requirement 2 (Techniques for solving distributed and dynamic planning) is presented.

Table 2. State of the art, challenges and requirements for future supply chain planning solutions

State of the art	• Collaborative practices and methodologies have been developed for coordination between long term supply chain partners. Examples include Vendor Managed Inventory and Collaborative Planning, Forecasting and Replenishment (Holweg et al., 2005). • Predominant manufacturing planning and control techniques are based on centralized production control, with infinite capacity, constant lead time and fixed routings in the single company (Alvarez, 2007). • Decision support tools for network planning and execution are based on optimisation and simulation such as Advanced Planning and Scheduling, Strategic Network Planning etc. (Turban, 2007)
Challenges and conflicts	Existing collaborative practices and methodologies: • Are not supported by low cost ICT-systems • Have a single-company perspective, fail to provide collaborative planning for the network and fail to include the non-hierarchical perspective • Are restricted to centralized planning and control, and lack flexibility and real-time information. • Are out of reach for most SMEs due to the centralized control, high complexity and high cost • Assume centralized control in hierarchical networks and consensus between stakeholders Furthermore, the tools does not: • Address uncertainty and risk adequately • Support a more diversified classification of tasks to enable improved planning results based on a more holistic view. • Enable effective human interaction in decision making • Include presentation and real time information from network • Support an "individual" real-time plan generation
Requirements	1. Planning and control techniques and principles with the capability to handle conflicting objectives, dynamic networks and distributed decision making 2. Techniques for solving distributed and dynamic planning. 3. Full integration with dashboard solutions, allowing real-time decision support with advanced what-if capabilities and graphical, interactive planning boards 4. Simple ICT-supported collaborative methodologies for non-hierarchical network collaboration which: • Consider new manufacturing planning and control techniques for non-hierarchical networks • Explicitly address operational (and selected tactical and strategic issues) as well as operational uncertainties and risk, and cope with the dynamicity and complexity of manufacturing systems • Automate routine tasks, leaving human schedulers to concentrate on exceptions handling

A NEW SUPPLY CHAIN PLANNING APPROACH

Whilst the planning and optimisation procedure used in Advanced Planning and Scheduling systems is the current state-of-the-art for a single company or a hierarchical supply chain/network, planning among individual companies belonging to several non-hierarchical networks require other solutions. The reason for this is quite simple: an APS system need to have a joint goal and clear constrains for the planning engine to work, and this is not obtainable when dealing with several non-hierarchical networks. Furthermore, the hierarchical demand planning approach is based on the premise of aggregation and disaggregation which is reflected in the master demand schedule as well as the structures for capacity and material, the bill-of-resources and bill-of-materials structure. Today's APS systems planning and control capability depends on the ability to aggregate and disaggregate plans and the data they are based on. This makes the structure of the planning foundation critical, unfortunately a simple linear disaggregation of information is not always possible due to the nature of the planning foundation and the multiple usage purposes of the information contained herein.

We therefore present a relative simple solution based on individual ERP or APS plans in the respective companies followed by improvements in between partners. It is assumed that requests from customers (customer orders) have been accepted as far as possible by the ERP/APS system, possibly based on customer priorities (se below) in case of resource or materials shortage.

However, such a plan is normally based on standard customer lead-times to allow the individual ERP-plans to create realistic plans at the first attempt. The option of optimising the joint plan is therefore primarily based on the difference in between standard customer lead-time and actual lead-times in the company.

Solving the challenges related to collaboration in Non-hierarchical network is not new. A concept of Extended Value Chain Management (EVCM) is introduced by Görlitz (2002) as an add-on to the existing ERP-system. The idea is that the EVCM acts as a broker in between a customer and suitable suppliers in the market place. For the broker to identify one or more suppliers each SMEs needs to register on the market place. This solution, however, does not support the option of adjusting plans in between a customer and a supplier to enable a mutual (optimal) solution.

The outmost simple solution is therefore to allow partners to (manually) view the (production) plan and based on this utilise/request the available “free space”. A more far-reaching solution would be to allow customers to also move low priority jobs in order to create extra “free space” and thereby make way for more orders. This solution requires that jobs and customers are segmented and assigned a given priority such as illustrated in Table 3.

Assigning customer priority is a manual task. Job priorities need to be assigned automatically to allow the system to work without consuming extra resources. High priority jobs are typically related to bottleneck resources or customer orders with little or no slack. Low priority jobs could either be related to customer orders with slack or it could be stock orders. Cancellation or reduction of stock orders (jobs) might lead to higher costs depending on the details (in case of high setup costs the ERP-system might generate a stock order in connection with a customer order to reduce the total costs).

The planning approach could work in a more or less manual version where the customer-initiated changes are updated manually, but a more integrated approach would be more beneficial for all parties but also more costly. In both cases the production plan needs to be generated individually for each partner, allowing him to only view details of own orders/jobs whereas other orders/jobs only appear as a coloured (red/yellow/green) anonymous job. Further, no matter how information is changed in the system, the partners in the network likely request to keep track of the changes made. VMI vendors have already invented solutions for this and could be used as an initial source for ideas.

A strong combination of EVCM and the concept described above might lead to a more automated Collaborative Demand and Supply Planning (CDSP) model. This requires that standard interfaces are developed in between the ERP-systems and the CDSP, at least in selected areas such as items and order specifications. The process of exchanging data involves three steps:

- electronic data interchange through a message broker

Table 3. Job and customer priority rules

Jobs: Customers:	High priority (red)	Medium priority (yellow)	Low priority (green)
High priority	Orders are unlikely to be moved (customer requests change)	Orders might be moved (customer requests change)	Orders can be moved (customer initiate change)
Medium priority	Orders can’t be moved	Orders are unlikely to be moved (customer requests change)	Orders might be moved (customer requests change)
Low priority	No access to view plans		

- matching relations (e.g. dealing with different item id's, date-formats, units, timezones etc)
- process integration (in case of systems integration)

One might ask why any company should allow customers to make changes to current production plans and the answer is quite simple: to be attractive and flexible and thereby increase their competitiveness for high- and medium-priority customers. A simple comparison with our own diary would immediately create an understanding of the potential of segmenting and colouring our appointments - avoiding that we are left out of important meetings/activities because of minor/moveable arrangements.

CONCLUSION

In the highly competitive market that most companies find themselves in it is vital to organise the manufacturing and supply chain operations in the best possible way. The first step in this development process is to organise the internal operations in an appropriate and fruitful way, but for most companies there are similar improvements to be made by involving supply chain partners in the planning process. Information access and visibility, new planning and control principles, collaborative mechanisms and new information tools have to be developed in order to meet the particular challenges of SMEs in non-hierarchical networks. The paper discusses the current state of the art applications and outlines a new approach titled "Work Bench" to further improve the planning with special focus on non-hierarchical networks. Especially a simple approach to align production plans is presented.

ACKNOWLEDGMENT

We would like to acknowledge the other partners (SINTEF, Frauenhofer, IMI, ISOIN and UNIBG) of the PLANET FP7 proposal for valuable contribution.

Chapter 9
Instructional Design of an Advanced Interactive Discovery Environment:
Exploring Team Communication and Technology Use in Virtual Collaborative Engineering Problem Solving

YiYan Wu
Syracuse University, USA

Tiffany A. Koszalka
Syracuse University, USA

ABSTRACT

This chapter examines the instructional design of, and reports on research conducted within, a multiuser virtual environment created for a distributed Collaborative Engineering Design (CED) course. The course's Advanced Interactive Discovery Environment (AIDE) provided a variety of synchronous online tools and communication devices to support SameTime virtual team collaboration and problem-solving within the course. The research helped to unpack (1) which tools team members engaged with during collaborative learning activities, (2) how and why they used or did not use provided online features to support their individual learning and enhance team productivity, collaboration, and communication, and (3) how team members communicated socially. The research also describes how different team social communication patterns may be related to the patterns of team technology use. Relevant theoretical frameworks including social learning, media stickiness, cognitive imprinting, and recommendations on how different tools can be effectively integrated into multiuser virtual environments to facilitate learning are discussed.

DOI: 10.4018/978-1-4666-1945-6.ch009

INTRODUCTION

Dieterle and Clarke (2005) advocated that the best learning environments for students are those that are authentic, situated, and distributed across internal and external sources. With advances in computational technologies and network connectivity, Multiuser Virtual Learning Environments (MVEs) and Computer-Supported Collaborative Learning (CSCL) have become more integrated into instructional environments to provide learners with the tools to communicate synchronously in virtual ways. Simultaneously, authentic problem-solving experiences incorporating simulations and sharing applications like electronic whiteboards also began to be integrated into these new multiuser virtual learning environments to create a real-world situated learning experience. Educational environments were thus beginning to be designed to engage learners in the complex distributed collaborative activities experienced by practicing engineers and scientists (Shuman et al., 2002). Such environments can provide learners with dynamic, interactive multiuser virtual spaces in which they are able to engage in rich hands-on learning experiences, apply new content knowledge to legitimate problems, collaborate in problem solving, and use the emerging technologies of their practice.

Geer and Barnes (2006) suggested that with the rapid development of emerging technologies and virtual environments educators face a predicament of deciding which technologies are best suited to support expected learning. Given a lack of knowledge of emerging technologies and lack of pedagogical guidance about integrating technologies for collaboration and communication, educators are often left with mounting dilemmas and confusion about which technology-based resources are most effective for given pedagogies and learning expectations. In addition, the lack of understanding about how students learn in complex distributed collaborative activities and how their cognitive processes operate within synchronous virtual learning environments inhibits the design and implementation of effective and appropriate CSCL environments. As Pellegrino (2006, p.3) stated:

…most current approaches to curriculum, instruction, and assessment are based on theories and models that have not kept pace with modern knowledge of how people learn. They have been designed on the basis of implicit and highly limited conceptions of learning. Those conceptions tend to be fragmented, outdated, and poorly delineated for domains of subject matter knowledge.

In addition, little research has been provided that clarifies the role of communication in multiuser technology use, learning, and problem solving within synchronous computer-mediated learning environments. Limited research has focused on observations of team members becoming more task-oriented and developing clearer role expectations among themselves in online learning communities, with little focus on content or process learning (Jonassen & Kwon, 2001). Numerous researchers who study such multiuser virtual environments have found no conclusive evidence that these environments work, and when and most importantly why they do or do not work (Kirschner et al., 2004). Therefore, additional theories and confirming research are needed to better inform the instructional design (ID) of multiuser virtual environments that facilitate learning of subject matter and appropriately incorporate emerging technologies in pedagogically sound ways.

THEORETICAL FOUNDATON: SOCIAL COMMUNICATION, COGNITIVE IMPRINTING, MEDIA STICKINESS AND THEIR IMPLICATIONS TO ID

Social Communication to Learning in Multiuser Virtual Environments

From social constructivist perspectives, learning is observed to be a social process by which knowledge is generated through a network of collaborative interactions and is distributed among humans and tools that interact (Lowyck & Poysa, 2001). Collaborative learning theories suggest that effective learning requires learners with various types and levels of knowledge to work together toward a common knowledge development goal (Gokhale, 1995). Peers are key players in the human learning process as working together can be beneficial in helping each gain better understanding by 'tossing around' diverse ideas, considering the strengths and weaknesses of each idea, and revising their current knowledge and beliefs in light of new evidence and insights from others (Ormrod, 2008). During social interactions each learner constructs his or her own knowledge and skills and contributes to team member learning (Panitz, 1996).

A learner's cognitive growth can be promoted by peer interactions. Such interactions also tend to stimulate the learner's affect or feelings and motivations. For example, many learners find interactive collaborative learning sessions highly motivating, in part, because such environments address their social needs while they are studying subject matter (Ormrod, 2008). As Chen (1994) observed, students who felt uncomfortable in an educational communication environment avoided social interaction, were less argumentative, and were less willing to advocate their position or challenge other students on controversial issues. Fåhræus (1999) found communication pattern differences among productive and unproductive groups, specifying that the content of productive groups' messages contained higher frequencies of greetings, personal descriptions of participants' professional, social, technological context and questions, and feedback among group members.

Rourke and Anderson (2002) warned that although a moderate amount of social communication created a productive climate for learning, social communication that overtook critical discourse exasperated some learners. Learners welcomed interpersonal interaction during online collaborations. However, if the collaboration became too social and moved away from the task-orientation, learners became very dissatisfied. Thus, social-collaborative learning activities, focusing on learning tasks with a non-disruptive level of informal social communications, are impacting the learners' affective domain (e.g., feelings, emotions) and support cognitive development (learning).

Virtual multiuser environments involve complicated social patterns and communication strategies that often require multiple synchronous communication channels (e.g., voice, video, document sharing, whiteboard features) to engage learners in collaborative tasks and learning. Rourke and Anderson (2002) and others (e.g. CSCL researchers) suggested that further investigation should be made into the nature of these relationships between social communication and learning, especially in synchronous multiuser educational environments where little research has been shared.

Several factors have been identified in prior research that mediate a virtual team's communication, interaction, and its learning process. These factors include learners characteristics, prior content knowledge, cultural differences, provision of a CMC coach, and content of the course (Geer & Barnes, 2007; Hron & Friedrich, 2003; Prinsen, Volman, & Terwel, 2007; Ross 1996; Solimeno et al., 2008). To disclose and understand team communication within virtual multiuser learning environments, this study examined four social communication variables identified as important to synchronous CSCL team communications including the: (1) level of team member participation (Kapur & Kinzer, 2007; Prinsen, Volman, & Terwel, 2007; Ross, 1996); (2) amount of team socialization – time in off-task activities (Rourke & Anderson, 2002); (3) amount of in-team time on-task (Jonassen & Kwon, 2001); and (4) team communication [strategy] differences (Cho et al., 2007; Nussbaum et al., 2004). This data was considered with the team members' overall evaluation of their synchronous collaborative communication experiences and studied in light of the types of technologies provided during individual and collaborative learning activities.

Cognitive Imprinting Theory

Cognitive imprinting (Geer, 2005) accounts for a tendency of multiuser virtual learning groups to repeat early patterns of communication, which can indicate their cognition levels, as they collaboratively solve a problem as a team. Learner initial communication patterns were shown to be powerful in determining subsequent interactive behaviors in synchronous multiuser learning communities. Kapur and Kinzer (2007) found that inequities in team member participation patterns exhibited a high sensitivity to initial exchange and patterns tended to get locked-in early in the discussion, ultimately lowering the quality of discussion and, in turn, the group performance. Furthermore, Geer and Barnes (2007) suggested that the notion of cognitive imprinting can be taken as a means of characterizing the serially consistent cognitive behavior of the students within technology-facilitated learning environments, and further may reflect desired learning outcomes.

Technology Implementation: Media Stickiness Theory

Huysman et al. (2003) suggested the concept of media stickiness to explain the tendency of individuals or groups to maintain early choices of technologies despite the introduction of more useful and value-added technologies. Although distributed virtual teams exhibited distinctly different patterns and preferences for communication, collaboration, and learning technology choices, their choices were generally found to be made early in project work and remained the preferred practice throughout the project.

Both cognitive imprinting and media stickiness imply that team communication and technology adoption patterns rely on student initial cognitive behaviors. Once these cognitive behaviors became habitual the chance of changing patterns was limited. This may in turn constrain student learning of new concepts, skills, and knowledge, especially in creativity and higher order cognition development. Both theories seem to conflict with Rogers' theory of innovation adoption. Rogers (1983) suggested that adopting innovations, like new technology tools, concepts, or skills, is a process of passing from an initial stage of knowledge of an innovation, into a stage of forming an attitude toward the innovation, into a stage of making a decision to adopt or reject the innovation, into a stage of implementing (using) the new innovation, and into a final stage of making a decision to adopt [or not] the innovation.

To support adoption of synchronous multiuser collaboration tools, for example, training should help students develop knowledge and practice using the new technologies. Training should also provide instruction in technology-based collaborative communication skills (e.g., team management strategies) while encouraging students to experiment with the new communication technologies within the virtual environment. As Grabowski and Koszalka (2002) suggested, continuously engaging students with new technologies and repeating such activities helps students form knowledge and attitudes toward innovations that bring them value and aid in adoption.

However, knowledge and practice are not always sufficient in supporting the adoption process. As to technology adoption, it is still not clearly understood whether a lack of knowledge and attitude toward a new technology or a failure in the implementation (use) of a new technology is to blame for lack of adoption. More specifically, no empirical data was found that indicates sticking to an initially chosen technology is a failure in knowledge of a new technology or were there data found that indicate in which stage of the innovation-decision process it is most likely where technology adoption failures may occur. In addition, the concept of habitual inertia (inaction), implied in both the cognitive imprinting and media stickiness theories, is valuable in describing contexts where a constant and repetitive performance is expected to be developed. Therefore, examination of students' team learning processes and understanding of instructional and learning needs will help in understanding when learning inertia may occur, whether it needs to be maintained or stopped, and what instructional interventions may be appropriately designed and implemented to support technology adoption choices.

RESEARCH CONTEXT

A collaborative engineering design (CED) course was created to engage distributed teams of engineering students in a multiuser, blended synchronous and asynchronous, virtual environment to learn about and solve authentic engineering design problems. The CED incorporated a virtual multiuser work environment, the Advanced Interactive Discovery Environment (AIDE), to engage learners with a variety of tools that supported synchronous distributed, interdisciplinary, collaborative engineering design tasks. This environment allowed multiple learners entry into this virtual space to participate synchronously in live lectures and discussions to learn about and apply engineering concepts. Learners were able to employ a variety of communication and analysis tools in a virtual large class setting or in small team activities. While inside the AIDE, learners were able to share ideas and explore solutions orally and visually through audio and video conferencing, shared writing and drawing spaces, and data analysis application sharing. Dietele and Clarke (2005) identified that "…multiuser virtual environments enable multiple simultaneous participants to be able to access virtual contexts, … communicate with other participants, … and take part in experiences incorporating modeling and mentoring about problems similar to those in real world context". The CED AIDE SameTime environment created a significant, interactive, virtual collaboration learning experience by offering innovative instructional ways to students for knowledge sharing and decision-making tasks.

CED COURSE DESIGN

The Study Context, Instructional Design Foundations, and Multiuser Virtual Environments

Instructors from two universities collaboratively taught the semester-long CED course directly to the students from their home institute and synchronously through the AIDE at a distance for those at the partnering institute. Participating students from both universities simultaneously attended course lectures either in-person at their home institute or through multiuser virtual environment synchronous tools depending on which of the two professors was responsible for the session content. Students were assigned to distributed design teams with 50% from the local and 50% from the distance university. Each received instruction in the foundational engineering content and necessary technology skills to participate in the course activities. For several weeks however, the students were split into one of two engineering content learning tracks. Thus students, for the sake of a culminating activity, had different engineering expertise from which to collaborate on a resolution for a given engineering design problem, which required students to create a preliminary design of a thermo-structural system for a specific location on a hypothetical second-generation reusable launch vehicle (RLV) for NASA space missions. Each distributed team therefore had a mix of students from both universities and each of the two engineering content tracks. These distributed engineering design teams thus had to bring together different types of engineering knowledge to collaboratively solve a design problem in an authentic engineering working environment, that is, as distributed interdisciplinary teams working to solve complex engineering problems. The course instructors acted as project managers and mentors to help the teams be successful at their tasks.

The Advanced Interactive Discovery Environment (AIDE) for Engineering Education was developed in partnership between the faculties of the two universities. The AIDE integrated and advanced the best features of virtual, collaborative engineering environments, state-of-the-art simulation tools, and advanced learning management systems (Davidson et al., 2002). Pedagogical approaches, including generative, problem-based, and collaborative instructional strategies formed the structure of the course to fully engaged learners with the AIDE to learn content and learn how to resolve engineering design problems.

The course was also designed to promote skills development in using leading-edge technologies, working on distributed teams, writing project reports, and giving oral presentations. Teamwork was a critical aspect of the course design thus several team building exercises were presented. Early in the semester *best practices* labs were conducted to help students build productive teams using the collaboration technologies available in the AIDE.

Course Technology

The course infrastructure was built with four main components: (1) distance learning classrooms (DLC) equipped with video conferencing system for the synchronous full class instruction – See Figure 1, (2) IP-based web-conferencing to satisfy the needs of multiple simultaneous partial-class events and synchronous team collaboration, (3) asynchronous online information management and communication system provided a platform to document course materials, exchange files, and store engineering discipline-related resources, and (4) a physical design studio and individual tablet-pc provided a suite of technology tools for the students. See Table 1.

The provided multiuser synchronous communication features (SameTime [ST]) included video and audio, interactive shared whiteboard, application sharing, chats, instant messaging, document posting, and presence-awareness. The DST lectures and learners' team meetings were conducted through SameTime. The asynchronous AIDE services (e.g., course announcement, team work spaces, student drop-boxes, threaded discussion board, and team project management tools) also provided supports for team communication and learning activities. See Figure 2.

RESEARCH QUESTIONS

An initial data analyses suggested the course design fostered engineering content learning, CED problem-solving, collaborative technologies

Figure 1. Distance learning classroom. (a) Student view. (b) Faculty view

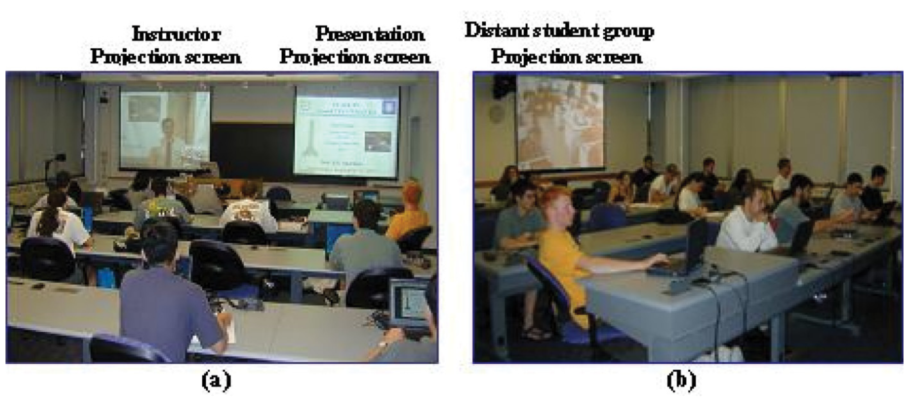

Table 1. Summary of provided classroom and virtual tools

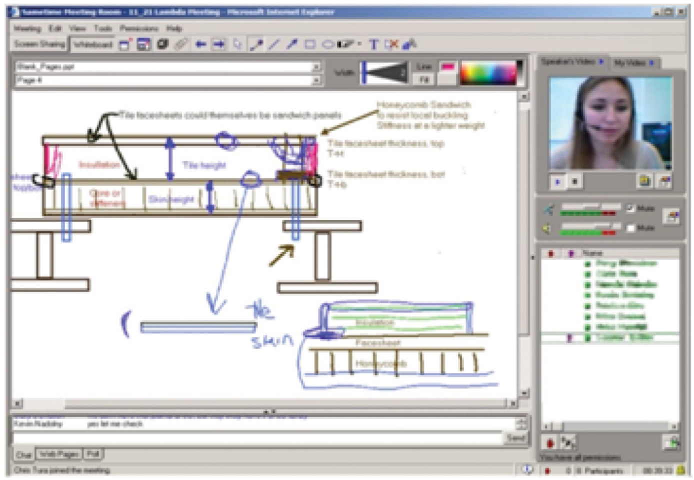
Location	Tools	Description / Key features
Distance Learning Classrooms	• Video conferencing equipment,	Facilitate delivery of instruction and 2-way communication and interaction
	• Projection equipment and electronic white board (facilitate local and distance education)	Facilitate 2-way communication and interaction
	• SmartBoard	Facilitate presentation, document, etc. sharing, communication, and interaction
Design Studio	• Physical lab (at each site) with computer stations	Engineering and analysis software loaded stations to facilitate computation and design activities; supports communication
Course hardware	• Tablet PC for individual students	Provide 24/7 access to AIDE ST for all students
Virtual (AIDE ST)	***Synchronous communications***	
	• Video / audio	Real time (taped/stored) video conferencing
	• Interactive shared whiteboard	Collaborative space where teams can draw, type, color, highlight, etc., all see and edit together
	• Screen sharing	Ability to show all team members an application or document, one person demonstrates and edits
	• Meeting Room Chat	Text-based communication, all can add and see comments posted
	• Polling	Ability for team members to vote in response to posted questions during meetings. question must be posted before a ST meeting session begins
	• Send Web Page	Ability to open and share a Web Page, one person implements and others can see
	• Hand raising	Ability for any team member to take control of talking (audio sharing) during ST session
	Asynchronous Communications	
	• Course announcements	Information, notices, reminders posted by instructors
	• Team work storage spaces	Storage space open only to specified team members
	• Student drop boxes	For submission of each student's assignments
	• Threaded discussion board	Traditional discussion board
	• Team project management tools	Templates to help teams management their progress and report to course managers

knowledge, and development of collaboration skills (Koszalka & Wu, 2008). However, two significant instructional design themes emerged from this initial analysis: designing effective uses of technology resources during collaborative activities and supporting team collaboration strategies. Learners reported that they were not aware of the value some of the provided AIDE tools, how to use them effectively in their collaborative work, or even about the existence of particular tools until late of the semester (Koszalka & Wu, 2008). This feedback appears to support Kirschner et al. (2004) conjectured that learners sometimes participated in online environments very enthusiastically, but often used the tools in a perfunctory way. Learners also tended to display different understandings of team participation and often reported that their team work suffered because of a lack of a team management planning and team structure in the virtual environment. It was not known whether the issue was in the design of the learning environment, the types of technology tools and resources provided, training on the technology tools, or instruction in team

Figure 2. Sample of Web-based synchronous meeting and discussion screen. Participants can see the current speaker, share applications, use chat, and markup whiteboard during the discussion



collaboration and the use of the technology tools during collaborative design activities.

The instructional goals of multiuser virtual environments were to equip learners with cognitive skills through which they learn how to be successful lifelong learners and problem-solvers when they are situated in different contexts facing challenges from new technologies, new people, and new problems. Hence, learners unable to use technologies or to effectively learn in a virtual multiuser CED environment may not yet have obtained the skills and knowledge to be successful in such complex and authentic environments. They may also lack the collaboration skills necessary to participate effectively in collaborative problem-solving activities. Based on these conjectures, the four research questions for this study included:

- Which AIDE SameTime (synchronous multiuser) web-conferencing technology tools did the teams use most often during the CED project? How and why do they use these tools?
- Are there different patterns between the two teams in learning and / or adopting of technologies during the team's AIDE SameTime synchronous web conferencing meetings?
- What type of technology-based communication patterns did each team display?
- Was there a relationship between team communication pattern and team use of AIDE SameTime (synchronous multiuser) technologies during meetings?

METHODS AND DATA COLLECTION

This was a mixed methods exploration of a virtual multiuser collaborative engineering design course with a focus on how learners engaged with the provided synchronous communication tools. A stratified random sample of the synchronous multiuser AIDE SameTime team recorded meetings was identified to ensure that data represented sessions held at the beginning, middle, and end of the course, representing all four units in the course.

The sampled videos were reviewed using a structured video review protocol. A SameTime Video Review Sheet (protocol) was composed of three parts developed from a combination of existing data analysis and demographic protocols and a synthesis of the literature and similar studies on social learning activities (Geer & Barnes, 2007; Huysman et al., 2003; Ross, 1996; Rourke & Anderson, 2002). Part I of the review protocol was a Technology / Media Use & Computer Tools Competence Table, adapted from Huysman et al.'s (2003) team media-use pattern table. Part II was a SameTime Tech-mediated Team Communication protocol created through the synthesis of the literature on variables of social collaboration that affect learning during distributed learning activities. Part III was a series of evaluative and demographic questions to provide descriptive information about the teams and their members. Each video was reviewed by two coders who used the SameTime Video Review Sheet to gather a variety of qualitative data.

DATA ANALYSIS

One-hundred and forty-two SameTime team meetings were recorded during the course, 83 were usable as data. A stratified random sampling technique was used to select ten videos, five each from two CED teams. The videos represented both teams and all time periods over the course. The ten videos represented approximately 855 minutes of team interactions. See table 2.

Three doctoral students were recruited and trained as coders. Each sampled video was reviewed by two coders. The inter-rater reliability of the coding was 89.96%. All data was imported into QDA Miner software for coding. Seventy-two sub-codes were produced under four major categories: (1) demographics, (2) technology use, (3) team communication, and (4) reflection.

RESULTS

Overall, the data suggested that the two teams had different technology use patterns and communication strategies. Specific results for each research questions are presented below.

R. Q. 1: Which AIDE SameTime (Multiuser Synchronous) Web-Conferencing Technology Tools Did the Team Use Most Often during the CED Project? How and Why Do They Use These Tools?

Major SameTime Tools Used

It was observed that audio, video, interactive whiteboard, window chat room and screen sharing were the five major SameTime multiuser tools most frequently used in the sampled synchronous meeting videos.

Interactive whiteboard: The WB was used when the team members collaborated on the team project. The most frequently used Whiteboard features included the pen, presenting, changing slides, and eraser. The two teams seemed comfortable using different editing and communicating features provided by the interactive whiteboard. They used these tools to review team documents, take notes, brainstorm, visualize their thoughts through writing or drawing, and cooperate on

Table 2. Descriptive information of analyzed team communication videos

Team	Sept. 12	Sept. 15	Sept. 21	Oct. 5	Oct. 27	Oct. 31	Nov. 5	Nov. 14	Nov. 29	Total video minutes
Alpha	1		1	1		1		1		484
Gamma		1		1	1		1		1	371
Subtotal	**1**	**1**	**1**	**2**	**1**	**1**	**1**	**1**	**1**	**855**

scheduling and team logistics, or to merely scrawl for fun.

Window chat room: This feature was frequently used to (1) backup to audio for brainstorming, (2) express an opinion, inform, comment, send out a query, or respond without interrupting the audio, or (3) joke, give a salute or acknowledge to teammate without interrupting the audio.

Screen sharing: The AIDE SameTime Screen Sharing features were used regularly by the Alpha team. The screen sharing does not allow multi-editors. The person sharing the screen took notes on his or her screen during team discussions and the other team members ensured that all changes were recorded correctly as they read the shared screen. As was observed, uploading the screen sharing document was time consuming and running the screen sharing tool slowed the performance of other SameTime tools (e.g., audio, video). The screen sharing feature was used less frequently by the Alpha team toward the end of the semester.

Computer audio and video: The audio and video features were the most commonly used synchronous communication features of the AIDE SameTime.

R. Q. 2: Are there Different Patterns Between the Two Teams in Learning and / or Adopting Technologies during the Team's AIDE SameTime Synchronous Web Conferencing Meetings?

Team Differences in Multiuser Technology Uses

At the beginning of the semester, both teams were observed practicing different technologies and tools to a certain level within the SameTime meeting environment. The two teams presented different technology use patterns and these differences included:

Number of tools used: The Alpha team members were observed using ST tools extensively while the Gamma team members were observed using only the basic meeting features, such as presenting documents and pen tools that the interactive whiteboard supports. Among the 14 mini-features of the interactive whiteboard, the Alpha team experimented and used 13 while the Gamma team only used 7 (see Tables 3 & 4). In addition, Gamma team was rarely observed using screen-sharing and send-web-page features in the sampled SameTime videos.

Use frequency of major tools: The Alpha team used interactive whiteboard 3 times more often and the window chat room 10 times more often than the Gamma team. In addition, the Alpha team used the screen sharing application four times while the Gamma team never used it (see Figures 3 and 4).

The window chat room was the technology reported most commonly used by the students in their daily life routines outside of classes; therefore, it was presumed that students felt more comfortable using chat than other SameTime technologies. Data suggested that the Alpha team used chat very commonly throughout the entire semester while the Gamma team was observed using the chat feature less often. The chat was used as the major salutation tool by the Gamma team when someone accessed the meeting late. As the Gamma team became more familiar with the SameTime environment and the audio equipment, they generally used oral conversation, rarely using the chat or other SameTime communication tools.

Issues and difficulties: The more frequently and higher number of technology tools used during sessions the more issues or difficulties arose. For example, the Alpha team used more different tools, more often, than the Gamma team. The Alpha team also encountered 43 technology issues, 8 times more than those encountered by the Gamma team. See Table 5.

Patterns of technology use: Both the Alpha and Gamma teams were observed experimenting with the SameTime technology regularly at the

beginning of the project. Their technology uses continuously increased until the middle of the semester. Pen and chat became the two dominant collaboration tools for the Alpha team. However, the Gamma team dramatically decreased their use of technology and seldom used the SameTime tools toward the end of the semester.

Window Chat Room		**7**	**8**	**0**	**0**	**7**	**22**

Tool choices: Both Alpha and Gamma teams were sometimes observed using less efficient tools for a task. For example, one person in the Gamma team consistently orally described his analysis work rather than using screen sharing tool to present his work. It was also observed that when both teams had to change slides or go back-and-forth more than one slide, they kept go-

Total	**43**					**5**	

ing slide-by-slide rather than using the dropdown menu to go directly to the desired slide. These choices decreased the productivity of the meeting.

Overall Evaluation of Use of Multiuser SameTime Tools

The data generated in this study confirms media stickiness existing in students' use of technologies by revealing:

Stickiness to the SameTime tools used at the early stage of the semester: In addition to the audio and video, the pen and chat were two new AIDE SameTime technologies that both teams stuck with throughout the semester. This suggests that the team members identified these tools as valuable to their collaborative work, easy to learn and use in virtual communication, and developed the skills to use them effectively; but found some of the provided tools were not efficient, or too difficult to use for their communications and problem solving activities.

Stickiness to the traditional way of using tools: Chat was promoted by the instructors and required to be used as brainstorming tool in one of the Best Practice sessions. The instructors required the teams to record their thoughts in the chat when the team brainstormed for their Ball-in-pipe assignment. However, chat was rarely observed being used as brainstorming and recording tool in the later team meetings. There was, on several occasions, one member of the Gamma team who was observed suggesting the use of the chat feature to record key ideas generated in the team discussions but his proposal was never accepted by other team members.

Traditional technologies used for communication outside of the SameTime environment: Additional data was gathered suggesting that students from both teams continued to use text messaging, cell phone, and emails most frequently outside of the ADIE to exchange documents or to inform each other of scheduling changes or other emergencies. This suggests that the student were comfortable with these everyday tools, saw value in them for communicating with their teammates, and perhaps were not as comfortable with using only the provided AIDE tools.

TEAM COMMUNICATION

R. Q. 3: What type of Technology-Based Social Communication Patterns did Each Team Display?

Team Participation

Alpha team: At the start of the semester, the moderator[1] of the meeting tended to take more initiative and be more expressive during virtual meetings. The moderator usually dominated the conversation and ensured that the team was on track. In general, the interaction among team members was well-balanced and participation of the team members was generally equal. It was often observed that two students would take one side of an issue or argument and the other two members would support a different idea or approach. After

AF[2] joined the Alpha team (mid-semester) the team dynamics were observed to change. AF appeared to have a good grasp of the content knowledge and be very focused on tasks. AF began to lead and dominate many of the discussions in a majority of the meetings.

Gamma team: In general, participation was roughly equal for members GL, BZ, and BK. MW[3] was observed to have a fair level of engagement at the semester start; however, MW's participation became less toward the semester end. BZ and GL were often observed taking over as leaders and polarizing the discussion. BK was not central to the group suggestions but his contributions were thoughtful suggesting he was listening and waiting for appropriate times to contribute. It is worth noting that when GL was not attending a meeting, the team dynamics changed slightly. BK and BZ took over as conversation leaders and BK became well conversed.

On-Task Performance

Both Alpha and Gamma teams appeared to be task-oriented and deadline driven during their synchronous virtual meetings. They each had specific tasks to accomplish in every session. The meeting usually started with technology normalization checking that all team members had the SameTime set-up and ensured proper SameTime functioning. Depending on tasks, meeting time was sometimes separated into individual work and team collaboration periods. During individual work time, each member worked on his own solution to a common problem and then the team collaborated by exchanging, discussing, and comparing individual thoughts. At the end of the meeting, the teams usually scheduled the next meeting time and discussed team logistics. Although common collaboration routines were used by both teams, on-task performance and communication patterns were different.

Alpha team: Alpha team meetings and working structures were relatively loose. Team members were observed having food or beverage during meetings, being late, stepping away in the middle of the discussion, or chatting casually. There did not appear to be a team management strategy and the team productivity was low. Feedback from one of the instructors suggested that the Alpha team had a weak plan for their design project, without specifics as to who was to complete each task and by when. The Alpha team did not have an effective scheduling process – they spent much longer in their scheduling phase than was necessary, leaving them less working time for their design project. The team spent up to 35 minutes at the meeting start trying to schedule the next session yet could not reach consensus on a time that fit everyone's schedule. After 15 minutes of content discussion, the team returned to discuss scheduling finally identifying a tentative schedule.

Content related jokes were generated during team conversations. The Alpha team members were occasionally observed teasing their team members. The jokes created by the team were entertaining and may have helped them relax. However, the jokes may also have been distracting to team productivity. It was observed that after joking around it sometimes took long periods of time to refocus on the meeting goals.

Gamma team: the Gamma team was strongly focused on project content and tasks. When the meeting started, team members briefly checked the technologies and greeted their peers. They quickly moved onto tasks. Based on the feedback from one of the instructors, the Gamma team had a reasonably good plan for their design project with dates, specific tasks, and assignments.

Socialization and Off-Task Time

Major reasons causing the team to get off-task included: waiting for other team members to login in, encountering technology problems, such as someone's voice was cut off, waiting for the screen sharing application to open, team members needing to step away, and frustration from the lack of focus during team discussions. The Alpha team was observed being off-task more than ten times. Meanwhile, it was rarely observed that the Gamma team was off task.

Team Dynamics and Communication Differences

Personality vs. Teamality: Every student appeared to react differently to a particular problem perhaps due to their personality differences. However, when the students worked as a team, every team started forming its communication characteristics, or we may name it *teamality*, regardless the diversity its team members' personalities appeared.

Alpha team examples: The five team members in the Alpha team sometimes appeared to behave differently. For instance, MA appears to like the role as moderator, often taking charge and making decisions quickly. AB appeared more detached, not participating very often, and seeking the most straightforward solutions. LS, in contrast, was observed using technology more and really wanted to tackle the solution by sticking to his own thoughts and plan. JR preferred a more pragmatic approach while settling for a feasible solution, if possible. AF joined the team late and showed excellent content knowledge among all the team members. However, the students together formed some unique team characteristics. The Alpha members appeared to have strong interests in exploring the ST technologies and therefore practiced most of the tools at the beginning of the semester. The ST tools, especially the Whiteboard features, were used as collaboration tools and also used for fun activities. For instance, team Alpha members sometimes use color pens to draw cartoon images or play games (e.g., tic-tac-toe) during the off-task periods. Therefore, compared to the Gamma team, they were observed to be able to choose more effective tools or use multiple tools in their practice. For example, they used rectangle tool to build tables or used color tools to differentiate or highlight key points. At another side, the team appeared to easily lose focus and their meetings therefore resulted in low productivity. This may be explained by: (a) more technical issues encountered by the team increased the average meeting time which may bring up meeting fatigue; (b) side-talks, off-track conversations, or jokes that distracted the team attention and delayed work progress.

Gamma team examples: Personality differences among the Gamma team members may explain their different levels of participation. GL and BZ seem to be more talkative and social. They usually appeared to dominate most of the team conversation and maneuvered the direction of the meetings. BK seems to be very confident in the content knowledge and he was very conversant when he started talking about the content and his analysis work. It was difficult to make any judgment about MW because he rarely spoke during the meetings. Although every person was observed having distinctive personalities, the Gamma team appeared to have different *teamality* from the Alpha team. The team was very task-focused. Members were rarely observed in side-talks or joking. The team seemed satisfied with basic communication features (e.g., audio). Therefore, the team used fewer AIDE features, encountered much fewer technology issues, and appeared to have more efficient and effective meeting sessions and produced higher-quality performance.

Other Differences

Two other factors seemed to contribute to the team dynamics and may have influenced team communication pattern: content and institutional differences.

Content knowledge differences: The students who had better content knowledge appeared to engage more in team conversations. Although these students may show different personalities, they appeared to be more confident, conversant, and prepared, often raising good questions about particular points and, in most situations, dominated in the entire meeting. For instance, AF in the Alpha team appeared to be a good leader steering the team in proper directions. BK in the Gamma team always participated at the key times providing insightful thoughts, clarifying explanation and ideas. These students were observed less engaged in the off-task activities and chatter. This trend was observed throughout the entire semester.

Institutional differences: The institutional differences were distinctive between the Gamma team members. The two CU students focused more on problem solving, searching and utilizing more resources outside of the course to help with their analysis process. Meanwhile, the two SU students were more concerned about the timeline of completing the design project and appeared to have more team management skills. Skills from students from the two universities contributed to the success of the team performance.

Overall Evaluation of Team Communication

Overall, three major team communication themes emerged from the data analysis. First, different personalities, institutional cultures, content knowledge and skills contributed to the dynamics of each team. Second, data suggested from the cognitive imprinting theory perspective (Geer, 2005), a team's initial communication patterns were powerful predictors in determining subsequent interactive behaviors. However, the data also suggests that the team's communication pattern may change when the team dynamics change. For example, when the GL was not present, BK became conversant. He and BZ were observed dominating the conversation. Third, an explanation for AF's minor engagement in meetings still remains mystery at this point. Data collected from the sample archival video data do not suggest rationale for his limited engagement. However, when GL and BZ called MW several times asking for his thoughts about the design project MW rarely was able to provide a complete answer. Perhaps MW did not have sufficient content knowledge or he was not motivated to participate. There were also several occasions when MW was not in the meetings and GL criticized his low quality work commenting that this was 'the crappiest work he had ever seen.' Other members did not make specific comments, however, seemed to agree with GL. Thus, dynamics of the team, cognitive and initial media preferences, and unidentified individual characteristics were related to communication effectiveness and team productivity.

CONCLUSION

Team Communication vs. Team Technology Use and Adoption

This study helps extend the media stickiness theory by discovering that a person's choice of a particular technology within a virtual multiuser learning environment and sticking to its use relies primarily on needs related to communication, socialization, or problem solving. This perspective aligns with Geer and Barnes' (2007) suggestion that "…high levels of creativity through collaboration … are not always necessary to their immediate goals … the learning of participants needs to be considered." (p. 135). When a team's communication needs are satisfied, motivation for using other new tools is limited therefore tools deemed useless are eventually dropped suggesting the team does not see the necessity of using the tool regardless of how well it was designed to meet a communication need. For example, the Gamma team was observed sticking to the pen tool to draw tables rather than using the rectangle tool. This may be explained by the fact that the pen was sufficient and easy to use and use of the rectangle tools was more time consuming. Changing to a new way of working required a cost-benefit analysis (Huysman et al., 2003) suggesting that the cost of using the rectangle tools was more than using the pen tool in this case. Students' communication needs played a major role in the variation of tools they use and how long they continue to use each tool.

Adopting particular technologies and sticking to their use are not simply a team or any particular individual's decision. A team's selection of specific technologies tends to have the following characteristics: technologies frequently used in team members' daily life are more often adopted by the team and personal interests in technologies intrigue members into practicing additional new technologies but does not necessarily lead to the adoption of a particular new technology. The second characteristic may conflict with what Huysman et al. (2003) suggested that "lack of internal communication process was one potential source of media stickiness in virtual teams" (p. 432). JD in the Alpha team suggested using the typing tool instead of pen writing at the beginning of the semester. Some of the team members followed him using the typing tool, however typing was eventually dropped while pen writing remained a common activity. External feedback does not seem to promote students' adoption of particular tools either. The two instructors commented several times that neither team appeared to use the SameTime technology adequately although they had sufficient technology competences. However, the feedback criticizing these teams' habitual way of working did not have enough power to make a permanent change in both teams' technology use.

Two possible explanations for the media stickiness observed in this study are: 1) students may realize that use of more tools causes more technical issues and 2) using many tools reduced the teams' productivity and ability to meet assignment deadlines. Due to the busy schedule of the team members, the teams usually had one hour meeting times in which they needed to accomplish multiple tasks including technology normalization, scheduling, team logistics, and content discussion. Therefore experimenting with different new tools may have been deemed a low priority on the team's task list.

Team's technology use may relate to the team's communication characteristics. It was observed that the Alpha team, who practiced more technologies and encountered more technology issues, had lower productivity. While the Gamma team, using few technologies and rarely encountering technology issues, had much higher productivity and performed better in team management. This possible connection may suggest that the Alpha team did not have good team management skills to prioritize tasks. This also suggests that if the students face multiple learning goals (e.g., learning technology and learning content knowledge), they may not be able to do well in every goal if the task load is beyond their ability. As some of the students suggested that the course should be designed as one-year course because there were too many concepts to learn. Therefore, two instructional interventions to consider in the future course design include: 1) providing constant feedback in terms of team management including topics such as how to prioritize tasks and 2) balance instructional goals, student learning load, and the time allowed for completing the course.

Various factors contributed to team dynamics, which results in the formation of a team's 'personality' – or its *teamality*. A team's teamality may suggest a team's communication pattern, its technology choices, and the team management strategy. These patterns would remain consistent and / or grow stronger (e.g., MW in the Gamma team appeared to participate less and less in the meeting throughout the semester) as the theory of cognitive imprinting suggests. However, the data in this study also implies that when the team dynamics are altered due to some change in the team (e.g., more members joined the team, or someone is not present in the meeting), teamality would also change, which hence impacts the team's communication patterns and team productivity. For example, the Alpha team was observed becoming more productive after AF joined. In the future instructional design, it may be important to switch team members at the beginning of the course (e.g., in the Best Practices sessions) to help students learn about different personalities and communication patterns in virtual teams. Hence, they may be able to more quickly fit into a team collaboration culture and to develop more mature and insightful thoughts about how to learn with a team.

This study has revealed very specific details about how two distributed teams worked within a synchronous multiuser environment. The video analysis, surveying, and document analysis have allowed an intimate investigation of how and why learners use system and non-system technology based tools to collaborate, problem solve, and learn. These data suggested a 'teamality' variable influenced by the team dynamics, technology choices, and individual members' characteristics. Further unpacking of this concept may help in designing more powerful synchronous virtual learning environments and tools that help learners engage in deep learning and develop the competencies to be successful in multiuser virtual environments.

ENDNOTES

1 Team members took turns as the team moderator. The responsibilities of the meeting moderator included: (a) scheduling meetings and notifying the team (b) checking the ST technology to ensure it was functioning normally before the meeting; (c) uploading meeting agendas, assignments, and relevant documents to ST meeting before the meeting; (d). recording the meeting; (e). closing the recording and meeting

2 The Delta team was dismissed because three students dropped from the course. The composition of each team was reshuffled and AF was assigned to the Alpha team.

3 GL and MW were from SU and BZ and BK were from CU

Chapter 10
Modes of Open Innovation in Service Industries and Process Innovation:
A Comparative Analysis

Sean Kask
INGENIO (CSIC-UPV), Spain

ABSTRACT

This broad study empirically compares the returns to different open innovation approaches, namely forms of pecuniary acquisition and non-pecuniary sourcing, on both product and process innovation in low-tech service and manufacturing firms. A fixed-effects analysis reveals differing patterns of the effectiveness of open innovation strategies across sectors and type of innovation outcome, along with decreasing returns from being "too open". In general, the purchase of intangible intellectual property and broad search breadth have greater effects on product innovation, whereas the returns to knowledge embodied in physical artefacts and to drawing deeply from external sources are greater for process innovation. Overall, external sources of knowledge more strongly predict innovation in low-tech service firms than in the manufacturing sector. The final section considers implications for managers and policy makers.

INTRODUCTION

Open innovation, which posits that firms should use external knowledge in their internal innovation process, is an approach which is increasingly embraced by firms. In the short time since the term *open innovation* has been coined (Chesbrough, 2003b), numerous academic research projects, conferences, and specialized service providers quickly sprung up dedicated to the topic (Fredberg, Elmquist, & Ollila, 2008; Lichtenthaler, 2011). Many corporations have recently started to formalize open innovation into designated departments and roles; consider, for example, Hewlett-Packard's "Open Innovation Office" or

DOI: 10.4018/978-1-4666-1945-6.ch010

the employees with the job title "Director of Open Innovation" walking the halls of General Mills, Nokia, and Unilever. A number of leading firms have introduced open innovation competitions and initiatives, such as Sarah Lee's Open Innovation Portal or Cisco's I-Prize competition (Drakos, 2008). Indeed, authors have observed a bandwagon effect as open innovation gains momentum, with many senior executives "under increasing pressure to justify their refusal to cooperate with the outside world and exploit the open innovation wave" (Gassmann, Enkel, & Chesbrough, 2010: 215). Supported by numerous case studies that corroborate the positive results of open strategies (Chesbrough & Garman, 2009; Huston & Sakkab, 2006; Rohrbeck, Hölzle, & Gemünden, 2009), open innovation has become an imperative for firms over a relatively brief period of time.

However, despite all the excitement as policy makers and firms race to embrace open innovation, most of the research is drawn from case studies on product development in large, multinational high-tech firms or niche business models and open source (Chesbrough & Crowther, 2006). This means that, as a young, emerging theory, it lacks empirical support and generalizability across diverse conditions and businesses (Van de Vrande, Vanhaverbeke, & Gassmann, 2010; West, Vanhaverbeke, & Chesbrough, 2006: 302).

This chapter looks at some of these understudied circumstances by addressing different sectors, modes of open innovation, and objectives. In particular, it (1) compares the effectiveness of various inbound open innovation activities between low-tech manufacturing and service sectors; (2) evaluates the returns to several strategies for conducting open innovation, including different forms of pecuniary (monetary) and non-pecuniary external sourcing; (3) and examines objectives beyond products to include a firm's process innovation. The chapter also includes a discussion and analysis of the potentially adverse consequences of being "too open". The analysis links these factors to firm innovation performance by comparing the "returns" or "effect sizes" across innovation type and sectors. Thus the general aim is to bring these important yet understudied topics into the open innovation discussion. A panel survey of innovation activities in 3,800 Spanish low-tech manufacturing and service firms over a four year period provides the sample for the analysis.

The remainder of the chapter is organized as follows: (1) the first section reviews the literature and generates several hypotheses. This includes a review of process innovation, the nature of innovation in the service industries, the relationship of different modes of inbound open innovation with these factors, and decreasing returns from over-searching. (2) The empirical section presents the data and variables used in the analysis. It explains the methodology and advantages of fixed-effects estimation. (3) The next section discusses the results of the empirical estimations in relation to the hypotheses and the significance of the uncovered patterns. (4) The concluding section proposes implications for managers and policy makers and identifies directions for future research.

THEORY DEVELOPMENT AND HYPOTHESES

Product and Process Innovation

To date, the open innovation literature has focused on the generation of commercial products. Unfortunately, this concentration on product development neglects an important avenue of firm competitiveness and profitability: process innovation (Niehaves, 2010). Process innovation is defined as "new elements introduced into an organization's production or service operations—input materials, task specifications, work and information flow mechanisms, and equipment used to produce a product or render a service—with the aim of achieving lower costs and/or higher product quality" (Reichstein & Salter, 2006). Process innovation is an important source of firm performance and productivity growth (Vivero, 2002), and new processes used to produce and deliver goods and services are often central to a firm's ability to compete in terms of costs, quality, and flexibility (Pisano, 1997). The following section links differences in product and process innovation to particular open innovation activities.

Further to simply including process innovation, the structure of the analysis enables a distinction between process innovation in service and manufacturing sectors. Process innovation in service industries can differ substantially from that in manufacturing since, often by nature, the delivery of the service is tied to the locus of its production (Berry, Venkatesh, Parish, Cadwallader, & Dotzel, 2006). Competitive advantage comes not merely from *what* a service firm does for a customer, but *how* it is delivered. Since some authors argue that services are commoditized at an even faster rate than most goods (Pine & Gilmore, 1999), even low-tech service firms must continuously innovate in order to remain competitive. Therefore, returns to sourcing strategies on process innovation are considered and compared between industries in the analysis.

Modes of Inbound Open Innovation

Innovative search describes the adaptive process by which organizations learn, develop and explore new technologies and new ways of doing things (Levinthal & March, 1981). Search efforts can be inwardly (e.g. R&D, operations analysis) or externally (e.g. imitation, external sourcing) focused (Nelson & Winter, 1973), can vary in depth and scope of information sources accessed (Katila & Ahuja, 2002), and can be directed towards sources both within and external to a firm's industry (Katila, 2002). Each search strategy can thus vary along many dimensions such as locus, timing, knowledge source, and the degree to which limited resources are directed towards exploring new ideas or exploiting existing knowledge (March, 1991). Chesbrough's argument for the shift towards an open innovation paradigm predicts search strategies that are more externally oriented. As such, there is variety in potential external search strategies available to firms. More generally, firms differ in the level and nature of "openness", defined as "the degree to which the firm seeks to draw in new knowledge and to re-use existing knowledge from external sources" (Laursen & Salter, 2004). Accordingly, different search strategies result in differing degrees of innovative performance depending on the nature of the innovation in question.

Although much of the original rationale for open innovation revolves around inadvertent spill-overs and missed opportunities to commercialize technologies developed in-house, or "inside-out" open innovation (Chesbrough, 2003b; Chesbrough & Rosenbloom, 2002), the research and practitioner interest to date has focused on the benefits of "outside-in" open innovation. This "inbound" open innovation involves identifying and appropriating external knowledge for commercialization or implementation. Two meaningful dimensions of inbound open innovation are sourcing (non-pecuniary) and acquiring (pecuniary) (Dahlander & Gann, 2010).

Acquiring involves the procurement and purchase of intellectual property (IP) or artefacts developed outside the firm. Firms may buy external technology for any number of reasons, such as insufficient internal R&D resources, diversification into new competencies, or simply to access cutting-edge, specialized technologies developed by other organizations (Lowe & Taylor, 1998). Since some pecuniary, commercial transaction takes place, acquiring infers that the firm foresees some immediate application for the externally-sourced knowledge artefact. In other words, since it is unlikely that a firm would expend financial resources simply for the purposes of exploration, acquiring occurs with exploitation and direct application or commercialization in mind. I further consider two forms of pecuniary open innovation: the acquisition of *intangible* (or disembodied) knowledge in the form of patents, licences, or other IP, and the purchase of tangible knowledge *embodied* in physical artefacts such as machinery, equipment, and software (Baetjer, 2000; Vega-Jurado, Gutierrez-Gracia, & Fernandez-de-Lucio, 2009).

The open innovation literature advises firms to seek out opportunities to licence in technologies, namely in the form of patents and IP, which can be commercialized as products in the firm's current business model (Chesbrough, 2006). Previous research, for example from the Finnish manufacturing sector, indicates that use of intangible knowledge is more often applied to product innovations whereas process innovation results from the incorporation of knowledge embodied in artefacts (Rouvinen, 2002). When a firm incorporates a new piece of machinery or software (embodied knowledge) into the production process, one firm's product becomes an input into another firm's processes. The incorporation of knowledge embodied in equipment into internal infrastructure allows firms to "know less than they buy" while still achieving improvement in processes (Flowers, 2007). Regarding intangible technological IP, since the internal processes of most firms remain secretive and proprietary, there is less of an incentive or market for firms to purchase intangible IP inputs into processes. Thus there is a distinction between purchasing components for a production process (buy to build) and purchasing capital goods for operational infrastructure and processes (buy to use). I draw the following hypotheses from this distinction between intangible and embodied knowledge:

H1a: *The effect of pecuniary acquisition of intangible technological IP is greater for product innovation than for process innovation.*

H1b: *The effect of pecuniary acquisition of embodied knowledge is greater for process innovation than for product innovation.*

In contrast to acquiring, *sourcing* entails scanning the environment for information related to new technologies and new opportunities, which the firm may then decide to act on, whether through instigating internal R&D or acquiring external technologies (Chesbrough, Vanhaverbeke, & West, 2006). The constructs *breadth* and *depth* (Laursen and Salter, 2006) are roughly analogous to external search scope and depth (Katila & Ahuja, 2002) but more precisely describe the variety and intensity of external sources from which organizations draw knowledge. These constructs thus represent variations in external sourcing strategy. An interesting aside from Laursen and Salter (2006) is that depth is a stronger predictor of sales from radical product innovations, whereas the effect of breadth is greater for sales from incremental product innovations. That is, the form of sourcing strategy impacts product innovation differently.

Some authors differentiate two forms of process innovation: *technological process innovation,* which results from the incorporation of new goods and embodied knowledge into production or service delivery, and *organizational process innovation*, which involves learning and more intangible changes in the coordination of human resources, such as new management practices or ways of doing things (Edquist, Hommen, & McKelvey, 2001: 14-17). The prediction in Hypothesis 1 (that the incorporation of embodied knowledge has a greater effect on process innovation than product innovation) follows from technological rather than organizational process innovation. Learning from external, non-pecuniary sourcing, such as through best-practice sharing at conferences, management training from universities, or working closely with clients to better serve their needs, can also influence organizational process innovation; external sourcing, and not just pecuniary inbound innovation, should influence process innovation, and different sourcing strategies, namely breadth and depth, can affect process innovation in different ways. For starters, the organizational changes required for process innovation are not easy to come by, with an emerging literature on the difficulties of organizational process change management (Kettinger & Grover, 1995). Organizational processes are intangible and often tacit in nature, requiring a fair amount of effort to understand and explicate, develop or imitate, and implement. Therefore, deeper, more intense relationships with external sources are needed to adequately develop, transfer, or implement organizational process innovations. Conversely, breadth of search provides firms with a wider yet shallower scope of available knowledge and opportunities which the firms may decide to further develop into products (Laursen & Salter, 2006). These differences in the nature of sourcing related to product and process development lead to the following hypotheses:

H2a: *The effect of non-pecuniary search breadth is greater on product innovation than on process innovation.*
H2b: *The effect of non-pecuniary search depth is greater on process innovation than on product innovation.*

Open Innovation in Service Industries

Despite making up significant portions of the economy, there is a relative paucity of research on innovation in service industries, not to mention in an emerging theme such as open innovation. Many leading firms currently have very different ways of defining service innovation and the processes which enable it (Anderson-Macdonald & Kask, 2010). However, despite the "manufacturing bias" in innovation studies (Drejer, 2004), there is good reason for the growing interest in the antecedents and outcomes of service innovation: developed countries are predominantly moving towards service economies, with the sector comprising well over 70% of the share of economic activity (Anderson, Howells, Hull, Miles, & Roberts, 2000; Boden & Miles, 2000; Gallouj & Djellal, 2010; OECD, 2000; Rubalcaba, 2007). The analysis of the consequences of growth in services – and corresponding reduction in the proportion of the labour force engaged in manufacturing – has a long history of theoretical and political debate, with views of the service sector ranging from a passive adopter of technology and "innovation laggard" (Baumol, 1967) to "the core engine of the new knowledge-based economy" (Gallouj & Savona, 2009). Whatever the impact of services on the economy as a whole, services represent a significant area of activity which has largely been left out of the open innovation discussion.

How might innovation in services differ from the innovation traditionally studied in manufacturing? Some authors propose a radically different model of innovation in services, suggesting a "reverse product cycle" whereby incremental improvements first increase the efficiency of delivery of existing services, only later to lead to improved service quality through process innovations and finally to the generation of new service products (Barras, 1986, 1990; Gallouj, 1998). Non-technological and tacit knowledge play an important role in service innovation (Tether et al., 2007), and informational activities within service firms, largely facilitated by ICTs and the network of actors and interactions between them, lead to knowledge creation that is not bound within specific domains in traditional R&D labs (De Bandt and Dibiaggio, 2002). This suggests that, although service industries share as many similarities as differences with manufacturing when it comes to innovation, interaction with the external environment is crucial for service innovation.

In light of this, the model compares the returns to open innovation activities between service and manufacturing sectors. Although some research has shown that service and manufacturing firms often exhibit comparable patterns of the use of knowledge sources for technological innovation (Sirilli & Evangelista, 1998), the relative returns to these sources may differ substantially between industries. If service firms benefit from interactions with external suppliers due to the nature of service innovation and are indeed more passive adopters of technological innovation, then inbound open innovation will more strongly predict innovative performance in service firms than in the manufacturing sector. This leads to the following hypothesis:

H3: *Overall, the effect of inbound open innovation activities are greater in low-tech service firms than in low-tech manufacturing firms.*

Decreasing Returns to Openness

Finally, although the hypotheses in this chapter and evidence from previous studies predict a positive effect of external knowledge on both process and product innovation, one highly-cited contribution proposes an inverted-u shaped relationship between the number of kinds of external sources and innovative performance of products (Laursen & Salter, 2006). Using a cross-sectional survey of British manufacturing firms, these authors find that firms drawing from external knowledge sources will have a better innovative performance than firms relying solely on themselves – up to a point. After a certain level, firms experience decreasing returns to external sourcing. Graphically, the relationship between innovative performance, in this case measured as the percentage of sales from new products, and breadth or depth takes on an inverted u-shape. A more recent, similar study using a slightly different econometric methodology looks at Finnish manufacturing firms, again finding strong support for the benefits of external search breadth but with some evidence for decreasing returns (Leiponen & Helfat, 2010). How is it that firms can be "too open"? Laursen and Salter posit that decreasing returns set in because of (1) natural constraints on absorptive capacity, (2) Not Invented Here (NIH) syndrome, (3) timing, and (4) limited allocation of managerial attention.

First, absorptive capacity is the ability to recognize, internalize, and exploit external knowledge to commercial ends (Cohen & Levinthal, 1990). Building absorptive capacity is seen as a prerequisite for firms to successfully engage in inbound open innovation (Spithoven, Clarysse, & Knockaert, 2010). Conceptualized as a *capacity*, it has limits. When a wide array of diverse external knowledge is accessed, much of that knowledge may or may not be appropriate or relevant to the firm. Sorting out which knowledge is relevant requires resources and great effort. Simply put, there may be too many ideas to comprehend and utilize at one point in time, leading to "information overload." Similarly to the absorptive capacity problem, attention-based theory of the firm places limits on the attention of managers (Simon, 1997). According to this theory, managerial attention is the most valuable resource in a firm, and the behaviour of the firm results from how decision makers focus and distribute their limited attention (Ocasio, 1997). The allocation of attention, especially from senior management, during the innovation search process is important for performance (Koput, 1997; Yadav, Prabhu, & Chandy, 2007). Managers who are bombarded by information have little time to contemplate it all and may direct their attention to "safe" projects.

"Not Invented Here" (NIH) syndrome, which the open innovation literature mentions often, is the rejection of knowledge and technologies originating externally to the firm, which can be detrimental to firm performance (Katz & Allen, 1982). Some level of scepticism stemming from the uncertainty of externally acquired knowledge can be healthy, but too much can be a major barrier to open innovation (Chesbrough, 2003b: 182). As the amount of external knowledge being accessed increases, the effects of NIH syndrome can become more apparent. Although not typically addressed in open innovation studies, the case also exists where firms overvalue external knowledge, which may lead to detrimental effects and poorer innovative performance (Lichtenthaler & Ernst, 2006). The "Not Invented There" (NIT) syndrome is defined as occurring when "people in management show more interest in what is going on elsewhere than in their own laboratories" (Laden, 1996). For NIT syndrome, "the other person's dessert always looks better", which causes management to spend more time evaluating external sources because they may already be technically feasible or on the market. Menon and Pfeffer demonstrate empirically the prevalence of some firms having a preference for external knowledge over their own internal knowledge (2003). This is due to (1) status associated with gaining knowledge from external sources and (2) the fact that external knowledge is rarer which makes it appear special and unique. Firms at a higher degree of external search breadth may be over-zealous and overly positive about drawing from external knowledge sources, resulting in inadequate focus on internal capabilities and mistaken selection of inappropriate knowledge. Thus the poorer innovation performance relative to the extremes of external sourcing may reflect both sides of the NIH-NIT coin.

Regarding the "timing" problem, too many ideas may come at the wrong time to be fully exploited. With a lot of potentially good ideas coming at once, the ratio of good ideas passed over is higher. Chesbrough touches upon a similar reason regarding timing, where accelerated cycle times for projects allows firms to assess only so many ideas or technologies at a time, leading them to eventually pass over some (Chesbrough, et al., 2006: 17). Some innovations take years before a use is discovered for them. For example, one of the inventors of the laser, Gordon Gould, said that for the first five years after its discovery, the laser was "a solution in search of a problem" (Brown, 1988: 310). When companies are inundated with ideas, some may get buried when the appropriate time finally emerges.

Research by Chandy et al. similarly finds this inverted u-shaped relationship between a firm's ability to convert ideas into innovations: "a strong focus on speed and on generating many ideas may actually hurt firms by lowering their conversion ability" (2006). They hypothesize that problem solving ability is influenced by four factors, namely (1) workload, (2) time pressure, (3) expertise, and (4) task importance. At high levels of external search breadth and depth, firms may be hurting their conversion ability, resulting in decreased performance. This paradox of allotting the right level of pressure in the open innovation process has also been noted in practitioner case studies (Mesaglio & Hunter, 2008).

Therefore, consistent with Laursen and Salter (2006), the following hypothesis predicts an inverted-u relationship between external sourcing and the performance of both product and process innovation:

H4: *non-pecuniary breadth and depth are positive predictors of both product and process innovation up until a point, after which firms experience decreasing returns to external sourcing.*

DATA AND EMPIRICAL ESTIMATION

Data Source

The analysis in this chapter is carried out using the PITEC (*Panel de la Innovación Tecnológica*), which is based the OECD's Oslo Manual. The survey is administered by a joint effort of the Spanish National Statistics Institute (INE), the Spanish Foundation for Science and Technology (FECYT), and the Foundation for Technical Innovation (COTEC). The unit of analysis is the single enterprise, whether part of a group or independent. The PITEC differs from most other OECD-based innovation surveys in two important and favourable aspects. First, firm participation is mandated by law (*Leyes* 4/1990, 13/1996, and article 10.1 of the LFEP), which limits problems associated with respondent selection bias; since many of the national innovation surveys in other countries are voluntary, this opens the door to respondent selection bias with only eager, innovative firms responding. Second, as the "P" in the acronym indicates, it is structured as a panel dataset, with observations repeated on the same firms over time. As discussed below, there are several advantages to panel data.

The dataset contains observations on more than 2,200 low-tech manufacturing and 1,600 low-tech service firms over four periods, with the most recent ending in 2007. Firms are assigned to 31 sectors according to the Spanish National Classification of Economic Activities (CNAE-93 - *Clasificación Nacional de Actividades Económicas*), roughly equivalent to the NACE system. The sectors are divided into high-tech/low-tech manufacturing and services along this classification system by the INE. The specific industries are included in Table 1.

Table 1. Manufacturing and service industries Included in analysis

Low-Tech Manufacturing	Low-Tech Services
Food and Beverages	Electricity, Gas and Water Utilities
Tobacco	Construction
Textiles, Tailoring and Furs	Sales and Repair of Automobiles
Leather and Footwear	Wholesale
Lumber and Cork, Paper	Retail
Editing, Arts, Graphics, and Copying	Hotel
Petroleum Refinement	Transport
Rubber and Plastic Materials	Transport, Travel Agencies
Glazed and Tile Ceramics	Financial Intermediation
Non-Metallic Mineral Products	Real Estate
Ferrous Metallic Products	Architectural services
Non-Ferrous Metallic Products	Testing and Analysis
Metallic Products (excluding Machinery)	Other Business Services
Shipbuilding	Education
Furniture	Film and Video Activities
Toys and Games	Radio and Television
Recycling	Other Sanitary, Social and Collective Services

Exploiting Panel Data: Accounting for Unobserved Firm Heterogeneity

Undoubtedly, there are many idiosyncratic and contextual factors which influence a firm's behaviour and ability to innovate, not all of which can be measured and included as variables in the analysis. Some obvious examples are star managers, proximity to resources such as clusters, organizational structure, etc. These are collectively termed "unobserved heterogeneity" in the management literature, and failing to account for it can result in bias due to omitted variables. Fortunately, the properties of panel data – repeated observations on the same firm over time – allow one to account for much of this heterogeneity via *fixed-effects models*. Fixed effects are factors at the level of the individual firm which remain more-or-less constant over time. In essence, each individual firm acts as its own counterfactual before and after some "treatment" of interest, in this case the use of various sources of knowledge. Because fixed effects models estimate variation in a firm over time, it is also called the *within* estimator. The inclusion of time and controlling for unobserved, omitted variables gets us closer to determining causal effects (Angrist & Pischke, 2009: 115-117). Although fixed-effect models are less efficient (i.e. it is difficult to achieve statistical significance), the estimates are consistent (i.e. the estimated coefficients are close to the "true" value). For these reasons, I employ a fixed-effects model described in the following description of the estimation procedure.

Dependent Variables: Measures for Effect of Product and Process Innovation

The dependent variables evaluate the effect of innovation on each firm's products and processes. The survey measures the *effect of product innovation* along three dimensions: (1) improved range of products or services; (2) penetration into new markets or increased market share; and (3) improved quality of product or services. The dependent variable, PROD_EFF, counts the number of effects rated as "high impact" and, therefore, ranges from 0-3. Firms rate the *effect of process innovation* along three dimensions which are relevant to both product and service firms: (1) improved flexibility of production or service provision; (2) improved capacity of production or services; (3) reduced labour costs. The variable PROC_EFF ranges from 0-3 where firms rated the impact of innovation on processes as "high".

Covariates

Two dummy variables measure pecuniary inbound open innovation: TECIP and EMBK. TECIP indicates whether the firm purchased external technological IP, such as patents or licences, during the period. EMBK indicates the purchase of external knowledge embodied in physical artefacts, such as in machinery, equipment, or software, used for product or process innovation. Finally, the log of R&D intensity, LRDIN, accounts for the internal resources used for innovation, measured as the spending on internal R&D as a percentage of total firm revenue.

NPBREADTH measures the number of kinds of external knowledge sources used for innovation which are considered *non-pecuniary*. This is similar to the *breadth* construct used by Laursen and Salter (2006), but excludes *suppliers* and *knowledge-intensive business services* as categories because of the potential to confound free or low-cost external public knowledge sources with pecuniary open innovation – firms handsomely pay suppliers and consultants, whereas fees for things like conferences or access to publications, if any, are negligible. The eight remaining types of external source include: clients, competitors, universities, public research organizations, technological centers, conferences and fairs, journals/publications, and professional associations. Likewise, NPDEPTH is the number of types of non-pecuniary external sources from which the firm has drawn intensely for innovation. Note that in order to test for decreasing returns and the inverted-u shape relationship predicted in Hypothesis 4, the regression models include the squared terms NPBREADTH_2 and NPDEPTH_2.

The within-regression accounts for variables that are subject to change in an individual firm over time, with constant variables accounted for with the fixed effects. This parsimonious approach thus excludes many unchanging characteristics that differ between firms and are normally included as controls in cross-sectional analyses. I do however include three variables as controls for changes in firm strategy or circumstances. First, LOGEMP, the log number of employees, controls for changes in firm size due to things such as growth, acquisitions, mergers, divestitures, etc. Second, since firms operating in international markets often face more diversified competition and have a higher propensity to innovate (Frenz, Girardone, & Ietto-Gillies, 2005), GEOMARKET indicates the geographical market in which the firm sells its products or services, taking on the values 1 (local market only), 2 (national, within Spain), 3 (inside the European Union), or 4 (international, outside the EU). Finally, dummies for each year in the panel control for cross-industry, macroeconomic fixed effects. Table 2 lists the descriptive statistics by industry for the variables before log transformation. With the exception of surprisingly higher R&D intensity and larger size of service firms, the dependent and key sourcing variables show no significant differences between industries.

Estimation Procedure

The dependent variables are discrete integers in panel data format, making a conditional fixed-effects (CFE) Poisson model appropriate (Hausman, Hall, & Griliches, 1984). The Poisson is attractive because it allows for a large number of zero values in the dependent variable and per-

Table 2. Descriptive statistics by industry for innovation-active firms, prior to log transformation

Variable	Range	Average (standard deviation)	
		Manufacturing	Services
Product Innovation	0-3	1.06 (0.616)	0.858 (0.545)

forms well in the presence of unknown forms of heteroskedasticity. Although normally used for discrete data counting the occurrence of some event, the estimator is consistent as long as the conditional mean is correctly specified, meaning that the dependent variable doesn't even need to be an integer (Santos Silva & Tenreyro, 2006). As per the usual convention, the variables are log transformed in order to provide a better fit with the distribution of the Poisson, which stipulates that the mean be equal to the variance lest the distribution is over-dispersed (Gourieroux, Montfort, & Trognon, 1984). Furthermore, these log-transformed variables are dimensionless and in the same range, enabling the comparison of effect sizes between product and process innovation. The CFE Poisson model drops those observations with either all-zero outcomes or unchanging sets of independent variables over time, which could introduce a systematic selection bias (Reitzig & Wagner, 2010). However, in the models run in this study, there is sufficient variability in the independent variables such that all innovative firms are kept in the analysis. In any case, fixed-effects models are robust against most kinds of selection bias since the selection characteristics are largely controlled for in the fixed effects (Kennedy, 2003: 312), such that the analysis estimates the variables within the firms of interest. Stata 11 executes the CFE Poisson regressions with the robust standard errors, which produces standard errors in line with more complex repeated-sampling procedures (Cameron & Trivedi, 2010).

The magnitude and significance levels of the coefficients tell an interesting story if one makes the comparison between industry, source of knowledge, and product or process innovation. Since the fixed effects controls for many idiosyncratic factors between low-tech manufacturing and service firms, we can compare the different estimated coefficients. A Chow test is normally the appropriate method in linear regression for determining if the coefficients of subsegments within a population, in this case low-tech manufacturing and service firms, differ statistically from one another due to some underlying structural break (Chow, 1960). However, a Chow test is not appropriate in the case of a non-linear maximum likelihood model such as the Poisson; instead, the better option is to run separate models on each group and compare the resulting estimated coefficients (Hoetker, 2007). Because of these "nonstandard standard error issues", I employ a non-parametric bootstrapping procedure on the difference in the estimated coefficients by accounting for the resulting residual variation matrix (Angrist & Pischke, 2009: 155-

164). Bootstrapping means simply repeatedly running the model on randomly drawn samples from the dataset (with replacement) so that the resulting standard error is the standard deviation of an estimator from these many draws. Although computationally burdensome, the advantage is that one does not make any assumptions about the underlying error distribution. The resulting p-values of the differences in coefficients tells us the magnitude and whether the coefficients for each variable are significantly different for the two industrial sectors. Using this procedure, Table 4 and Table 5 in the next section present the results of the comparison of coefficients across groups and type of innovation.

DISCUSSION OF RESULTS

Table 3 lists the results of the four CFE Poisson regressions. The same set of covariates is regressed on the variables for the effect of product innovation and process innovation in separate regressions for each of the service and manufacturing subsamples. With the exception of technological IP and the control variables, the covariates are all significant and positive in magnitude. The interpretation of individual coefficients in a Poisson model is as follows: the expected change in the (log) count of the effect of product or process innovation for a one-unit increase in the variable is equal to the magnitude of the individual coefficient.

Pecuniary Acquisition and Type of Innovation

Although a quick look at Table 3 reveals some interesting patterns in the returns to sourcing strategies across sectors and type of innovation, evaluation of Hypotheses 1-3 requires a statistical test to determine whether these differences are significant. To this end, Table 4 reports the results

of the bootstrapped standard error procedure described above in Estimation Procedure. The estimated coefficients for each variable's regression on product innovation are subtracted from the estimates for process innovation, by industry, in order to indicate the magnitude of the difference. The p-value tells us whether this difference in estimated coefficients is statistically significant.

Table 3 provides some support for Hypothesis 1a, whereby pecuniary acquisition of technological IP has a positive and significant effect on product innovation, however only for the low-tech service industry. Since technological IP is not significant in the case of process innovation or for product innovation in low-tech manufacturing firms, any comparison between industries is moot. The results in Table 4 strongly support Hypothesis 1b, indicating that returns to pecuniary acquisition of embodied knowledge are greater for process innovation than product innovation in both the services and manufacturing industries.

The finding that acquiring technological IP has no impact on process innovation nor on product innovation in low-tech manufacturing firms has intriguing implications for open innovation, especially considering the importance the open innovation literature places on inbound IP (Chesbrough, 2003a). These results echo findings from Tsai and Wang's study of the low-tech manufacturing sector, whereby technological IP sourcing had no predictive effect on more radical product innovation (2009). Similar results have been shown at the project level (Kessler, Bierly, & Gopalakrishnan, 2000). Other findings, however, indicate that sourcing technological IP becomes effective in high-tech industries as a firm's internal R&D capacities increase (K.-H. Tsai & Wang, 2007), suggesting that the impact of acquiring IP is a function of the technological intensity of the sector. Interestingly, in contrast to findings from the manufacturing sector, external IP sourcing seems to have a significant relationship with product development in low-tech *service* firms.

Non-Pecuniary Sourcing and Type of Innovation

Relatively strong support for Hypotheses 2a and 2b is evident in Table 4: the effect of non-pecuniary search breadth (2a) is greater for product innovation in both the service and manufacturing industries. On the other hand, returns to non-pecuniary search depth (2b) are significantly larger for process innovation, but only for manufacturing firms. This indicates that, at least in low-tech sectors, firms casting a wide yet shallow net (non-pecuniary breadth) are more likely to discover avenues for product innovation. This more superficial level of external sourcing may not be as appropriate for finding and implementing innovative processes. The comparable magnitude of the effect of non-pecuniary search depth on product and process innovation in service industries is intriguing. Although the effect of depth is slightly higher for process innovation in service firms, this difference is not enough to be statistically significant. This finding serves as evidence for dissimilar kinds of innovation processes between these two broad sectors.

Open Innovation in Manufacturing and Service Industries

In order to test Hypothesis 3, which predicts higher overall relative effect of inbound open innovation activities in service firms, Table 5 lists the results of the bootstrapping procedure on the difference in the estimated coefficients between industries.

Taken as a whole, the significant and positive results in Table 5 largely support the hypothesis of greater returns to inbound open innovation for service firms as compared to the manufacturing sector. For product innovation, the effects for the purchase of technological IP and non-pecuniary sourcing are significantly higher for service firms. The same trend is evident for process innovation in service firms. From Table 3 and Table 5 there is weak evidence that internal R&D is more important for manufacturing firms since the difference is not statistically significant. This is likely partly due to the markedly lower level of significance of the internal R&D coefficient for service firms, which in itself further supports evidence for lower returns to internal R&D in low-tech service firms. Despite the higher average R&D intensity in service firms evident in Table 2, the returns from internal R&D are lower than for manufacturing firms. The service firms seem to live up to their reputation as adopters of externally developed technology, although ultimately services get higher innovation returns to external sourcing than their low-tech manufacturing cousins.

Decreasing Returns from Being "Too Open"

Finally, Hypothesis 4 predicts decreasing returns to breadth and depth of non-pecuniary external sourcing. The significant and negative coefficients on the squared terms in Table 3 strongly support this. That is, an inverted-u shaped relationship exists between both product and process innovative performance and the breadth and depth of external sourcing. The relationship holds equally for service and manufacturing industries.

It is possible to roughly calculate the inflection point at which decreasing returns occur by setting the first derivative of the estimated coefficients equal to zero and solving. Given the scale for breadth and depth, which ranges from 0-8, on average decreasing returns set in for non-pecuniary breadth after about 5.5 external sources and for non-pecuniary depth at 4.5. Stated in a

Table 5. Statistical significance of difference between estimated coefficients

more meaningful way that is comparable and consistent with results from Laursen and Salter (2006), firms sourcing from more than two-thirds of the available external knowledge sources and using more than half of those sources intensely experience decreasing or even negative returns. Unsurprisingly, these results also indicate that decreasing returns set in much sooner for depth than breadth: depth requires higher involvement and quickly strains internal resources.

The recent enthusiasm surrounding open innovation and the detrimental effects of over-searching indicated in this analysis suggest that firms' external search strategies can be "too open". The presence of decreasing returns to external sourcing highlights the importance of neither being too open nor too closed to the external innovation ecosystem. That is, focused and targeted open innovation efforts lead to optimal returns.

FUTURE RESEARCH DIRECTIONS

Thanks to much attention from the academic research community, a fair amount of progress has been made in our understanding of open innovation over a relatively short period of time. However, as an emerging theory there are still many questions to explore. First and foremost, an objective of this chapter is to bring low-tech service industries and process innovation into the open innovation discussion. As such, this comparative analysis provides some initial clues about how open innovation differs across these subjects, but much further research is needed.

Innovation survey data is only able to capture the breadth and depth of different *categories* of external sources used for innovation. Although this is a good proxy for a firm's external sourcing strategy and level of openness, access to more granular data on the actual nature and number of actors and interactions with external sources of knowledge would provide a much richer understanding of the optimal external orientation of the firm. This kind of data could well be supplemented with a better understanding of the relationship between organizational forms and internal practices which influence a firm's ability to benefit from various open innovation strategies.

Although the analysis in this chapter focuses on search strategy regarding external sources of innovation, it does not address the myriad tools currently being proposed and used by firms generally included under the umbrella of open innovation. These include crowdsourcing competitions, the use of open source strategies, lead user methodologies, co-creation and mass customization. Although there is a growing volume of research into these specialized tools, many questions remain regarding their effectiveness and appropriateness across diverse contexts, such as various types of intended innovation outcomes, innovation of commercial services versus goods, or how these tools and techniques can be combined.

CONCLUSION AND IMPLICATIONS

This chapter addresses the following questions: How effective are various open innovation strategies (pecuniary and non-pecuniary) across sectors (manufacturing and services) and objectives (product and process innovation)? And how open should a firm be?

First, the literature and empirical analysis suggest that forms of pecuniary and non-pecuniary external sourcing are differentially effective according to innovation objective, namely product and process innovation. Predictably, external knowledge embodied in artefacts, such as equipment, components or even software, is effectively integrated into firms' processes but is a weaker predictor of product innovation. Although the open innovation literature places an emphasis on the acquisition of intellectual property, in this sample from low-tech industries, the acquisition of patents and other intangible IP did not predict process innovation and predicted product innovation only in service firms. This could be significant for low-tech firms in general; physical artefacts (and software systems) are "pre-packaged" knowledge that can be more easily exploited, whereas low-technology firms may face greater knowledge barriers to valuing and exploiting intangible intellectual property. Different approaches to drawing from non-pecuniary external sources of knowledge also impact a firm's propensity for product and process innovation. In general, greater "depth" of interaction is needed for process innovation, whereas "breadth" – drawing from a broad range of external actors – seems to be more pertinent for the effect of product innovations.

This chapter contributes empirical evidence for the effectiveness of knowledge sourcing in low-tech sectors. Similarly to the lack of research on service innovation, low-tech industries face a paradox, with these "traditional" industries making up the bulk of economic activity in many countries but still being largely left out of innovation studies (Hirsch-Kreinsen, 2008). Although any comparative analysis between high- and low-tech firms would be out of the scope of this chapter and no specific hypotheses are given regarding low-tech industries, it aims to serve as a starting point to bring these important sectors into the open innovation discussion. In general, the analysis reveals that external sources of knowledge have a greater impact on service-sector firm innovation in comparison with their low-tech manufacturing counterparts, who seem to benefit more from investments in internal R&D.

The arguments and evidence brought forth in this chapter are intended to draw attention to the fact that practitioners must carefully consider what kind of open innovation strategy is right for their business and intended objective. Not all modes of inbound open innovation provide the same returns depending on the nature of innovation in question, and overzealous external sourcing can actually lead to inferior returns and performance. Instead, focused efforts are likely to bring optimal results. The documented benefits of openness aside, history provides us with no shortage of *management fads* (or the more politically correct term of *management fashions*) whereby firms rush to adopt the latest and greatest management practices in hopes of gaining competitive advantage or even for fear of not being viewed as progressive (Phillips Carson, Lanier, Carson, & Guidry, 2000). Open innovation's rapid growth shares many characteristics of a management fashion, and there is danger that it will be unsustainable if the open innovation process is not properly managed and approached with realistic expectations (Gassmann, et al., 2010: 213). Often the expectations on managers to adopt the latest "big thing" in management, in this case open innovation, result in pressure to implement a process which may or may not be the most rational, effective course of action. One study found that firms employing popular management techniques did not have higher economic performance – although they were perceived as more admired and competent (Straw & Epstein, 2000). Clearly firms should engage in open innovation practices. However, as with any emerging management practice, there is danger of managers jumping in with both feet first, and after the realities of the difficulty of implementing any new process set in, abandoning it. The implication for firms is to embrace an open innovation strategy with selective external sources and particular objectives in mind while maintaining investments in internal capabilities.

In addition to implications for management, policy makers are now increasingly considering open innovation (OECD, 2008: 113-127). Some of the means in which policy is directed towards fostering open innovation include (1) technology and knowledge transfer policies; (2) the organization of the public sector research base such as universities and science parks; (3) establishment of public innovation intermediaries (Lee, Park, Yoon, & Park, 2010); (4) public funding for open innovation research and projects with a strong collaborative nature; and (5) policies directed towards the fair and tradable use of IP, i.e. the appropriation regime. The implications of this research for policy makers are twofold. First, open innovation clearly creates value but brings with it yet unknown difficulties. Knowledge is often "sticky" and difficult to transfer or value (von Hippel, 1988), especially for firms with few internal capabilities (Cohen & Levinthal, 1989). That is, investment in resources and capabilities internal to the firm still matter, both for the creation of new knowledge, whether tradable or destined for internal use, and for the generation of the absorptive capacity required to recognize and commercialize existing external knowledge. Open innovation is not a panacea, so policy makers must carefully consider policies which divert public funding away from the development of internal firm R&D to schemes simply supporting open innovation. Second, there is likely not a viable "one-policy-fits-all" approach to facilitating open innovation practices among firms. As argued in this chapter, firms are very heterogeneous in how they source and apply external knowledge, and furthermore the relevance of inbound open innovation may vary according to any number of factors such as a firm's industry and whether product or process innovation is the intended outcome. Policies directed at fostering open innovation will likely need to consider how the intended outcome may be contingent upon the idiosyncrasies of various industries and types of innovation.

ACKNOWLEDGMENT

The foundation for this work was sparked during a research stay gratefully sponsored by Keld Laursen in the Department of Innovation and Organizational Economics at Copenhagen Business School, Denmark, made possible by a researcher mobility grant from the PRIME Network. The econometric techniques benefited from coursework during a studentship at London Business School, funded by a mobility grant from the Spanish Scientific Research Council (CSIC), and a research stay at SKEMA Business School in Sophia Antipolis, France. I also thank my advisor, Jordi Molas-Gallart, for comments, support, and guidance.

Chapter 11
Production Competence and Knowledge Generation for Technology Transfer:
A Comparison between UK and South African Case Studies

Ian Hipkin
École Supérieure de Commerce de Pau, France

EXECUTIVE SUMMARY

The ability to execute the physical part of manufacturing will assume greater importance as new technology and knowledge become significant drivers of strategic direction. The case studies described in this chapter address the interaction between technology transfers (TT), production competence and knowledge in enhancing performance in manufacturing organizations. Reference to British and South African case studies provides a useful comparison of production competence in the developed and developing world. In both countries, operators and maintainers lacked detailed knowledge of equipment functionality and performance parameters. United Kingdom (UK) companies demonstrated a deeper understanding of fundamental principles of the underlying production process, enabling them to remedy production deficiencies more thoroughly. South African companies showed greater management commitment to training and group solving approaches.

ORGANIZATION BACKGROUND

New equipment and systems play a vital role as production-oriented firms strive to meet changing customer demands and increased competition. Technology is key to achieving competitive advantage to this and requires an exchange of technical know-how and the transfer of competencies to facilitate organizational learning, consolidation of new technologies, and establishing routines and production skills (Lynskey, 1999). Frequently recurring factors that contribute to poor performance of new technology in both developed and

DOI: 10.4018/978-1-4666-1945-6.ch011

developing countries are inadequate knowledge of plant and processes, managerial commitment, information systems, and lack of production competence. This chapter describes an investigation into the impact of such factors on TT in a number of UK and South African manufacturing organizations that have recently acquired new technology, and assesses how similarities and differences in these organizations affect production performance.

SETTING THE STAGE

It has long been suggested that equipment performance is dependent on production competence (Ferdows and De Meyer, 1990; Leonard-Barton, 1995). Employees who understand how something is made are better able to manage manufacturing practices than those who deal only with the underlying symptoms of a process (Gourley, 2006). An environment where knowledge assimilation and sharing generate continuous learning capability lends itself to absorptive capacity (Tu et al, 2006). Early proponents such as Cohen and Levinthal (1990) see absorptive capacity (AC) as the ability of a firm to recognise and utilise the value of new information that comes from continuous learning. Mowery and Oxley (1995) construe AC as a comprehensive set of skills that engages with the tacit component of transferred and imported knowledge. Jones and Craven (2001) emphasise the need for communication networks that diffuse knowledge and technology.

Production competence and knowledge generation may be seen as a function of AC, which Zahra and George (2002) define as: “AC is a set of organizational routines and processes by which firms acquire, assimilate, transform and exploit knowledge to produce a dynamic organizational capability” (p.185). Like many commentators these authors view AC as an essentially organizational phenomenon.

In order to understand a knowledge-based process Rouse and Daellenbach (2002) suggest that we should follow the value generation trail back to its source. This requires “unpacking the process, beginning with performance, then looking for sources of advantage in the form of capabilities and competencies. Unless the sources of firm-specific superiority can be understood, the nature of the competitive advantage is doomed to remain largely a mystery. We will merely have substituted a black box of competencies for the black box of organizations.” (p.966) Rouse and Daellenbach (2002) also suggest a theoretical and empirical understanding of what occurs in TT as well as how this takes place:

- Resources, technology and knowledge (tangible and intangible) are bundled, linked and incorporated as management processes.
- Management processes and structural relationships are converted and organised into routines and systems.
- Routines and systems formalise capabilities that lead to production competencies.
- Competencies become the means whereby products and services are generated to provide value and competitive advantage.

Resources and Knowledge

Resource-based paradigms help to explain the success of firms through an analysis of technological skills, complementary assets and routines. Capabilities are clusters of tangible and intangible abilities that span individuals and groups (Coates and McDermott, 2002). Manufacturing firms need a competitive focus to optimise quality, cost and flexibility and develop competencies in the long term, so it is necessary to identify the tangible and intangible knowledge and skills required, and formulate policies to prioritise these. Knowledge further assists designers in understanding the consequences of any changes that may be made in improving product features (Cristofolini et al, 2009).

Knowledge is a useful lens through which to view the development of competencies. Interlinking technical areas allows firms to combine multiple knowledge and functional domains to overcome challenges in implementing new technology. Pools of knowledge lead to competencies so an essential factor in their emergence is an orientation towards learning and developing knowledge. Training and familiarisation are prerequisites for the creation and use of new competencies. Knowledge is a resource that supports a firm's ability to excel in achieving these competitive priorities. Among the reasons for inadequate knowledge is a firm's over-optimism about the knowledge of its own processes, and its inability to build, debug and operate new processes (Bohn, 1994).

Management Support

Firms need management processes that will transcend organizational boundaries and co-ordinate activities across diverse environments and social dynamics (Dekkers, 2009). They benefit from leadership roles played by proactive individuals, boundary spanners and technology champions (Irwin et al, 1998). These facilitate crossing technical boundaries to find multidisciplinary solutions through innovation and bringing together diverse experts. Managers should lead in offering support for new equipment, while being sufficiently flexible to accommodate the emerging behaviour and actions that unfold from operators of the technology. This requires rethinking established processes that affect, or are influenced by, the technology.

Technological competence depends on the ability and contribution of development teams, but managers set the process in motion, provide facilities for training and encourage organizational learning as a means to develop requisite capabilities. Managers should also encourage the process of knowledge acquisition, through "legitimizing familiarisation activities" (Dimnik and Johnston, 1993, p.161). Crossan and Berdrow (2003) emphasise the development of shared understanding amongst individuals and taking coordinated action through mutual adjustment. This will initially be unstructured and informal, but may be institutionalised by embedding the learning that has occurred by into systems, structures and procedures. Within a constantly changing environment, managers must manage the tension between institutionalised learning and the processes of intuitive interpretation and integration.

The more individuals work with colleagues and benefit from physical and psychological proximity, the more they develop mutual trust and are willing to share their specialist knowledge (Uzzi and Lancaster, 2003). The effect is faster knowledge assimilation through observation, the facility to draw on a pool of contextual knowledge, and a shared sense of where expertise lies. Reagans et al (2005) refer to this as a 'relationship-specific' activity where knowledge is assimilated and embedded in the link connecting people performing distinct roles.

Information and Systems

Management scientists and operations researchers have developed decision-making tools for operations and maintenance that are intended to replace subjective decisions with objective ones and assist managerial control through faster, more comprehensive and accurate knowledge of operations, and reducing idiosyncratic judgement and mystique. However, Pintelon and Gelders (1992) claim that little use is made of such techniques and challenge the benefits of a large quantity of explicit data, even if it can be gathered. Researchers can identify some key information systems when assessing TT, but cannot access others that are invisible and buried in the minds of the actors. For example, computerised maintenance management systems have been developed as a form of data repository. Although maintainers perceive the lack of failure data as a barrier to maintenance intervention, it is questionable how much useful data is stored in computerised maintenance systems. Aharoni

(1993) suggests that the diversity of information systems emphasises how the richness in quality and nature of information systems can be imbued with value, context and meaning. However, researchers must assess whether information systems enhance production or support organizational governance through a form of indirect exertion of authority. Even if the systems governing each individual's task within an organizational routine are explicit, the complex totality of the system may well be unknown to most participants, and is therefore tacit. Few systems can accommodate knowledge, know-how, social capital, and other socially complex, difficult-to-transfer data.

Production Competence

Coates and McDermott (2002) define competence as: "a bundle of aptitudes, skills, and technologies that the firm performs better than its competitors." (p.443) The importance of understanding equipment performance is widely supported in the literature on process competencies and organizational learning (Leonard-Barton, 1995; Marmier et al, 2009). Processes dependent on technological subsystems require subtle skills and expertise that are often difficult to codify. The secrets and capabilities of a complex process are understood most effectively through direct, first-hand observation and interaction (Lynskey, 1999).

Galbreath (2005) posits that knowledge is assimilated as capability when familiarity with tangible assets through employee learning, and interaction between management and operational personnel become evident in operational routines. Training can at best only go part-way in imparting this expertise. Assimilation is delayed in conditions of uncertainty when knowledge elements lie beyond an organization's sphere of expertise (Rosenkopf and Nerkar, 2001). This may be due to novelty and layers of complexity which even knowledgeable operators are unable to comprehend (Dehane et al, 2008; Sorenson et al, 2006).

Macher (2006) notes that problem solving is often a trial-and-error exercise where particular parameters are modified, learned about, and improved. A range of solutions is likely to emerge, and their impact may be interpreted in differing ways by multiple stakeholders with possibly contradictory interests. Above all, the success of a technology depends to a large degree on the competencies of personnel, since documented and accessible explicit knowledge may form only a small part of the knowledge that should be shared. The management of collective knowledge in firms and the ability of individuals to work together to convert knowledge into customer value are essential competencies. The challenge for researchers is to develop theory that will "identify unique, proprietary, and special abilities in manufacturing firms and understand how competencies that lead to competitive advantage both occur and are capitalized upon in the firm" (Coates and McDermott, 2002, p.438).

CASE DESCRIPTION

Four organizations that had recently implemented new technology were selected for this study. Broadly comparable firms in two sectors were studied (paper and food): two from the United Kingdom (referred to as PaperUK and FoodUK) and two from South Africa (PaperSA and FoodSA). A brief description of each is provided.

- *PaperUK*: This 30 year old UK paper operated ageing equipment, beset with breakdowns. It produced speciality paper for the printing industry and operated several paper machines, coaters and a finishing department. Production targets were only met with excessive maintenance overtime. Low profitability meant that capital expenditure had been severely limited, so the life of existing equipment was to be extended through maintenance and some small technological advancements. Management had installed a computerised maintenance management system (CMMS), but this was recognised as deficient in its lack of user friendliness. This could not be construed as a knowledge-based operation as the vast quantities of data accumulated over the years were difficult to access, and had little credibility. No direct interface between the CMMS and the production system existed. As part of a long-term plant upgrade a supplier was appointed to install a new coater on one paper machine in close association with a team of paper mill staff from engineering, operations and maintenance. Commissioning of the new coater was accompanied by the installation of a new CMMS, in order to raise the level of knowledge of plant operation and failure data. This represented a substantial upgrade potential for the maintenance function. Reliable information was seen as essential for effective maintenance. The CMMS was to be used to attain the original functionality of equipment, and to ensure higher plant availability. 12 individuals were interviewed in PaperUK.

- *FoodUK*: This UK food company was confronted by tremendous cost competition from global players, and was attempting to find niche markets to build on its quality competitive advantage. Lower operating costs were essential provided quality standards could be maintained. Labour intensive quality checking was no longer sustainable: this was expensive and not sufficiently reliable. Customers had been criticising the company for not meeting its agreed acceptable quality level standards, and several major customers had been lost. In some areas production stoppages could be tolerated depending on downline processes and orders. Opportunistic repairs during production stoppages were becoming the dominant way of doing maintenance, although it was recognised that this was not effective maintenance. A large backlog of data had not been entered into the existing maintenance management system. This food factory installed laser screening equipment to monitor raw materials used in the manufacture of tinned foods and take remedial action to prevent substandard products from entering the manufacturing process. The challenge was to ensure that operators were sufficiently knowledgeable and proficient in utilising the new technology, and to guarantee that strict quality standards were met. 13 individuals were interviewed in Food UK.
- *PaperSA*: The strategy of this South African paper mill was to produce high quality paper at a cost lower than its competitors. Despite an industry characterised by depressed prices, there were profitable markets for the company's products. The company had no knowledge-based system for maintenance since the few historical failure records were based on perceptions of certain members of the engineering and maintenance departments, as well as opportunistic maintenance which was undertaken during scheduled and non-scheduled production stoppages. Maintenance and production staff were required to enter failure and performance data at terminals in the operating control room. This paper mill comprised paper machines, winders, rewinders, core and log handling, and packing machines. Various new projects had been undertaken including an upgrade of the logsaw and associated equipment, and a new packaging machine. The choice of equipment and quality standards was made on the basis of extensive consumer market research which indicated where customer values lay. Significant management was expended in ensuring that operating staff

accepted the new quality standards, which were at times at variance with previous operating practices. 9 individuals were interviewed in PaperSA.

- *FoodSA*: This food-processing factory had pockets of low unit cost competitive advantage brought about by earlier investment in new technologies. The low cost advantage was eroded by fierce competition, and extensive down time on several sorting machines. Maintenance had been predominantly preventive, but management felt that a more structured approach was required, which required information to be recorded in a computerised system. Production departments were to be convinced that maintainers possessed valuable knowledge that would reduce the frequency and duration of production stoppages. Although a number of variables in raw materials influenced the quality of the end product, the level of output variance was limited as quality was strictly in accordance with American fast-food quality. New sorting equipment had been acquired, but no maintenance history was available. The challenge for the company was to acquire sufficient knowledge of the equipment to ensure high levels of available and reliability. 10 individuals were interviewed in FoodSA.

CURRENT CHALLENGES FACING THE ORGANIZATIONS

This section recounts occurrences and experiences in the case organizations in relation to the main points identified in the 'setting the scene' section of this chapter. One of the common features in all case studies was that previous operating practices and equipment were not delivering the required performance. New technology was introduced in each case, but knowledge of new processes was lacking, and managers were not sure how this deficiency should be addressed. Their actions were essentially trial and error, and largely unstructured.

Resources and Knowledge

Resources are the assets owned or controlled by a firm, and include new equipment and knowledge vested in people. In investigating the challenges facing the case organizations, it is instructive to identify subtle knowledge acquisition, working practices and adjustments that maximise the benefits that can be derived from new technology.

New laser equipment at FoodUK replaced manual raw vegetable quality monitoring. Settings by suppliers and plant engineers were based on trial and error. In assessing the quality of the incoming product and monitoring the output, operators were able to use their previous experience of the manual process (tacit knowledge) to set the machine to ensure minimum rejection of acceptable products and maximum rejection of unacceptable products. In order to achieve this, a great deal of management time and effort was dedicated to persuading operators of the value of this knowledge. This was necessary since operators had initially distanced themselves from the technology, expressing the sentiment that the technology had effectively displaced them.

FoodSA also had varying qualities of incoming raw material. Machines were set to allow sizes to vary between limits, depending on customer requirements. Operators followed procedures laid down by supervisors since they were not aware of operating parameters within which outsized materials could be tolerated. FoodSA's explicit instructions were not relaxed to accommodate the type of tacit knowledge demonstrated in FoodUK.

These examples illustrate the importance of delicate adjustments that lie beyond standard operating procedures. According to one respondent at FoodUK the basis for successful use of this equipment resided in 'an uncanny knack' by certain operators to apply incremental fixes and fine adjustments to meet specified quality requirements. Despite their documentation and engineering drawings (explicit knowledge), process engineers were unable to do this. FoodSA's procedures did not encourage the degree of flexibility that would permit some experimentation on the basis of tacit knowledge.

Personnel in the UK companies possessed greater knowledge than their South African counterparts. Although only some events are recounted, it was clear that the experience and initiatives of the UK operators in particular (on the basis of tacit knowledge) added significantly to production output. In neither food company was there any formal approach to knowledge acquisition. PaperSA did make a concerted effort to acquire knowledge of customer quality standards, and to ensure that products adhered to these requirements.

Management Support

Managers in the case studies acknowledged the importance of training staff members involved with operating and maintaining new equipment. PaperUK engaged the supplier of the coater equipment to train operators and maintenance craftsmen. However, the training did not encourage 'ownership' of the plant by the newly constituted team because several features of the coater replicated difficulties with older equipment and operators felt their opinions had not been taken into account when the new coater was specified. Management support was perceived to be wanting. The result was a lack of knowledge assimilation: while knowledge could be acquired through the training, operators did not accept or readily assimilate it.

Much discussion preceded the acquisition of the new equipment at PaperSA, especially regarding internal quality standards. It was possible to meet external requirements but internal standards remained a source of contention. The amount of glue sprayed onto a toilet roll to secure the final sheet (the 'tail') determined how many sheets were glued together while the length of 'tail' affected final packaging. Management established a team of operators, maintenance and process staff to address this type of issue, but only when a champion emerged in the group did team members demonstrate a concerted effort to investigate appropriate specifications for the equipment. In absorptive capacity terms, this reflected assimilation and transformation: the competitive advantage gained from first mover advantage in setting and adhering to appropriate standards was truly transforming.

In this instance the South African managers involved their staff more in discussions of the new technology. This provided a legitimate basis for the group to propose quantitative performance standards which were subsequently accepted as company quality policy, and led to an industry leadership position.

Information and Systems

As part of FoodSA's ISO9000 certification exercise, detailed production procedures were produced and systems established to provide an audit trail for quality inspections. Managers' attention was more directed towards compliance with the system than with production requirements.

PaperSA attempted to make use of its computerised system in determining maintenance intervention. However, existing schedules were done on a conservative time basis. Many failures were prevented, but no one could quantify the costs of such excessive maintenance. The maintenance system was thus of little use: some data existed, but seldom was this analysed to produce information, and no evidence was apparent of a knowledge based maintenance system.

PaperUK had a long-established computerised maintenance system, and managers were adamant that procedures should be based on failure history (data). Failures were recorded, but the data captured was not suitable for establishing maintenance tasks. The emphasis was on data input, rather than ensuring meaningful outputs.

Experiences in the case studies show that information systems were used to little effect. The nature of data collection was suspect, and procedures for analysing information were not satisfactory. While some data was thus collected, it was not adequately assimilated, and failed to transform the maintenance systems of any of the case studies. The findings of this study suggest that all case studies suffered from a lack of accurate data and inability or reluctance to use information systems: operators and maintainers were unable to base remedial action on any documented history and experience.

If time-based maintenance is adopted, then a period of time must elapse before meaningful data can be collected for new equipment. The case studies did not demonstrate that they were going to collect failure data for the new equipment in a meaningful manner, nor that this would be competently analysed.

Production Competence

In order to assess the levels of production competence in the four cases, respondents were asked to provide certain performance related information pertaining to their plant. The items contained in this paper related to the following (the results are summarised in Table 1):

- primary function of the new equipment, with performance standards in terms of output quantity and quality
- details of how non-achievement of the primary function would be detected, and the nature of the consequences
- details of protective systems (safety to humans and equipment protection)
- details of the most severe failures (in terms of cost or safety), with most appropriate remedial action, and the basis for this.

Table 1 shows, for example, that all respondents at FoodUK were able to describe the primary function of the laser technology, and the production supervisor and operator were able to quantify output. However, no one could provide precise quality standards.

The information in Table 1 and interview results confirm that production competence in the UK was greater than in South Africa, but they still demonstrate various degrees of ignorance about production and maintenance issues. While operators were generally familiar with the function and performance of their equipment, maintenance craftsmen were poorly informed. The implication is that those who maintain equipment were not fully aware of its functionality. While most respondents would identify the failure to fulfil the primary function, they were generally unaware of the consequences in the longer term (such as safety, environmental or health implications, costs, effects on customer service). There was a low level of awareness of safety and equipment protection. Respondents were familiar with the most common causes of failure, but none could define precisely the basis on which remedial action was taken (in terms of meeting functionality requirements, assessing root causes of failure, determining consequences of loss of functionality, maintenance tasks and intervals, and so on).

The topics discussed above provide some useful pointers pertaining to TT in the four cases. This section discusses implications of the findings for managers. Table 2 summarises the findings encountered in broad terms.

SOLUTIONS AND RECOMMENDATIONS

The research suggests that the way in which firms manage their resources and competencies will determine the extent to which these will result in enduring sources of competitive advantage through superior performance and functionality. The challenge for managers is to determine what distinctive ways and routines should be harnessed

Table 1. Summary of selected measures of production competence by company and position

FoodUK				
Measure of production competence	Prod supervisor	Operator	Craftsman	Process engineer
Details of primary function Output rate (quantity/time unit) Quantification of quality standards	Yes Yes No	Yes Yes No	Yes No No	Yes Yes Yes
Detection of failure of function Consequences of failure of function	Yes Yes	Yes No	Yes No	No Yes
Safety protective systems Equipment protection systems	Yes No	Yes No	Yes Yes	No Yes
Details of most severe failure Details of appropriate action Basis for remedial action	Yes Yes No	Yes Yes No	Yes Yes No	Yes No No

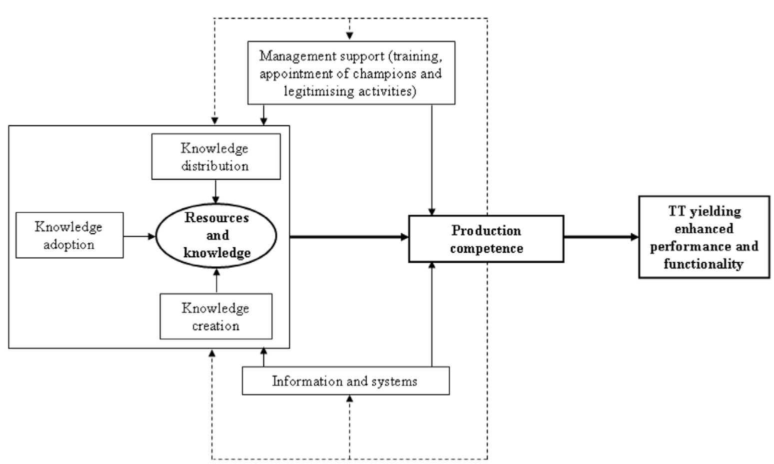
Table 2. Summary of findings

	FoodUK	PaperUK	FoodSA	PaperSA
1. Resources and knowledge	Tacit knowledge improved performance through an ability to apply subtle changes to process	Operator experience enabled minor adaptations to operating procedures to improve performance	Little scope for enhancing tacit knowledge because procedures were rigidly followed	Specified production processes prevented learning through experimentation. Little tacit knowledge evident
2. Management support	No special support evident to enhance TT	No special support evident to enhance TT	Training and consultation demonstrated management support	Extensive consultation enhanced TT through management support
3. Information and systems	Systems contributed little to TT	Systems contributed little to TT	Systems assisted in monitoring production output	Systems used incorrectly; excessive maintenance increased costs
4. Production competence	Reasonable levels of competence led to meeting desired performance standards in relatively short time	Reasonable operator and craftsman knowledge resulted in good flexibility to meet varying customer demands	Operators and craftsmen not familiar with plant and process. Large wastage of raw materials	Low levels of competence resulted in low initial output and variable quality

to achieve these. Findings show that the UK cases demonstrated greater knowledge and insight of processes, and operators and maintainers had higher levels of production competence than the South Africans. Management intervention in the South African cases was more supportive for TT. Information and systems were of little direct benefit in any of the cases. The transfer of knowledge to competencies is not a one-to-one linear process because of the indeterminate nature of knowledge and the diversity of competencies required for effective utilisation of new technology. Typical competencies include technological skills and complementary assets, as well as routines and capabilities that appear as clusters of tangible and intangible abilities spanning individuals and groups.

Competencies identify the key resources that need to be regenerated, expanded and built on in a firm's future activities, as tacit knowledge can generate more durable advantages (as was found in the UK cases). The feedback loops suggest that competencies help identify the tangible and intangible assets that need to be acquired, and

Figure 1. Relationship between resources, competence and performance



the direct attention that needs to be nurtured and prioritised inside the firm. This is illustrated in Figure 1.

Governance decisions and management support may have both beneficial and detrimental effects. A control spiral can result in yet further control (such as FoodSA's emphasis on procedures and documentation, rather than analysing the broader picture of what the true purpose is of such control). Incremental adjustments in a firm's governance structure may be desirable to permit evolutionary experimentation, encourage individual initiative and enhance organizational learning frameworks, through training, appointment of champions and legitimising activities.

The UK firms encouraged the creation and deployment of knowledge, and the findings suggest that knowledge as a resource accelerated technical progress. The primary motivation for encouraging the emergence and development of pools of new knowledge is therefore to achieve learning and competencies in technology, engineering and processes that will then enable the firm to pursue and develop new opportunities. Respondents in the cases found that technology transfer was frequently hindered by the tacitness of knowledge and complexity in new equipment (thus, the process engineer at FoodUK was unable to arrive at optimal settings).

This paper has investigated a number of issues relating to TT in two UK and two South African organizations. Of course, TT encompasses many more concepts than the four identified, and only limited generalisation from four case studies is possible. However, the study has demonstrated that a relationship certainly exists between knowledge, production competence and TT, as illustrated in Figure 1. This becomes apparent when the benefits of greater levels of knowledge are manifested in enhanced production competence, which in turn leads to improved performance and functionality. The UK companies benefited from the knowledge and competences vested within them, when compared to the South African firms. Yet, there is more to TT than knowledge and competences: management support and information systems can play an invaluable important role. Management support was stronger in the South African firms, but information systems did not play a significant part in any of the cases.

Several recommendations are appropriate for managers embarking on successful knowledge-based TT. Managers must develop resources and knowledge if full benefit is to derive from the technology. Management support is a necessary but not a sufficient condition to achieve this. Without specific management attention, information systems are unlikely to assist in knowledge-based decision making, so managers should establish firm processes to collect and analyse data, and utilise this in an analytical manner. Managers should also make determined efforts to enhance production competence. Again, this does not happen on its own, and proactive initiatives are required to enhance an understanding among operators and maintenance staff of how technology operates.

KEY TERMS AND DEFINITIONS

Absorptive Capacity: is a set of organizational routines and processes by which firms acquire, assimilate, transform and exploit knowledge to produce a dynamic organizational capability (Zahra and George, 2002).

Production and Process Technology: is embodied in the equipment or the means to produce a specific good, or provide a service. It is manifested in the finished product/service.

Technology Transfer: is the process by which science and technology are diffused throughout human activity. Wherever systematic rational knowledge developed by one group or institution is embodied in a way of doing things by other institutions or groups, we have TT. This can either be transfer from more basic scientific knowledge into technology or adaptation of an existing technology to a new use. TT differs from ordinary scientific information transfer in that to be really transferred, it must be embodied in an actual operation of some kind.

Technology: may be construed as differentiated knowledge about specific applications: typically the assets that form the basis of a firm's competitiveness.

Chapter 12
Tracing the Implementation of Non-Functional Requirements

Stephan Bode
Ilmenau University of Technology, Germany

Matthias Riebisch
Ilmenau University of Technology, Germany

ABSTRACT

A software architecture has to enable the non-functional properties, such as flexibility, scalability, or security, because they constitute the decisive factors for its design. Unfortunately, the methodical support for the implementation of non-functional requirements into software architectures is still weak; solutions are not generally established. Recently, there are only few approaches that actually deal with non-functional requirements during design; even fewer take advantage of traceability, which supports a mapping of requirements to solutions through the development process. Therefore, in this chapter the new architectural design method TraGoSoMa is presented, which supports these issues. The method uses a so-called Goal Solution Scheme, which guides the design activities, supports conflict resolution, decision-making, and the classification of solutions. For illustration purposes the chapter uses a case study from a reengineering project for a Manufacturing Execution System (MES) that is restructured according to the SOA principles and integrated with an Enterprise Resource Planning (ERP) system.

INTRODUCTION

Motivation

Performance, scalability, flexibility, security and other so-called non-functional requirements or quality properties are crucial for the success of nearly every software project. They bear even more risk than functional requirements, because they can hardly be implemented after making the major design decisions. The software architecture has to enable these non-functional requirements, because they constitute the decisive factors for its design. Several architectural methods emphasize the analysis of non-functional requirements (Hofmeister et al., 2000) and the design considering them (Bosch, 2000; Bass et al., 2002). Furthermore, in the field of requirements engineering

DOI: 10.4018/978-1-4666-1945-6.ch012

functional and non-functional requirements and their interdependencies are modeled using some mature and established goal-oriented approaches (Chung et al., 2000; Yu, 1995; Amyot, 2003). Therefore, some development steps of requirements engineering and architectural design are strongly related with each other. However, bridging the gap between these two research areas is still a critical issue (Galster et al., 2006) especially in the case when non-functional requirements change.

Service-oriented architectures are frequently applied for business-critical purposes. For these systems a long life expectancy constitutes an important concern, during which they have to be adjusted to a high number of changes to maintain their operation and their business value. Thus, evolvability is an important issue for this type of systems.

Traceability links support changes, and therefore the evolution of software systems, by expressing relations between artifacts in different phases of software development (Letelier, 2002). They facilitate program comprehension by expressing dependencies explicitly. They relate design decisions to constraints, and they are used to trace dependencies for checking the completeness of changes. These benefits can be achieved from fine-grained traceability links on the level of design elements and design decisions.

There is a considerable amount of research for managing traceability and for maintaining their accuracy during changes, which is for example discussed in (Mäder et al., 2006). However, the tracing of non-functional requirements usually requires a very high number of links, since typically a high number of a system's components depend on one such requirement.

There are some critical issues that make the whole process complex: for example (a) the mapping of high-level non-functional requirements to their low-level solutions and mechanisms, as well as (b) detecting and solving conflicts among non-functional requirements resulting in trade-offs, and further (c) the missing structuredness of existing methodologies or even their complete absence.

The management of traceability links, and with them the non-functional properties, requires a high human effort, first because of the high number of links and second because of missing rules inhibiting effective tool support. In order to reduce the effort for establishing, maintaining, and validating the traceability links, our work presents contributions to facilitate tool support, and hence, traceability of non-functional requirements, in several ways, which are described in the next sections.

Challenges

The proper treatment of non-functional requirements is a very important part of architectural design. Unfortunately, the methodical support for the implementation of non-functional requirements is still lacking even if this book addresses it. The absence of a consolidated set of solutions for non-functional requirements, the abstraction gap between requirements and design as well as the many influencing factors on design decisions reduce the applicability of detailed design instructions.

From the point of view of software architectural design there are only few methods that lead to an improved design process by especially considering non-functional requirements: for example the QASAR method (Bosch, 2000) or the Attribute-Driven Design (ADD) method (Bass et al., 2002). On the other hand, in requirements engineering there are adequate approaches for dealing with non-functional requirements in a goal-oriented way: for example the NFR framework (Chung et al. 2000), the i* framework (Yu, 1995), or the Goal-oriented Requirement Language (GRL) (Amyot, 2003). Although efforts are made to push these goal-oriented methods towards support for architectural design, and therefore some overlapping in the development steps can be observed, further research has to be done to bridge the gap.

The goal-oriented techniques are valuable for dealing with the interdependencies and the refinement of functional and non-functional requirements, and to some extent are able to map high-level solutions to those goals. However, despite some research on their support for architectural design, (e.g., Grau & Franch, 2007 or Liu & Yu, 2001), on their own they are rather unsuitable and insufficient for the whole architectural design process. Therefore, from our point of view, we have to adjust and integrate these techniques into the software architectural methodologies and publish this knowledge to software architects. This will help them as a means for going from the problem space to the solution space and for choosing and evaluating proper architectural solutions especially for non-functional requirements.

As another aspect, traceability promises strong benefits for the design and evolution of service-oriented architectures and applications especially if traceability links are available on a fine-grained level. However, this leads to a very high number of traceability links. Thus, the complexity of the link structure and a high overhead effort for its maintenance constitute hampering factors. This holds especially for the traceability of non-functional properties, since usually a high number of design elements depend on each non-functional requirement, and this results in a high number of traceability links related to these requirements.

The integration and application of the above-mentioned methods provides the potential for an improved traceability. However, the traceability concepts have to be integrated within these methods, and vice versa the methods have to be adapted to make use of traceability. As a next step after integration, a proper tool support for the management of the traceability links has to be built, covering the establishment, the maintenance, the validation, and the exploitation of the links.

Objectives and Contribution

In this work we present the design method TraGoSoMa (an acronym for Traceability-driven Goal Solution Mapping) for a proper treatment of non-functional requirements during architectural design. The method is intended to give a better support and guidance for architectural design activities while dealing with non-functional goals. It supports the conflict resolution between competing goals and a classification of solutions to the goals they are derived from, as well as a systematic selection based on methodical decision-making. TraGoSoMa clearly is a software architectural design method, even if it partly integrates requirements engineering activities and goal-oriented techniques for modeling non-functional requirements. With its Goal Solution Scheme as a core concept the method maps non-functional goals and subgoals to architectural principles, which are essential criteria for finding the right architectural design, and it maps them further to the functional and technical solutions. Therefore, it enables an accumulation of architectural know-how. Beyond, the application of the method facilitates traceability link establishment, and thus, a better maintainability of the software. The method is illustrated in the next sections with the help of a case study.

BACKGROUND

In this section we briefly investigate the contributions of state-of-the-art methods for non-functional design. Therefore, we discuss Bosch's Quality Attribute-based Software Architectural (QASAR) method (Bosch, 2000) and the Attribute-Driven Design (ADD) method (Bass et al. 2002). We express how our approach is influenced by the goal-oriented approaches from requirements engineering, such as the Non-Functional Requirements (NFR) framework of Chung et al. (2000) and the i* framework which was introduced by

Yu (1995). Moreover, we relate our traceability framework for non-functional requirements to other works concerning traceability.

The Design Method QASAR

A frequently performed way of constructing a software architecture for both kinds of requirements is described by Bosch's QASAR method (Bosch, 2000). QASAR considers non-functional requirements by architectural transformations. The method describes three phases. In the first phase, the functional requirements are implemented by functional components with the Functionality-based Architectural Design (FAD) method. FAD uses core abstractions of functional concepts—the so-called archetypes—to derive architectural components by functional decomposition. In the second phase, the developed architecture is assessed in order to decide whether the non-functional requirements are fulfilled or not. Different approaches for the assessment of the non-functional requirements can be used in this phase, e.g., scenario-based evaluation, simulation, mathematical modeling, or objective reasoning. Once the non-functional properties of the architecture are assessed, in the third phase the architecture is transformed to satisfy the non-functional requirements specifications. This transformation leads to suitable functional structures and components, which are developed for the implementation of as many as possible non-functional requirements. All remaining non-functional requirements are implemented by changing all affected components. In this phase the changes are scattered over the system.

We consider QASAR as a very important method of architectural design and we will use its core concept—the fulfilling of non-functional requirements by functional solutions—in our TraGoSoMa method. The drawback of QASAR, the scattered implementation of the remaining non-functional requirements, results from its third phase. The scattering is accompanied with a demand for a very high number of traceability links and hampers maintainability. We want to address this issue in the TraGoSoMa method by a careful consideration of the non-functional properties.

Attribute-Driven Design

The ADD method of Bass et al. (2002) is a step-by-step method for designing software architectures. ADD considers non-functional requirements at least as important as functional ones and takes them as input together with other constraints. The non-functional requirements, or quality attributes, have to be specified as quality attribute scenarios before. Then, with ADD the requirements are transformed into a conceptual architecture by a recursive refinement, which is applied in several design steps.

First, an architectural element is chosen to be refined, beginning with the system itself. Next, those requirements that influence the architecture the most have to be determined. These architecturally significant requirements—called architectural drivers—are quality, business, or functional goals and can be identified by prioritization. In a further step, architectural styles and patterns are chosen that satisfy the architectural drivers. In this third step, for the one architectural element that is to be refined and its high-prioritized architectural drivers, the most appropriate solution has to be chosen. The fourth step is about the actual refinement. The chosen style is instantiated and corresponding architectural elements are created. The new elements are assigned with functionality they are responsible for, and their interfaces are specified for information flow. In the fifth step, the refinement of the child elements is prepared by verifying and refining their requirements descriptions. Finally, all steps are repeated for further decomposition until all architectural drivers are fulfilled.

ADD, just as QASAR, achieves the fulfilling of quality goals by allocating functional components. Its strength is that it concentrates on the most significant architectural drivers for choosing a proper functional solution utilizing appropriate architectural styles and patterns. We will use this concept in our TraGoSoMa method by prioritizing requirements. However, ADD also has its drawbacks. First, the method ends with only a conceptual architecture and no concrete components; hence, the design process has to be continued by other means. Furthermore, ADD does not exactly describe how to identify the architectural drivers. This step is apparently left for the requirements engineer. Additionally, due to its recursive nature, the capability of the ADD method to evaluate alternative solutions for the overall architecture is limited. If an architectural element is refined once and the method continues with the child elements, there is no possibility to consider an alternative for the previous decision. Besides, there is nothing about traceability support with ADD, which is an important issue we want to address with our TraGoSoMa method.

Goal-Oriented Approaches

In the field of requirements engineering goal-oriented approaches are a popular way to elicit and model requirements. The Non-Functional Requirements (NFR) framework by Chung et al. (2000) constitutes one of these approaches for dealing with non-functional requirements. The framework uses the concept of so-called softgoals that represent non-functional requirements. Softgoals are goals that have no clear-cut definition or criteria for their satisfaction. Development decisions often contribute only partially to or even against these goals within acceptable limits. Because softgoals are accomplished rather partially than completely or not at all, they are considered as fulfilled, and then called *satisficed*, if an adequate level of the criteria is reached. The interdependencies between softgoals can be categorized into several contribution types according to their weak or strong positive or negative influence on satisfying a softgoal.

The NFR framework describes several interleaving and iterative activities to arrange softgoals with their interdependencies in a Softgoal Interdependency Graph. First NFR softgoals are established and refined into subgoals by decomposition. Then, different architectural solutions are developed as so-called operationalizations for the softgoals. Furthermore, softgoals can be refined by so-called argumentations, which model domain characteristics and developers' expertise. Beyond, during the refinement, decisions about the criticality of different goals can be made. Performing these activities, different alternative solutions and corresponding design trade-offs are elaborated in a well-founded way. Implicit interdependencies among softgoals are detected and documented together with design rationale. Alternative solutions are evaluated regarding their contribution to the non-functional requirements. Finally, an adequate solution is selected based on the evaluation.

Another important goal-oriented method is the i* framework, which was presented by Yu (1995). Akin to the NFR framework, i* uses the notation of goals and softgoals to model system requirements. In addition, it contains further elements, e.g., tasks, resources, and actors, and it uses different types of links, as for example contribution, decomposition, and means-end. Therefore, it can be utilized to not only describe the system's requirements but also the organizational context.

In 2008 the User Requirements Notation (URN) (Amyot, 2003) was approved as an international standard as ITU-T Recommendation Z.151. URN consists of the Goal-oriented Requirement Language (GRL), which is based on NFR and i*, and Use Case Maps (UCM), which are used for scenario modeling. GRL as an elaborate notation can be used especially to model non-functional requirements as goals.

We consider the described goal-oriented approaches as appropriate means for modeling non-functional requirements. By explicitly considering non-functional requirements right from the beginning and providing a well-defined evaluation process, they can help to design software architectures. Therefore, our TraGoSoMa method builds on them and uses their notation of softgoals for non-functional requirements and contribution links for the interdependencies.

However, the approaches focus on the refinement of non-functional requirements and their analysis from a requirements engineering point of view. From an architectural point of view, despite some works also dealing with architectural design as for example the one of Grau and Franch (2007), further design activities and notations have to be used. We argue that there are several drawbacks. For example, in the goal-oriented approaches, architectural constraints from the environment as well as interdependencies with technical solutions are not considered. They cannot assure that a selected solution can be implemented with a specific technology. Furthermore, the goal-oriented approaches do not consider general design principles in their decomposition and refinement, although they are very important for choosing proper solutions during architectural design. Beyond, the comprehension of the quality goals' background is an important issue for architectural design. That is way giving only goal models as input to software architects as a means for description is rather insufficient. Therefore, we integrate these techniques in a context of further design steps. Furthermore, in the work of Chung et al. (2000) they only concentrate on accuracy, performance, and security requirements—on the last one in a rather outdated way—and are not concerned with traceability issues. We will later discuss traceability and also some security aspects, when describing our TraGoSoMa method, in more details.

Traceability

Traceability is a concept to relate artifacts from different development stages, such as requirements analysis, design, and implementation via links. The use of traceability links is advantageous even if additional effort is required. Traceability links facilitate system comprehension by providing information about dependencies between artifacts and entities. Requirements traceability enables to trace back the origin of a requirement to its elicitation and to document every change made to it. Important works in this field are the ones of Gotel and Finkelstein (1994), Pohl (1996), Ramesh and Jarke (2001), Letelier (2002) as well as Pinheiro (2004). Other approaches for traceability link establishment consider links between requirements and test cases, for example the scenario-driven approach by Egyed (2001) and the approach by Olsson and Grundy (2002).

In the scope of our work, traceability links can be used to trace design decisions during the development process. Approaches regarding traceability from requirements to design and between various design artifacts have to be considered. Traceability links for design shall be established and adapted while building or manipulating models or other development activities. Therefore, the steps of link establishment have to be embedded into the steps of design methods. We have to state that—to the best of our knowledge—there are no approaches of this kind. For establishing traceability links regarding non-functional requirements and design artifacts there is the probability-based retrieval approach by Clelang-Huang et al. (2005) called Goal-Centric Traceability. Their user evaluation step to discard incorrectly retrieved links to increase precision is valuable. However, they can only identify links that are incidentally included in the descriptions of artifacts that were elaborated regardless of traceability. They cannot identify links, if the investigated artifacts do not cover the relations. Therefore, the completeness and correctness of the links can never be optimal. The incremental approach of Latent Semantic Indexing by Jiang et al. (2007) aims at the identification of related elements with link recovery. It can be helpful for finding links in existing designs and maintaining their change, but it cannot provide all links.

For the definition of relations between design activities and traceability links, a standardized definition of the syntax and semantics of the traceability links is necessary. Unfortunately, the definition of a standard set of traceability link types is still an unresolved issue. Due to different research goals, a high number of traceability link types has been defined, for example in (Pohl, 1996) or (Ramesh & Jarke, 2001). As a step towards simplification and abstraction, we will later restrict ourselves on a small set of types.

For an exploitation of the traceability links, they have to be established on a detailed level, for example to generate test cases; they have to connect model elements and expressions. As a result, the number of links and the complexity of traceability information are high. The issue of maintaining and checking the links leads to a high effort and thus tool support is essential. An overview of research topics, results, and open issues in the field of traceability is discussed in (Mäder et al. 2006) and (Winkler & von Pilgrim, 2010).

There is already support for traceability by requirements management tools, e.g., Requisite Pro or Doors, and by goal-modeling tools, such as jUCMNav (Roy et al. 2006). However, their support for linking other artifacts than requirements is limited. Mäder et al. (2008) present an approach that tackles the problem of automated traceability for UML-based development. Their *traceMaintainer* is a rule-based prototype tool for traceability link maintenance. Nonetheless, there is a need for further work, because the tool does not cover initial link establishment and tool support should not be limited to UML models as well. For an automated link establishment, the definition of proper rules is an important issue. Therefore, as a first step, in (Bode & Riebisch, 2009) we already described in detail, how traceability links can be established during several development steps and between different design artifacts using the example of the category-based design methodology Quasar (Siedersleben, 2004).

In the next section we illustrate our design method TraGoSoMa for tracing the implementation of non-functional requirements. We establish traceability links between non-functional requirements, architectural principles, and functional solutions. Therefore, we present a set of link types and their semantics, and we explain how they are applied while performing the several design activities according to our Goal Solution Scheme. With the help of these traceability links according to the Goal Solution Scheme, especially the comprehension of the transformation of non-functional requirements to solutions is supported. The design-decisions are traced and rationale for the decisions can be connected to the links. Furthermore, with the help of the links and an evaluation of the decisions, the completeness of solutions for the non-functional requirements can be checked.

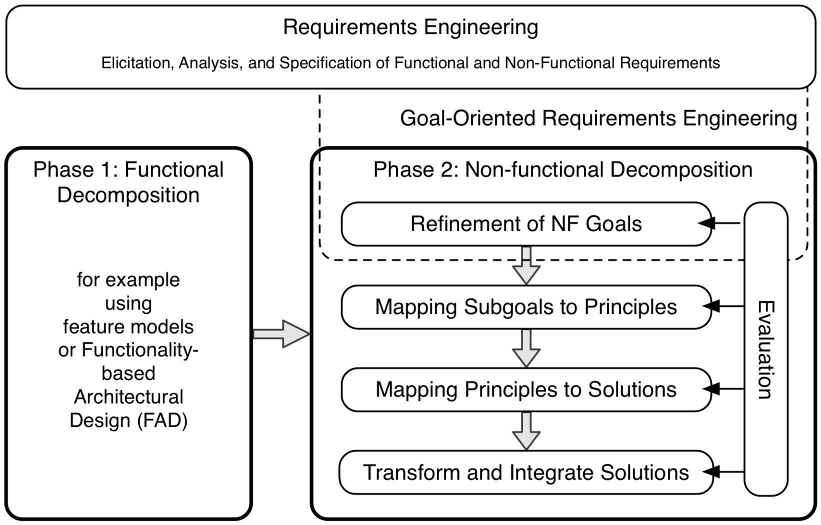
ARCHITECTURAL DESIGN PROCESS OF THE TRAGOSOMA METHOD

In this section we present the design method TraGoSoMa, named by an acronym for Traceability-driven Goal Solution Mapping. We first give a short overview of the method; afterwards we introduce our case study, which illustrates the design activities, and the Goal Solution Scheme, which constitutes a core concept and drives our method. Further, traceability issues are discussed and the phases of the design method are explained in detail.

TraGoSoMa Method Overview

The method TraGoSoMa represents an architectural design method with focus on non-functional properties. It starts after elicitation, analysis, and specification of the requirements and consists of different phases and steps illustrated in Figure 1. First of all, a functional decomposition of the sys-

Figure 1. Phases and steps of the TraGoSoMa method related to requirements engineering



tem is performed akin to QASAR's FAD method. This could be done using different approaches, such as feature models or function trees, and results in candidates for architectural components, the responsibilities of which are determined by functional requirements. We propose to perform decomposition according to the functional requirements first, because this is for example necessary to determine the security-relevant parts of the system; see (Bode et al. 2009) for details. However, designing for the non-functional goals is even more important, but less understood today. So, in the second phase of our method especially the design for non-functional requirements is handled.

This second phase is strongly connected to the Goal Solution Scheme. The first step is performed, if not already provided from the requirements specification. The soft, imprecise, mostly vague, ambiguous, and competing non-functional requirements, such as flexibility, scalability, or security, are modeled as goals and refined into subgoals. This enables the resolution of conflicts between the goals by prioritizing the subgoals accordingly. In this step, we utilize the goal-oriented approaches discussed before, instead of pure scenario-based techniques as proposed by most architectural design methods. In a second step, these subgoals are mapped to the design principles, which support the subgoals. We introduce this mapping, which is not performed in the goal-oriented approaches, because general design principles are very important for choosing proper solutions during architectural design. Additionally, the architect has to be involved in this modeling process since only providing goal models as input for further design is not enough. In the third step, possible functional solutions and technical components, as so-called solution instruments that support specific principles and subgoals are identified, and traceability links are established accordingly. In this second and third step several architectural decisions have to be made about which principles and solutions are considered for design of the software architecture with regard to trade-offs and synergies between different subgoals. These decisions are significant, because the effect of the relations between subgoals can be mutual enhancement or reduction. A final fourth step in the second phase further combines the functional decomposition of the first phase with the findings from the second.

As a result of the second phase, the architectural components are defined according to functional and non-functional responsibilities, and functional solutions are elaborated for non-functional responsibilities. The solutions and technical components established in the second phase with the help of the Goal Solution Scheme are integrated into the software architecture. Therefore, adequate architectural transformations have to be performed akin to the third phase of QASAR. The kind of these transformations, and how they are applied, is discussed in a later section. All activities in the second phase of the TraGoSoMa method have to be subject to an early assessment within an iterative design process. With the evaluation all decisions and the contributions of the solutions to the non-functional requirements are checked. We deal with this issue in an extra section.

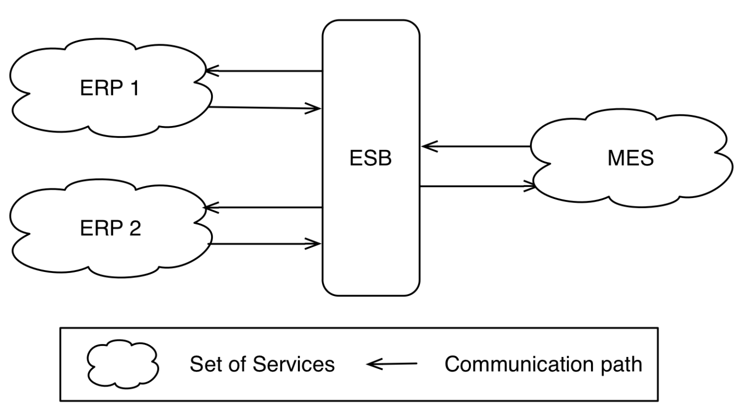
In the following sections we assume the requirements specification and functional decomposition to be done and concentrate on the second phase of the architectural design process dealing with the non-functional properties. We also explain how this approach facilitates design traceability.

Service-Oriented MES Case Study

For the illustration of the TraGoSoMa method we use a case study from a reengineering project for a Manufacturing Execution System (MES) that is restructured according to the SOA principles. A MES manages the manufacturing in modern flexible plants (VDI, 2007). It is connected to Enterprise Resource Planning (ERP) systems, which handle manufacturing plans and actions and represent a business perspective, while the MES is able to manage the manufacturing actions on a more fine-grained level. An MES has access to the abilities and the limitations of the real manufacturing processes and, therefore, it is able to optimize them, and simultaneously provides an increased flexibility. The MES covers tasks, such as detailed scheduling and process control, the management of machines, material, and personnel, etc. For the case study we focus on the integration between ERP and MES. The requirements to the interface between both are defined by the ANSI standard ISA-95 (ISA, 2000). As the platform for the MES interface the Enterprise Service Bus (ESB) (Chappell, 2004) has been chosen, in a style similar to a middleware. Figure 2 shows the integration interface and its environment.

There are some non-functional properties an MES has to fulfill: a high flexibility and scalability, time behavior as well as security. As an example for a security requirement we mention the information flow control. In our case it is important to protect the business-critical private information of the customer 1 from an unauthorized access by its competitor customer 2. Even if

Figure 2. Overview of the integration interface



both give manufacturing tasks to the producer, no details about the order must be disclosed to the competitor through the ESB or the MES, for example details concerning amount, specification, and technological process. Flexibility is necessary regarding different planning algorithms, control principles, and regarding the integration with a variety of machines and ERP systems. The requirements for scalability arise from the need for mastering complex manufacturing tasks with a high number of variants and elements, and for the interoperation with multiple different ERP systems due to outsourcing.

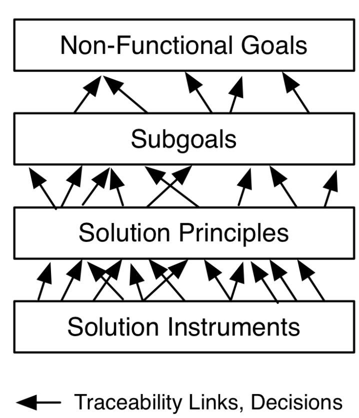
Goal Solution Scheme

The Goal Solution Scheme was developed to guide the designer to deal with non-functional properties while designing the architecture, to ease resolving conflicts between competing goals and design principles, and to facilitate decision-making. It has some similarities with goal-graphs from requirements engineering. However, the scheme extends it by the explicit consideration of design principles and a classification of functional and technical solutions. As indicated in Figure 3, the Scheme maps non-functional requirements to their subgoals, to solution principles supporting these goals, and further to solution instruments, such as technical solutions and components, for an implementation of the principles. The mapping is represented by traceability links, which are visualized in Figure 3 by the arrows. From top to bottom the scheme represents possible refinements and decisions during the implementation of non-functional requirements. The traceability links carry the information about the design decisions. By providing guidance the scheme refines the design methods and facilitates the establishment and maintenance of traceability links related to the design activities.

The scheme guides the activities within analysis and design and represents them by transitions between the layers. The upper transition supports the resolution of conflicting non-functional properties by a refinement to subgoals. Such a specification and refinement of non-functional goals can also be provided by the goal-oriented approaches we discussed above, e.g., the NFR framework, i*, or GRL. However, we included this transition step because this kind of specification of non-functional goals is seldom provided to software architects in practice. The comprehension of this transition is necessary for the software architects as well, because they have to contribute to the prioritization of the non-functional goals and they have to implement the goals by selecting proper principles. Since we do not want to reinvent the wheel, we adopt the goal-oriented notation for softgoals and the contribution links, even if this leads to an overlapping with requirements engineering models.

The next transition of the scheme guides the designer from non-functional goals to solution principles, which is a novelty step regarding the design progress towards a solution in comparison to the goal-oriented requirements engineering approaches. In the lower transition of the scheme, technical solutions and existing components are mapped as solution instruments to the principles, making decisions on how to implement the goals and principles by solutions. A similar concept is used for the Factor-Strategy Models of Marinescu

Figure 3. Structure of the Goal Solution Scheme



and Ratiu (2004) who use design rules and principles to map metrics to quality goals.

As a major contribution the scheme facilitates the prioritizing for decision-making. Furthermore, the scheme supports the resolution of conflicting non-functional requirements by an identification of potential trade-offs and synergies. It provides a fine-grained sequence of design steps. In this way, the scheme represents a refinement of the design activities, which are represented by traceability links. A reduction of the traceability link complexity is achieved, since one or a few principles and solution instruments implement one subgoal. In an ad-hoc design non-functional requirements are implemented in a scattered manner leading to a much higher number of links, for example 10 or 100 times higher.

The Goal Solution Scheme constitutes the central concept for the simplification of the traceability links. It facilitates the traceability in several ways:

- Significant reduction of the number of links,
- Guidance for the designer by sequences of proposed design activities, which enables tool-supported decisions and automation,
- Simplification of link checks for accuracy, completeness, and consistency by a comparison between chosen solutions and relations within the Goal Solution Scheme.

As a result, the scheme provides an alignment of solution principles and solution instruments, it classifies them according to their impact on non-functional properties, and it provides a stock of reusable solution instruments to the architect and the designer. The solution instruments serve as a source of proposals for design alternatives during decision-making.

The scheme is not a design artifact that requires additional maintenance and effort. It rather is a data structure on a meta-level, which indicates and guides how the architectural design steps should be performed in the TraGoSoMa method. If traceability links are established appropriately and managed in a repository, the organization of the repository reflects the Goal Solution Scheme. Beyond, a software architect can use the scheme as a knowledge base, where solution instruments are mapped to principles and goals.

Traceability Links

As mentioned previously, traceability links connect artifacts in the sequence the developer has built or accessed them. Furthermore, they carry the information about the design decisions that lead to the related solution instruments, such as components. For the link tracking, evaluation, and exploitation, the type of the traceability link is important, because it determines a link-semantics as mentioned in the background section; the number of link types should be small.

Additional information can be stored attached to the link, e.g., design decisions. Important elements an explicit traceability link comprises are:

- a unique identifier for its recognition and to avoid ambiguity,
- a start element as source of the link, including type and context of this element,
- an end element as destination of the link, including type and context,
- the type of the link.

For the decision-making, traceability links are advantageous because they make decisions explicit and comprehensible. Alternatives can be estimated. Software architecture design decisions should always be documented with their design rationale (Clements et al. 2003). Therefore, they are recently seen as first class entities. Duenas and Capilla (2005) for example introduced a decision view for software architectures. The Goal Solution Scheme facilitates the tracing of such decision entities to their related artifacts. Therefore, a link may contain additional information:

- a reference to a design rule for this specific activity,
- the decision connected with the development activity, including the goal of the decision, alternatives, the rating of the alternatives and the choice,
- the link status concerning the certainty of correctness (e.g., after changes of the connected elements or during reverse engineering activities),
- the creator of the link,
- a temporary priority to control the tracking of the links.

As introduced by earlier works (Mäder et al., 2007), we distinguish four different link types, which are sufficient for the most design situations:

- *refine* – for an activity increasing the level of detail, either by specialization or by decomposition including the AND and OR types.
- *realize* – represents a step towards the solution (e.g., between a non-functional goal and a design principle or between a principle and a solution)
- *verify* – compares the behavior and the properties of requirements and of the developed solution or its parts (e.g., between a use case and a test case) and
- *define* – relates the establishment of an identifier and its usage.

Additional link types can be introduced for dependency types from utilized models as for example UML models. In order to be able to handle the goal models and their contribution links we added the link type

- *contribution* – which can express degrees of positive or negative influence between model elements.

With the help of the contribution links an evaluation of alternatives can be achieved, for example in relation to the goal models. However, positive contributions can also be linked as realizations, when a solution is chosen. The realization links then enable tracing which path was taken from the problem space to the solution space and how the goals are achieved by the implemented solution.

Traceability links can be tracked in both directions, regardless of the direction that is defined by the link type. Besides, a distinction between implicit and explicit links is necessary. Explicit traceability links are established, while a developer performs a software development activity. Implicit traceability represents existing associations between elements of the system model using identifiers, for example between an analysis and a design artifact. These traceability links are references, but they are evaluated if traceability links are tracked during their utilization.

The type of the traceability links is defined according to the TraGoSoMa design activities. The transitions in the Goal Solution Scheme represent these activities. In the first transition the non-functional goals are decomposed and thus linked to the subgoals by links of the type *refine*. In the second and third transition the positive and negative influence has to be represented. Therefore, links of the type *contribution* are established. In addition to the influences, these transitions represent steps towards solutions. Consequently, the link type *realize* is used to express this aspect. A possible decomposition on each level of the Goal Solution Scheme, for example a decomposition of solutions, can also be traced by links of the type *refine*.

Goal Refinement and Elaboration

The several non-functional requirements for a product are often competing and conflicting in their interdependencies. As a solution they have to be prioritized. If this is not possible on the top-level, a resolution is attempted after a refinement. By refining the requirements vague interdependencies can be concretized and previously hidden dependencies can be made explicit. To determine the mutual impact of the relations and to detect conflicts and synergies, the requirements or goals can be classified in dominating (fundamental) and supporting (instrumental) ones (Wohlfarth, 2008).

The refinement of the non-functional goals is covered by the first transition in the Goal Solution Scheme. This is the first step in the second phase of our design approach. The refinement of the non-functional properties is necessary for their comprehension and makes them more specific. It can be performed according to the abovementioned goal-oriented approaches, e.g., the NFR framework.

For the refinement standards can help, for example the ISO 9126 (ISO, 2001). This standard for instance provides subgoals for maintainability, namely analyzability, changeability, stability, testability, and maintainability compliance. Furthermore, the Goal Question Metrics (GQM) method can be applied to identify subgoals. This structured querying technique helps to analyze influences on a goal (Basili et al., 1994). The Factor-Strategy Model of Marinescu and Ratiu (2004) uses a similar principle for mapping quality goals to metrics.

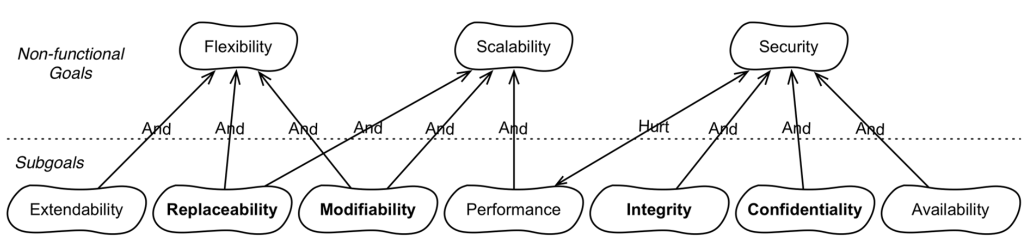
According to the NFR framework (see section *Background*) non-functional requirements have a type and a topic. As an example, the requirement "Security of accounts" has the type "security", which indicates the specific NFR, and the topic "accounts", which targets at the subject. Non-functional requirements can be refined regarding type or topic. The refinement of maintainability mentioned above is a refinement regarding the type of the NFR.

In our case study the top-level non-functional requirements are *flexibility*, *scalability*, and *security*. According to the ADD method they constitute architectural drivers. After a consideration of their relationships on this level we can assume that flexibility and scalability are in a rather synergetic relation to each other, because they both deal with change, while security might be conflicting to the others, because it implies restrictions of the information flow and the data access. This guess has to be proven in the next steps. For a precise analysis and a solution for our MES project, a refinement has been performed. Figure 4 shows parts of the results. The refinement is presented using the i* notation for softgoals and links.

For flexibility, there is a definition in the IEEE standard glossary of software engineering terminology (IEEE, 1990), although a detailed discussion of its subgoals is missing. Regarding flexibility some discussion can be found in the literature (Zeng & Zhao, 2002; Nelson et al., 1997; Eden & Mens, 2006; Morgan, 2006). We elaborated the subgoals *extendability* (IEEE, 1990), *replaceability* (ISO, 2001), and *modifiability* (Bengtson et al., 2004) for our example. We focus on the latter two because of their high priority.

Scalability is lacking a definition by a standard; however, some works discuss this quality attribute (Hill, 1990; Bondi, 2000; Duboc et al., 2006; Duboc et al., 2007). Scalability is always

Figure 4. First transition of the goal solution scheme (cut-out from the case study)



concerned with *performance,* or efficiency in terms of the ISO 9126 (2001), and how well a solution to a problem will work when the size of the problem increases. However, if a system performs well it is not necessarily scalable, too. Therefore, we considered replaceability and modifiability as subcharacteristics of scalability as well. If an MES has to face changes for example due to an increasing complexity of the manufacturing tasks, modifications are necessary. Moreover, it should be easy to replace parts of the whole system with more efficient ones, if this is necessary to scale up and retain a high performance.

For security there are several definitions from the International Organization for Standardization (ISO), e.g., (ISO, 2001; ISO, 2005), and Chung et al. (2000) comprehensively discuss its refinement in their NFR framework. The most important subgoals are *integrity*, *confidentiality*, and *availability*.

Before the refinement, we already mentioned our assumption for a synergetic relation between flexibility and scalability, as well as the possible conflict between scalability and security. The conflict could neither be verified nor solved on the top level, because both scalability and security are essential. However, after the refinement of the non-functional goals illustrated in Figure 4, we can try to solve the conflict and verify the synergetic interdependency between flexibility and scalability. The latter could be verified by the mutual positive influence of replaceability and modifiability on both top-level goals. Beyond, a negative interdependency between performance and security was detected, because security mechanisms, as for example encryption, require extra operations, often are time consuming, and can hamper performance. This confirms the conflict; however, for a resolution a further refinement to principles is necessary. For the further design process of our case study we will concentrate on the subgoals replaceability, modifiability, as well as integrity, and confidentiality because of their high priority.

The abovementioned refinements are expressed using *and*-contribution links according to the i* notation. In the Goal Solution Scheme they are represented by traceability links of the type refine. The *hurt*-contribution can be traced with links of the type contribution if necessary.

Decision about Solution Principles

After the first step of the second phase of TraGoSoMa, the top-level goals are refined into subgoals and are more specific. But, they are still non-functional and still cannot be implemented directly. In the second step, the transition from the subgoals to the design principles is performed, as presented by the Goal Solution Scheme.

As a step from the problem space to the solution space, in this second step, design principles and guidelines are assigned to the subgoals. These principles and guidelines give hints or advice for the functional solutions. Of course, lots of principles exist and even more relations between non-functional goals and these principles are imaginable. Therefore, the designer has to analyze the subgoals and to decide on suitable principles. It is always the case, that there are different non-functional goals that have symbiotic relations or in contrary compete with each. In order to resolve conflicts, knowing about the interdependencies between the different subgoals is important. A goal model contains these dependencies and the trade-offs.

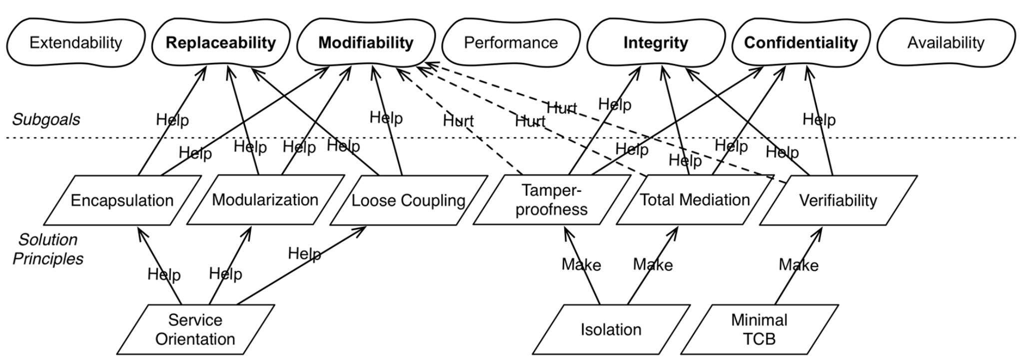
For illustration an example for a decision is discussed here. The principle of high encapsulation supports changeability. On the other hand, a strong encapsulation has a negative influence on testability, because inaccessible attributes are hard to control. Because of the refinement from the first step, both changeability and testability are known to be subgoals of maintainability and contribute to it. Now, by assigning encapsulation to these subgoals the trade-off becomes visible and can be considered. Frequently, multiple different principles contribute to the same subgoal. In these cases a decision can be made, which principle is applicable or how to prioritize them.

Trade-offs between different non-functional subgoals and solution principles often are still not tangible enough. Then, they have to be elaborated further on the solution instruments level of the Goal Solution Scheme. This is necessary to be able to decide with clear rationale, which principle to choose to achieve the highest degree of goal fulfillment. In this case, the principles are mapped further to solution instruments and the decision-making is postponed to the next step, when the criteria for adequate solution instruments are more precise than those for the principles. Based on the solution instruments' contributions to the principles and the non-functional goals, the different alternatives can be weighed and the decisions, which alternatives to choose, can be made. For the goal-oriented approaches some evaluation techniques exist, anyway, it is always reasonable to decide as soon as possible to reduce further effort.

For our case study, the second transition of the Goal Solution Scheme is partly shown in Figure 5. The subgoals result from the refinement in the previous step of TraGoSoMa. Starting from the higher prioritized subgoals, appropriate solution principles are chosen. For the subgoals replaceability and modifiability, we decide in favor of the architectural design principles *encapsulation*, *modularization* and *loose coupling*. These principles are well known to support changes. Already Parnas (1972) discussed the importance of modularization for changeability and flexibility, which is one of our most important non-functional goals. Moreover, *service orientation* was identified to support encapsulation, modularization, and loose coupling. A service-oriented architecture obviously can help in this scenario, because loose coupling is one of its core principles. It further helps encapsulation and modularization. In addition to the contribution links shown in Figure 5, the mentioned principles are explicitly related to the subgoals replaceability and modifiability by traceability links of the type realize. This type of links is established, because the principles represent a step towards the solution of the non-functional goals, and to document the design decisions for choosing service orientation.

The security subgoals integrity and confidentiality are discussed as another example. To integrate such requirements, security policies have to be applied, as a comprehensive set of rules that are designed to achieve the system's security goals (Goguen & Meseguer, 1982). Security policies are applied to determine a so-called *trusted computing base* (TCB) (Lampson et al. 1992). The TCB comprises the functional parts of a system that enforce and protect the security policy. For the implementation of a security policy and a trusted computing base, there are fundamental principles that refer to the so-called reference

Figure 5. Cut-out of the transition from subgoals to principles for the case study



monitor concept (Anderson, 1972). A reference monitor must be tamperproof, always invoked and small enough to be analyzable and verifiable, which is represented by the principles *tamper-proofness*, *total mediation*, and *verifiability*. These reference monitor principles are further supported by *isolation* and a *minimal TCB* as principles for the architectural design. Isolation of the security relevant functions in the security architecture of a system is a necessary consequence to be able to realize a tamperproof reference monitor that cannot be bypassed (Gasser, 1988). Correctness and completeness are additional necessary properties not further discussed here (Department of Defense, 1985). These decisions and the causes are again documented by traceability links of the type realize.

However, in this design step, conflicting relations between the security principles and the subgoal modifiability were identified as well. They are shown as *hurt*-contribution links. Modifications in the software architecture can have a negative influence on the minimality of the trusted computing base and vice versa. The other security principles are affected by changes as well. Tamperproofness can easily be breached if a modification is performed in a wrong way. Therefore, changes should only be made on those architectural parts that have not to be isolated due to security reasons.

These conflicts confirm our earlier assumption that security is in conflict with flexibility and scalability. However, at the principles level their interdependencies have been clarified and we have a much better understanding of the conflict than on the goal or the subgoal level. Anyway, the conflict between the fundamental security principles and the subgoal modifiability cannot be resolved in this transition of the Goal Solution Scheme. The conflict resolution has to be postponed to the next design step, when a related solution can be analyzed more precisely than the principles.

Decision about Solution Instruments

In the third design step the actual transformation of the non-functional properties to a functional solution is performed. This step is closely related to the third step of the QASAR method (Bosch, 2000). A similar mapping of solution instruments to goals can also be found in the NFR framework and the i* framework, where operationalizations, or tasks respectively, are assigned to decomposed softgoals.

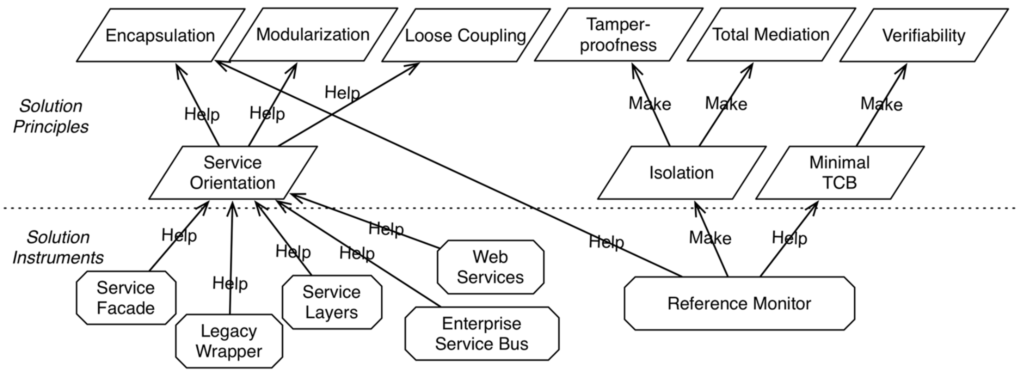
In our method solution instruments can be functional concepts or even existing technical components, which either support the realization of non-functional goals or completely fulfill some of them. In this third design step a large number of solution instruments is possible. In order to find the most adequate ones, the designer weights the different alternatives, akin to the last step.

The explicit linkage from goals to principles and solution instruments classifies the latter ones according to their contributions to the non-functional goals. The Goal Solution Scheme serves as a knowledgebase, which enables the incremental collection and the reuse of the solutions in a goal-oriented way.

Of course, the decisions are also influenced by other technical or organizational requirements and constraints. For example the technical component JGoodies (2008) explicitly facilitates usability with its subgoal user satisfaction by an easy alignment and balancing of visual elements. However, it cannot be chosen, if the project demands for the C++ programming language, because JGoodies is based on Java and Swing. To consider such architectural constraints, a two-stage process can be applied. In a first step, all solutions that are inappropriate are ignored. In a second step, the remaining ones are ranked according to their satisfaction of the goals to find the best solution.

Figure 6 shows a part of the Goal Solution Scheme for the transition from principles to solution instruments for our case study. To realize service orientation, and thus the principles encap-

Figure 6. Cut-out of the transition from principles to solutions for the case study



sulation, modularization, and loose coupling, the solution instruments *Web Services* and *Enterprise Service Bus* (ESB) for the integration of the MES and ERP are chosen. The reason for these decisions is that well-defined web services according to the Service-Oriented Architecture (SOA) paradigm inherently reinforce those principles (Erl, 2007). A component-based Common Object Request Broker Architecture (CORBA), for example, could have been an alternative for a service-oriented architecture. However, for our case study a CORBA infrastructure was not available.

As an example from our case study, one realized service shall be mentioned. The service *MachineAvailability* can be used for the interaction of the detailed planning of an MES and the general planning of an ERP. Using this service the ERP can request status information about machines, such as their availability. When implementing the web services, architectural and design patterns, such as *Service Layers* (Fowler, 2003; Erl, 2008), *Service Facade*, or *Legacy Wrapper* (Erl, 2008), contribute to the realization of the principles, and hence, to the non-functional goals.

The application of a reference monitor solves the integration of the security aspects. The security principles are integrated with the help of the ESB to gain control of the communication between the MES and ERP system and to isolate the security-relevant architectural parts. Aside, it must be considered to keep the TCB as small as possible. A discussion on the integration of security with web services can be found in (Fischer & Kühnhauser, 2008). With this kind of solution the conflict between the security principles and the subgoal modifiability, which was detected in the last design step, cannot be resolved completely. However, it can be implemented in a controlled way by controlling access to the security relevant functionality. Hence, the realization of a reference monitor not only positively contributes to the reference monitor principles, but also helps encapsulation, and therefore, even modifiability despite the conflicts.

As an alternative to the reference monitor, in an ad-hoc approach or according to the discussion by Chung et al. (2000), one could have considered only multiple single solution instruments, such as encryption mechanisms, or roles and rights, for security purposes. Of course, these solution instruments can contribute to confidentiality and maybe availability and integrity. However, as a drawback, without considering the reference monitor principles the system would be much more vulnerable.

In this step of the TraGoSoMa design method again all decisions about solution instruments for the solution principles are made explicit by traceability links. As shown in Figure 6 all solution instruments are mapped to the corresponding solution principles. The chosen solution instruments, such as the patterns Service Layers, Service

Facade, and Legacy Wrapper, are traced with links of the type realize. Additionally, elaborated alternatives not discussed here can also be linked with the type contribution and may be reused later. Figure 6 depicts only the mentioned solution instruments. Actually, much more solution instruments are contained, and the architect can easily extend them by additional ones.

Merging the Functional Solutions

In the fourth step of TraGoSoMa's second phase the solution instruments from both origins have to be merged, from functional goals and from non-functional ones. In this step a balancing between both types of requirements has to be performed (Harrison & Avgeriou, 2007). The functional requirements—the first type—have been elaborated into candidates for functional components as in phase 1 (see Figure 1) by a functional decomposition, for example following the FAD method by QASAR. For non-functional goals—the second type—solution instruments in the form of components are integrated, which are developed according to the Goal Solution Scheme in the second phase.

The merge can be performed by architectural change operations of different types. The simplest case is to only *add* the functional components that implement non-functional requirements from the second phase to the components of the first phase. A second type of transformation is to *replace* functional components. For example, if a functional component from phase one is insufficient in fulfilling the non-functional requirements, it is replaced by the solution instruments elaborated in the second phase. A third type of transformation is to *remove* a previously decomposed functional component to enable the realization of a non-functional goal. Baldwin and Clark (2000) mention three more elementary types of changes called modular operators: *split* a component into two, *port* a component for extraction to a new one, and *inversion of hierarchy* for moving components from a lower position in a hierarchy to a higher one. As another example, we mention the implementation of security goals. To solve this task by the reference monitor concept (Anderson, 1972) a separation of security-relevant and security-irrelevant functional components is performed to achieve a minimal Trusted Computing Base applying the *inversion of hierarchy* operation (for more details see Bode et al., 2009). In the case security-relevant and security-irrelevant functions are covered by one component, it has to be *split* or partly *ported*.

As the result of the merge a software architecture has been developed. Its components are functional ones, which can be implemented directly. All responsibilities that are due to functional and non-functional requirements are assigned to these components.

Evaluation of the Decisions

For an early assessment of the architectural design any iteration should include an evaluation. The assessment technique depends on the characteristics of the assessed products and on the criteria to be evaluated.

There are several well-established assessment techniques for software architectures. Two types are especially suitable—questioning and measuring techniques. The techniques of the first type, for example structured scenario-based inspections with the Architecture Tradeoff Analysis Method (ATAM) (Kazman et al., 2000), are performed by experts. Based on the assessment criteria, the scenarios are established, for example an intrusion scenario for an evaluation regarding security or an extension scenario regarding maintainability. Evaluations of this type can be performed early, even if the architecture is not complete. Performing the evaluation in a structured, formally defined way by external experts can reduce the disadvantage of the subjective nature of the result.

The measuring techniques provide objective, quantitative results. However, they require formal models and well-defined evaluation criteria. Examples for this type are metrics for architectural quality, e.g., for modularity by relating the number of all inner dependencies of a component to the outer ones. In (Brcina & Riebisch, 2008) traceability links between model elements are evaluated for evolvability, and for example the effects of tangled or scattered components are assessed as criteria for architectural quality.

FUTURE RESEARCH DIRECTIONS

The consideration of non-functional properties constitutes a long-term goal for architectural development, even beyond SOA. Further work is needed to close the gap between requirements engineering and architectural design regarding integration of methods. Maybe aspect-oriented techniques can help regarding this issue as well. Moreover, there is a special need for integrating the mentioned concepts with the Model-Driven Architecture (MDA) approach.

The need for a rigor specification of non-functional requirements can be fulfilled only for some categories, e.g., security. Many others, e.g., usability, flexibility, and scalability, are specified by informal or semi-formal descriptions. Ontologies can help to analyze the semantics of these descriptions based on the terms and their relations.

For the early evaluation of the results of architectural decisions, a prototyping is necessary in some cases, for example for requirements regarding efficiency and scalability. The generation of the necessary prototypes shall be based on the architectural decisions and documents to minimize the additional effort.

CONCLUSION

In this paper the architectural design method TraGoSoMa has been presented, which provides improved support and guidance for the architect to consider non-functional properties. The method aims at the definition of components and their implementation illustrated with a SOA example. As an important element the method introduces the Goal Solution Scheme, which represents the alignment between non-functional goals, their subgoals, the applied solution principles, and the solution instruments for implementing the required properties. By using this scheme, the conflict resolution between competing goals is supported, the solution principles and the solution instruments are classified according to the non-functional goals supported by them, and the systematic selection of solution instruments during architectural decisions is facilitated. Furthermore, the Goal Solution Scheme supports the accumulation of architectural know-how by a stepwise extension of the classification and the solution instruments. The scheme expresses traceability links in an explicit way, while the method facilitates their establishment, and thus, supports the maintainability of the software. Especially important is the traceability between non-functional goals, such as scalability, efficiency, and security, and the chosen solution instruments.

Regarding state-of-the-art methods, the contributions of the method can be compared to the QASAR method as well as to the works of Chung et al. and Yu as discussed in the background section. The QASAR method is extended by enhancing its second design phase by a systematic procedure for non-functional properties, which reduces the effort for transformations, and by improving the third phase by reducing the scattering of the changes to the design. In comparison to the goal-oriented approaches from requirements engineering, we consider architectural constraints from the environment as well as interdependencies with technical solution instruments. Furthermore, as a novelty step, we map non-functional goals to solution principles and integrate the goal-oriented activities in the context of an architectural design method. We use a design decision process, especially considering well-known solution principles to find conflicts, synergies, and solution instruments. Beyond, we include the establishment of traceability links into our method.

The method is applied for the redesign of a Manufacturing Execution System (MES) in order to integrate it into a service-oriented environment of business systems in manufacturing. With the help of this case study, we illustrate the several design steps, and therefore, show the importance of such a methodical design and its relevance for industrial use.

KEY TERMS AND DEFINITIONS

Architectural Design Method: A systematic approach with analysis, synthesis, and evaluation activities to create a software architectural description from functional as well as non-functional requirements taking organizational and technological constraints into account.

Enterprise Resource Planning: The complex task to efficiently use all resources of an enterprise, such as financial assets, production facilities, or personnel, to control and optimize business processes.

Manufacturing Execution System: A software system responsible for the organization and execution of the production process in a factory with numeral scopes of duty as management of all required activities within the production process or the exchange of information with the environment as to ERP systems (for a comprehensive definition see (VDI, 2007) for a comprehensive definition).

Non-Functional Requirement: Also quality requirement, quality attribute, or quality goal – a software requirement that describes not what a software system has to do, but how it should be done and under which constraints, and therefore, defines its quality (for a comprehensive discussion see (Chung et al., 2000) for a comprehensive discussion).

Software Architecture: The description of the organizational structure of a software system, its architectural elements, their properties, interfaces, relations, and behavior, as well as a set of decisions and guidelines for the design of the system.

Software Quality: The totality of characteristics of a software product that bear on its ability to satisfy specified requirements (cf. ISO, 2001)).

Traceability: The capability to track and recover in both a forwards and backwards direction the development steps of a software system and the design decisions made during on-going refinement and iteration in all development phases by relating the resulting artifacts of each development step to each other (based on (Gotel & Finkelstein, 1994)).

Section 2
Development and Design Methodologies

This section provides in-depth coverage of conceptual architecture frameworks to provide the reader with a comprehensive understanding of the emerging developments within the field of Industrial Engineering. Research fundamentals imperative to the understanding of developmental processes within Industrial Engineering are offered. From broad examinations to specific discussions on methodology, the research found within this section spans the discipline while offering detailed, specific discussions. From basic designs to abstract development, these chapters serve to expand the reaches of development and design technologies within the Industrial Engineering community. This section includes 14 contributions from researchers throughout the world on the topic of Industrial Engineering.

Chapter 13
Learning Parametric Designing

Marc Aurel Schnabel
The Chinese University of Hong Kong, Hong Kong

ABSTRACT

Parametric designing, its instruments, and techniques move architectural design education towards novel avenues of deep learning. Akin to learning and working environments of engineering and manufacturing, it offers similar advantages for architects. Yet it is not as simple as using another tool; parametric designing fundamentally shifts the engagement with the design problem. Parametric designing allows architects to be substantially deeper involved in the overall design and development process extending it effectively beyond production and lifecycle. Leaning parametric design strategies enhance architects' critical engagement with their designs and their communication. Subsequently, the computational aid of parametric modelling alters substantially how and what students learn and architects practice.

INTRODUCTION

Parametric design techniques offer obvious advantages for engineering and manufacturing processes, now architects have emerged to apply these methods in their working environment suggesting solutions and novel designs at an earlier stage of the process. Through the coupling of architectural design with parametric modelling methods, the chapter presents techniques that enhance students' learning and knowledge about designing and architectural building processes. This allows a deeper comprehension of the design objectives and aids architectural designers in their decisions to find solutions.

A dilemma of semester-based teaching is that students reach their highest level of skills and experience at the end of a term, after which they leave for their break and are therefore unable to apply their freshly gained knowledge immediately. At the beginning of the next following term, however, the knowledge and skills they had gained earlier are likely to be either inactive or not employed, and learning foci may have shifted to other aims.

DOI: 10.4018/978-1-4666-1945-6.ch013

The architectural design studio presented here addressed these issues by integrating the learning experience from the beginning by focusing on parameters that create or inform about the design. The objective of this 'parametric designing' was to allow students to understand the impact each step and variable has on the design and follow the impact it has onto the project. Students developed and communicated their design parameters by utilizing their knowledge throughout the design-studio environment. Because of this, students began to think about design problems in different ways. The studio explored design by basing it on parameters and their connecting rules. In order to build up a philosophy around parametric dependencies and relationships, the participants used digital instruments that aided them to create and express their designs. With these instruments, they could develop expertise to engage creatively in designing. The studio cumulated in an architectural art exhibition highlighting the coupling of architectural design with digital modelling and fabrication methods. Students presented architectural solutions that challenged and addressed environmental and programmatic issues, dimension, space and volume, as well as theoretical and conservational topics, resulting in novel designs created with freedom of innovation, interpretation, and definition some of which without any boundaries. The notion of non-conformity added to the core of this collection of works, held together by the idea of spatial concepts and parametric designing in architecture.

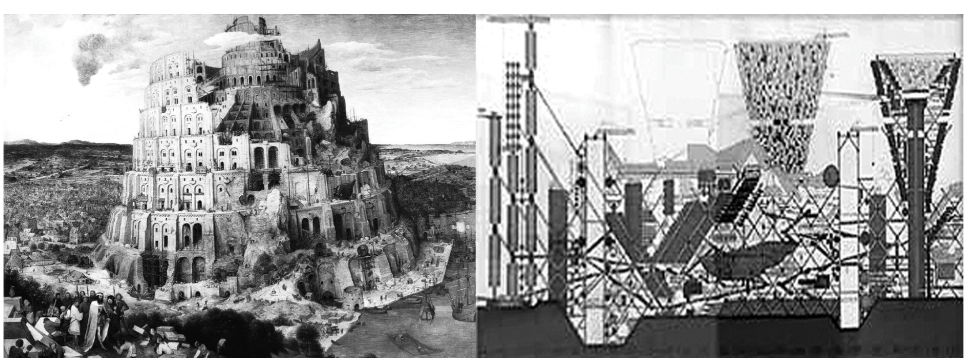
BACKGROUND

Pieter Bruegel, a Netherlands' Renaissance painter, depicted a representation of the 'Tower of Babel' as a building that is constantly redefining its needs, as it grows larger and more complex (Figure 1, left). The painting shows a tower nearly reaching the clouds and illustrates all the problems then associated with cities, buildings and life within and the constant change and reaction to new situations during the process of building.

The exploration of the relationship between human beings and the natural world, and the subsequent implications of interactions between them, has deep roots in our social and cultural understanding of society. Cities, therefore, are direct reflections of their inhabitants, as their architectural expressions directly influence the living conditions of their people. In recent practice, architects have designed and described buildings through the means of (master-) plans, sections, elevations, or descriptions of render-perfect, complete architectures in which change was not part of the picture. A few, however, have tried different approaches to communicate architecture.

In the 1960s and early 1970s, Archigram already presented an idea that reacted against the

Figure 1. Right: Pieter Bruegel's 'Tower of Babel. Right: Archigram's Plug-in City



permanence of houses in what it called the "Plug-in City" (Figure 1, right). They proposed architecture that is ever changing and adaptable to different social and economic conditions (Karakiewicz, 2004). Their proposal did not develop further than a conceptual stage, yet it lays in contrasts to the common practice that also Le Corbusier describes as non-intelligent building machines, whereby these machines would not think, and would therefore be unable to adapt to change.

More recently 'LAB Architecture Studio' translated planning codes of Beijing's 'Soho Shang-Du' into series of parametric design rules whereby the outcome both complies with and confounds the rigid regulations (Davidson, 2006). As a result, the architects did not prescribe a fixed definition of architecture, but a set of rules and instructions that inform about and can generate the outcome. This allows a reaction on a variety of site-specific variables that can be modified according to the need, yet fit into the overall design intents of the architects.

These samples point out the constant demand for architecture to adapt and react to a variety of parameters that are driven by its use and context. The gap between the architectural design conceptions and the translation of these designs into the real built environment can be addressed fundamentally differently by an intersection of process and outcome (Eastman, 2004). Parametric design and digital fabrication techniques suggest controllable and adaptable solutions at an earlier stage of the process that react to the given situations and the outcomes.

PARAMETRIC DESIGN STUDIO

Architectural design studios are an essential learning experience for architectural students. Their traditions and proceedings are well established. Studios go beyond pure skill training and require reflection upon, and the creation of, knowledge. These studios are, additionally, informed and supplemented by courses and seminars that contribute to the overall learning goals. Yet there can be a gap between skill training and application of knowledge. At the end of the studio, students may not be able to identify how they arrived to their solution and solves a given problem, or what were the individual contributors that made their design successful.

In computational architectural studios, the same phenomena can be observed. These studios present the underlying concepts of architectural design using computational instruments, and have at the same time to provide for software skills and other technical knowledge (Kvan, 2004A). The integration of digital media into design studio curricula often fails, because the compound acquisition of skills prevents a deep exploration of design and the theoretical aspects involved at the same time. Participants can employ computational instruments within a studio context only after they have learned subject matters and acquired proficiency in their skills. By then, the studio may consider these skills no longer valid or has ended.

Parametric applications have inherited two crucial elements. These are that all entities start in a multi-dimensional space and allow the study of architectural conditions in a cloud of data and variety of representations, rather than the conventional two-dimensional or layered design environment. The underlying notion of parametric designing is based on the contextual construction of a formal and spatial systemic intelligent simulation; or in other words data, variables, and their relationship to other entities, which can then respond to variations of necessities (Ambrose, 2009). Students learn about cause and effect in both abstract environments as well as at specific situations of their design task. This is where architectural education is in the process of changing fundamentally. Design studios and courses are now increasingly reacting to the quantum leap architectural computing has presented to design education, and introducing computational parametric tools to the design studios that go beyond

Computer Aided Design (CAD) (Picon, 2010). Yet one has to be careful that novel technologies and learning methodologies offer current pedagogies to address certain known issues and cannot eliminates all problems connected with learning and education.

PARAMETRIC DESIGNING

Architecture in general can be expressed and specified in a variety of ways. Commonly, drawings describe geometric properties that can explain, depict, and guide the construction of buildings or streets. Alternatively, performance specifications can describe observed behaviours. It is also possible to describe properties as relationships between entities. Spreadsheets, for instance, specify the value of each cell as the result of calculations involving other cell entries. These calculations or descriptions do not have to be explicit. Responsive materials change their properties in reaction to the conditions around them. A thermostat senses air temperature and controls the flow of electric current, and hence the temperature of the air supplied. Using such techniques, artists have created reactive sculptures and architects have made sentient spaces that react to their occupants or other relevant factors. Streetlights turn on if light levels fall below a threshold; traffic flow can be regulated according to need; walls can move as users change location.

Links to a variety of data can be established and subsequently serve as the bases to generate geometric forms using parametric design instruments. When designing spaces, it is usual to collect some data of the type of architectural qualities desired. These are then, for example, translated into master plans, which are themselves specific spatial descriptions. Performance requirements for spaces can then be written, linking the description of the architecture to experiential, financial, environmental, or other factors (Picon, 1997).

Design studios mimic the typical working processes of the architectural profession and are the essential learning experience for architectural students. Research is now looking into how the framing of design problems using parametric methods enhances the overall process (Schnabel et al., 2004). The here presented studio, therefore, couples parametric methodologies within the generation of architectural design, ultimately reframing the problem and proposing new answers to design thinking and learning. Participants in this study solved a typical architectural design problem using computational applications that focused on the parametric dependencies of spatial entities, generative scripts, and form finding. The re-representation of the design intent sharpens the question at its centre (Gao and Kvan, 2004), while taking full advantage of available parametric modelling software to explore it. This approach tested the limitations set by conventional, design-only methods. The cognitive aspects of the design generation and their relationships to parametric design methods operated as an influential factor for the understanding of the projection of design intent, framing, generation of spatial knowledge within architectural design and the reflection about the outcome produced in this process (Ambrose, 2009).

Problem Framing

The studio engaged the participants in design processes by using sets of variables and series of relations to question, create, and define the form and function of the resulting designs. Thus, the students examined interaction techniques between their design intent, their framing of the design problem, their subsequent generation and reflection on their development by testing the rules and parameters. Participants engaged in a collaborative architectural design studio involving the creation and fabrication of architecture. This formed the basis for a transfer of knowledge to the larger context of the issues ahead in their future professional careers (Riese and Simmons, 2004).

The studio took a distinctive neighbourhood within the larger urban context of Sydney, Australia as its base of exploration. The specific site surrounding, a mix of residential, public and commercial buildings, offered a medium dense area with a variety of architectural languages.

Driven by a fast growing population, an architectural strategy that steers further development was sought. The city's scale, its growth through migration and the need for new housing have an impact on its inhabitants' sense of place and sense of community. Earlier urban planning did not anticipate the changes that arose over years of population growth. Hence, a new strategy for development that could address these issues was sought to create a new identity for the place and the city itself (Forrest et al., 2002).

The site of the studio had typical architectural characteristics and requirements. Located at a riverbank, in close proximity of a parkland, cultural-, office- and residential buildings, the site offered a variety of inspiration as well as constrains for an architectural design exercise. Students had to address and responded to the local and overall conditions of open space, city, work, living and environment.

The studio built upon design studios where participants explored design methods and tools beyond their original definitions and perceived limits (Schnabel et al., 2004). To allow the students both to acquire skills and training within their studio and to apply this knowledge to their design, the studio had an integrated digital media component that addressed parametric modelling in architectural design.

Two groups of fifteen students of the postgraduate architectural program each joined this studio, which was guided by two design tutors and one architectural consultant in digital media. The studio was structured in four phases that related to and built upon each other (Figure 2). The aim was to acquire and integrate parametric design knowledge and to use it as the base of the design creation of their architectural proposal. As a result, the final design could be modified and manipulated based on the parameters and their dependencies, allowing the students to gain a deeper understanding of their design processes and outcomes as well as the reaction of their proposals with the various influences of the site.

Creating

The project's first component included the collection and understanding of data that arrived from the site. In order not to overwhelm the students, the tutors asked them during this first stage to limit them to investigating only two points of interests, which became their key-parameters. Hereby the students could focus on the selections of parameters that they believed would influence their building proposal or their site's perception, this parameter could be a real or abstract item (Figure 3).

The parameters they chose informed them about the variables and correlation of their guid-

Figure 2. Four phases and exhibition of the design studio with learning reflections and projections

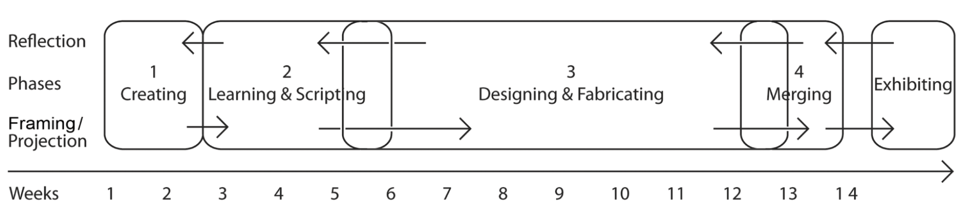


Figure 3. Two parameters (floor-heights) used by a student team (R Beson & N Minasian)

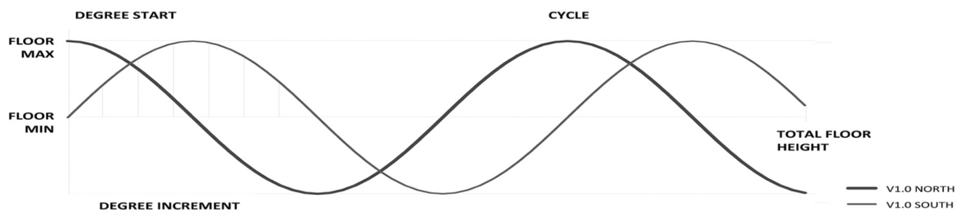


ing design principles that formed their initial rules. These provided them a description based on dependencies and interconnected relationships of relevant information. The chosen parameters helped the students to understand what impact certain variables may have on a design strategy and the design itself. This component concluded after two weeks with presentations of data, parameters, and individual interpretations of the site.

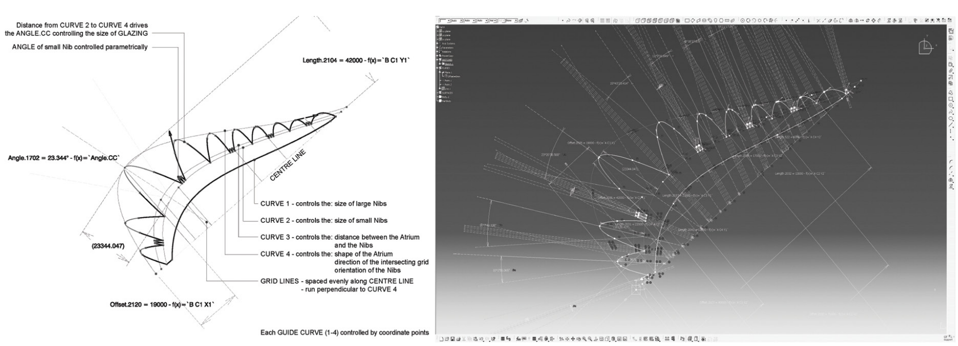
Learning

The program's second component focused on the understanding and creation of parametric concepts and the acquisition of design-application skills that allow rule-based three-dimensional design. Participants were trained intensively during studio time in the use of *Digital Project* TM (2004). This software allows users to not only create three-dimensional models, but also to establish rules, create parameters and their dependencies on a variety of entities (Figure 4).

Parametric functions require a different understanding of the conceptual approaches to design. Creating rules and dependencies, which then create the design, involved the students in a higher level of problem framing and definition of the concept of design. It allowed the visualization and modelling of highly complex forms that may result from non-traditional design data, such as noise data or spatial requirements.

The students focused on their own parametric and rule-based design analyses from the first component and subsequently studied mainly only the aspects relevant to these in relation to the use and operation of the software, the creation of rules, and parametric and generative design. During this phase, they used the time allocated to the design studio to establish a basic understanding of the software in its relationship to the design intent developed during the first phase. After three weeks of intensive training in architectural computing, the students reached a sufficient level of skills

Figure 4. Development of parameters, dependencies and rules within software analogue (left) and digitally (right) (Beson & Minasian)



that enabled them to use the parametric software as an aid for the creation of their own designs.

Scripting

'Script' is derived from the term for written dialogue in the performing arts, where actors are given directions to perform or interpret. Subsequently, 'scripting' is a creative process that describes the artistic intent of the designer. Scripts can define a set of rules that combines parameters in the named way. Software applications can be programmed and adjusted by scripts allowing for example repetitive tasks to be automated or to generate solutions that fit to a range of parameters (Biloria et al., 2005). Instead of using only compositional methods for designing, the students utilized scripts to form their own generative properties and base for their design exploration (Figure 5). Sourcing related or suitable general available scripts students quickly learned how to edit and control their design by amending the parameters or rules to fit their design intent (Celani, 2008). This phase differs greatly from conventional studios because students are engaging in software training and skill acquisitions of how to generate and manipulate instructions for computer programmes that can aid their design process.

Designing

The program's third component, scheduled for seven weeks, concentrated on design creation, reflection, and the communication of architectural design proposals. Using the data of the first component and the skills of the second, the students then started to establish and visualize their designs in three-dimensional forms that created spatial expressions of their findings and explorations.

Due to the emphasis on parameters, the studio was in particular interested in describing a building form by creating dependencies of parameters that defined the relationship of data to architectural expressions. With the use of a parametric modeller, it was easy to create geometric entities, solids and voids, and relate them to the context of the design task. This method made it obvious how one can learn about design and understand the various steps and elements through the logical steps laid out by the chosen parameters, variables, rules or scripts.

Fabricating

Another stage in the creative process is the fabrication of the digitally created designs. Recent computational applications and digital fabrication technologies have allowed architecture to take novel directions. The combination of architectural computation with computer-controlled machinery has nearly made it possible for shapes, however complex or irregular they seem to be, to be rationalized and created as physical entities with the ultimate aim to result in a buildable architecture (Oxman and Oxman, 2010). The studio subsequently made extensive use at all stages to explore

Figure 5. Variations generated by a script to modify facade-tiles (Beson & Minasian).

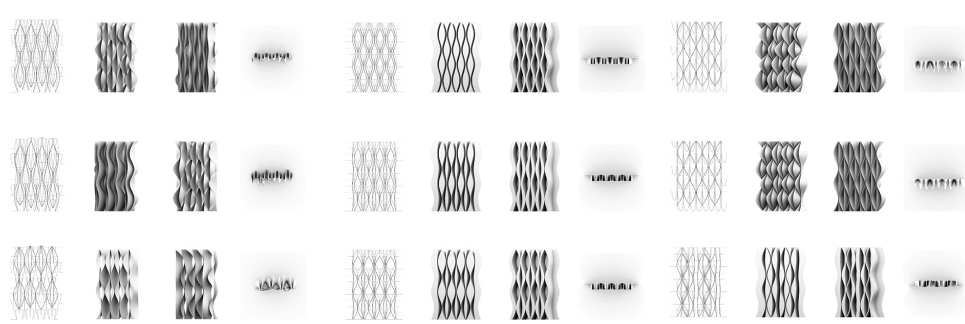


Figure 6. Facade details from the digital model fabricated by rapid-prototyping (Beson & Minasian)

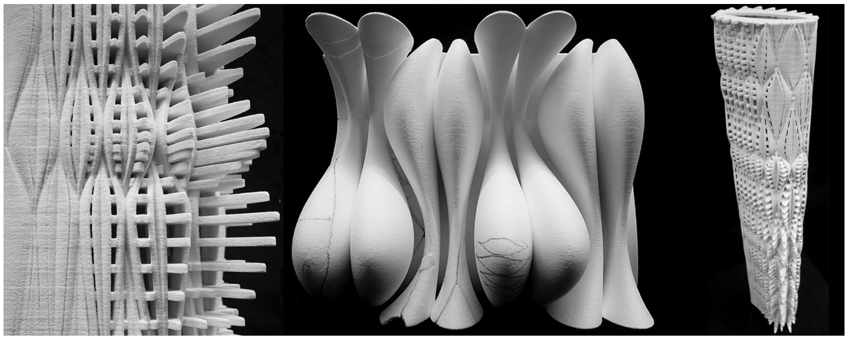

the transformation of virtual design conceptions to physical objects via the use of computer-aided manufacturing (Figure 6).

Merging

The program's next following component brought together the various aspects and results of the earlier modules. Within two weeks, the students merged their individual designs into larger cluster files. This synthesis created compound descriptions and dependencies that were highly complex and interrelated, yet both the content as well as the tool allowed seamless communication to a larger audience by describing the rules and parameters (Figure 7). This phase created a design with shared authorship of all participants and allowed the students to study and understand the complexity and the interrelationships of architectural designing that they normally would have been unable to perceive immediately. Through their collaboration and exchange the students built up a collective intelligence that was driven by the individual contributions. The change of a single variable modified the whole design. Participants understood therefore the complex dependencies that one variable has in a large building and the impact it can have on the design.

Exhibiting

The design explorations culminated in an exhibition displaying the designers' engagement with parametric designing and fabrication (Figure 8). To mark the distinctive final stage in a celebrative conclusion of design development, the event exemplified how digital architectural design can conceptually and artistically engage with a

Figure 7. A joint model that combined facade, interior spaces and atrium details

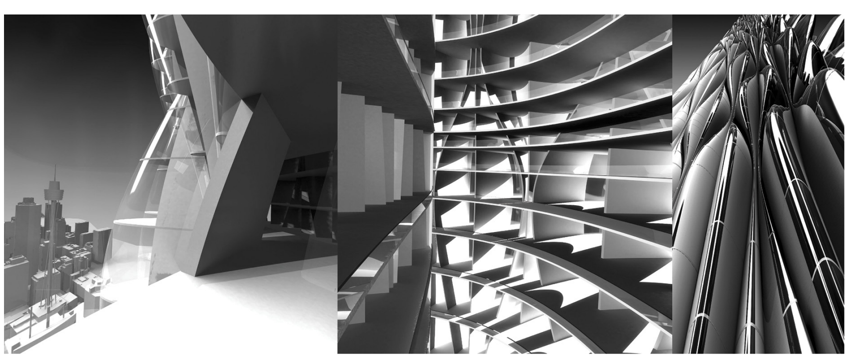

Figure 8. Exhibition of final designs at Brand Smart Centre (left) & Tin Shed Gallery, Sydney (right)

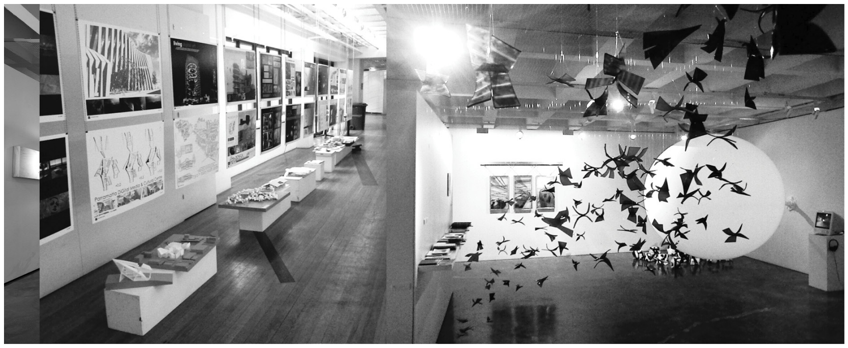

particular site, where a variety of solutions to problems in architectural design were developed from a diversity of multi-faceted and eccentric approaches (Schnabel and Bowller, 2007). The participating designers pushed creativity to new boundaries in definition of their artwork and cultural contexts, setting the direction for poetic viewpoints on innovation in architecture and spatial design. The exhibition forms a crucial learning experience whereby both processes and outcomes are presented in a formal way that is self-explanatory to a wider audience.

The compiling of all projects into a single exhibition removed the designers from the context of individual ownership, providing them with the invaluable opportunity to reflect on both, their own and their colleagues' proposals as a coherent collection of contributions towards one common engagement of design.

OUTCOMES

Participants of the parametric design studio were able to employ digital media skills from very early on throughout the studio and expand on these with their understanding and communication of design issues from there.

The students had already acquired a very high level of skills in using a specific parametric instrument within the first half of the studio. This enabled them to employ the instrument as an amplifier to learn about their designs. Subsequently, they were not limited by their knowledge or level of skills in order to be able to express themselves. The students produced a variety of individual design proposals as well as one large design-cluster. They created rules, scripts and parameters that allowed complex and interrelating designs to emerge. These representations could not be generated or communicated using traditional architectural design methods or instruments.

For example, one proposal related street lighting, neon-signs and display-windows with human activity around the building site. These parameters provided the engaging surface for the building mass. Subsequently they controlled the use, orientation and appearance of the building. The author took references to Japanese inner cities, where innovative ways of spaces are created by the means of lights, advertising and projections. Void, volume and density is controlled and created by the rhythm and intensity of lights. The student transferred this concept into parameters, which redefined the spatial understanding of the site and used these variables to create an architectural proposal.

Other results used parameters that related to the relationships between people and attraction to spaces with responsive structures. Students created self-opening canopies that reacted to people, activities, ferry schedules, weather conditions and the possibilities to collect rainwater to provide a comfortable environment in all conditions.

One team reacted with different floor-heights to various needs of public and private programme of their building and related their spaces to vista and light penetration of their building (Figures 3-6). These explorations then were merged with parameters controlling the interior space, atrium and program to form an overall design of a mix use building (Figure 7).

In the studio's last component, all students presented in-depth clusters of multifaceted architectural design proposals for the site. They demonstrated a high level of thinking processes resulting in the generation of compound rules and dependencies that finally create the architectural design schemes. Each student contributed simultaneously to create a variety of design proposals. The participants gained a high level of expertise with digital parametric tools as part of their development at the studio, and used this knowledge to design parametrically. The outcome clearly showed that thinking, learning and creating within parametric designing requires a novel and deeper understanding of the overall design goal and its anticipated outcome. The studio also showed that a social engagement with team members created a common knowledge to which everyone not only contributed but also benefitted. Students subsequently build up a social intelligence that allowed them to address both skills and design problems.

Students reported of the step learning curve of understanding how parametric software is structured differently to conventional software. They reported that they could not just design intuitively as they would do in conventional studios and had to stick to the rigour process of the parametric design methodology. The skill training in the software and the translation of the design intent proved not always to be straight forward. Some students only gained the full understanding of the potential parametric modelling offers at the end of the studio where all solutions were presented. While others had difficulties in developing a logic string of design steps that relate to the parametric approach, they preferred or felt back to intuitive or conventional designing.

Parametric modelling subsequently does not solve all issues connected with design-learning. It allows however, an alignment of cause and effect and a reflection of the design intent, the process and outcome. This differs from conventional design studios where these dependencies only seldom can be established. The studio allowed participants to learn about designing and problem framing. They were able to theorize and reflect on design creation for this and other design tasks. Consequently students engaged in a deeper learning that allows them to transfer and adapt their knowledge to new situations. Results can be explored at: www.parramatta.tk and www.disparallelspaces.tk.

DISCUSSION

In the early stages of computational architecture, designing in layers was a popular enrichment to conventional designing because it allowed architects to deal with problems that are more complex, with each different layer playing a specific role. It singled out issues and allowed dealing with them one at a time. Items that are more complex were divided into separate issues and dealt with one by one. Parametric design opens up a novel set of opportunities. It enables architects to study causes of problems and their relationships to, and dependencies on, other elements directly within a three-dimensional environment.

This shift of design thinking and creation needs to be addressed in the teaching and learning of design. Additionally, parametric designing provide for unpredictable events in connection with an overall architectural framework. Architects and architecture itself can respond to unplanned changes and their resulting consequences. The outcomes of this design studio showed that parametric dependencies allowed for such a level of ambiguity that is desired and required in creative and learning environments.

One objective of the studio was to frame an intellectual question that created design descriptions based on rules, scripts and parameters. The more interesting outcomes resulted from the ability to redefine and reframe the problems themselves by stepping out of preconceptions based on experience and exploring sets of unpredictable answers and then reflecting back on the starting point. Hence, in certain ways, parametric designing act at a higher level of the problem framing. The establishment of meta-rules has instituted a form of problem framing that demands the reference of one problem or parameter with other ones.

The learning outcomes of the parametric design studio demonstrate how non-linear design processes led to architectural design understandings that differ from conventional approaches to design learning due to their different nature of design thinking, framing, creation, and intuition. Despite three-dimensional representations of an architectural space being only a medium aiding the understanding and communication of spatial arrangements, the designers' comprehension of complex spatial qualities was enhanced by the parametric design environment, partly due to the logic structure and dependencies of one step to the next. The steep learning curve and the time needed to adjust to the parametric and sometimes stringent or seemingly limiting methodology of parametric designing shows that conventional designing is the pre-dominant approach to design and deeply routed in the design-thinking of students. Yet despite these difficulties students unanimously reported that the here presented studio helped to understand how to design and they highly valued the approach to thinking about and executing designing.

The use of parametric instruments allowed all students to design within an environment based on rules and generative descriptions, amplifying their understandings of creative processes and their learning outcomes. Each designer bridged the rift between their knowledge and ambition, creating architectural designs and learning about the act of architectural designing.

NEXT STEPS

The increasing marginalization of architects in the building industries (Bennetts, 2008) suggests that professional and educational ideals and professional work are poorly aligned. Unlike other professions, architects are trained in a variety of fields of knowledge and skills that are not directly related to the daily routine of the architectural praxis. Subsequently architecture students have an increasing amount to learn following graduation. Architects have discovered how digital instruments alter any aspects of their routines of working. However, academic and educational environments are not able to follow in the same speed. Learning designing has shifted from the single learner to a collective engagement with a variety of learners, novices, experts and instruments that aid, analyze, generate, design and review. Less than a decade ago many schools of architecture did not allow students to deliver CAD drawings for design projects assuming that would limit the exploration and understanding of design. In fact, the early experiments in using the computer in the design process quite often failed only because of the restrictions of the available infrastructure, facilities and skills. Today, students are familiar with architectural computing even before they enter the university (Dokonal and Hirschberg, 2003).

Still many questions remain unanswered and new questions arise in the relationship between architectural design and architectural computing. Architectural design is both an imagination and the ability to convey this idea. The learning of architectural design has to make use of the advantages that complex architectural computing offers without loosing the qualities of the established conventional methods. The current

'Net-Generation' (Oblinger and Oblinger, 2005) of learners, who are more conversant in using computational instruments than their teachers, are changing the dynamics of architectural education. This is a challenge to established curricula and institutions.

The herein presented studio is a successful attempt to integrate architectural computing into the learning environment by aligning skills and knowledge of the students with the objective to generate knowledge about designing, computation, architecture and realization.

Akin to Maver's (1995) comments, parametric designing and for that matter, architectural computing is certainly far from being resolved and offering the perfect solution. As the needs, goals and problems are rapidly developing architectural design and its learning needs to facilitate the evolution and progress. Synergies between the different realms, media and technologies are constantly evolving and adjusted to foster the evolution of architectural praxis and the building industry (Eastman et al, 2008).

CONCLUSION

The parametric design studio method presented in this chapter addressed computational concepts of architectural designing that influence the recent learning environment of architectural education. It coupled the setting of studio-learning with an in-depth digital media training in order to close the gap between acquisition of skills and the reflection of knowledge, as well as to explore new avenues of framing and integrating compound design issues. The use of digital parametric instruments allowed the participants to design within an environment based on rules and generative descriptions, amplifying their design understanding and their own learning. The students connected their knowledge with their ambition to create their own design proposals.

The synthesis of all individual projects removed the students from individual ownership of their designs, but allowed them to reflect on both their own and their colleagues' designs as a complete cluster of contributions (Kvan, 2004B). This related to earlier research into design studios based on the same principle, in which media were applied outside their normal pre-described purposes, and innovative design methods were deployed by interplaying digital media and design explorations (Schnabel et al., 2004).

With the employment of parametric design methods that allowed students to experience the dependencies and rules of the various individual contributions spatially, as well as the overall common proposals, the design was communicated using digitally controlled manufacturing processes and digital representations.

The studio was phased in such a way that each section built upon the next and became an essential part of the overall design learning and creation. They addressed and expressed certain aspects of the process. A holistic discussion about design, form, function, and development is consequently established - a significant venture not only within the architectural realm, but also in all other dialogues involving spatial representation.

KEY TERMS AND DEFINITIONS

Architectural Computing: Architecture that is aided or generated by computational means.

Computational Architecture: Architecture and its design that arrived from or in collaboration with computational means, instruments or aids.

Design Education: The pedagogical approach to teach and learn to design.

Design Learning: Learning of how to design with the aim to become a good designer.

Design Process: The elements that contribute to the making of a design.

Parametric Designing: Designing using a parametric methodology that employs parameters, rules, and systems.

Parametric Design Studio: Design Studio that employs parametric designing as core method of enquiry.

This work was previously published in Computational Design Methods and Technologies: Applications in CAD, CAM and CAE Education, edited by Ning Gu and Xiangyu Wang, pp. 56-70, copyright 2012 by Information Science Reference (an imprint of IGI Global).

Chapter 14
Service Design:
New Methods for Innovating Digital User Experiences for Leisure

Satu Miettinen
Savonia University of Applied Sciences, Finland

ABSTRACT

Service design is establishing itself as a method for developing services and service business. Service needs, new ideas and ways to utilise technology are encountered when the customer and the end user participate in the design process. This chapter focuses on service design methods and the process of how service design can help in innovating customer-orientated service concepts for e-tourism. Service design connects the areas of cultural, social and human interaction. Use of design methods acts as a link between the different views in the service design process. Service design is an emerging field where the terminology and methods are still developing. Mager (2009) has pointed out that the need for service design is evident, as economic development has changed dramatically during the last four decades from manufacturing to provision of information and services. Service design looks at service development from the designer's point of view. Design thinking has the ability to create concepts, solutions and future service experiences for users.

INTRODUCTION TO SERVICE DESIGN THROUGH A CASE STUDY

The tourism industry is a complex area where service design provides a new perspective to service development. In the tourism context service design can be related to at least two approaches: a) Service design as a tool for improving a customer experience, innovating new service opportunities and ROI (return on investment), and b) Service design as a tool for innovating new sustainable service systems and well-being. Stickdorn (2009) writes about tourism as a service-intensive industry depending on the customers' service experiences and their consequent assessments of its quality. There are a number of factors that make tourism service challenging: the importance of service quality in tourism, the high proportion of SME's

DOI: 10.4018/978-1-4666-1945-6.ch014

in the tourism sector, the fragmented constituent parts of tourism product bundles, the significance of expectations and overall customer satisfaction. The design of services has become an increasingly important issue. Service design needs to respond to a new service-dominant logic where companies need to make more attractive value propositions than their competitors. For tourism service providers, superior value propositions rely on the consumers' experiences.

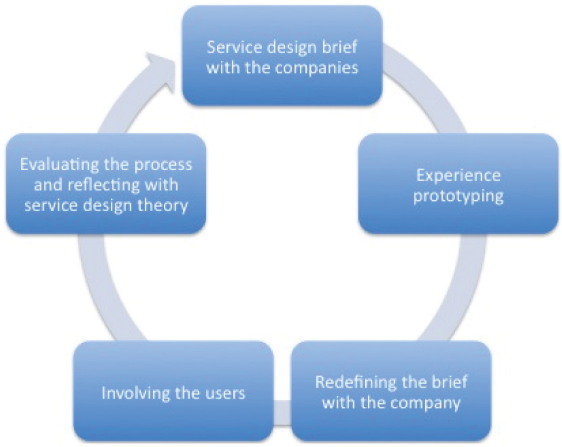
Cipolla (2009) has distinguished a *relational service model,* where the "clients" and "providers" are interwoven. This means that it is difficult to think about *service scripts* or guided (standardised) service performances. As a case she presents an example called "the Living Room Restaurant". This is a service open to everyone, i.e. total strangers are received in a family living room. The "host" family invests their "trust" in others, but there is also a certain level of trust required from "guests": they are entering someone else's place, and it is not known if this unusual service could be a trap. There are mechanisms to relieve this tension: indications about the service trustworthiness can be passed on by word of mouth, for example. The case Living Room Restaurant is a paradigmatic example where we can observe the highest level of trust-making. Relational services propose the achievement of well-being based on interpersonal encounters: an approach that focuses more on "actions" or "relations" than on "things", which leads to sustainable practises. Services that promote ways of living based on sharing and collaboration reinforce the transition towards sustainability: they regenerate the local social fabric and promote the creation of new common goods.

Iteration and co-creation are processes that can also be used to develop services in the tourism area. An iterative design process is based on a cyclic process of prototyping, testing, analysing, and refining work in progress. This applies well in a service design process where prototyping tools are in active use. Innovating opportunities for new co-creation processes between the client and the user is part of the service designer's everyday working life. Prahalad and Ramaswamy (2004) discuss co-creation experiences as new ways to create value. The focus on value in business transactions has shifted to experiences, and experiences are increasingly created through services. Consumers are co-creating value with the firm. Co-creation allows the customer to co-construct the service experience to suit her context, and the service design process offers methods to enable this. Value creation and interaction processes are thus central to service design. Thackara (2008) describes a process where designers transform public services and work with local communities in a co-creation process. Designers have co-developed and prototyped the ideas with the community, and later these ideas have been tested and launched.

The tourism industry brings new challenges to the service design process. Service products are offered by number of service producers as Stickdorn (2009) notes and there may be a lack of communication between the service providers. This means that iteration rounds will be repeated to include all the stakeholders and special attention has to be paid to identifying both the right service channels and all the users of service channels to include them in the co-creation process.

This chapter looks at one specific tourism development case. The case was part of the "Experiencing Well-being – Developing New User Interfaces and Service Platforms for Leisure" project, which was funded by the Finnish Funding Agency for Innovation and Technology, TEKES. The case worked with the development of a future digital service for leisure. This chapter studies how the service design process was used in this case. The aim of the chapter is to learn about the service design process and methods through a practical case study. This was divided into five parts: a) brief, b) experience prototyping, c) redefining the brief, d) involving the users and e) evaluation. This formed an iterative service design process.

Figure 1. Iterative service design process represented in this chapter



BACKGROUND OF SERVICE DESIGN AND TOURISM

Service design has developed as an academic field since the 1990's when the University of Applied Sciences in Cologne first introduced service design as an academic inquiry. Service design has established itself as a part of holistic and innovative design education. It aims to ensure that service interfaces are useful, usable and desirable from the client's point of view and effective, efficient, and distinctive from the supplier's point of view. Service designers visualise, formulate, and choreograph solutions to problems that do not necessarily exist today. They observe and interpret requirements and behavioural patterns, and they transform them into possible future services. (Mager 2009)

Morelli (2002) has defined the service product as a result of interaction between different actors and technological elements during the use phase. He proposes that the design activity should emphasise elements of convergence between several social and technological factors: a) the social, technological, and cultural frames of actors participating in the development of the system, and b) the technological knowledge embedded in the artifacts used for the service. Service design is producing new definitions as well as methods that can be used in tourism service development.

A thorough understanding of the tourism context and the tourist experience can benefit the tourism service design processes as well as the designers who are working with product development, service design and research in the tourism context. The service design process can work as a framework that enables a designer to work in tourism service production. In a tourism experience social interaction between the local producers and tourists play a role. (Miettinen 2007)

Desmet and Hekkert (2007) state that user experience is shaped by the characteristics of the user (personality, skills, background, cultural values and motives) as well as those of the product (shape, texture, colour and behaviour). Physical actions and perceptual and cognitive processes (perceiving, exploring, using, remembering, comparing and understanding) will contribute to the experience. It is further influenced by the context of interaction (physical, social, and economic). Saffer (2007) points out that service design, like systems design, focuses on context. People use products in environments of structured processes. Service design is the design of the whole system of use: the system is the service. Tourism is one of the areas where services are both designed and provided (Miettinen 2007).

Miettinen (2007) has studied the service architecture of a creative tourism experience. Creative tourism shifts the focus from the artifact to the production process of that artifact. The creative tourism experience is a multi-sensuous experience where the feel of materials, smells, the relationship with local craftspeople or other creative producers and their working context becomes an important part of the experience. The creative tourism experience is not only the cultural workshop encounter with local craftspeople but also an experience that commits the tourists in a deeper understanding of the local context. Social contact with local people is constructed through creative experience.

The service architecture intends to describe a user's journey through the various touchpoints (objects, spaces, systems, and people) of the service. People work as significant touchpoints in the creative tourism experience. They deliver the service of teaching crafts skills and several other learning or cultural experiences. They are also the touchpoints that deliver information about the local way of living. This indicates that a robust co-production of service is taking place. The service architecture also shows how the creative tourism experience is divided into pre-, ongoing and post-travel experience (Wang 2000). In this process one user can also pass his or her expectations onto a forthcoming user and create expectations and anticipations. Interaction between different touchpoints is quite linear: one point follows another. This is the nature of tourism and depends on the travel itinerary. The creative tourism workshop experience however is more diverse. There are layered delivery points, and several processes take place at the same time: working with creative craft processes, visiting craftspeople, and learning from the social context. Interaction between different touchpoints is mainly effected through the action of the participants. The participants are telling narratives, inviting for a visit, teaching and sharing skills. These interactions are corporeal and embodied as well as visual and auditory. (Miettinen 2007)

The methodology used for service design research is continually developing as well as the access to analysed information from the tourism development cases where service design methods were used. This knowledge helps to develop both new tourism services and service design theory related to the area.

DEVELOPING A DIGITAL SERVICE FOR LEISURE

This section focuses on a case study on digital service development for a mobile e-tourism service for Hudle oy (http://www.hudle.fi) and local dance festival Kuopio Dance Festival (http://www.kuopiodancefestival.fi). The aim of the development case was to create a new user interface for the needs of the local tourism and leisure industry. Service design methods helped in innovating a new user-driven leisure, tourism and well-being service utilising technology.

Figure 2. The architecture of the creative tourism experience

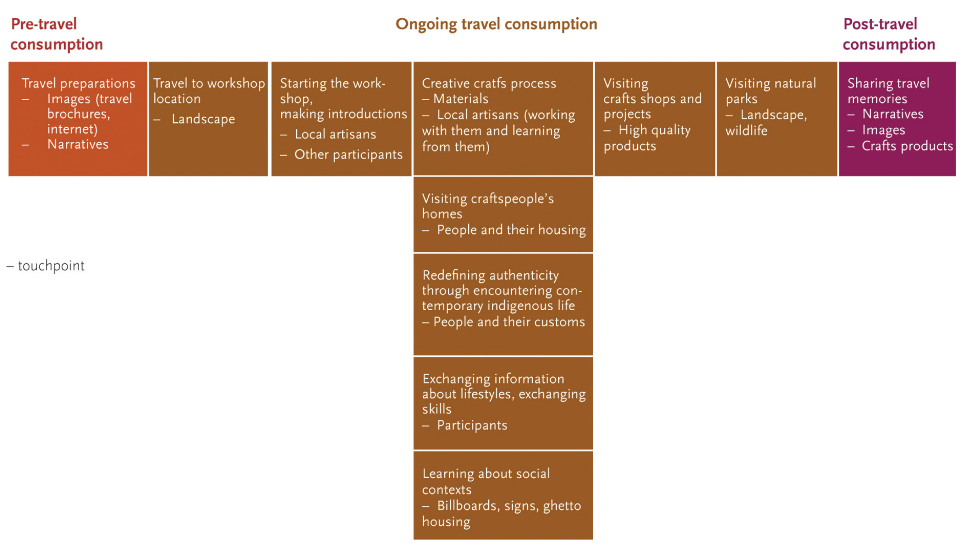


Table 1. A literature review concerning the new research agenda within the service design field

Issue	References	Main contribution
Service design methodology	(Miettinen and Koivisto 2009)	The book presents the key service design terms and methods. It is divided into three areas: an emerging field, service design practise, and case studies. The book discusses the following: a) Design thinking and innovative methods work as tools for co-creating services and desirable value propositions, b) Service design is a tool for designing a more sustainable society, and c) Interaction design offers us insight into creating more user-oriented services.
	(Moritz 2005)	Moritz presents the background on the development of service design, including changes in the economy and in design: how service design can be made accessible in a practical way. It includes service design tools that can be applied in practise.
Service design and improving public services	(Parker and Heapy, 2006)	Parker and Heapy define the service design approach for organisations as a strategy to shape the service organisations around the experiences and interactions of their users. Service designers focus on how people experience services, in order to understand how service organisations can create better relationships with their users and customers. They argue that engaging people in co-production needs to happen at the point of delivery through conversation and dialogue. Learning to understand and map how people experience the point of delivery, the interface with people and their lives, is essential to creating conditions for co-production. Understanding the user is thus the starting point for designing services, and understanding the user experience forges a strong link between the customers and the service design. Parker and Heapy further introduce an interesting goal for service design: to find ways of enabling professionals and laypeople to work together, creating spaces for simultaneous empowerment. Service innovators have focused on creating spaces where professional and personal autonomy can grow simultaneously.
	(Thomas 2008)	Design is key to the challenges of public service transformation. The articles in this pamphlet present a powerful case for design and how it can help achieve better designed public services while fulfilling what can be competing objectives of personalisation and value for money. The contributors to this pamphlet range from social innovators and designers to policy-makers and leaders in government, health and social care. In their articles, they set out the range of projects and innovations where design is already playing a role.
Service design and technology	(Kimbell and Seidel 2008)	The first part of the book focuses on the designing that happens when practitioners within science- and technology-based enterprises work with service designers on projects to design (or re-design) their services. The second area of focus is on how a multi-disciplinary community of practitioners, designers, and academic researchers evolved their understanding of the process and language involved in designing for services.

The service product was developed during an iteration process with stakeholders: Kuopio Tourist Service Ltd (http://www.kuopioinfo.fi/), Rauhanlahti Spa (http://www.rauhalahti.fi), Kuopio Dance Festival and Hudle oy. The first round of negotiations and the design brief was formed in co-operation with these four stakeholders. The first brief focused on service design: a) firstly as a tool to commit the stakeholders in a common service development process, b) secondly as a method to visualise the service where several stakeholders are producing the service together and c) thirdly to prototype the service product. Service design was used as a tool in innovating a new use for existing technology and applying it in the development of a new leisure service.

Service development started with scenario work. The goal of the scenario work was to visualise the service concept with the stakeholders. Scenario work made it possible to focus the design work around certain themes connected with leisure. These themes were drawn out from the analyses of the previous work. Service scenarios were visualised by different methods: using narratives and pictures. The starting point for the project was background research on the area of tourism and leisure as well as the local leisure cluster to benchmark the service selection in the market and development needs of the local tourism cluster. The results of the background research provided the information needed for preparing the context mapping (Sleeswijk Visser, Stappers, van der Lugt & Sanders 2005, Stappers & Sanders 2003) workshop with the stakeholders and users. The aim of the context mapping workshop was to reveal conscious and sub-conscious information about experiences, hopes and expectations related to selected themes. It was easier to discuss and negotiate the service design brief with the stakeholders based on visual material on service scenarios.

The next step of the service development process was the experience prototyping of the service scenario. The aim of the experience prototyping was to test the feasibility of the chosen service scenario: logistics, customer experience and financial influence of the service product in a cheap and quick way. Experience prototyping of the service product also provides much information on the context related to the service experience as well as the architecture of the travel experience: pre-, ongoing and post-experience. This offers a fast and competitive way to realise new customer-orientated service products. (Buchenau and Fulton Suri 2000, Miettinen 2007)

The results of the experience prototyping were analysed with the stakeholders. The video was experienced as a very good prototyping method and it visualised the service concept easily for all the stakeholders. It seemed difficult to commit many service providers in the development process at the same time. Involving users of the various service providers was also challenging for the same reason. We moreover wanted to focus the challenge more in the direction of innovating the technology-based future service, as the prototyping had focused more on existing technology. The group took the decision to carry on the development work with a more focused user group. The service scenario was also focused more on the future.

The development process continued with designing a concept for a future digital service for

Figure 3. The image is taken from the experience prototyping video of the new service product. It depicts a welcome sign for the tourists entering the Kuopio region. It explains to the guests how to join the Kuopio channel using their mobile phones and receive information about different services. The experience prototyping was carried out by video: arriving in Kuopio by car, seeing the sign, accessing the Kuopio channel, using services and special offers of different service providers (restaurant, theatre) and signing out from the channel. (Photograph by Olli Happonen)

leisure. This concept was discussed with Hudle and Kuopio Dance Festival, who agreed on prototyping the concept with the festival visitors. The concept was transformed into an animation. The visitors to the dance festival had the opportunity to see the animation on how the new future service would work and give their feedback. This feedback will guide the future service development.

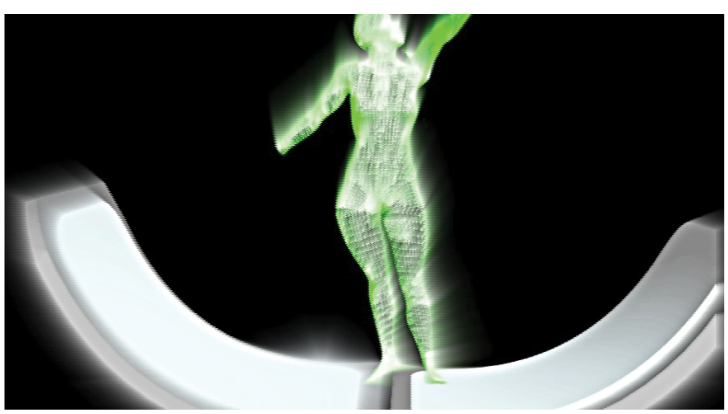
A designer can use a variety of tools to involve the user in the product development process and to acquire user knowledge. Research on user experience offers new kinds of approaches to developing tourism services. The aim of the research project was to create new user interfaces and environments for the needs of the local tourism and leisure industry, and increased knowledge of the user experience and the user are the key elements in designing new services. Existing theory on service design methods and processes helped during the iteration process, finding the right tools and methods. Documentation of the process and the methods is also one way to produce new information about an emerging field.

Experiences from the case study taught us several things. Service design is a tool to commit the stakeholders in the iteration process. It is a process that helps the stakeholders communicate their needs and wishes for the services and better understand the end user's needs. Service design methods can help in concretising abstract service processes with visualising techniques. In this case the video production helped the stakeholders visualise the service in practise: how the end users are able to use the technology and how the stakeholders can financially benefit from the use of technology in their services. Prototyping helped in testing the feasibility of the service concept and developing it further. Involving the users in the service development process transfers knowledge of the user experience in the service and guides the whole development process forward. The end users communicate their experience of the service: if it was credible, enjoyable, easy to use, and so on. This feedback is valuable information that will be fed back into the iteration process.

SERVICE DESIGN IN FUTURE

Service design methods are developing further with increasing research experience and projects as well as with consultancies specialising in service design. In the area of tourism not only technological concepts and service development benefit

Figure 4. The image is taken from the animation of the new service product and depicts a hologram phone: a phone that reflects a hologram image. This phone can produce services for the visitors of the Dance Festival: for example, teach dance steps. This service enables extending the service offering of the Dance Festival both to pre- and post travel experience. (Photograph by Olli Happonen)



from service design but also traditional person-to-person modalities. For example the use of drama methods and enacting the service situations will help the staff to develop their person-to-person service processes, communicate better with the guests and innovate new service opportunities. In future, service design will be a more and more important means in developing tourism services both for committing the stakeholders in the development process and engaging the users/guests in the service development process.

Mager (2009) notes that in these changing markets improvement and innovation of skills are of crucial importance to service providers in order to keep customers and in order to win new ones. Companies need to develop more sensitive antennas for tuning into what today's consumers expect and value, as well as learning what it takes to reach and retain them. Service design is in many cases dealing with human behaviour: behaviour of employees, behaviour of customers and co-customers. Due to co-production customer behaviour is of greatest relevance to the success or failure of the service. Therefore research on the way design can influence behaviour is of major interest within the service design field. The social and public service sector will especially need to focus more on the opportunities of behavioural change through the use of design and service design interventions.

One of the main areas of service design development in future is the public service sector. Tim Brown (2008) from IDEO discusses design thinking and reminds public servants to ask the obvious: What is it like to be admitted into a hospital, call the police or collect the dole? These questions are an excellent start for unlocking innovation by using design tools such as observation and storytelling. Andrea Siodmok (2008) from the Design Council, UK, writes about developing public services with service design. There is a growing pressure on the public sector to deliver "more for less". This makes innovation an imperative, where new ideas will need to be effectively developed, prototyped, tested and implemented. More flexible user-centred services will place greater pressures on many public sector organisations. The good news is that there are many examples of successful design and innovation in the public sector.

It is only natural that designers will contribute to positive societal development more and more using their design thinking and service design tools and methods to create more user-orientated service systems. This will create pressure on design education, and several new design disciplines such as service design education will develop. This will bring new actors into the workforce creating new solutions.

CONCLUSION

This development case was part of a larger research project on service design methods and the main focus was on developing and testing methodology. As such the case study was very fruitful. This development case was also based on earlier knowledge of service design methods and on how the tourism experience is constructed. The main outcome of the case and present research work is that the service design methods are under significant development work. There are different tools and methods, evidenced by many emerging websites and blogs. More systematic academic definitions and research work is needed. The future looks bright and the development work continues both at the academic and the practical level with companies. The most active side of service design has been the fact that the area seems to combine the very active hands-on development with business and methodological enquiry.

Our co-operating partners and stakeholders were enthusiastic about service design and its possible benefits to a company. There are already success stories available as Mager (2009) describes. Virgin Atlantic, for one, has its own department for service design. The Volkswagen research department is integrating a service design approach into their research. McDonald's has set up a customer experience innovation centre using the service design approach as a major facilitator for innovation. Numerous service companies, including telecommunication providers, insurance companies, banks, hospitals, transportation and hospitality industries are integrating service design on an organisational or on a project basis. We also need these success stories at a regional level and with our SME companies who are our partners on a daily basis. The tools and methods need to work also using very small resources.

One of the main tasks of the case study and the research work has been focusing on the results of the iteration process. There is still a lack of literature on service design research. The reflective and discursive evaluation between different research findings and theories is still quite weak. It is important to document and ground the research processes well in order to formalise new theoretical knowledge that can be used in further research projects. The research process has shown that the new methods and tools that service design can offer e-tourism can produce user-orientated service products when the stakeholders are committed in the development work. Yet much more development work is needed at the regional level with SME's that need easy to use and low cost development tools for their work with users. This is our next development phase.

APPENDIX: CASE STUDY

Develop a Service Channel for Well-Being

Study your local tourism sector and the well-being services it offers: spas and various traditional and new age treatments, physiotherapy, medical treatment and other services that support the guests' personal well-being. You should develop a new service product: "a Service Channel for Well-Being". Keep in mind the service consumption can be extended pre-, ongoing and post- travel experience and think about all these parts of the experience. Start the project by designing and visualising a concept for the service channel.

Questions

1. What are the methods to participate with and identify the stakeholders in the project?
2. How can you involve the users in the development work?
3. Make sure to prototype the channel!

Possible Paper Titles/ Essays

1. Service design and tourism: an emerging area
2. *Creating new service opportunities with service design methods*
3. *Co-creating the tourist experience with service design*
4. Services and new business models in e-tourism

This work was previously published in Digital Culture and E-Tourism: Technologies, Applications and Management Approaches, edited by Miltiadis Lytras, Patricia Ordóñez de Pablos, Ernesto Damiani and Lily Diaz, pp. 36-47, copyright 2011 by Information Science Reference (an imprint of IGI Global).

Chapter 15
A Mass Customisation Implementation Model for the Total Design Process of the Fashion System

Bernice Pan
Seamsystemic Design Research, UK

ABSTRACT

Global economic development has been increasingly segregateing the design and manufacturing functions of industries both geographically and administratively. In response, fashion companies in advance economies have increasingly operated as brand houses that engage in design and marketing as their sole activities. The total design processes of the contemporary upstream fashion supply chain is therefore investigated and analysed as an integrated fashion system. A new conceptual model of mass customisation aligning the activities and interests of the collective fashion supply chain producers is subsequently developed with its associated implementation strategies. This model takes a consumer-centric approach, and places designers/brand houses as the instrument and channel for mass customisation. The objective is to enable the prospect for small medium fashion enterprises to deploy the vision and principles of mass customisation in a more coordinated, cost effective, and responsive way. The prospective benefits and practical issues of this new model are discussed.

INTRODUCTION

Fashion companies in advance economies have increasingly become brand houses performing the functions of design and marketing exclusively at two polarised ends of the lengthy and fragmented fashion supply chain (FSC). This includes, firstly, functions of total design processes interacting with off-site manufacturers at the FSC up-stream. Secondly, it includes the functions of marketing and sales interacting (directly or indirectly) with end-consumers at the FSC down-stream.

DOI: 10.4018/978-1-4666-1945-6.ch015

This chapter refers to end-consumers collectively as the fashion 'Customers'. It refers to all participants of the FSC design and manufacturing functions collectively as the fashion 'Producers'. This includes most critically, brand-houses/designers companies, textiles suppliers, and garment manufacturers. The "Fashion System" refers to all workings of the global fashion apparel industries.

Mass customisation (MC) has been recognised as an effective strategy in response to the contemporary climate of "the Fashion System" in an age of diverse Customers demand, product proliferation, global competition and information technology. This climate has been further challenged by the global economic downturn and the impact of currency fluctuations on trading supply and demand. However, MC implementation tends only to be deployed in the mass market sector by global corporations with large scales of economy and extensive technological investment capability, whilst more than 90% of the Producers in the Fashion System are small-medium enterprises (SMEs).

This chapter explores the strategic and practical possibilities of mass customisation for the total design processes (TDP) at the FSC upstream. This includes all processes from design conceptualisation (creative direction) and sourcing to design development and pre-production. The set time conditions of the seasonal calendar are established as the key parameter of the FSC. These time conditions are often neglected in studies of design processes, yet they provide a critical and competitive basis to all works of the Fashion System. The set components and definition of the fashion garment is established as the key output of the FSC. The garment components are what all efforts of the Fashion System ultimately work towards and generate revenues from.

A new model for a mass customised FSC is developed to enable a two-way balance between a consumer-centric demand and a design-led supply process. This balance is critical to the optimisation of the contemporary Fashion System. Due to the process-based principles, the new model does not necessarily require large investment or substantial technological intervention for brand-houses or small medium designers companies to implement, but warrants the benefit of mass customisation.

BACKGROUND

The Fashion Design Process: A Calendar of Prescribed Timing for Supply Push

For fashion brand houses and apparel designers' labels companies, the FSC design process generally includes all stages from ideas generation and creative direction to garment prototype development (Secor, 1992). Much published research explores the design and development process with respective diagrams devised to illustrate key sequential stages.

Carr and Pomeroy (1992) classified four phases with linear operative steps in each: 1) Origin of styles, comprising market research, design, concept, and market screening. 2) Sample development phase, including prototype pattern, sample, and range meeting. 3) Business objective refinement phase, encompassing pattern adaptation and testing, while production planning and scheduling is also carried out. 4) Attainment of commercial products. This takes the process from production pattern, grading, markers, production templates, specification, into two strands of feedback from manufacturing and marketplace. And while technological advances and geographical shifts of fashion design and development have evolved since the 1990s, the process stages and functional output of the FSC processes have remained largely unchanged.

Gaskill's (1992) retail product development model splits activities after 1) Trend analysis and concept development, into three parallel areas of 2A) Fabrication selection, 2B) Palette selection and 2C) Fabric design. This is then followed by

3A) Silhouette and style direction on one hand, and 3B) Prototype construction and analysis on the other, before remerging into a single final phase of 4) Line presentation. The internal factors of target market definition and merchandising process are pointed out, as are the external factors of domestic and foreign markets. However, they are not specified in terms of the stages or time table within which those activities take place.

Wickett *et al.*'s (1999) detailed activities guide for apparel product development, personnel and sources are identified in seven phases of 1) Trend analysis, 2) Concept evolvement, 3) Palette selection, 4) Fabric selection, 5) Fabric design, 6) Silhouette and style directions, 7) Line presentation, with an additional category listing influential internal and external intervening factors.

Sinha's (2001) summarised the generic fashion design process in four phases of 1) research and analysis, 2) synthesis and selection, 3) manufacturing, and 4) distribution, and indicated key factors at each phase. Mc Kelvey and Munslow's (2003) design process flow chart is not dissimilar, though it is completed with an additional promotion phase following completion of range or collection. This would typically be a marketing function carried out or directed exclusively by the brand house, baring no relation or responsibility to the manufacturers.

Forza and Vinelli's (2000) research describes sequential activities in the FSC and points out the substantial reliance design and productions has on forecasting, however inaccurate. Information on customers is typically managed completely independent of activities in the FSC. Their production stage chart illustrates the occurrence of monthly activities on a larger scale from yarn to textile to apparel production and distribution, though does not address specific time factor or relationships between the activities and processes. Le Pechoux's (2001) on the other hand, explores the dynamics and processes of fashion industries as a complex system; addressing the non-linear nature of cyclical iteration processes involving external and internal factors.

Senanayake and Little (2001) reviewed various mechanisms for the textiles and apparel industry's new product development (NPD) measures, and referred to the merchandising calendar in the format of a scheduling Gantt chart, with a full list of 40 activities and respective timing in a total of 35 weeks from concept to production for one season's product range.

Pan's (2006) research addressed a full range of parallel functions in the FSC processes with reference to the fashion calendar timeframe and main interacting participants amongst the collective Producers. An Amalgamated Process Map was devised to show a typical 16-18 wks development period from concept to completion of a full range of up to 200/300 show prototypes for brand houses that produce 2 main seasonal collections per year. The 'Producers' selection point' and the 'Customers' choice point' for the critical total design processes of the FSC were identified.

All process models reviewed reveal that the lengthy total design processes carried out collectively by 'Producers' prior to launching products in the market place, involve a series of screening and selection of design options and combinations. These range from ideas, trends and moods to the palettes of fabrics, colours, silhouettes, and fabrication to the final merchandise stories, mix and timing. Judgment calls are made by Producers loosely according to the evaluation of trend forecasting, observation of market happenings, assessment of past sales, and availability of resources. With the exception of resources availability, all factors considered by the Producers in fact contribute towards a high-risk speculation of what Customers may want in months to come. In this sense, Producers act on behalf of Customers to pre-empt decisions on what they should want.

The cyclical pressures to achieve the right decisions mix occur at set calendar times (typically just before the deadline for the pressing commencement of each following process stage) at one polar end of the FSC upstream, some 6-12 months prior to fashion collection launches at the market place. These decisions therefore directly impinge on the marketing and sales activities: affecting the responses from industry buyers and press at international trade shows, and eventually determining the Customer driven retail sales performance at various regional markets across the globe. It is therefore fair to categories the contemporary Fashion System ultimately as one that exercises a strong "Producers" supply-push approach, with "Customers" well shut-out of the loop of its core design functions and processes.

THE MASS CUSTOMISATION TENET

A Dilemma in the Power Struggle of Demand Pull

Mass Customisation (MC) has since the 1980s been advocated as the prospective paradigm that combines the benefit of mass production efficiency and craft production individualization. The aim is to effectively respond to global turbulence in a market of ever-fickle desires of individual customers, ever faster moving trends, and ever finer segment differentiation, indeed a climate of today. Gilmore and Pine II who pioneered the theory of MC defined it as 'markets of one', whilst Davis defined it as 'individual segmentation' (Davis, 1996; Kara & Kaynak, 1997). Brannon (2000) efines in *Fashion Forecasting*, as the medium between mass production's 'one-size-fits-all' and haute-couture's 'one-one-a-kind', where traditional supply chain is inverted by making Customers an integral part of the initial stages of product development.

Kay declared as early as 1993 that it is possible for all aspects of production and delivery systems to be done effectively to meet Customers' individual needs with the following formula: Mass customisation = custom-focused x lean production x continuous variety x short cycle development x flat and empowered management culture (Kay, 1993). Thackara (1998) further defines the relationship between suppliers and customers in '*One-to-one on-line: fashion, the internet, and the role of design*', outlining how mass customisation provides the platform on which the sales transaction is the beginning of an inter-dependent relationship between the seller and buyer as opposed to the end of a marketing process. This approach repositions functionality and quality as merely a starting point. In a contemporary market place where Customers are increasingly spoiled by the wide range of choices of more-or-less perfectly performing products, it is the logical response that service becomes part of product within a holistic concept for organisational design.

However, despite extensive academic and industry research providing conceptual and practical guidelines, benchmarks, and matrixes for MC, propelled by the challenging economic climate and maturing Customers' behaviour that beckons MC (particularly in the notoriously fast-moving Fashion System), the paradigm is still far from a wide-reaching reality some two to three decades later. Tseng and Pillar (2003) believe the missing gap is the capacity and mentality within companies to put the demands and wishes of each single customer at the centre of the value chain. On the other hand, Blecker & Abdelkafit (2006) argues that there is still a lack of common framework concerning the effective implementation strategy to aid MC practice.

Six levels of mass customisation involving Customers at varying degrees in the Producers' processes can be classified as below with respective contemporary fashion case examples. Level one has the most detached relationship between the Producers and Customers and level six has the most engaged. As the level of customisation increases, Customers involvement moves further upstream of the supply chain (Lampel & Mintzberg, 1996; Blecker & Abdekafit, 2006).

1. The 'Basic Customiser' combines 'push-through' forces of strong market understanding with responsive manufacturing systems,

and expects customers to find what they want from a larger variety of product offering. This is typically an approach taken by large scale companies whom have the resources to develop, buy-in, and offer vast product assortments and design lines. Spanish retail giant Zara is a well-know case whose fast reaction towards seasonal fashion trends, effective use of sales information, and efficient manufacturing system stunned the global industries with its phenomenal success. Moreover, its impact forced other large retailers (particularly US ones) to re-examine their own processes.

Aggressive British large retailer Top Shop is another successful 'push-through' example, using effective marketing and buying strategies as well as exclusive design commissions to curate a wide variety of on-trend products and smaller designers' labels. It caters to the tastes and styling of a wide range of younger age-group Customers', yet fosters their loyalty to Top Shop as an umbrella brand and destination.

2. The 'Alteration Customiser' employs a third party between Producer and Customers to carry out the customisation or personalisation of standard products. Examples are commonly seen in up-scale department stores such as Harrods or Selfridges, where in-house tailors or seamstresses would be called in to make minor garment alterations necessary to fit the specific customer making the purchase.

A small number of designers' boutiques or menswear suiting retailers also have such function or have recommended subcontractors or suppliers whom provide such service to their customers. It is a 'reactive' and an expensive way of obtaining customization (for Customers in above case examples) as products are not designed for effective customisation (Tsigkas et. al., 2001).

3. The 'Cosmetic Customiser' deals only with packaging, distribution or point-of-sale changes. For instance, Thomas Pink shirting company is able to offer customers the service of embroidered personal initials on the cuffs of shirts purchased from its standard ready-to-wear range.

Growing high-end fashion internet retailer Net-a-Porter makes the simple gesture of a 'Cosmetic Customer' by providing 4 choices of packaging options of basic, discreet, signature, and wedding wrap during the check-out point on-line Customers' purchases.

4. The 'Transparent Customiser' provides unique products by monitoring customers and without necessarily making its customisation explicit (Anderson-Connell et. al, 2002), as opposed to a user making the request. The iconic internet retailer Amazon of the internet era is a pioneer and leader of such Customisers, where a full purchasing history of Customers are recorded in its database, and repeated customers are recommended a range of different products in similar styles or genre to what they had previously purchased.

Many internet retailers now employs this effective methodology and Koodos is a designers brand discount site which recommends complementing garment separates or accessories in similar price points or styles Customers shop on site.

5. The 'Self-Adaptive Customiser' produces products with features designed into them so that Customers can change aspects of it according to their individual preferences without aid from manufacturers or retailers. Common examples would be seen in a reversible jacket or a pair of cargo pants where leg parts can be removed and worn as shorts.

Elliot Rhodes takes the 'self-adaptive' principle to design and retails a wide range of fashion belts where Customers can select, self-assemble and interchange belt buckles and embellishment from a standard range to accessories for a variety of fashion and functions.

6. The 'Collaborative Customiser' (Pure Customiser) involves Customers into the product design process termed co-design (Fiore et. al, 2000, Anderson-Connell et. al, 2002). This is the most sophisticated level of mass customization, also known as core/pure customization. This approach nurtures a 'Prosumer' (Toffler, 1980; Piller, 2003) relationship between Producers and Consumers, involving Customers within the design development and/or manufacturing process. A Suit That Fits.Com deploys the classic made-to-measure technology to enable customers to select from their standard range of styles, cuts, fabrics, and finishes to assemble and deliver the product of Customers' personal choice.

DEPLOY demi-couture is a pioneering case in the high-end fashion sector, where Consumers' requests or feedback are incorporated into the design and merchandising processes at the FSC upstream. Garments are designed and constructed with multiple functions, styles, and/or specific customer requirements so that Customers can customise each outfit for numerous looks and occasions. Product life cycle is simultaneously increased as the Prosumer relationship is extended after-sale as loyal Customers build-up a much more versatile and creative personalised wardrobe.

Alford (2000) suggests that the MC concept is suitable for low-volume applications with customisation available at a cost premium from the standard product. Okonkwo (2007), however, argues that the rules for the fashion market place have changed and that customisation need not necessarily be applied at a cost premium to the brand-houses. And in fact, Customers are increasingly expecting and not just desiring personalised attention from their goods/service providers in the following lateral areas: 1) Customising of standard products, 2) Customising point of delivery, 3) Customising of retail shopping experience, 4) Producing bespoke goods, 5) Customising of online shopping experience, 6) Allowing Customers to customise the process.

Whilst there is no shortage of concurrent views for key drivers and market suitability of mass customisation, namely: 1) heterogeneous demand, 2) short product life cycles, 3) mature markets and, 4) more conscious Customers (Kotler, 1989; Pine, 1993; Westbrook & Williams, 1993; Hart, 1995; Kotha, 1995; Feitzenger & Lee, 1997; Gilmore & Pine, 1997; Peppers & Rogers, 1997; Bardakci & Whitelock, 2003), mass customisation in its higher-level and purer forms, is yet to be substantially adapted by the Fashion System on a broader basis for a wider consumer base. More importantly, MC confronts the Fashion System with several of its inherent paradoxical attributes, particularly in the high-end fashion sector. It has thus has been met with skepticism and with substantial reluctance for experimentation and ultimate change. The reasons can be summarised through the following dilemmas that constantly thrusts the FSC towards mass customisation in concept, yet consistently drag it away from it in practice:

Perception Hindrance

Whilst varied product ranges and features are now clearly crucial in meeting an increasingly knowledgeable contemporary Customers' demands; whilst individual tailoring is an elitist's luxury too expensive to sustain both for Producers and Customers, and whilst Customers' willingness to spend extra for additional individuality or personalised convenience has become well known (Taylor et. al., 2003) – the attributes of mass customization would offer an attractive response.

Ironically however, even as the fashion Producers strive to gain greater market share and customer base 'en-mass' in a globalised economy, a remarkable proportion of the Fashion System practitioners are unable to reconcile the increased individuality afforded by mass customisation with warranted conformity offered by 'exclusivity' (e.g., luxury goods baring the same look and logos sold in mass quantities globally). This is driven by a fear of loosing their brand superiority and authority through enabling Customers to specify or personalise their own branded products (Okonkwo, 2007).

Resource Hindrance

Whilst the fashion life cycles commanded by seasonal changes are naturally short, fierce global competition has further propelled ever changing trends and shifting niches, and thus ever shorter product life cycles and un-salvable product features through 'planned obsolescence' (Easey, 1995; Jones, 2002). In full view is the front end momentary glory of the latests, the newests and the musts-haves, fully aided by the contemporary fashion's all powerful counterpart – the media.

This phenomenon would have logically beckoned the practice of mass cutomisations, as it has in many other industries. However, un-like most other industries, fashion brand houses and designs companies in advance economies by-and-large have very low entry barrier and require relatively low technological investment, particularly since shedding almost all of their manufacturing activities some two decades ago. This factor coupled with the apparent necessity to allocate hefty marketing budgets in order to succeed, means both financial and human resources for substantial back-end development, innovation or upgrade commands low or no priority.

Operation Hindrance

In an inherently labour-intensive industry, where each production run of a product style was ultimately never long enough for even a mass retailer in its mass production hay-day to fully automate garment manufacturing (partially due to the nature of handling wide varieties of soft fabrics); where operational skills of individual workforce is heavily relied upon; where competition fierce, entry barrier low, and the need to distinguish one product from a vast array of others paramount; a shift to mass customized production would have seemed both natural and slight.

However, the ever compressed design-development time for the 'new season' revolving chains of cyclic deadlines up from Designers, Textiles Manufacturers, and Garment Manufacturers and down to trade and consumer press, marketing and sales, means that there is never the window or aspiration to reflect, review, or restructure for substantial or collective changes. In order to implement mass customisation effectively, a period of time would be required to coordinate supporting technology and methodology, and devise, update, improve or revise the relevant processes.

Nevertheless, early adapters of MC in the Fashion System, such as Levi's made-to-measure jeans and Nike ID shoes, have maintained their leading positions and proven competitive advantage in the global market place a decade on. They have invested heavily in enabling technology (and marketing) in relation to Customers and Producers. However, studies on these cases have also concluded that success will depend on customers' satisfaction level during early pre-manufacturing steps, and suggested that FSC may need specialised MC processes (Lee & Chen, 1999).

Alford's research concluded that it is possible to transform the management of the customised supply chain by increasing involvement of suppliers and use of product data management systems to effectively combine resources and expertise in geographically dispersed areas. It will also help cope with escalating complexities in managing the varieties and volume of data that mass customisation introduces into the supply chain (Alford et. al. 2000). However, it was identified that optimisation requires an effective and coordinated approach to inform and support relationships and management decisions in the design and production process.

Tseng and Piller (2003) further suggests that building a value chain that places individual Customers demands and wishes at the centre implies much more than investing in technologies. By presenting Customers' co-design prospects, process could be shortened and streamlined to focus on proving real value to Customers, thus increasing competitive advantage to Producers. All authors of MC research agree that industries will greatly benefit from knowledge and utilisation of Customers' information (i.e. real demand), and that much work is to be done throughout the supply chains in order to realise the true gains of MC. The how and where of this balance between Producers' supply push and Customers' demand pull in a new MC process specific to the Fashion System is therefore the central objective of this research.

THE PARAMETER AND OBJECT OF THE FASHION SYSTEM

It is clear that the common objective of the FSC Producers is to produce clothes from conceptualisation to consumption speedily, profitably, and to the Customers' purchasing choice. This research therefore disassembles the current FSC design processes into the following factors with subsequent findings:

The 3 'Constants' of the Fashion Parameter

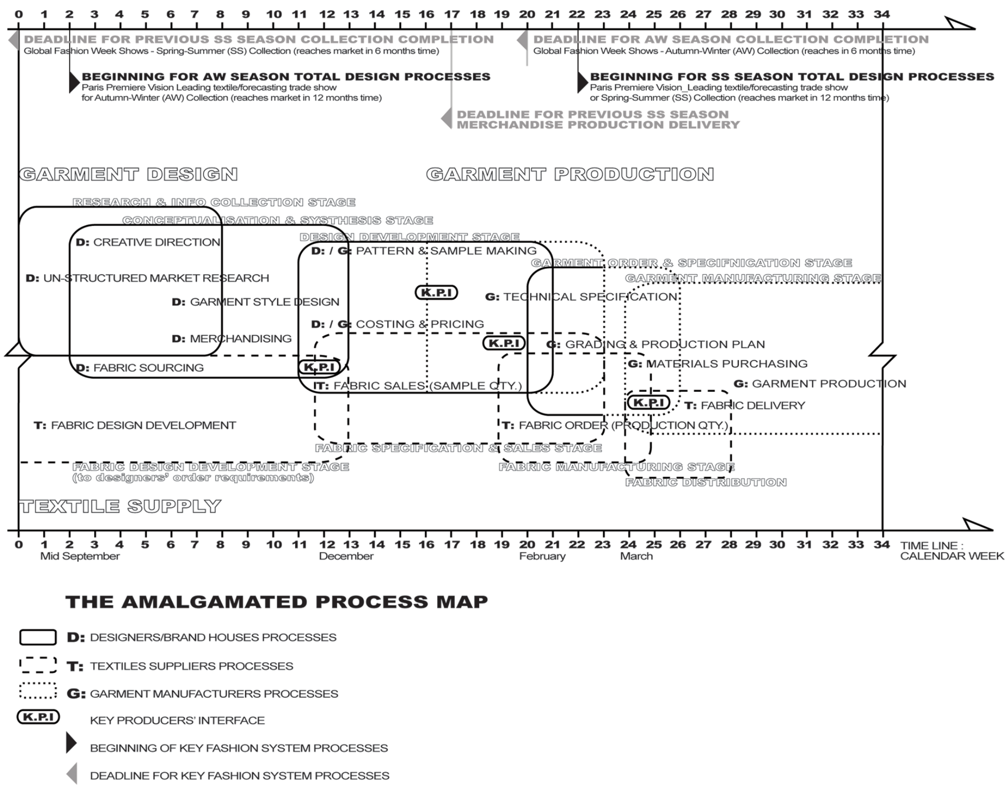
The three key conditions of the Fashion System to which all Producers are subject to, are identified as: 1) the time line, 2) the communication plane, and 3) the decisions points of the FSC total design process. This research therefore considers the three factors as 'constants' of the process model.

Time Line

The parameter of time line is marked into two types of effective periods: 'processing time zone' and 'interacting time zone'. These definitions set the first parameter for the model, and two terminologies refer to the activities segments that must be carried out by the three key Producers of Designers/Brand houses, textiles suppliers, and garment manufacturers. The reference of calendar weeks in the fashion season is common to all parties. Processing time zone refers to the periods where the back-end supporting and preparatory works are carried out in order for the essential communication to take place between the three Producers parties. This typically occupies in a longer time span of calendar weeks. Interacting time zone occupies a shorter time span and refers to the periods where the actual contact and communication is made at the front-end between FSC parties. Zipkin (2001) refers to the activities of this 'interacting time zone' as the 'elicitation process', and categorised the key information as identification, selection from menu of alternatives, technical measurements, and reaction to prototypes.

The key steps of the FSC total design process are shown in the Amalgamated Process Map (Figure 1). All activities for embarking on a new season collection or range design begin officially with fabric selection at or around the major textiles and trend forecasting tradeshows in mid September for the following year's fall-winter fashion collection. The most notable leader for all mid to high-end fashion sector Producers is Premier Vision trend forecasting and textiles tradeshow in Paris. This calendar time to which this tradeshow takes place is thus denoted as week 1 of the Amalgamated Process Map. The same design process is repeated at a maximum

Figure 1. The amalgamated process map



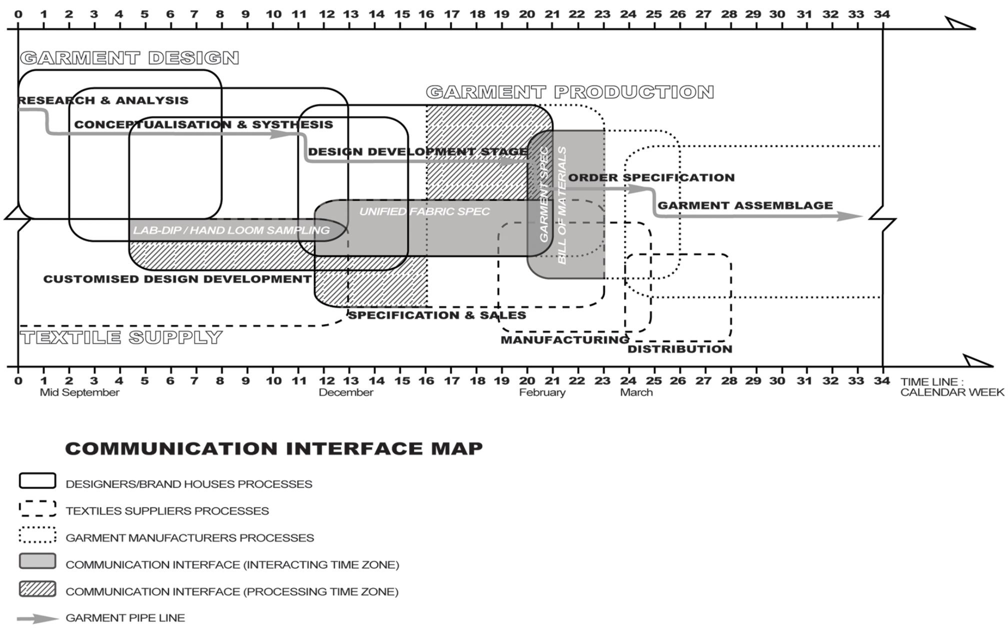
of once every 6 months (each 'fashion season'), and starts again in February for spring summer collections for its following year.

Communication Interface

The design and control of design development process is often ad-hoc based on individual managers' experience without sufficient communication structure (Tsigkas *et. al.*, 2001). Field research analysis showed that smooth and accurate communication between the three key Producers parties carried out by their respective front-end teams in the 'interacting time zone', depends heavily on the correct design information relayed to, and prepared by, the back-end support team in the 'processing time zone'. It also shows that the nature, format, and to some extent, the content being communicated, are in fact the same season after season. These being: accurate and consistent samples and specification packages, and bill-of-materials for both fabrics articles and garments styles.

It is clear that the reduction of information duplication and repeated procedures can improve efficiency and effectiveness thus speeds up processing time for all parties in the FSC. Furthermore, sharing of correct information accelerates problem solving cycles and enables the anticipation of potential issues and obstacles during the design development processes (Muffato & Roveda, 1999). The communication interface (Figure 2) between specific operating teams of the three parties is therefore established as the second parameter for the model. The communication interface is defined by the unification of fabric and garment specifications in terms of the channels, format, and information content for

Figure 2. Communication interface map



interacting FSC parties, with reference to timing requirement and duration allowances set in the fashion system time line.

Decision Integration

Key decisions for both the Producers' selection point and the Customers' choice point (PSP and CCP in Decision Point Map) are converged to become an 'Integrated decision point' (Figure 3). These are the points in time (between weeks 8 to 18) when the most critical decisions for the fashion output of garments are made, from colour and fabric palettes to silhouettes and merchandise mix. They are therefore the specific points where information on Customers' preferences and requirements should be incorporated into Producers' decisions in the relevant FSC process stages.

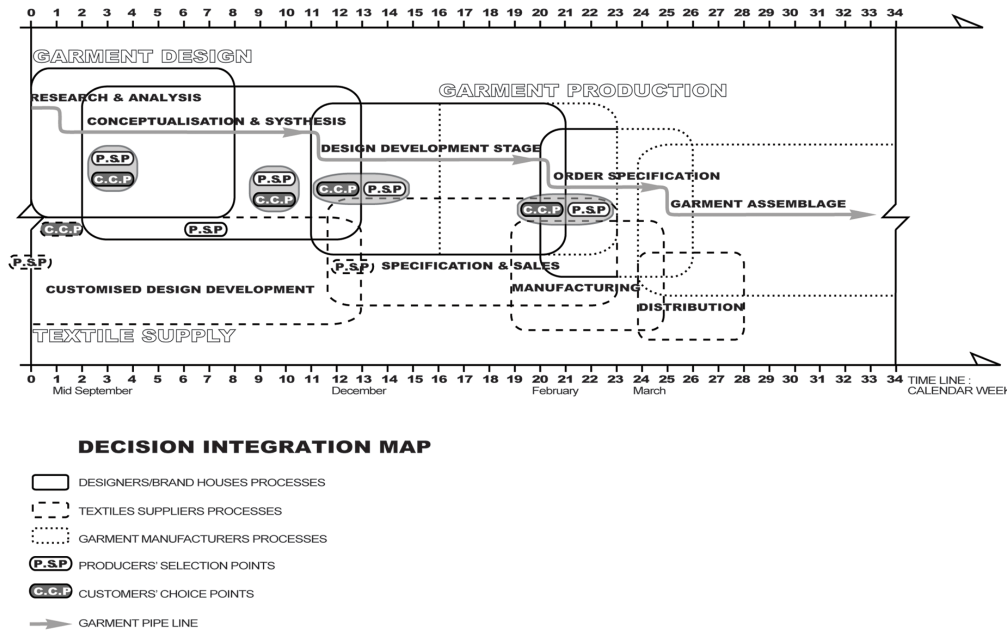
The 3 'Variables' of the Fashion Object

The 3 key components of the Fashion Object, i.e., the garment, to which all 'Producers' output ultimately go towards, are identified as 1) fabric, 2) colour, and 3) silhouette. It is through the incessant changes of these very factors that variety and newness of garments are created season after season to supply Customers. This research therefore considers these factors as 'variables' of the model.

Fabrics

Fabric is undoubtedly one of the first key components of a garment. Fabric selection in the total design process typically entails the pooling of all sample swatches collected from trade shows and individual suppliers' presentations or from Designers' own sourcing and market research. Designers then decide on a palette of desirable fabric appearance, construction, hand-feel, and special features or functions to compile a creative

Figure 3. Decision integration map



direction 'mood board' and/or start silhouette designs with.

In the field research conducted, a range of fabric specifications sent from high-profile, international sample Designers/Brand houses to textiles suppliers were collected and analysed. The specifications showed a wide variety of formats and quality of information. Some were with fragmented hand-written descriptions accompanied by photocopied art work and sample texture of fabric requirement. Others saw formulaic files of large retailers containing lengthy technical lists stretching up to 3 pages, yet with large areas or information irrelevant or not-applicable to most fabrics commonly used, hence barely filled in. Researcher therefore identified information common to all companies and crucial to textiles suppliers' proceedings for fabric production, with references to the following: 1) literature on textiles manufacturing processes, 2) field research on textiles suppliers' order processing and production steps, and 3) key sample textiles suppliers' fabric library cataloguing systems and information referencing methods.

A proposed 'unified fabric specification' with clear information on purchase order, fabric construction and end-use (garment) requirements was subsequently devised in order to assist designers/brand-houses to accurately and efficiently communicate their requirements to their textiles suppliers. Relevant personnel at the textiles manufactures responsible for fabric order processing, as well as industry experts in textiles development were consulted to verify the validity and practicality of the 'unified fabric specification' as a communication interface.

Colours

Colour is a most critical factor in garment design that dictates and reflects the changing seasons and trends in the Fashion System. Whilst Customers may not be fixed on fabric or silhouette (cut) when shopping, most have instinctive and clear ideas on colours, particularly when choosing apparel goods set against their own complexion (Wilson *et. al.* 2001). Field research on consumer's clothes shopping preference showed that 63% surveyed women find colour to be the first thing that catches their attention.

The lengthy series of Producers' 'pre' selection and screening processes for colours take place prior or in parallel to fabric palette selection. They are carried out first by global trend forecasting agencies and fibre, yarn, textile manufacturers, then by Designers/Brand houses, industry buyers, followed by media/press. However it is the final purchasing decision of Customers that determine the success of a colour choice.

From the Designers/Brand houses' point of view, consequences of getting the colour palette wrong could result in costly retention of unsold garment units and loosing market shares to competitors (Wilson et. al. 2001). Instrumental in designer's process in arriving at the final colour choice is the Textiles Suppliers' responsiveness and capability of providing custom physical colour lab-dip match samples or hand-loom swatches as accurately and quickly as possible.

From the textiles suppliers' point of view, the colour specification issue is a complex and costly one and the chances of not getting the colour 'right' in the eyes of the client (Designers/Brand houses) are extremely high. This is due to the following: 1) the subtle differences and subjective preferences in match colour acceptance level, 2) the same chemical colour formula will result differently on different types of yarn, construction, and finishing, and 3) discrepancy in light sources between Textiles Suppliers and their clients'. Even when high-quality textiles suppliers typically provide 3-4 derivatives for one colour match in each lab-dip package, research shows that more than 70% of the colour match samples are approved only after 3 tries of lab-dips (with an average turnaround time of 2-3 week for each 'try'). In addition, Designers/Brand-houses often take up to 2 weeks to reply with approval or request for further lab-dips, due to in-house communication and decision between relevant design or management personnel. It is therefore clear how these reiterative processes lead to an in-efficient 8-10 week period to conclude on fabric development and lengthens the FSC total design process, as marked in the Amalgamated Process Map (Figure 1).

Silhouettes

Silhouette is referred to as the three dimensional cut, overall shape and volume of the design (Mc Kelvy & Munslow, 2003). For the ease of description, Researchers refer to the silhouette factor in the garment design process as a term which comprises the aspects of garment cut; shape; style; construction; proportion, specified through pattern-making and garment specification.

During the period of the fabric and colour selections and decisions, the total creative directions and styling for the seasonal collection/range are conceptualised. The actual designs (drawings) of garment silhouettes (styles) typically begin 2-3 weeks later by Designers. This opens up some 4-6 weeks of garment designing and is carried out concurrently with the continuation of fabric and colour development screening and selection aforementioned. Pattern makers on or off-site then translate drawings with descriptive notation for detailing, finishes and measurement requirements into flat patterns for on or off-site garment sampling.

Design Synthesis

At the end of the parallel processes described in 3.2.1-3.2.3, a set of composite decisions based on three variables above are made on behalf of end Customers by Designers alone in SMEs, or collectively with their in-house textiles and merchandise managers, their company executives in larger fashion corporations. This takes place at the 'collection presentation' process step during weeks 14-18. The collective Producers' aim is that at first sight (of physical retail garment or marketing campaign imagery), the colours, textures, and shapes will attract Customers enough for them to want to buy.

As observed from all sample Designers/Brand houses, a fair percentage of garment silhouette in each company's season collections are repeated designs or consist of similar core shapes from previous collections. This may not always be immediately apparent due to different usages of fabric, colours, and embellishing details. However, further research on the design development processes showed two key evidences for common occurrence of silhouette design repetition.

Firstly, styles in new season collection development are often referred to as a certain previous season style name and/or number with the new addition of a certain detail, both in Designers' verbal descriptions and sketch notations. At times descriptions of such nature replace formal drawings or initial specification altogether. Secondly, certain key pattern blocks are frequently re-used for different garments with minor alteration or addition of lines and details to generate new season silhouettes. This was seen particularly often in the work of Designers/Brand house with in-house pattern makers, where archive patterns were frequently accessed for referencing purposes during the construction of new styles. However, the practice of silhouette repeats and moderate alteration is dependent upon individual Designers'/Brand-houses' preferences and work methods, and this practice is not carried out in a systematic or consistent approach in any of the sample companies observed.

The main reasons that the design of garment silhouettes often repeat from season to season, as widely seen in the market place in general, are as following: A) Long-term over-arching trends on silhouettes last for several years and through the seasons (Jackson, 2001). B) Each designer/brand house develops certain garment cut and fits typical to its products that are recognised by their clientele and thus maintained as classic items carried over the seasons. C) Although there are countless looks and styles to which the Fashion System generates constantly, between the variety of fabrics and colour palettes, there are arguably a finite number of key silhouettes amongst each garment type that would be accepted by a wider clientele. For instance, there is a limit to which the silhouette of a pair of full length trousers can vary, before its potential buyer group is dramatically reduced (irrespective of price points), and sales prospect compromised.

Nevertheless, repetition in garment silhouettes, wholly or partially, is by no means a lesser expression of creative design, for it is the combination of the three variables of fabric, colour, and silhouette that generates desired value and newness for Customers. The example of the famous Burberry checks print used on typical swimwear fabric for a basic bikini silhouette illustrates that high value can be re-created by altering just one variable of a design. In fact, when closely examined, most garment silhouettes consist of some elements where aspects are not created completely from scratch and have not or could not form parts of another garment silhouette.

This dissected view of the garment object highlights the significance of systemic repetition in the contexts of design process. That is, if within in each garment silhouette there is always some portion of it re-produced from parts of another garment previously designed, it takes no great leap towards two possible prospects. Firstly, the generating and communicating of largely the same information of garment pattern and specification can be logically organised for frequent access and cross-referencing. This would reduce the common occurrence of repeat information and/or process duplications as widely observed in the FSC processes, thus allow for a more streamlined and sustainable process saving both time and resources. Secondly, components for repeatedly designing garments with partially shared silhouettes, (e.g. jacket of same bodice cut yet different lapels and sleeves shapes), can be methodically rationalised and utilised – thereby capitalising on the natural existence and characteristics of silhouette repetition as a design variable, without compromising the creative totality of a garment.

CONCLUSION AND DISCUSSION

Proposed New Process Model and Implementation Strategy

The Collective Activity Model (Figure 4) which maps out the total design process emerges as a new prospective model of mass customisation for the FSC. The new model is characterised by the following attributes: firstly, the rationalised and directional flow between Producers and Customers is cross-referenced against the calendar time line of the existing Fashion System. Secondly, Designers/Brand houses are positioned in the critical role of integrating Producers' design-development processes at the back-end and Customers' real choices collated directly from the market retail front end. Thirdly, the Customers' information is incorporated into 4 key points in the FSC upstream process; points 1 and 2 are 'opinion-based' information that aid Producers' final colour, fabric, and silhouette selections. Points 3 and 4 are 'decision-based' information that aid Producers' sizing and quantity order. Fourthly, the moderate changes to the collective FSC upstream processes do not require all participants of the fragmented FSC to radically re-engineer their existing functions and processes. Finally, the model allows for further compression of MC delivery lead-time by systemising aforementioned communication interfaces and design synthesis.

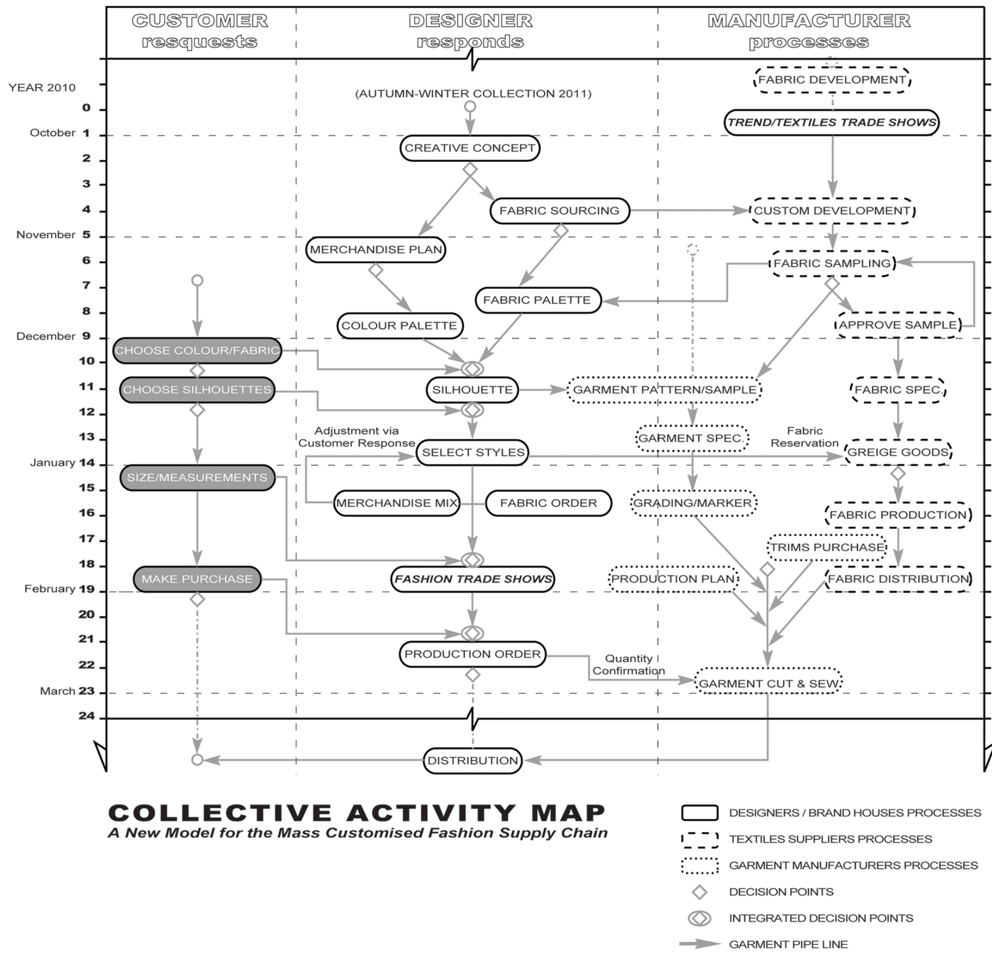
The new model therefore offers the potential for Producers to supply the garment in a more accurate manner, and for Customers to demand the garment in a more personalised fashion. However, it does not require significant organisational re-structure and technological investment, nor presents the high risks that would prevent fashion SMEs from experimenting with this new model for mass customisation whilst constantly under the seasonal time pressures. Three key implementation strategies are discussed in the following sections with reference to Customers and Producers. In this new model Producers are differentiated into Manufacturers, and Designers for clarity of the strategic propositions.

On Consumption: Customer Requests

With a central focus on mass customisation, the field research survey and analysis on sample female shoppers in central London investigated what and how the fashion Customers demand, and what their unfilled demands are. The results cast light upon its reciprocal relationship with supply. From the Customers' point of view, most Producers are unresponsive and insensitive towards their precise needs and wants, despite the enormous investment to attract Customers through Designers/Brand-houses marketing efforts. The survey showed that 64% of respondents wished they could easily access customised garments, and a total of 63% of respondents have clothing alteration needs 'frequently' or 'all the time'.

This unresponsiveness to Customers (from garment style, to colours, fit, availability and price) translates directly into lost sales on a significant scale and in turn results in loss of market share for the Producers. The consequences account for two facts: firstly, in a stiffly competitive, densely populated, yet marginally differentiated fashion system, customers can find easy substitutes for most fashion trends and merchandise. Secondly, due to widespread information technology, customers are fast becoming knowledgeable about fashion trends and products. They are thus increasingly able to declare what they like and dislike, and to even specify what they need and want. This illustrates their full readiness for all levels of mass customisation offering.

Figure 4. Collective activity model: A mass customised FSC



New Model Strategy 1: Customers' information input built-in

Whilst theories of postponement and modularisation for mass customisation have previously separated the production-driven push system and the customer-driven pull system, and identified the 'decoupling point' in the value chain (Blecker & Abdelkafi, 2006) from which standardised and customised products are separated in the pipeline, this research emphasizes the importance of a combination of supply-push and demand-pull approach for the FSC. 'Integration Decision Points' are identified in the total design process with the precise timing and contents necessary. Customers' feedback and general preferences or wish-lists (particularly that of repeat Customers) on product attributes such as fabrics, colours, and silhouettes can be continuously collected by Designers/Brand houses, stored in its central data-system such as electric point of sales systems (EPoS) or others generic database or spreadsheet softwares, and regularly updated, analysed, and utilised. Data can then be incorporated at the key 'integrated decision points' as illustrated in the 4 points of the Collective Activity Model (Figure 4). Furthermore, this information can be shared with long-term supply chain partners (e.g. textiles and garment manufacturers) as basis for new product development and/or quality performance improvement.

This intervention aids Designers/Brand houses' capability to anticipate the real and customised demand of the Customers, fine-tune their decision making for merchandise plan and make it more closely aligned with the Customers' needs and wants. It also in turn helps to reduce the errors associated with predicting some 12 months in advance and 'ordering in the dark', which often results in slow sell-through, costly mark-downs en mass, or large stock keeping. Furthermore, it creates a continuous 'feedback chain' for the collective processes between Producers and Customers through the FSC process, which is much more effective and timely than a long 'feedback loop'. It thus presents a direct contrast to the long feedback loop of the existing Fashion System practice, where information on customers is typically not gathered until the end of each season's sell-through cycle, and not incorporated into Producers designs until a minimum 3-4 months later, if at all. The new model therefore enhances the optimal balance between Producers' supply push and Customers' demand pull, by activating a MC implementation strategy at the heart of the FSC upstream processes.

On Production: Manufacturer Processes

Given that a) The prospect of mass customisation is indeed highly sought-after by the fashion Customers; and b) the validity and precision of design information passed through the FSC pipeline is of paramount importance in order to achieve the garment, as intended by the Producer and desired by the Customer; the field research investigated what and how textiles and garment manufacturers currently supply, and how they may re-organise existing processes in order to capitalise on this demand. The high occurrence and high cost of process reiteration, information duplication, and ad-hoc communication was identified throughout the FSC upstream processes, and is therefore a key area in the existing FSC practice that beckons streamlining.

New Model Strategy 2: Producers' Information Flow Re-Channeled

Fabric and garment specifications are identified as the critical design information generated by Designers and processed by Manufacturers all the way through the FSC pipeline to affect and/or determine the final garment sale to Customers. A set of unified fabric and garment specifications and their accompanying bill of material are thus proposed for designated functions between the FSC Producers, at particular communication interfaces in the total design process in the FSC upstream as illustrated in Figure 2. This ensures the correct content share at the right calendar time and between the right parties, and reduces the large margins for human error whiles reducing process delays thus streamlines process efficiency.

On Design: Designer Responds

On surveying international brand houses/designers companies, field research found that sample Designer/Brand-houses produce an average of some 800 garment styles per company per year, irrespective of the finer differences in each company's sub-season merchandising. The figures total the number of garment styles that actually sailed through the series of Producers' screening and selection processes in the lengthy FSC pipeline and end-up on the retail shelves. In other words, plenty more styles are designed, partially or fully developed, but dropped somewhere along the FSC pipeline. According to Eckert's research on ratio of design ideas to samples, only an approximate 30% of garment styles make it through as final merchandise (Eckert, 1999).

New Model Strategy 3: Designers' Information Creation Managed

As fabric, colour, and silhouettes are identified as the three key components of the garment object that repeatedly change in response to the parameters of a cyclical fashion system, it follows that using combinations and permutations of these three variables would offer an efficient strategy for the creation of new garment styles. A clear organisational and management structure of information classification and referencing can be devised to generate assembling options for the fashion garment, both in terms of design and production. This provides the creative and economic advantage for mass customised fashion garments and dramatically reduces complexity, time and resources wasted through repetitive process reiteration. Furthermore, it provides Producers with the ready capabilities to combine different design components, whist presenting Customers with a far more enticing product offering in the form of relevant options incorporating their individual requirements. The result is a far more mutually beneficial Prosumer relationship increasing both Customers' satisfaction and Producers' brand loyalty.

FURTHER RESEARCH

The proposal of this new model as an MC implementation strategy suitable for SMEs in the FSC, opens up new opportunities and possibilities for both Producers and Consumers with enhanced prospect for the synergy of 'Prosumers' co-design. It is noted that Burberry, amongst a handful high-end brand houses, has since this year taken the lead to take direct orders from Customers at the fashion week catwalk trade shows for goods delivery in 3-4 months time. DEPLOY demi-couture has also been pioneering in holding loyal Customers previews during collection design development processes, in order to collate Customers feedback for new season design finalisation and merchandising decisions. These new scenarios demonstrate that for worthy, desired fashion goods, Customers are indeed interested to engage in certain FSC processes and willing to wait for the necessary delivery lead time.

However, further study and testing remains to be done in this new arena of a mass customised design process, beyond the more widely explored aspects of sizing, made-to-measure, and enabling technology. Areas of key relevance are highlighted: 1) The in-depth investigation on the total design processes of FSC companies that have already adapted various types of MC strategies, 2) the precise content, mechanism, and system for translating Customer demands into sophisticated garment designs, and 3) the prospect of modularisation as a design management strategy for a mass customised FSC. Continuous research is also carried out on the optimisation matrix for collection design and development using mathematic permutations and combinations of the garment components. And whilst a challenging global economic conditions and market turbulence is faced by all, this climate will only serve to intensify the potential and necessity for variety and customisation (Pine, 1993; Harts, 1994), in order for Producers to fulfill Customers' demand more precisely.

Chapter 16
Integration of Fuzzy Logic Techniques into DSS for Profitability Quantification in a Manufacturing Environment

ABSTRACT

Production control, planning, and scheduling are forms of decision making, which play a crucial role in manufacturing industries. In the current competitive environment, effective decision-making has become a necessity for survival in the marketplace. This chapter provides insight into the issues relating to integration of fuzzy logic techniques into decision support systems for profitability quantification in a manufacturing environment. The chapter is divided into five sections with a general introduction of the topic, followed by a thorough literature review on the existing techniques. Thereafter, fuzzy logic algorithms using logistic membership functions and resource variables for decision making aiming at quality improvement are discussed. A case study involving a textile firm is then described with the computational results and findings, and finally, future research directions are presented.

INTRODUCTION

Decision making has become very important in several areas of human endeavor and in real-world situations, it involves information which is fuzzy in nature (Metaxiotis *et al*, 2003 and Monfared & Yan, 2004).However, most of our traditional tools for formal modeling, reasoning and computing are crisp, deterministic and precise in character. By crisp we mean dichotomous, which is, yes-or-no type rather than more-or-less type. In conventional dual logic, for instance, a statement can be true or false and nothing in between. In set theory,

DOI: 10.4018/978-1-4666-1945-6.ch016

an element can either belong to a set or not, and optimizing a solution is either feasible or not. Precision assumes the parameters of a model represent exactly either our perception of phenomenon modeled or the features of the real system that has been modeled (Sakawa & Yana, 1985).

A practical decision making problem is best tackled by mathematically modeling it. Often, a reasonable amount of mathematical models with incorporation of fuzziness are used in order to assist decision makers for making rational decisions. A discussion on fuzzy linear programming (FLP) with imprecision and uncertainty for decision making problems is provided. FLP handles fuzziness in the parameters where the model is parameterized to find a satisfactory solution in the form of function of membership values. This ensures easy computation (Delgado *et* al, 1989).

The continuous linear-programming involves decision variables that are fractional. However, when all decision variables are integers, it is known as integer-programming (Beasley, 2011 and Harvey, 2011),. A number of methods have been developed for integer programming such as enumeration, cutting-plane and group-theoretic techniques and they have been applied to various applications such as capital budgeting, warehouse location, scheduling, etc. (Bertsimas *et al*, 1999 and Ghanizadeh & Fakhri, 2009) However, often real-world problem, the realistic assumption is that does not always involve integers. That is the rational for this work where FLP method is used effectively for solving linear programs which involves non-integers. In this chapter, a methodology using logistic membership function to solve the FLP problem is presented.

BACKGROUND

The mathematical formalization of fuzziness was originally pioneered by (Zadeh, 1965). This paved the way for more research in the application of fuzzy in real-world problems (Orlovsky, 1980). Some earlier work on fuzzy decision making can be found in (Tamiz, 1996, Zimmermann, 1987, Kickert, 1978, Zimmermann, 1991). In the last decade, manufacturing companies decided to adopt intelligent solutions, since the traditional manufacturing decision-making mechanisms were found to be insufficiently flexible to respond to changing production styles and highly dynamic variations in product requirements (Kusiak, 1990 and Metaxiotis *et al*, 2002). (Custodio *et al,* 1994) discussed the issue of production planning and scheduling using a fuzzy decision system, whilst, several outlines concerning the development of a rule-base for the specification of manufacturing planning and control systems were made by (Howard *et al*, 2000). (Watada, 1997) has proposed one form of logistic membership function to overcome difficulties in using linear membership function in solving fuzzy decision making problem. Non linear logistic membership function was presented by (Vasant & Bhattacharya, 2007 and Bhattacharya & Vasant, 2007). Some representative publications can also be found in (Zimmermman, 1985, Yager *et al*, 1987, Dubois & Prade, 1980 Klir, & Yuan, 1995 and Ross, 1995)

The approach proposed here is based on interaction with the decision maker, the implementer and the analyst in order to find a compromised satisfactory solution for the fuzzy linear programming (FLP) problem. In a decision process using an FLP model, source resource variables may be fuzzy, instead of precisely given numbers in crisp linear programming (CLP) model. For example: machine hour, labor force, material needed and so on in a manufacturing center, are always imprecise, because of incomplete information and uncertainty in various potential suppliers and environments. Therefore, they should be considered as fuzzy resources, and FLP problem should be solved by using fuzzy set theory. In this chapter, a methodology to solve fuzzy linear programming problem with logistic membership is considered.

FUZZY SYSTEM

The heart of the methodology for the FLP problem as stated by (Rubin and Narasimhan, 1984) lies in the construction of membership function for the objection coefficients, technical coefficients, resource variables and decision variables. In this regards many researchers used the FLP approach in solving its applications problems in their work.

Various types of membership functions were used in fuzzy linear programming problem and its application such as a linear membership function, the linear fuzzy constraints, a tangent type of a membership function, an interval linear membership function, an exponential membership function, inverse tangent membership function, logistic type of membership function, concave piecewise linear membership function, piecewise linear membership function, flexible membership function, and dynamics membership function. As a tangent type of a membership function, an exponential membership function and hyperbolic membership function are nonlinear functions, a fuzzy mathematical programming defined with a nonlinear membership function results in nonlinear programming. Usually a linear membership function is employed in order to avoid nonlinearity. Nevertheless, there are some difficulties in selecting the solution of a problem written in a linear membership function. Therefore, in this chapter, a modified s-curve membership function is employed to overcome the deficiencies of linear membership function. Furthermore, S-curve membership function is flexible enough to describe the vagueness in the fuzzy parameters for the manufacturing problems (Vasant, 2005).

FUZZY MODEL

A linear programming problem is defined by (Elamvazuthi *et al*, 2010):

$$\begin{aligned}&\text{Maximize} \quad Cx\\&\text{Subject to} \quad Ax \le b, \quad x \ge 0.\end{aligned} \tag{1}$$

in which the components of a *1*x*n* vector *C*, an *m*x*n* matrix *A* and an *n*x1 vector *b* are all crisp parameters and *x* is an *n*-dimensional decision variable vector (Atanu *et al*,2008).

The system (1) may be redefined in a fuzzy environment with the following more elaborate structure:

$$\begin{aligned}&\text{Maximize} \quad \sum_{j=1}^{n} \tilde{c}_j x_j\\&\text{Subject to} \quad \sum_{j=1}^{n} \tilde{a}_{ij} x_j \underset{\sim}{\le} b_i, \quad i = 1, 2 \cdots m\end{aligned} \tag{2}$$

All fuzzy data $\tilde{c}_j \equiv \tilde{S}(c_j^a, c_j^b)$ and $\tilde{a}_{ij} \equiv \tilde{S}(a_{ij}^a, a_{ij}^b)$ are fuzzy variables with the following logistic membership functions (Kickert, 1978).,

$$\mu_{\tilde{c}_j} = \begin{cases} 1 & if\ c_j \le c_j^a \\ \dfrac{B}{1 + Ce^{\alpha\left(\frac{c_j - c_j^a}{c_j^b - c_j^a}\right)}} & if\ c_j^a \le c_j \le c_j^b \\ 0 & if\ c_j \ge c_j^b \end{cases} \tag{3}$$

$$\mu_{\tilde{a}_{ij}} = \begin{cases} 1 & if\ a_{ij} \le a_{ij}^a \\ \dfrac{B}{1 + Ce^{\alpha\left(\frac{a_{ij} - a_{ij}^a}{a_{ij}^b - a_{ij}^a}\right)}} & if\ a_{ij}^a \le a_{ij} \le a_{ij}^b \\ 0 & if\ a_{ij} \ge a_{ij}^b \end{cases} \tag{4}$$

where,

$$B = 1, C = 0.001, \alpha = 13.8$$

(Atanu et al, 2008).

The membership function of the resource variable b_i is given by

$$M_{bi} = \begin{cases} 1 & b_i \langle b_i^a \\ 0.999 & b_i = b_i^a \\ \dfrac{w}{1 + ue^{\left[\frac{b_i - b_i^a}{b_i^b - b_i^a}\right]}} & b_i^a \langle b_i \langle b_i^b \\ 0.001 & b_i = b_i^b \\ 0 & b_i \rangle b_i^b \end{cases} \quad (5)$$

where M_{bi} is the membership function of b_i and b_i^a, b_i^b the lower and the upper boundary of the fuzzy coefficient $\tilde{b}_i$ respectively.

$$\begin{aligned} M_{bi} &= \frac{w}{1 + ue^{\alpha\left[\frac{b_i - b_i^a}{b_i^b - b_i^a}\right]}} \\ e^{\alpha\left[\frac{b_i - b_i^a}{b_i^b - b_i^a}\right]} &= \frac{1}{u}\left[\frac{w}{M_{b_i}} - 1\right] \\ \alpha\left[\frac{b_i - b_i^a}{b_i^b - b_i^a}\right] &= Ln\frac{1}{u}\left[\frac{w}{M_{b_i}} - 1\right] \\ b_i &= b_i^a + \left[\frac{b_i^b - b_i^a}{\alpha}\right] Ln\frac{1}{u}\left[\frac{w}{M_{b_i}} - 1\right] \end{aligned} \quad (6)$$

Since b_i is a fuzzy coefficient for the resource variables, it is denoted as

$$\tilde{b}_i = b_i^a + \left[\frac{b_i^b - b_i^a}{\alpha}\right] Ln\frac{1}{u}\left[\frac{w}{M_{b_i}} - 1\right] \quad (7)$$

Figure 1 shows the membership function for resource variables.

The 'decision' in a fuzzy environment can be intersection of fuzzy objective functions. The relationship between constraints and objective function in fuzzy environment is fully symmetrical (i.e., no difference).

$$\tilde{D} = \tilde{C} \cap \tilde{G}$$

$$M_{\tilde{D}} = M_{\tilde{C}} \cap M_{\tilde{G}} \to Min\{M_{\tilde{C}} \cap M_{\tilde{G}}\}$$

In general, if we have (n) of objective function $(\tilde{G}_1, \tilde{G}_2, \ldots\ldots, \tilde{G}_n)$ and (m) $(\tilde{C}_1, \tilde{C}_2, \ldots\ldots, \tilde{C}_n)$

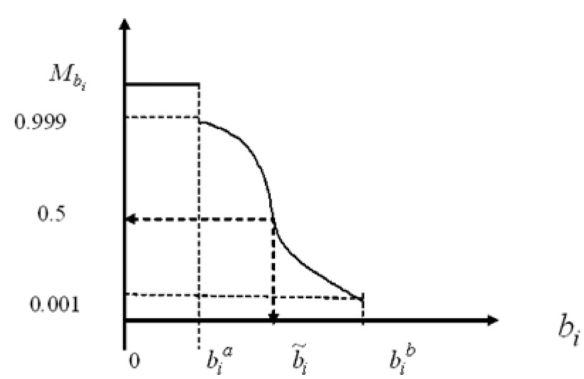
The decision

$$\begin{aligned} \tilde{D} &= \tilde{G}_1 \cap \tilde{G}_2, \ldots\ldots, \tilde{G}_n \cap \tilde{C}_1 \cap \tilde{C}_2, \ldots\ldots, \cap \tilde{C}_m \\ M_{\tilde{D}} &= \{Min\{M_{\tilde{G}_1}, M_{\tilde{G}_2}, \ldots\ldots, M_{\tilde{G}_n}\}, \\ & Min\{M_{\tilde{C}_1}, M_{\tilde{C}_2}, \ldots\ldots, M_{\tilde{G}_m}\}\} \\ M_{\tilde{D}} &= \\ & \{Min\{M_{\tilde{G}_1}, M_{\tilde{G}_2}, \ldots\ldots, M_{\tilde{G}_n}, M_{\tilde{C}_1}, M_{\tilde{C}_2}, \ldots\ldots, M_{\tilde{G}_m}\}\} \\ &= \{Min\{M_{\tilde{G}_j}, M_{\tilde{C}_i}\} \\ & i = 1, 2, \ldots\ldots, m \qquad j = 1, 2, \ldots\ldots, n \end{aligned} \quad (8)$$

$M_{\tilde{G}_j}$ = Degree of satisfaction for fuzzy objective function

$M_{\tilde{C}}$ = Degree of satisfaction for fuzzy constraints

Figure 1. Membership function for resource variables



$M_{\tilde{D}}$ = Degree of satisfaction for fuzzy decision

For example, the objective function "x should be substantially larger than 10" characterized by the membership function

$$M_{\tilde{G}}(x) = \begin{cases} 0 & x < 10 \\ (1+(x-10)^2)^{-1} & x \geq 10 \end{cases} \quad (9)$$

Constraint "x should be in the vicinity of 11, characterized by the membership function

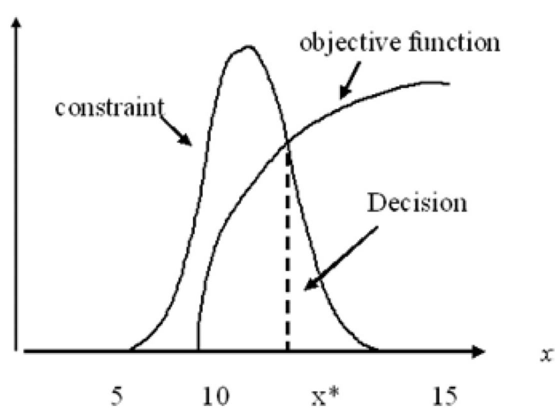
$$M_{\tilde{C}}(x) = (1+(x-1)^{-4})^{-1} \quad (10)$$

The membership function of the decision

$$M_{\tilde{D}}(x) = M_{\tilde{C}}(x) \cap M_{\tilde{G}}(x)$$
$$M_{\tilde{D}}(x) = \min\{(1+(x-10)^2)^{-1}, (1+(x-1)^{-4})^{-1}\}$$
$$M_{\tilde{D}}(x) = \begin{cases} 0 & x < 10 \\ (1+(x-10)^2)^{-1} & 10 \leq x \leq x^* \\ 1+(x-1)^{-4})^{-1} & x \leq x^* \end{cases} \quad (11)$$

Figure 2 shows the membership function of the decision.

Figure 2. Membership function of the decision



CASE STUDY

The data for this case study was derived from (Ertugrul & Tus, 2007). In this example the profit for a unit of sheet sales is around 1.05 Euro; a unit of pillow case sales is around 0.3 Euro and a unit of quilt sales is around 1.8 Euro. The projected sales are approximately 25.000 sheet units, 40.000 pillow case units and 10.000 units quilt units. The monthly working capacity and required process time for the production of sheets, pillow cases and quilts are given in Table 1 (Ertugrul & Tus, 2007).

Based on the Table 1, monthly production planning and profit for home-textile group is determined. x_1 presents the quantity of sheets that will be produced, x_2 presents the quantity of pillow cases and x_3 presents the quantity of quilts. The aspiration of the objective function is calculated by solving the following application data.

Application Data 1

If it is assumed that around 1.05 ≡ $\tilde{S}(1.02, 1.08)$, around 0.3 ≡ $\tilde{S}(0.2, 0.4)$, and around 1.8 ≡ $\tilde{S}(1.7, 2.0)$, then, the above problem can be modeled mathematically with fuzzy objective coefficients as follows Atanu *et al*, 2008):

Maximize

$$\tilde{S}(1.02, 1.08)x_1 + \tilde{S}(0.2, 0.4)x_2 + \tilde{S}(1.7, 2.0)x_3$$

subject to

$$\begin{aligned} &0.033x_1 + 0.01x_2 + 0.0033x_3 \leq 208; \\ &0.056x_1 + 0.25x_2 + 0.1x_3 \leq 4368; \\ &0.0067x_1 + 0.04x_2 + 0.17x_3 \leq 520; \\ &0.1x_1 + 0.1x_2 + 0.01x_3 \leq 780; \\ &x_1 \geq 25000; \\ &x_2 \geq 40000; \\ &x_3 \geq 10000; \end{aligned} \quad (12)$$

Table 1. Required process time for sheet, pillow case, and of a quilt (Ertugrul & Tus, 2007)

Departments	Required unit time(hour)			Working hours per month
	Sheet	Pillow case	Quilt	
Cutting	0.0033	0.001	0.0033	208
Sewing	0.056	0.025	0.1	4368
Pleating	0.0067	0.004	0.017	520
Packaging	0.01	0.01	0.01	780

Application Data 2

Maximize

$1.05x_1 + 0.3x_2 + 1.8x_3$ (profit)

Subject to

$$
\begin{aligned}
&0.0033x_1 + 0.001x_2 + 0.0033x_3 \leq (170, 208)\\

\end{aligned} \tag{13}
$$

Simulation Algorithm

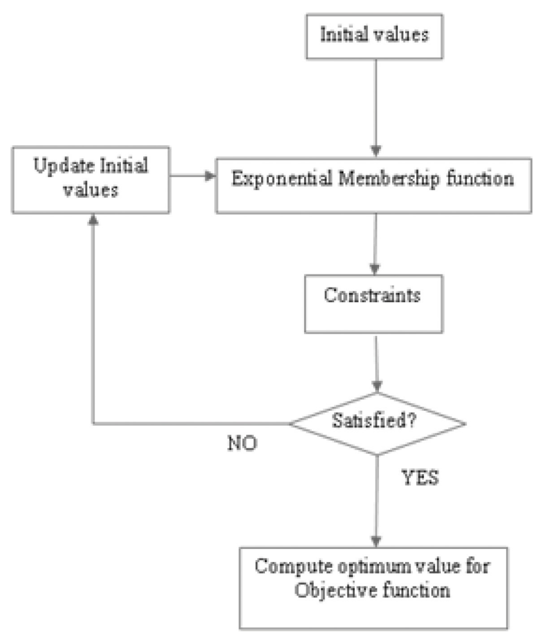
The fuzzy model in Equations (12) and (13) has been solved by using modified logistic membership function methodology and recursive iteration techniques. This was achieved through simulation based on the algorithm shown in Figure 3 (Elamvazuthi *et al*, 2010).

The algorithm for textile firm production planning is as shown below:

Step 1: set the initial values
Step 2: fuzzify using the exponential membership function
Step 3: incorporate the constraints
Step 4: if constraints satisfied, then, go to step 5
Step 5: compute the optimum value for the objective function output results
Step 6: else, re-establish initial values by using a recursive function with M = 748 (iteration, (Elamvazuthi *et al*, 2009)
Step 7: end

The numerical example is solved by using a recursive method for various iterations. This was carried out using the C++ programming language on a personal computer with a dual core processor running at 2 GHz (Intel Corporations, 2011 and Stroustrup B., 2011).

Figure 3. Algorithm



RESULTS AND DISCUSSION

The following section provides the computational and simulation results of the fuzzy model for application data 1 and 2 (Elamvazuthi *et al*, 2009 and Elamvazuthi *et al*, 2010).

Results of Application Data 1

Figure 4 shows the 3D outcome of the iteration with *M*=784 for various alpha values with respect to the objective function *G*. The values of α_1 and α_2 vary from 0 t o1. The optimum values for the objective function as per Figure 1 are 86,807.7 (maximum) and 86,755.4 (minimum).

Figure 5 shows the 3D outcome for *M* = 749 iterations and various alpha values with respect to *G*. The optimum values for the objective function as per this figure are 86,691.8 (maximum) and 86,639.5 (minimum).

Figure 6 shows the 3D outcome for *M* = 750 iterations and various alpha values with respect

Figure 4. 3D plot for iterations M=748

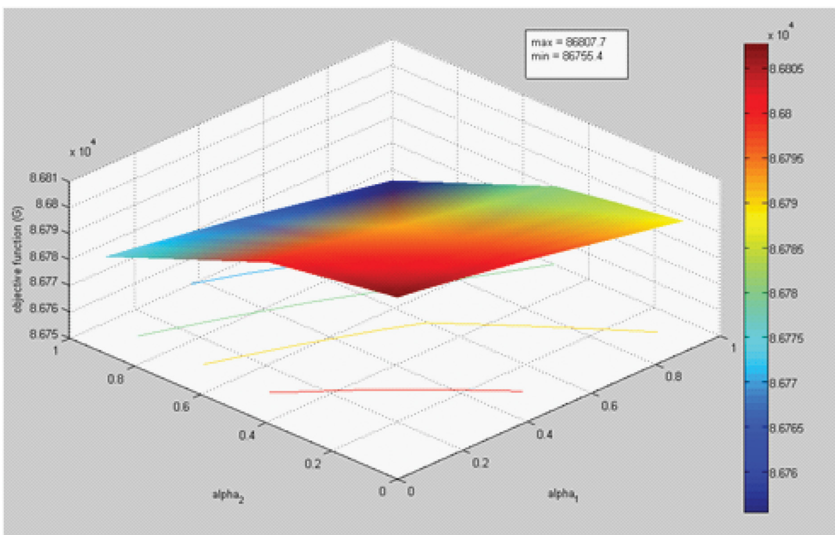


Figure 5. 3D plot for iterations M = 749

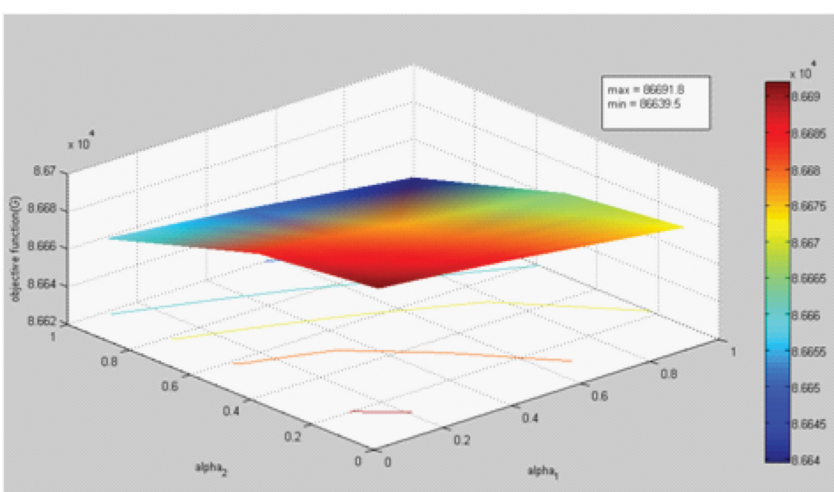

to *G*. The optimum values for the objective function as per this figure are 86,576.2 (maximum) and 86,524.0 (minimum).

Figure 7 shows the 3D outcome for $M = 751$ iterations and various alpha values with respect to *G*. The optimum value for the objective function as per this figure are 86,440.7 (maximum) and 86,408.0 (minimum).

Figure 8 shows the linear approximation for *G* with respect to iterations 748 to 751.

It can be seen that as the iterations are increased, the values of the objective function decrease. The percentage error is minimum at iteration, $M = 748$; however, after that it increases until it peaks at $M = 750$; thereafter, the percentage error decreases again to a level lower than that at $M = 748$. This shows that the maximum number of iterations that can be used for similar cases in the future can be limited to $M = 750$.

Figure 6. 3D plot for iterations M=750

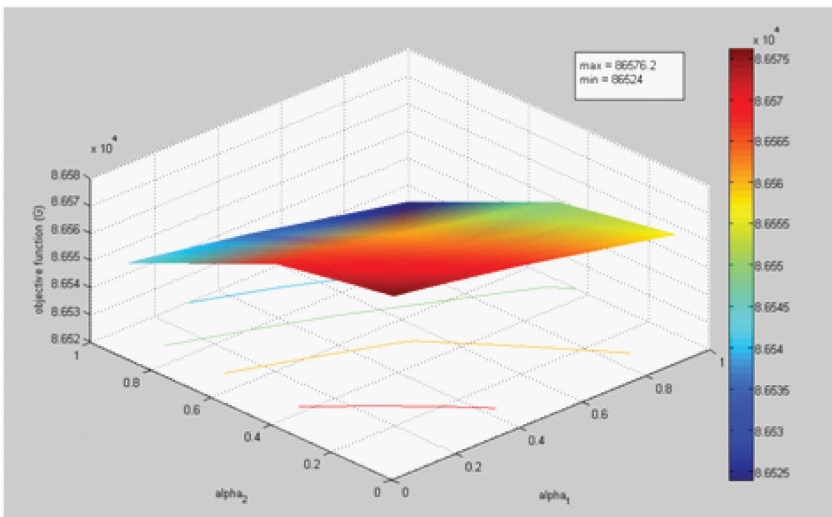

Figure 7. 3D plot for iterations M=751

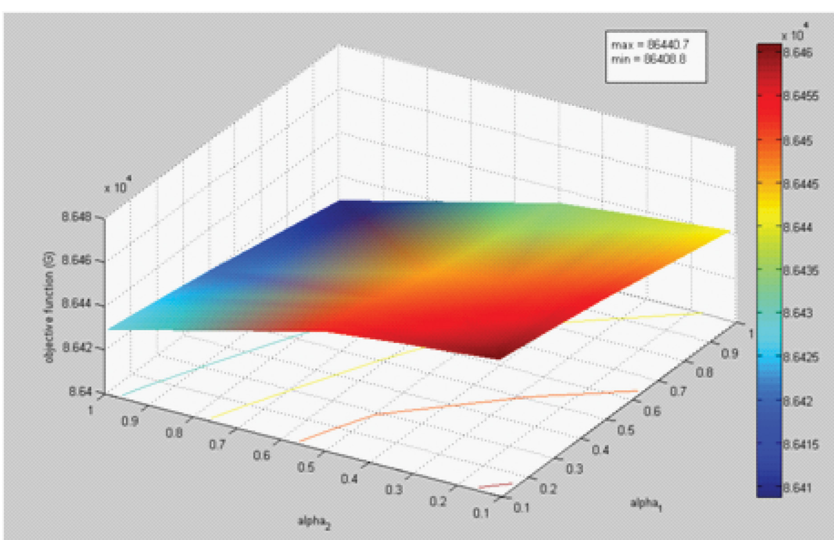

Figure 8. Objective function (G) versus iterations

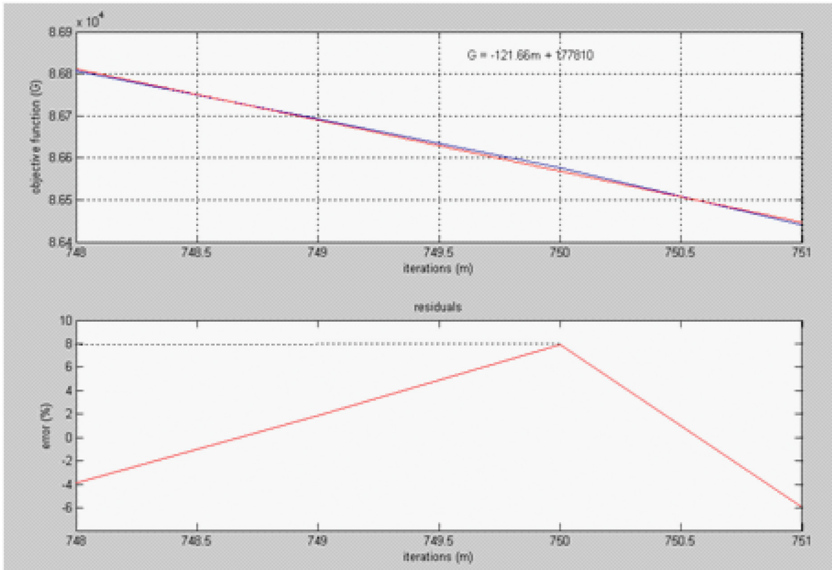

Figure 9, Figure 10, and Figure 11 show the linear approximation for the decision variables x_1, x_2 and x_3 with respect to the number of iterations.

It can be observed that x_1, x_2 and x_3 decrease as the iterations are increased from $M = 748$ to $M = 751$.

Table 2 presents results that involve α_1, α_2, and α_3 with $M = 748$ for G, x_1, x_2 and x_3.

Table 3 summarizes the result for $M = 748$ to 751 for x_1, x_2 and x_3 with maximum and minimum values of G. The overall maximum value for G is 86807.7 at $M = 748$ and the overall minimum value is 86408.0 at $M = 751$.

Table 4 compares the best objective function and decision variables x_1, x_2 and x_3 of the proposed method with previous work by other researchers.

Figure 9. Decision variable, X1 vs. M iterations

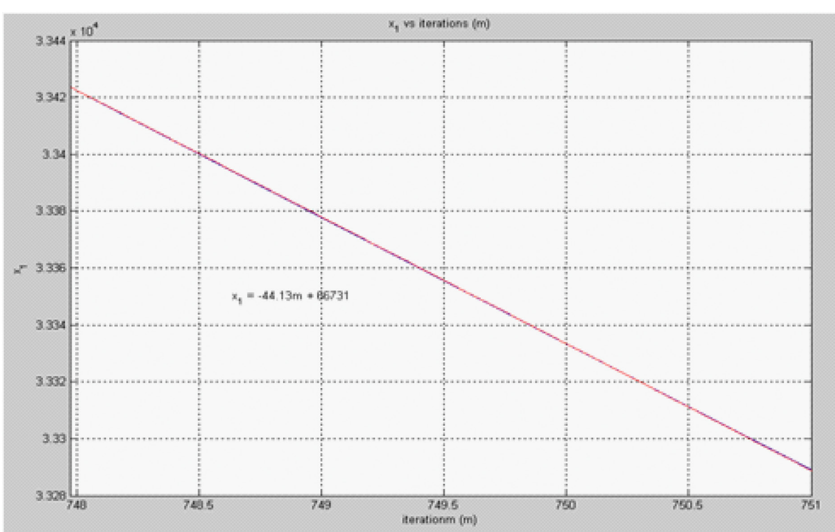

Figure 10. Decision variable, X2 vs. M iterations

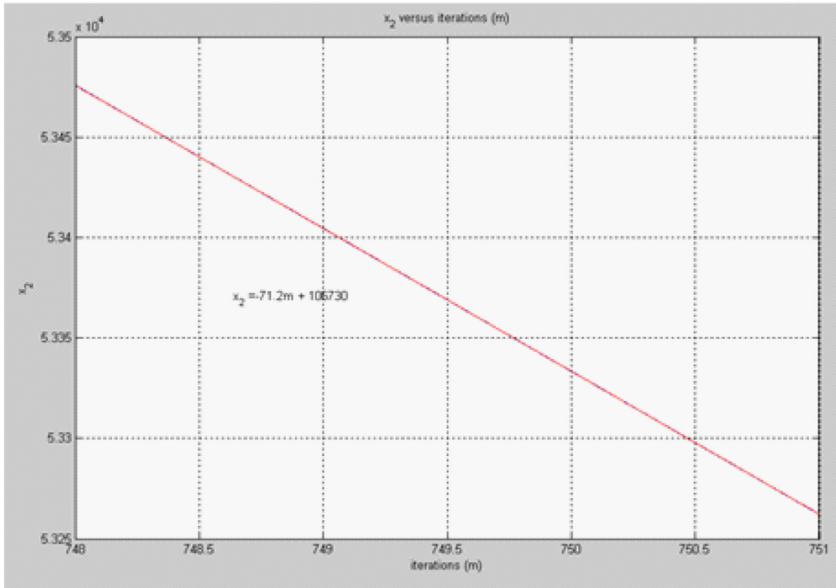

Figure 11. Decision variable, X2 vs. M iterations

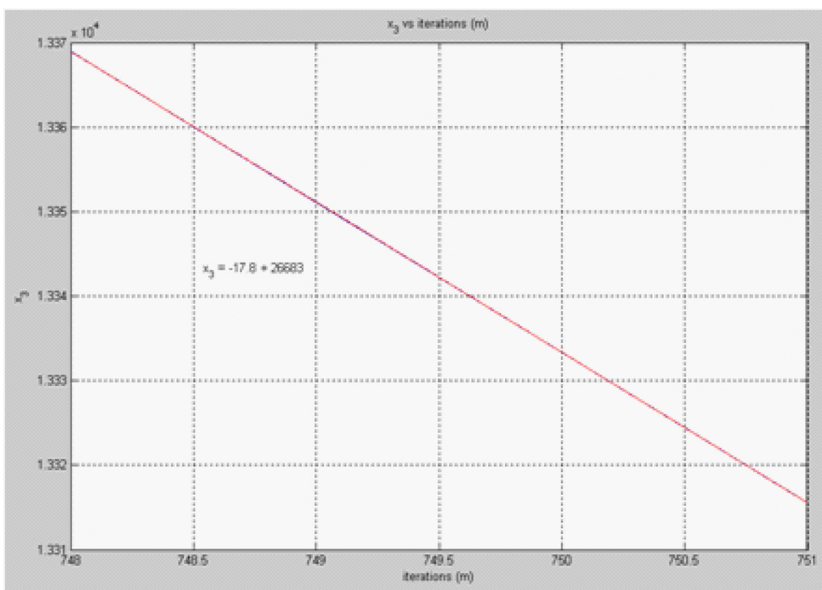

From Table 4, the optimum value for the objective function using the proposed method outweighs the results obtained in (Klir & Yuan and 1995 and Ross, 1995). *Fuzzy Logic with Engineering Applications*, New York: McGraw- Hill.

It can be deduced that the recursive iteration method proposed here is an efficient and effective way to solve our example fuzzy problem of production planning in the textile industry.

Results of Application Data 2

Table 5 shows the results obtained for the objective function versus parameter d (Vagueness factor); Table 6 shows results obtained for the objective function versus θ (level of satisfaction), and Table 7 shows results obtained for the parameter d versus α(degree of possibility for three decision variables). The major contribution of this chapter is on the comparative results obtained on the objective function for various parameters d in (Ertugrul & Tus, 2007).

Figure 12 shows the relationship of α versus *d* parameter. One can precisely observe that the α value decreases as the value of d parameter increases.

Figure 13 depicts the 3D outcome the objective function, G versus θ versus *d*.

It can be seen that the objective function increases as the d parameter and θ are increased.

Figure 14 depicts the outcome the objective function, G_{max} versus θ.

It can be seen that the objective function increases as θ is increased.

Figures 15 to 23 show the outcome the objective function, versus d for various θ, ranging from 0.1 to 0.9. It can be seen that the objective function increases as θ is increased until it reaches steady state for the objective function.

For θ = 0.1, the G_{max} = 83715.2 and G_{min} = 83678.6. M is fixed at 748 iteration.
For θ =0.2, the G_{max} = 85530.9 and G_{min} = 85493.6. M is fixed at 748 iteration.
For θ =0.3, the G_{max} = 87325.3 and G_{min} = 87287.1. M is fixed at 748 iteration.
For θ =0.4, the G_{max} = 89196.5 and G_{min} = 89157.6. M is fixed at 748 iteration.
For θ =0.5, the G_{max} = 91039 and G_{min} = 90999.2. M is fixed at 748 iteration.

Table 3. Summary of iterations, decision variables, and objective function

M	x_1	x_2	x_3	G (max)	G(min)

Tus, 2007). The authors strongly believe that the proposed iterative method on decision variables can be possibly applied to other large scale industrial production problems in real life applications. The major advantages of the proposed method is on the computational time in finding the objective function as well as the strength of the method on obtaining a very high feasible solution for the decision variables. The authors have put more emphasis on the well developed algorithms on the particular interest for the increasing the values for the decision variables.

FUTURE RESEARCH DIRECTIONS

In the future, hybrid optimization techniques can be applied to this industrial production planning problem in the textiles firm. Genetic algorithms, simulated annealing, tabu search and other heuristics and meta-heuristics techniques will be a very significant approaches in order to provide a satisfactory optimal solutions(Zhu & Zou, 2005, Ramirez *et al* 2009, Dawei & Shiyuan, 2007, Sharma & Lees, 2004, Sun *et al*, 2007 and Ismail, 2008).

CONCLUSION

In this chapter, the fuzzy model with fuzzy resource variables is successfully solved by fuzzy linear programming method with modified S-curve membership function. The recursive iterative technique has been intensively applied on the optimal solution for the objective profit function and feasible solutions for the decision variables. It can be seen that objective function using the proposed method produces a maximum value which better than previous research results. Furthermore the computational time (CPU) for the current method, in finding the optimal solution, is less than one second. Therefore the current method adopted in this chapter is very flexible, robust and importantly it is highly productive. We can observe that fuzzy linear programming provides more information to the decision maker and implementer to solve practical decision making problems in the application area of textiles industry. This modern artificial intelligence approach is a very useful tool in the decision making process when the environment is under turbulence and unpredictable uncertain.

KEY TERMS AND DEFINITIONS

Decision Support System: A method to model data and make quality decisions based on it to support business or organizational decision-making activities

Fuzzy Linear Programming: An application of fuzzy set theory in linear decision making problems to determine an optimal solution by considering a number of constraints

Fuzzy Set Theory: Set membership that handles the concept of partial truth where the truth values fall between completely true and completely false

Logistic Membership Function: An appropriate function to represent the degree of truth

Manufacturing Environment: An industrial operational facility to fabricate products

Objective Function: A function that can be made as large or as small as possible

Optimal Value: Best state that a value could achieve

Quality Improvement: Systematic approach to improve product / service level compared with accepted standards

Resource Variable: A resource is used to represent dynamic data that holds as a reference to an external resource

Chapter 17
Control Model for Intelligent and Demand-Driven Supply Chains[1]

ABSTRACT

Orchestrating supply chains is challenging. This chapter describes how to control a supply chain to make it truly demand-driven – based on the assumption that all relevant information is made available to all partners in real time. The chapter explores the elements of a framework for intelligent and demand-driven supply chain control, with regards to the overall concept and associated principles, and demonstrates these in a case example. Challenges to the realization of the proposed control model include trust and power, supply chain dynamicity and uncertainty, and required investments in competence, standardization, and information and communication technology. Some of these can be met through initial small-scale implementations of the proposed model, to demonstrate effects, and by exploiting facilities for information sharing and collaboration, like supply chain dashboards and control studios. Future research within operations management, technology and information and communications technology (ICT) will support broader realization of the proposed control model.

INTRODUCTION

Integrating and coordinating supply chain and network operations are considered prerequisites for achieving high efficiency and competitiveness. Focusing on the performance and competitiveness of the supply chain, rather than the single company is a trend in several industries. Increased outsourcing and globalization greatly expands the complexity of supply chain operations and planning and control processes. A supply chain often has a decentralized geographical structure with complex logistics, where the various organizational units have a high degree of autonomy.

DOI: 10.4018/978-1-4666-1945-6.ch017

Thus, supply chain operations require a well-defined orchestration of a broad set of activities, resources and companies, with the common goal of fulfilling the demand of the end customer.

Designing supply chains is challenging due to their heterogeneous system characteristics, diversified product and material flow structure, trade-off situations, and conflicting interests and goals of the participants. Products vary in value, volumes and shelf life. Today, offering high customer service means either maintaining a high stock level or having frequent deliveries. Conflicts of interest often arise when a manufacturer aims to utilize economies of scale by producing large volumes and buffering products in stock, only to discover that there is end customer demand only for a minor part of the volume. Meanwhile, the wholesaler strives to keep stock levels low and buy only according to end customer demand.

A number of challenges related to supply chain and network operations can be identified. First, operations of supply chains require development of a unified set of control principles which simultaneously harmonize the interests of the involved companies and the entire network. These control principles should also adapt operations to end customer demand, and provide for the right balance of cost, time and service performance measures for each product and the supply chain as a whole. Second, a number of technical challenges are related to the information and communication technology (ICT) solutions that are required to provide supply chain members with access to real-time information on network operations. This includes data capturing technology, communication platforms, visualization technology, and decision support tools which require solutions to standardization issues and considerable investments. Third, the aspects of trust and companies' lack of willingness to share market and demand information is an obstacle to achieving demand-driven collaboration. Many companies perceive demand information to be a key element in protecting their own power position and staying competitive.

The main focus in the work described in this chapter is the interplay of the first two challenges; *how to control a supply chain to make it truly demand-driven,* based on the assumption that all relevant information is made available to all partners in real time. The objective is therefore to explore the elements of a framework for intelligent and demand-driven supply chain control with regards to the overall concept and associated principles, and to demonstrate these in the case of a supply chain for processed salads.

In this chapter, a concept and a number of associated principles are illustrated, in the form of a control model based on the use of real-time information. The chapter contributes to theory and knowledge through its description of an integrated framework for supply chain control and associated principles and the demonstration of these in a practical case. The aim of the framework and principles is to assist managers of supply chain organizations by highlighting and exploring possibilities and some key issues related to control of supply chain operations. A further contribution to practice is derived through the exemplification of how the framework and proposed control model can be applied in an actual supply chain.

The work is based on the *control model methodology* (Alfnes, 2005; Alfnes & Strandhagen, 2000). Viewing network and supply chain operations from a control model perspective is a systematic approach that enables integration and network partnerships for increased competitiveness. This methodology has been applied in numerous industrial cases over the past decades, with the experiences and results serving as a practical platform for a deductive research approach. This action-based, reengineering type of methodology, focusing on visual presentation and communication between involved supply chain members, also enables them to meet the challenges related to lack of trust and understanding between supply chain partners.

BACKGROUND

The supply chain approach is assumed to be a winning strategy for improving competitiveness and conducting business development. A vast amount of literature shows how a holistic and integrated supply chain strategy can lead to competitive advantages and other synergy effects, such as increased trust and less complex contract mechanisms between business partners, increased service levels, reduced costs and increased economies of scale (see e.g. Bowersox, Closs, & Stank, 1999; Christopher, 1998; Min & Mentzer, 2004). However, the success of a supply chain strategy depends on a number of factors, such as how well the supply chain as a whole is operated and controlled, to what extent operations are in line with demand and customer requirements (Simchi-Levi, Kaminsky, & Simchi-Levi, 2008; Slack, Chambers, & Johnston, 2001; Vollmann, Berry, Whybark, & Jacobs, 2005), how responsive the chain is to changes and uncertainty (Reichart & Holweg, 2006), and whether the companies involved are able to collaborate as if they where a unified entity (Tyndall, Gopal, Partsch, & Kamauff, 1998). In addition, ICT provides unprecedented potential as enabler of new ways of operating the supply chain and for companies to interact and share information (Clark & Lee, 2000; Ellinger, Taylor, & Daugherty, 1999).

Supply chain operations extend the control span and increase the complexity of the planning and control task. The increasing need for coordination, integration and collaboration among organizations has led to a wide range of business initiatives and projects that seek to investigate the potential of supply chain strategies, solutions and developments this requires, and how this will affect existing business models and relationships. Some relevant examples from past and ongoing research and development (R&D) projects are described below.

The pharmaceutical industry is characterized by a wide variety of products, both prescription and non-prescription drugs, with limited shelf life. These products are offered through a supply chain that experiences continuing pressure for reducing costs, lead times and stock levels, while simultaneously increasing turnover rates and product availability. A significant challenge for pharmaceutical supply chains is how to achieve improvements and shorten the time from production to market. The R&D project Automed (2004-2007, see www.sintef.no/automed) focused on the supply chain from a pharmaceutical production plant, through a pharmaceutical supplier and a wholesale unit, to a chain of Norwegian pharmacies. Analysis found that supply chain performance could be significantly improved, for instance, that cost levels could be reduced by 25-30%, lead time could be halved and stock levels reduced by 30%. In order to realize this potential, the involved companies had to change their entire supply chain approach towards tighter integration and application of demand-driven, pull-based control principles based on sharing of point-of-sales (POS) data. Part of the potential was realized through the implementation of an automated replenishment solution, where the responsibility for pharmacy replenishment was shifted backwards in the chain to the wholesaler.

A study of the grocery sector shows similar challenges. In a project called Smart Vareflyt, or Smart Flow of Goods (2007-2009, see www.sintef.no/smartvareflyt), nine supply chain members in the Norwegian grocery industry (fresh food producers, packaging producers, grocery wholesalers and retailers, and logistics service providers) cooperated, in order to investigate how real-time information would affect the flow of goods and information and what effects sharing of demand information in the supply chain could have on performance. Reducing supply chain lead time and increasing shelf life for perishable products in stores is a high priority issue in the grocery industry. A main objective of the project was to test and demonstrate the potential of radio frequency identification (RFID) of products and packaging and application of electronic product code information services (EPCIS) for information sharing. Analysis showed that the various supply chains could improve their performance if the traditional make-to-stock (MTS) approach were replaced by holistic demand-driven control principles utilizing real-time demand information, such as POS and RFID captured data. The potential effects of reduced lead times and stock levels were of particular importance for perishable products. The project also demonstrated how access to both real-time and historic demand information could be utilized to develop automated decision support and visualization systems supporting supply chain operations.

For global manufacturing operations, important challenges include how to coordinate geographically distributed and diversified networks of plants and facilities and how to control and execute operations according to demand and customer segments. In the Origo project (2006-2008, see www.sintef.no/origo), a Global Control Centre environment was developed to deal with coordination of planning and control tasks in a global network of fishhook production facilities (see Dreyer, Alfnes, Strandhagen, & Thomassen, 2009). A similar project was Optilog (2005-2010, see www.sintef.no/optilog) where the focus was on developing new collaboration models and associated supply contracts that capture the need for improved operational coordination and information sharing along a construction supply chain, from pipe manufacturer, through wholesaler to contractors.

A number of common elements can be seen in the above mentioned examples:

- A rethinking of the traditional manufacturing planning and control (MPC) paradigm, such as MTS, push and batch principles, towards demand-driven control principles such as make-to-order (MTO), pull and continuous, automated replenishment
- Fulfillment of demand based on replenishment and collaboration concepts, instead of traditional ordering and purchasing practices
- Potential for performance improvement and achievement of reduced costs, lead times, stock levels, and throughput time, through sharing of demand information and utilization of updated and real-time information
- Redesign and adjustment of supply chain operations to demand and customers' needs, including coordination and integration of supply chain processes into a unified control model
- Utilization of updated and real-time information in automated decision support systems and control models, enabled by modern ICT solutions

The remainder of this section will describe essential elements of these topics, as well as recent developments and the authors' views on how these developments are expected to shape the future business environment.

The MPC task in a supply chain involves determining what, who, when and how to act, in order to meet customer demand with the exact supply in a coordinated chain (Jonsson & Lindau, 2002; Vollmann, et al., 2005). Each node in the chain cannot be managed in isolation (Shi & Gregory, 1998), and the MPC system must support cross-company processes in a manner that avoids increasing amplifications, stock levels, and lead and response times (Dreyer, et al., 2009). Today, most of the planning and control systems used in supply chain operations are based on the traditions of MTS and MRP/MRP II, where forecasts and expectations of future demand are the main inputs (Zijm, 2000). In addition, economies of scale arguments are frequently used when dimensioning and controlling processes like production, warehousing, distribution and transport. The main planning and control logic of ERP (Enterprise

Resource Planning) systems is still based on aggregation, optimal batch sizes, order quantities, transport frequencies, and sequencing (Alfnes & Strandhagen, 2000). The consequences are that a number of supply chain operations are decoupled from actual end customer demand, and inventories are used as a buffer against uncertainty and fluctuating demand.

The next generation supply chain MPC models are derived from the principle of sharing demand information among all members of the supply chain, so that production, warehousing, distribution and transport can be operated based on demand, rather than expectations and forecasts. Moving the information decoupling point backwards in the supply chain is an essential element in this. The more members of a supply chain that have an undistorted and near real-time view of consumer buying behaviour, the more responsive the supply chain is as a whole (Mason-Jones & Towill, 1999).

In order to develop demand-driven MPC models, several collaborative models for orchestrating supply chain and network activities have been developed. The aim of models such as collaborative planning, forecasting and replenishment (CPFR), vendor managed inventory (VMI) and automated replenishment programs (ARP) is to achieve seamless inter-organizational interfaces by specifying control principles and operations models for the flow of materials and information (e.g. Daugherty, Myers, & Autry, 1999; Mattsson, 2002; Sabath, Autry, & Daugherty, 2001). The main principle is to tie and adjust network operations to customer demand and MTO strategies, instead of the traditional forecast and MTS approaches.

Performance monitoring is essential to ensuring efficient optimisation of operational processes, and, over the last few years, the focus has shifted to incorporate a supply chain perspective (e.g. Chan & Qi, 2003; Holmberg, 2000; Lapide, 2000; Van Hoek, 1998). Supply chain performance measurement requires continuous follow-up, based on a consistent and comparable holistic structure or hierarchy of indicators. These are used to measure the performance of the supply chain as a whole and of the individual members, based on agreed upon strategies, performance targets and priorities. Both reactive or "lagging" indicators showing how the supply chain has performed, and proactive or "leading" indicators showing the efficiency in operational supply chain processes, are required (Bititci, Turner, & Begemann, 2000; Holmberg, 2000; Neely, et al., 2000).

In any supply chain or network, there will be a mixture of principles which must be aligned with the manufacturing environment and the specific control situation of the supply chain. Automation can be built into the control model through the use of ICT tools and a conversion of control principles into mathematical algorithms, expressions and logic (Strandhagen, Alfnes, & Dreyer, 2006), making it possible to replace much of the current manual decision-making with status monitoring, surveillance, and exception handling.

Increasing access to real-time demand and event information in the supply chain is expected to lead to a shift in planning and control concepts towards purer demand- and pull-driven supply chains (Kärkkäinen & Holmström, 2002). Technology advances within areas such as RFID, sensor technology and EPCIS will enable access to more real-time information than the existing technology solutions. RFID tags contain information that can be read from a distance, considerably increasing the number of points where data can be obtained throughout the supply chain, compared with today's barcode system. Combining RFID technology with sensor technology further enhances the intelligence of such data capturing technologies, and will enable the development of intelligent and automated planning and control concepts. Advances in ICT have also enabled the development of control center concepts, where dashboards, real-time monitoring systems and visualization applications support information transparency and control on all process levels

(Boyson, Harrington, & Corsi, 2004; Dreyer, et al., 2009).

A control model can be used as a tool for developing a common understanding and organizing operations (Alfnes, Strandhagen, & Dreyer, 2006). The model is a formalized way of describing the underlying logic and the defined control principles of the MPC, which can be used as a foundation for reengineering and improvement processes. The model consists of six "views" on enterprise operations that should be mapped and modeled: *resources* (machines, equipment, facilities, etc.) *materials*, (products, components and materials), *information* (information elements accessed, stored, processed, and transferred), *processes* (administrative, physical and support processes), *organization* (organizational entities, assignment of responsibilities and authority, etc.), and *control.* Control is the key perspective of the model, describing how operations are organized and controlled in manufacturing and distribution, through the following building blocks (Strandhagen, et al., 2006):

- Control principles and methods; defining main principles for how operations are controlled in the chain and for each operations area (e.g. push, pull and ordering)
- Customer order decoupling points (CODP); dividing the supply chain into parts based on forecasts and parts based on customer orders/demand
- Main operation processes and buffers/stocks
- Operations areas; specifying operations that constitute separate areas of responsibility
- Material flow; specifying the main routes through the operations processes
- Information flow; specifying the flow of information related to the supply chain

Summing up the developments and key issues described above, we see that control models provide a foundation for unified and shared control that enables demand-driven and intelligent control concepts. Such control models should enable flexible networks to respond to customer demand by utilizing their own and suppliers' capacity and resources. However, to avoid conflicting interests, the unified control model should contain a number of carefully designed and collaboratively developed control principles. In addition, access to and sharing of real-time information in the network and the utilization of ICT for information processing, visualization and decision support are key elements in the realization of intelligent and demand-driven supply chain concepts.

TOWARDS A FRAMEWORK FOR INTELLIGENT AND DEMAND-DRIVEN SUPPLY CHAIN CONTROL

The complexity and variety of global supply chains, as described in the previous section, points to the need for capturing a more holistic picture of supply chain planning and control that will support future developments in industrial business cases. In response to this need, a conceptual framework and associated methodology have been developed, based on the above elements and experiences from numerous cases. Capturing control as its key element, the framework is called a c*ontrol model for intelligent and demand-driven supply chains*, consisting of the following parts:

- *A concept;* providing an overview and general description of each of the key elements
- *A set of principles;* describing the shifts required in moving towards demand-driven supply chains based on real-time information
- *Case illustrations;* describing of a set of business cases illustrating application of the concept and associated principles within a number of different industrial sectors,

types of supply chains, product segments and/or particular processes

- *Generic control model;* a generic model template that allows for specific model development for individual business cases
- *Guidelines;* a set of additional and practical guidelines (supporting the general guidelines of the control model methodology) that specifically address issues related to real-time based demand-driven supply chain

At the current state of this research, the concept and the principles have been developed, and the remainder of this chapter will focus on describing their essential elements. A first version of the generic control model has been used as a template in a number of cases and projects where the framework has been applied, and one of these cases is used in this chapter to illustrate the principles and model. The generic model and guidelines are the focus of our ongoing research.

A Concept for Intelligent and Demand-Driven Supply Chains

The concept is the starting point of the control model for intelligent and demand-driven supply chains. Figure 1 shows the individual elements that need to be addressed and interconnected, in order to realize the concept. Each of the elements is described in more detail below.

Control

The control element consists of a description of the processes and principles applied to direct the flow of goods and information in the supply chain. For each process in the supply chain (supply of material, production, assembly, wholesale, retail, etc.) the control principles (including placement of CODP) specify issues such as when, how, and where to act, upon which criteria and in what quantities.

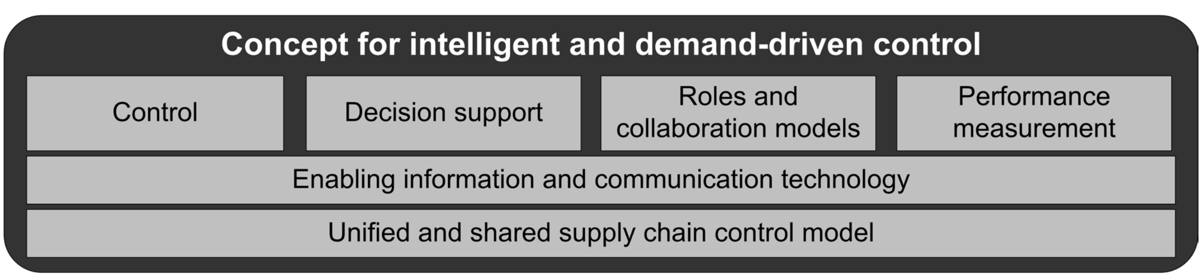
Decision Support

This element is the description of how decision support is applied in supply chain control. It describes all application areas of decision support, with particular focus on applications related to operative decision-making. Examples include the use of optimization methods or advanced simulation tools in evaluation of lot-sizes or order quantities.

Roles and Collaboration Models

Roles and collaboration models outline how supply chain processes are coordinated and who is responsible for what. All processes and information flows that cross organizational boarders, as well as business and organizational mechanisms such as contracts and price instruments, are also described.

Figure 1.



Performance Measurement

Performance indicators show how good and effective supply chain operations are, indicating when and where changes and improvement actions should be made. This description contains the three main application areas of monitoring, cause-effect analysis and management reporting, and it describes the processes of data collection, analysis and presentation, as well as the systems assigned to support such processes.

Enabling ICT

All the other elements of the control model emphasize the need for ICT tools and an architecture which can support transactions, information processing and decision-making in real time. This element of the concept identifies and describes the key technologies and systems applied to support the supply chain control tasks.

Unified and Shared Supply Chain Control Model

All the elements of the control concept are collected into a unified control model. The control model can be seen both as a way to structure and formalize operations activities, and as a fundament for reengineering and improvement processes.

Principles for Intelligent, Demand-Driven Control

Essential to the framework is a set of principles that will support the shift towards demand-driven supply chain control based on real-time information, where each principle is a general rule for how to realize the concept. Table 1 briefly describes the general topic of each principle.

Each of the eight principles should be applied and described in a unified control model. This control model must be established between all partners in the supply chain and communicated to all those involved in supply chain operations. The control model should also be the logical

Table 1. Principles for intelligent, demand-driven control

	Topic	Main principle
1	Capturing and utilizing real-time information	Real-time information on POS data, stock levels, marketing plans, manufacturing and transport status, etc. should be captured and utilized for decision-making.
2	Information sharing	Information should be shared continuously with supply chain partners through databases, information hubs or portals that store, integrate, process and present relevant information from the ICT systems of each actor.
3	Reconsidering the CODP	CODP placement should be differentiated and moved up or down stream in the supply chain according to product and market characteristics.
4	Pull control	Decisions on manufacturing, shipment, etc. should be proactive and based on a “buy one – produce and deliver one” strategy.
5	Supplier-driven replenishment	Replenishment responsibility should be moved upstream in the supply chain (supporting VMI concepts).
6	Individual product and process control	Control of each product or product segment should be determined individually according to product, demand and market characteristics.
7	Automated and integrated decision support	ICT should be used for automated decision-making and provide decision support tools. Human decision-making should be shifted to surveillance and status monitoring.
8	Measuring supply chain performance in real time	A new set of leading and lagging performance measures should be developed and integrated with control parameters. These measures should be implemented in a visual dashboard showing supply chain performance in real time.

basis for the development of supply chain control dashboards or studios. The following sections describe each principle in more detail.

The Principle of Capturing and Utilizing Real-Time Information in the Supply Chain: Information on supply chain operations is often historic data on POS data/demand, stock levels, marketing plans, manufacturing and transport status, etc. and typically based on batch, periodic, or entry point approaches which accumulate demand. Consequently, decisions are made based on the past, not on the current situation. However, technological developments have now enabled access to up-to-date and real-time information, which will lead to a major shift towards supply chain control based on continuous insight into the current situation, thus allowing real-time execution and handling of events. Information on actual events is available, and instead of waiting until the next period or an order-point is passed, the information can immediately be made available to supply chain partners. This is particularly relevant and critical for immediate suppliers of the items in question. Access to real-time information means decisions can be made based on facts and realities rather than on assumptions and expectations, which contributes to a more precise statement of demand, stocking of the right product mix, etc.

The Principle of Information Sharing: The ability to capture real-time information, described in principle (1), provides for improved information quality. However, if information (real-time or otherwise) is not continuously distributed and shared among supply chain partners, the value of information for improved decision-making is highly limited. Since the benefits, in terms of improved supply chain responsiveness, increase as the information order decoupling point is moved up the chain, information on consumer behaviour should be made available as far back in the chain as possible. To increase usefulness of market information, filtering and aggregation routines should be established for each node. The information volume will be significant, and establishment of a unified ICT architecture and development of tools for processing and presenting relevant information elements is necessary. One solution would be the establishment of databases, information hubs and portals to store, integrate, process and present information from the entire supply chain, integrating information from the ICT systems of each supply chain member.

The Principle of Reconsidering the CODP: The access to real-time information will allow reconsideration of the placement of the CODP in general and individually, by product or product group. The move could be upstream, as well as downstream, in the supply chain. Where to place the CODP depends on a number of variables, including product and market characteristics, and a main rule for demand-driven supply chains whether real-time information is available is to move the CODP upstream. An argument for this is that real-time information makes the administrative lead-time near zero, increases responsiveness, and thereby eliminates the need to make or move goods based on forecasts. For products with high value and customer-specific elements, this will be a main principle. For standard products and commodities with long transportation time, where the decision on final destination can be made while the goods are being moved, real-time information can allow moving the CODP as far forward in the supply chain as to the unload process.

The Principle of Pull Control: The overall planning and control principle should be make-to-order according to a "*buy one – produce and deliver one"* strategy. A pull-based solution is therefore essential in demand-driven supply chains. However, with access to real-time information control, decision-making can be shifted from reactive to proactive. A supplier can act and send shipments based on real-time insight into customers' stock levels and thus not have to wait for an order before initiating the appropriate activities. Additionally, since information is made available continuously, the existing control principles based on economy of scale reasoning, such as order point, periodic batch review, economic order quantity (EOQ), etc., will be challenged. Real-time planning and control models differ from more traditional models by:

- Dynamic and continuous determination of order quantities and shipment frequencies
- Individual and automatic product decision-making
- Decision-making based on:
    - A holistic perspective, taking into consideration a number of factors such as sales, stock levels, manufacturing, transport routes, substitution products, packing quantities, etc.
    - Simultaneous handling of information on history, current status and forecasts
    - Aggregated information (from items to product-groups, components and materials)

The most radical shift is that decisions on manufacturing and shipping order quantities and frequencies are dynamic, continuous and event-based. As systems are designed to be triggered by events and automatically recalculate, fixed order quantities and batch processing of information is abandoned.

The Principle of Supplier-Driven Replenishment: In a more traditional control situation, the customer is responsible for communicating a demand signal to the supplier in the form of an order. With access to real-time information, the responsibility for ordering is shifted to the supplier, who replenishes the customer with the exact product quantities at the right time, for instance through VMI solutions. However, such solutions require that the supplier has continuous access to correct information on the customer's demand, stock levels, marketing plans, etc. The need for a more holistic supply chain perspective requires that replenishment decisions (automated or manual) are made as far upstream as possible. The principle is that the upstream supply chain members have the advantage of being able to combine information for all subsequent nodes and can utilize this to adjust capacity and achieve economies of scale benefits.

The Principle of Individual Product and Process Control: Ideally, each product or product group should be dealt with individually, in order to take into account specific product, demand and market characteristics when handling the product through the supply chain. A real-time and demand-driven supply chain should therefore have a clear process orientation, where control is organized around the product and how it flows through the main operations processes (manufacturing, warehousing, distribution, replenishment, etc.). This will typically be in line with concepts such as multi-echelon inventory control, automated replenishment, and collaborative planning, forecasting and replenishment (CPFR). Real-time information, integrated decision support and ICT tools enable such differentiated control models down to an individual product level, thus creating flexibility.

The Principle of Automated and Integrated Decision Support: Real-time information, in combination with a unified control model, can be combined with decision support tools to automate operative decision-making. Such tools include mathematical algorithms, optimisation functionality, ICT, automated analyses, and integrated support tools, such as simulation and what-if analysis. Decisions will not be made in isolation, but rather will be based on a unified foundation, in order to handle trade-offs and alleviate sub-optimization. Through its processing capacity, ICT can identify patterns in demand and supply much more quickly and provide more accurate forecasts for short- and long-term operations. ICT tools can integrate information from several nodes, as well as integrate forecasts, current status and historical data. As the degree of automated decision-making is radically increased, it is essential that information on decisions is presented automatically and visually in dashboards or studio environments for human surveillance and status monitoring.

The of Measuring Supply Chain Performance in Real Time: Within a traditional control paradigm, supply chain operations are evaluated based on past performance, and indicators seldom predict consequences on future performance, thus providing a weak foundation for corrective actions and improvement efforts. With access to real-time information, a new set of performance measures which include leading and lagging parameters should therefore be developed and integrated with control parameters. Real-time key performance indicators (KPIs), showing the exact current performance for the entire supply chain (e.g. lead time, average stock levels, inventory throughput time and fill rate), should be continuously accessible to all partners. Further, ranges for acceptable performance should be established for each KPI. Automatic and electronic procedures can be programmed to generate alerts whenever an indicator falls outside of the agreed ranges. The whole set of performance measures should be integrated in a visual dashboard solution, thereby providing a powerful tool for supply chain performance improvement. Ideally, supply chain members should have access to a flow map showing, in real time, the movement of goods and materials through the supply chain and how the supply chain as a whole is performing.

Case: Control Model in a Fresh Food Supply Chain

In this section, a control model for an intelligent and demand-driven fresh food supply chain will be described in terms of the principles presented above applied to a case study in the Norwegian grocery industry - the production and distribution of processed fresh salads. The information from the case stems from a three-year user-driven R&D project called *Smart Flow of Goods* (2007-2009, see www.sintef.no/smartvareflyt). The project was initiated by major players in the grocery industry (three food manufacturers, two manufacturers of packaging material, two wholesaler – retailer dyads, and two logistics solution providers). The aim of the project was to develop new intelligent and demand driven control models for the supply chain, enabled by RFID technology and intelligent control principles.

The focus and activities in the case were determined in cooperation between practitioners and researchers, based on the specific needs and challenges of the participating organizations and their supply chains. Data was derived using the control model methodology (Alfnes, et al., 2006). Solutions were developed through scientific methods (combined action research and case methodology, use of theory, literature, scientific methods for data collection and analysis, etc.), combined with practical knowledge and experiences from the food and grocery industry.

The following sections provide a description of the fresh food industry and the salad supply chain, including current problems and challenges facing the supply chain members. Then, a new control model will be outlined based on the principles described in the preceding sections.

The Salad Supply Chain

The fresh food industry is influenced by a number of trends affecting most global businesses, e.g. globalization, increasing cost focus, time pressure, environmental concerns, customization, and financial rationalization and consolidation (see e.g. Christopher, 2005; Hofmann & Reiner, 2006; Turban, Leidner, McLean, & Wetherbe, 2006). Food supply chains are complex and form large networks, and the grocery industry's solution to its logistics challenges has tended to set a standard for other industries. The logistics structure is often centrally coordinated, enabling use of cross-docking and terminal facilities in distributing goods to retailers in parallel with direct shipments from producers. Control concepts in the Norwegian grocery industry are dominated by traditional push and forecasting based control. Information on consumer demand is, in many cases, not accessible due to lack of, or infrequent, information sharing, and those who have access to demand information do not necessarily utilize it for control purposes.

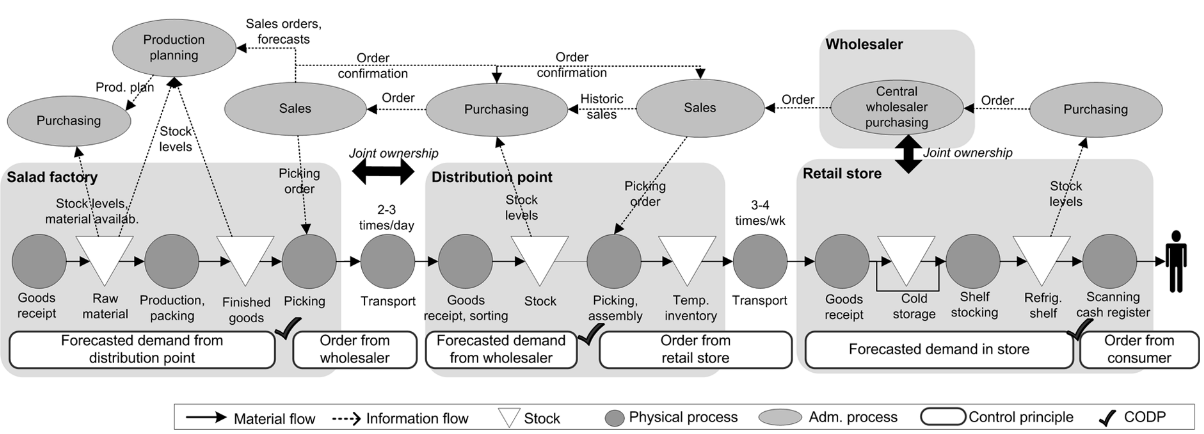
Despite the limited cooperation and information sharing along the food supply chain, Norway is seeing signs of a shift towards more dialogue and collaborative search for industry solutions that can create more efficient and demand-driven supply of food products. The Norwegian grocery market is dominated by a handful of large players within each stage of the supply chain and there is a near full consolidation into four chains of wholesaler – retailer dyads, which control 98% the market. In the past few years, a number of collaborative initiatives have been launched by government and the industry itself, with the aim of increasing efficiency, ensuring supply of safe and high quality food products, reducing waste or scrapping along the food supply chain, etc.

Traditional food items are produced in high volumes with small profit margins. Simultaneously, changing consumer preferences and tough competition are forcing food producers to offer a broader product selection, while continuously reducing costs, which requires increased efficiency in production and logistic operations (Bolseth & Alfnes, 2001).

The case example consists of a supply chain for the distribution of salads from the producer, through a distribution point to a typical grocery store. The focal product consists of various types of processed salads, all with a shelf life of around 8-10 days from the production date. The current supply chain for salad is illustrated in Figure 2, showing supply chain members, material and information flows, stock points, physical and administrative processes, and control principles and associated CODP.

The physical flow starts at the salad factory, where raw materials are supplied from a set of local, national and international primary producers. In total, the factory produces 200 variants, of which salads represent an atypical product, distributed both directly to restaurants and larger institutions and through wholesalers or distribution points to retail stores. The production process for most products consists of quality inspections, cutting, washing, and assembly into various product mixes, before packing and storing. Salads are manufactured to stock. Orders from distributors or wholesalers are used for procurement and production and supply planning. The weekly production plan is based on the principles of optimal batch-sizing. Products are kept in stock

Figure 2.



until orders arrive from distribution points or wholesalers, and turnover for salad products is high, due to the extremely short self life.

From the factory, products are shipped to a distribution point, where retailer orders are assembled. Requirements at the distribution point are calculated by the sales department based on a combination of historic sales data and forecasting techniques. In this particular supply chain, the distribution point is a cross-docking facility, and within a 8 – 10 hour timeframe the products are transported to retail stores. Operations at the distribution point are based on orders from retailers. Accumulated orders are received from a central information system operated by the retail chain's wholesale unit. Orders from each store are placed daily into the central system, based on predefined ordering principles and manual inspection routines. Orders from stores vary in both quantity and items. Throughout the supply chain, products are kept within a strictly regulated temperature zone.

The main challenges and problems associated with current operations and control in the supply chain are:

- A high number of stock points or buffers along the supply chain
- Large amounts of waste/scrapping, due to long lead times and temperature sensitive products
- Forecasting and planning in each node, based on forecasted demand from subsequent node
- Forecasting based on historic sales and extensive manual parameter adjustments, based on experiences and market knowledge
- Limited information sharing and use of available information for operations planning and control
- Limited use of POS data in operations planning and control backwards in the chain

A New Control Model for the Salad Supply Chain

Based on the above challenges and issues, a number of potential improvements to the as is situation were developed, as part of the *Smart Flow of Goods* project. The following section describes how each of the principles above can be addressed through a new control model for the supply chain. Some of the proposed solutions were implemented in the case during the project, while others reflect the ideal intelligent and demand-driven control situation for this supply chain.

The new control model involves changes related to the control and structural aspects of the supply chain. The main principle for the new control model is demand-driven control of the entire supply chain, based on continuous sharing of real-time demand and stock information in retail stores. Also, activities related to order, supply and production should be automated, to as a great an extent as possible, with only exceptions and corrections handled manually.

The new control model is based on real-time POS and inventory information being captured and communicated backwards in the supply chain from retail shops (principle 1). This information is an essential input to the proposed replenishment model between the distributor and the retailer. The information will also be made available to the salad factory, for improved production planning and control. Due to the very short shelf life of salad products, demand information must be made available continuously or daily at worst, to enable the factory and the distribution centre to respond quickly to any changes or disruptions in consumer demand.

Due to the high perishability of processed salads, any time spent in stock reduces the quality of the product. The current finished goods stock point in the factory is mainly there as a demand and transport buffer and therefore represents non-value adding activities and time. The finished goods stock point will therefore be moved downstream, such that only the distribution point has a stock of finished goods. CODP will be at production/packing line in the factory (principle 3), with activities in the supply chain based on a combination of a push and pull strategy (principle 4). Downwards from the factory transport, picking, packing and labeling will be based on the replenishment needs of retail stores. Upwards, production at the factory will be based on a push strategy, where production is executed on forecasted accumulated demand, adjusted with consumer demand information. Production batch sizes will be set according to availability of raw materials and production capacity.

As part of an automated,VMI strategy, the distribution point will assume the responsibility for replenishing all retail stores, based on real-time information on POS and stock levels (principle 5). In this way, stock at the distribution point and the entire retail chain will be controlled according to multi-echelon principles, where the stock levels of the two echelons of the supply chain are considered in concert. Operations at the distribution point will be planned and controlled based on aggregated information about replenishment needs for all retail stores. For retail stores, the VMI solution will eliminate the need for traditional purchasing and order processes, while the manufacturer will be able to control the goods flow, from the purchasing of raw material to production, through access to real-time information on distribution needs.

ICT is a key enabler of the new control model, and the implementation of an efficient infrastructure for capturing and sharing information is essential. A supply chain dashboard will be implemented to store, aggregate and visualize demand information (principle 7). In addition, decision support tools will be integrated into the dashboard. POS data and stock information from retail stores will be transferred to the system on a continuous or daily basis, where the distributor and factory can use the information in their own planning.

The new IT infrastructure will also involve the acquisition of commercially available software to support the VMI solution. Such software will calculate the replenishment needs of finished goods for the distribution point and all retail stores, based on historic demand patterns, lead time, demand uncertainty, specified service levels, and information on ongoing and upcoming campaigns and other market activities.

A jointly developed system of performance indicators will be integrated into the supply chain dashboard (principle 8). These parameters will enable supply chain members to continuously measure and monitor performance against established objectives for the supply chain and each individual member. The indicators will form a hierarchy showing how the performance of individual supply chain members affects overall supply chain performance. Lagging indicators include sales, productivity, quality control costs, and rush order costs, while leading indicators include measures of service levels, stock levels, stock values, returns, product and delivery quality, lead times, and supply chain responsiveness.

This proposed control model refers only to one product group: processed salads. Since this is an atypical product for the factory and the rest of the supply chain, separate control models should be created for other products and product groups. Although there will be differences between the specific models, they will all be based on the same principles of demand-driven control enabled by sharing of real-time information. Each model should take into consideration the characteristics of the products, their demand patterns and variability, particular requirements related to production and distribution processes, etc.

Issues, Controversies, Problems

The previous sections of this chapter have highlighted possibilities and the essential elements managers must deal with in order to realize intelligent and demand-driven supply chain operations.

However, the control model presented is based on a normative approach for dealing with complexity and improving supply chain efficiency. The model was developed using a general approach based on some simplifications and introducing several elements and principles as building blocks in a new environment for operating supply chains. In addition to the recommendations and principles set forward in this chapter, there are a number of other issues which supply chain managers will have to address, both within their own organizations and in their supply chains, before such a normative model can be applied in a real supply chain setting. Some of these issues, controversies and problems are discussed below.

Efficient Coordination Across Organizational and Geographical Boundaries: Although the case dealt with in this chapter focuses on a domestic supply chain, the issues discussed and the model developed is possibly even more relevant in the context of global network operations. In any situation where the scope of operations span is beyond a single organization single-site, the planning and control task takes on a supply chain or network perspective. The high complexity and coordination challenges involved in supply chain operations therefore require a holistic and integrated approach to planning and control, where one single, agreed-upon control model should support seamlessly integrated processes across organizational and geographical boundaries. However, the unified supply chain control model presented here does not guarantee efficient coordination of all operations, particularly since it does not solve the issues related to the lack of a central coordinating facility or unit in a supply chain of autonomous members. The joint development of a unified control model is, however, a step in the right direction.

Dealing with Inter-Organizational Issues Related to Information Sharing, Diverging Interests, and the Power and Trust Balance: The power position and relative strength of supply chain members is discussed both in the literature and practice. In the food supply chain, many retailers have gained a major strategic position through integration of retailing and wholesaling activities, allowing them to control access to demand information. This information is frequently not shared with other partners in the supply chain, because retailers are worried that suppliers might use it to gain a competitive advantage. In the normative framework explored in this chapter it is assumed that retailers share demand information, even though, in reality, retailers tend to be restrictive in sharing this information. Also, in many instances, suppliers lack models for how to utilize demand information to improve their own operations.

Ability to Handle Dynamics, Uncertainty and Variation: For supply chain operations, it is extremely challenging and resource-demanding to cope with variation and uncertainty. This means that the models suggested in this chapter need to be dynamic and flexible, which somewhat breaks with the normative approach of the models. Still, this is one of the most important issues to address, in order to handle supply chain complexity.

Simultaneous Participation in Multiple Supply Chains: Each partner in a supply chain needs to deal with the fact that they most often are part of several supply chains simultaneously. Thus, solutions developed in cooperation with partners in one supply chain might not be appropriate for all or indeed any of the other supply chains the company participates in. Also, solution working well for one partner in a particular supply chain may not be successful or applicable for other partners due to the heterogeneous nature of business processes and relationships. The "one size fits all" approach is hardly applicable in a supply chain setting, thus, a major challenge is categorizing and finding principles which simultaneously differentiate and harmonize.

Use of and Investment in ICT: Electronic data capture and information processing and sharing requires considerable investment in technology (RFID, dashboards, EPCIS, etc.) and competence. This can be particularly challenging for small and medium sized enterprises (SME) with limited resources. For many companies and sectors, this is a contributing factor to the limited interest in and application of new technologies, such as RFID and automated replenishment systems. The investment level, the upgrading of competence and the pace of technological development are all obstacles to a higher degree of ICT application.

Standardization of Information and Interfaces: Information has to flow freely with low friction and be understandable for all members of a supply chain, in order to create value. This means that data should be standardized and that the organizational and technology interfaces should be harmonized. Thus, advances within global information standards are highly important in enabling a greater degree of information sharing in a supply chain.

Explosion in Information volume and Information Security: Developments in data capturing technology, mobile and wireless communication platforms, track and trace solutions, etc. have led to an explosion in information volume. The ability and capacity to deal with ever increasing information volumes in an appropriate and secure manner is an issue of high relevance. This also includes the question of data protection in general, and personal information in particular.

Solutions and Recommendations

Despite the challenges and issues outlined above, there are developments and initiatives which can provide support in overcoming some of the obstacles. This section outlines some recommendations and solutions which can assist supply chains in realizing the concept of intelligent and demand-driven supply chains.

At present, there is a lack of business cases which demonstrate solutions using the proposed control model. By implementing a well-defined model in a variety of representative contexts and sectors, the potential effects and implications for supply chains can be evidenced. One first step could be to implement selected elements of the control model. Although the technical solutions for capturing real-time information are still not in place in most supply chains, each supply chain member already captures large amounts of data which can be very beneficial to their supply chain partners. A manufacturer might find that regular updates containing the POS data, stock levels and marketing plans of key customers could be used to improve production planning and control.

Development within the area of system standards is continuously evolving. Through, for instance, the EPCIS standards and interfaces, the ability to exchange information with supply chain partners is improving. Further, technology and system developments with regards to integration, functionality and cost are paving the way for smoother and more efficient supply chain cooperation. Data collection devices such as RFID, antennas, mobile broadband solutions, etc. will soon be reaching a level of functionality and cost that make implementation on a broader scale realistic.

Of particular importance in the realization of efficient supply chain collaboration and information sharing is the development and implementation of supply chain control dashboards. Such dashboards originate from executive information systems and control rooms in the process industry. A dashboard integrates relevant information from all supply chain partners' information systems (e.g. enterprise resource planning, supply chain management, advanced planning, manufacturing execution, etc.), thus supporting a true supply chain perspective, enabling visualization of performance indicators, and supporting operations, planning and control on all process levels (Dreyer, et al., 2009). In the Automed R&D project referred to earlier, a prototype of a dashboard for pharmacy products was developed in cooperation with Oracle. *Figure 3* shows a screen shot of the "Stock availability" function, where forecasts and sales for a stock keeping unit (SKU) is shown graphically for the manufacturer, supplier, wholesaler, and, in this case, aggregated for all pharmacies

Figure 3.

in the pharmacy chain. The dashboard allows aggregation and drill-down between levels, to get more detailed stock level information from an overall supply chain status and down to individual pharmacies.

The use of supply chain dashboards can either be individually by employees within each company, or as part of a collaborative environment where groups and teams are involved in the execution of supply chain activities. In a studio environment (virtual or physical) members of distributed and complex supply chains can cooperate and make decisions in a holistic and integrated manner. Distributed and linked studios in a supply chain can serve as information and communication nodes that enable integration of operations activities and distributed and interactive supply chain planning, across geographical distances and organizational levels. Supply chain studios provide members with access to network-wide real-time information (Wang & Wei, 2007), enable visualization of the available information (Boyson, Corsi, & Verbraeck, 2003) through, for instance, supply chain dashboards, secure interaction between advanced ICT based decision support tools and human decision-making (Barthélemy, Bisdorff, & Coppin, 2002), and create a coordinated and collaborative environment (Deek, Tommarello, & McHugh, 2003) for planning, control and decision-making.

FUTURE RESEARCH DIRECTIONS

True real-time operations of supply chains are still seen only very scarcely and only at very limited subparts of supply chains, for instance, between two members of a complete chain. There are numerous development and research areas that need to be addressed, in order to realize real-time controlled supply chains.

Within the operations management area, the following issues remain to be addressed:

- Further development of control principles and collaboration mechanisms, from the level of principles into guidelines, rules, formulas and algorithms.
- Shift toward applying optimization and simulation (operations research) at a truly operative level, integrating optimization and simulation with control algorithms and systems like ERP, DRP (distribution requirements planning), scheduling, etc.
- New perspective and role of performance measurement, shifting perspective from a focus on lagging indicators to support for on-line decision-making
- Study and understand obstacles and possible solutions with regards to power issues, willingness to cooperate, collaboration models, incentive mechanisms, etc. in different industrial sectors.
- Study and understand obstacles and possible solutions regarding the human role and behavior in the new paradigm, where human and manual decision-making is replaced by surveillance, status monitoring and automated decision support through visual monitoring facilities.

Regarding new technology, including the ICT perspective, relevant and important issues for future R&D include:

- General development of ICT performance: processing capacity versus cost, system integration capability, visualization facilities, man-machine interfaces, etc.
- Future of RFID, sensor and mobile technology for close-to-zero cost of tracking individual items
- Standardization of data exchanges based on global coding (EPC)

It will be in the true interplay among these R&D challenges that we will see the realization of future demand-driven supply chains.

CONCLUSION

Increasing the competitiveness of supply chain systems requires a supply chain which is integrated and coordinated, where operations are driven by demand and real-time principles. A supply chain is, by nature, a complex and heterogeneous system with a wide range of products, processes and companies, as well as diversified material and informational flow structures. A unified planning and control model is an efficient approach to coping with the associated issues and challenges. In this chapter, we have explored and developed such an approach in the form of a framework for intelligent and demand-driven supply chain control, where we assume that all relevant information is made available to all partners in real time. In order to capture a more holistic picture of supply chain planning and control that supports future developments in industrial business cases, the framework consists of a concept and a number of associated principles. Based on the control model methodology, these principles have been demonstrated through a control model for processed salad products.

The following is a brief description of the main elements of the principles. Replenishment and shipping decisions should be based on real-time information about POS data, stock levels, marketing plans, manufacturing and transport status, etc. CODP placement should be differentiated and moved upstream or downstream in the supply chain, according to product and market characteristics. Manufacturing and shipment of goods should be based on the principle of *"buy one – produce and deliver one"*. Replenishment responsibility should be moved upstream in the supply chain. Human and manual decision-making should be replaced by surveillance, status monitoring and automated decision support through visual monitoring facilities. The control of each product or product segment should be determined individually according to product, demand and market characteristics. Information hubs should be established to collect, store and present information from the entire supply chain, integrating information from the ICT systems of each supply chain member. A new set of performance measures, showing leading and lagging parameters, should be developed and integrated with control parameters. Finally, these measures should be implemented in a visual dashboard and made available for monitoring.

Implementation of truly demand-driven supply chains is dependent on developments and improvements within technology and standards. Solutions that are affordable for ordinary companies and SMEs are expected to become readily available in the near future. A major implementation obstacle, however, is the lack of trust, open sources and collaboration between supply chain members – issues that require further research. The concept and principles proposed in the chapter have already proven their potential through a number of cases, where results have been achieved, and further changes and solutions are being developed.

KEY TERMS AND DEFINITIONS

Control Dashboard: A decision support tool which presents and visualizes key performance measurements that are used to support control processes in a company or supply chain/network.

Control Model: A formalized description of how operations are organized and controlled in manufacturing and distribution, including control principles and methods, CODP, main operation processes, buffers and responsibility areas, and material and information flow.

Control Principle: A definition of what initiates processes in the system. In a pull system the amount of work in process is limited by orders from the subsequent process, while a push system has no limits and work is initiated based on forecasts.

Control Studio/Centre: A physical or virtual workspace and interface supporting collaboration between supply chain planning teams and local managers at different nodes of a network/supply chain. Information to support decision-making is made available through modern and integrated ICT solutions.

Customer Order Decoupling Point (CODP): The point in the supply chain where demand changes from dependent to independent, where the firm becomes responsible for determining the timing and quantity of material to be purchased, made, or finished (Vollmann, et al., 2005); usually coinciding with an important stock point from which customers are supplied.

Information Decoupling Point: The point in the information pipeline where market driven and forecast driven information flows meet, i.e. where information on real customer demand is available to upstream supply chain participants.

Point of Sale (POS) Data: Information about an individual sales transaction (product code, price, number of units), traditionally captured by a bar code scanner at the cash point of a retail outlet. The information is stored in a database and often consolidated on chain level.

Supply Chain Planning and Control: The task of determining what, who, when and how to act to efficiently manage the flow of material and information in order to meet customer demand with the exact supply in a coordinated chain.

Chapter 18
Reducing Design Margins by Adaptive Compensation for Thermal and Aging Variations

ABSTRACT

Corner-based design and verification are based on worst-case analysis, thus introducing over-pessimism and large area and power overhead and leading to unnecessary energy consumption. Typical case-based design and verification maximize energy efficiency through design margins reduction and adaptive computation, thus helping achieve sustainable computing. Dynamically adapting to manufacturing, environmental, and usage variations is the key to shaving unnecessary design margins, which requires on-chip modules that can sense and configure design parameters both globally and locally to maximize computation efficiency, and maintain this efficiency over the lifetime of the system. This chapter presents an adaptive threshold compensation scheme using a transimpedance amplifier and adaptive body biasing to overcome the effects of temperature variation, reliability degradation, and process variation. The effectiveness and versatility of the scheme are demonstrated with two example applications, one as a temperature aware design to maintain I_{ON} to I_{OFF} current ratio, the other as a reliability sensor for NBTI (Negative Bias Temperature Instability).

INTRODUCTION

IT infrastructure has become an essential foundation of human society. Information storage and computation span every aspect of our daily life, from personal entertainment and education, to government and business operation. Moreover, for real-time service providers, data centers and their connections to outside terminals need to be running for a long time without interruption. Examples are banking systems and servers, online shopping and tracking, supply chain management, and multimedia streaming. The unprecedented increasing dependence and requirement on transaction avail-

DOI: 10.4018/978-1-4666-1945-6.ch018

ability and speed call for the deployment of more high performance and reliable computing devices.

However, this leads to at least two problems. At the macroscale level, without careful design and planning the environmental impact due to technology development is unsustainable. For example, the energy cost of IT infrastructure and its carbon footprint doubles in less than five years (Pedram, 2009). Technology-equipped buildings occupy 70% of total electricity usage and emit 40% of greenhouse gases annually in the US (Kleissl & Agarwal, 2010). At the microscale level, high performance and reliability could be at odds for concurrent circuit designs based on the semiconductor technology. For example, high performance designs usually come with high power/temperatures and high stress levels on devices, leading to thermal and reliability problems. In particular, they can cause the instability (including both short time variation and long time shifting) of the threshold voltage of the basic circuit element—CMOS transistors.

The threshold voltage, or V_{TH}, is a critical parameter in circuit design. V_{TH} determines the current flowing through the transistor at least linearly, and in turn affects its equivalent resistance, transconductance, pull-up or pull-down strength and ultimately the speed and power of circuits. Even in advanced sub-micron technologies the dependence of the transistor current on V_{TH} can still be quite super-linear when all short channel effects are considered (Qi & Stan, 2007). The effects in the sub-threshold region are even more prominent since the leakage current grows exponentially as V_{TH} decreases.

Although threshold voltages are specified by technology vendors and treated as fixed and static values in simulations at design time, run-time factors like temperature variability and reliability degradation, as well as process variation, can considerably change V_{TH} both in the short and long term for individual transistors. With the small margins of most circuit designs today, even a relatively small amount of shift can have a significant impact or even lead to circuit failure. On the other hand, preventing these failures by initial overdesigning with large upfront built-in margins can impose large penalties in area and power. For example, an optimized reliability-aware sizing algorithm proposed in (Paul, Kang, Kufluoglu, Ashraful Alam, & Roy, 2006) still incurs an area overhead from 3.31%-13.6% for ISCAS testbench circuits. This conventional method variation by overdesign to tolerate reliability hazards, thermal issues and process leads to unsustainable increase of cost both for the designer and the users.

In this chapter, we propose an adaptive threshold compensation scheme using a transimpedance amplifier and adaptive body biasing to compensate the V_{TH} shift dynamically. The effect of body biasing on modulating transistor threshold voltages has been heavily exploited in recent years to achieve low power and combat process variation (Karnik, Borkar, & De, 2002; Tschanz, et al., 2002). The scheme employed in this chapter works for a range of applications including, but not limited to, manufacturing process variations. Two example applications are presented in this chapter. The first compensates for temperature induced I_{ON} to I_{OFF} mismatch and the second compensates for threshold shifting due to the long time aging/reliability effect.

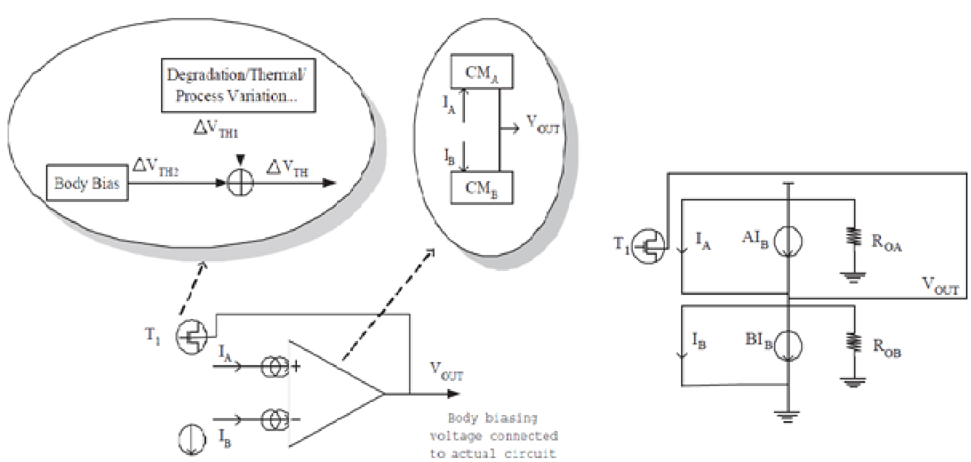
Adaptive compensation of threshold voltage reduces necessary design margins, and enables typical case-based design instead of the traditional worst case-based (or corner based) design. Worst case-based design leads to over-pessimism and unnecessarily large margins/guardbands for the majority of components that do not fall on the tail of the distribution caused by manufacturing or runtime variations. The over-designed components not only take chip real estate and impose non-recurring penalty for designers and manufacturers, but also consume extra power and impose a recurring penalty on the consumer and the environment. The proposed module can also be deployed in large numbers and distributed across the whole chip for adaptive compensation at a finer granularity, and thus achieve more aggressive savings. We believe distribution and adaptation are two key strategies for low-power energy-conserving sustainable computing, and both are embodied in the proposed threshold voltage compensation scheme.

ADAPTIVE THRESHOLD COMPENSATION SCHEME

Figure 1 shows the proposed threshold compensation scheme. It is mainly composed of two parts, the first being the transistor, T1, which could either be a PMOS or an NMOS. T1 serves as a 'proxy' for the transistors in the actual circuit whose threshold voltages need to be compensated due to various reasons including, but not limited to, process and temperature variation and reliability degradation due to aging. The net effect of these factors is the threshold voltage shift noted as ΔV_{TH1} in Figure 1. Ideally, we want to maintain the original V_{TH} value of T1 by offsetting ΔV_{TH1} by ΔV_{TH2}, a voltage shift in the opposite direction of ΔV_{TH1}. In this scheme, ΔV_{TH2} comes from the body biasing effect of T1. Providing the appropriate body bias voltage V_{OUT} to generate ΔV_{TH2} is the goal of the second part of the compensation circuit, shown as a differential transimpedance amplifier on the right.

The transimpedance amplifier mainly comprises two sets of current mirrors, denoted in Figure 1 as CM_A and CM_B. The two differential inputs are the current I_{DS} from the proxy transistor T1, and a reference current I_B. I_A and I_B are fed into CM_A and CM_B separately, and propagated along to the last stage after being amplified with current gains A and B. Notice that the arrows on I_A and I_B simply mean that they are input variables of the circuit, not necessarily the direction of the currents. The composite current gains A and B can be achieved with multiple stages of current mirrors within CM_A and CM_B. The last stage settles to an equilibrium state only if $A \times I_{ON} = B \times I_{OFF}$. This balance provides the output voltage V_{OUT}. V_{OUT} is the body biasing voltage connected to the actual circuit component that needs threshold compensation. It is also fed back to the bulk of the proxy transistor T1 to complete the closed loop system.

Figure 1. The proposed transimpedance amplifier as a closed-loop feedback system and its equivalent small signal circuit model



Threshold Compensation Capability Analysis

The threshold compensation system can be analyzed with the equivalent small signal circuit also shown in Figure 1. Since later we will demonstrate an example application of the threshold compensation circuit for NBTI, the following analysis is performed assuming the proxy transistor T1 is a PMOS, since NBTI only affects PMOS transistors. For the ease of notation, all V_{TH} and ΔV_{TH} carry signs within themselves. Therefore, for a PMOS transistor in the saturation mode, according to the alpha-power law model (Sakurai & Newton, 1991).

$$I_A = K\frac{W}{L}(V_{DD} + V_{TH})^{\alpha} \tag{1}$$

Notice that for PMOS transistors V_{TH} is negative. The meanings of the parameters are summarized in Table 1.

Applying Taylor expansion:

$$\Delta I_A = \alpha K\frac{W}{L}(V_{DD} + V_{TH})^{\alpha}\frac{\Delta V_{TH}}{(V_{DD} + V_{TH})} \tag{2}$$

Referring to Figure 1, here:

$$\Delta V_{TH} = \Delta V_{TH1} + \Delta V_{TH2}$$

The output body bias voltage:

$$V_{OUT} = (AI_A - BI_B)\frac{R_{oA}R_{oB}}{R_{oA} + R_{oB}} \tag{3}$$

R_{OA} and R_{OB} are the small signal output resistance of the two current controlled current sources AI_A and BI_B respectively. Assuming the reference, current I_B stays constant:

Table 1. Parameters used in the derivation

DEFEINITION/DESCRIPTION OF PARAMETER	
PARAMETERS	DESCRIPTION
W, L	width and length of proxy transistor T1
K	device-transconductance parameter of T1
α	short channel coefficient of T1
V_{DD}	power supply voltage for T1
V_{TH}	actual threshold voltage of T1, signs embedded
V_{TH0}	threshold voltage of T1 without body effect
ΔV_{TH1}	threshold voltage shift of T1 due to non-ideal factors
ΔV_{TH2}	threshold voltage change of T1 from body biasing
ΔV_{TH}	net V_{TH} change, $\Delta V_{TH} = \Delta V_{TH1} + \Delta V_{TH2}$
	body effect coefficient, or bulk threshold parameter of T1
I_A	current from proxy transistor T1, and input to CM_A
I_B	reference current, and input to CM_B
A,B	current gain of CM_A and CM_B
R_{OA}, R_{OB}	small sig. output resistance of the last stage
V_{OUT}	output body biasing voltage to actual circuits

$$\Delta V_{OUT} = A\frac{R_{oA}R_{oB}}{R_{oA} + R_{oB}}\Delta I_A \tag{4}$$

Equations (2) and (4) can also be obtained by taking derivatives directly. Finally, considering the body biasing effect, the threshold voltage of T1 is (Sakurai & Newton, 1991):

$$V_{TH} = V_{TH0} + \gamma(\sqrt{2\varphi_F - V_{BS}} - \sqrt{2\varphi_F}) \tag{5}$$

This can be further simplified (Sakurai & Newton, 1991) to:

$$V_{TH} = V_{TH0} - \gamma_1 V_{BS} \tag{6}$$

thus:

$$\Delta V_{TH} = -\gamma_1 \Delta V_{BS} \tag{7}$$

Notice that this ΔV_{TH} is essentially the ΔV_{TH2} in Figure 1. Also for PMOS, ΔV_{TH} and V_{BS} have embedded negative and positive signs.

Combining Equations (2), (4) and (7), we get:

$$\begin{aligned} &\Delta V_{TH2} \rightarrow = \\ &\alpha K \frac{W}{L}(V_{DD} + V_{TH})\alpha \frac{1}{(V_{DD} + V_{TH})} \\ &\gamma A \frac{R_{oA} RoB}{R_{oA} + R_{oB}} (\Delta V_{TH1} + \Delta V_{TH2}) \\ &\quad = C(\Delta V_{TH1} + \Delta V_{TH2}) \end{aligned} \tag{8}$$

where:

$$C = -aK \frac{W}{L} \frac{(V_{DD} + V_{TH})^{\alpha}}{(V_{DD} + V_{TH})} \gamma_1 A \frac{R_{oA} R_{oB}}{R_{oA} + R_{oB}}$$

and $C>0$.

Now we rearrange Equation (8):

$$\frac{\Delta V_{TH2}}{\Delta V_{TH1}} = -\frac{C}{1+C} \tag{9}$$

Equation (9) is quite interesting. Remember that the ultimate goal of the whole system is to use ΔV_{TH2} to compensate the threshold voltage change ΔV_{TH1} caused by non-ideal factors, therefore ideally we would like $\Delta V_{TH2} = -\Delta V_{TH1}$. However, Equation (9) demonstrates that the exact equality is really impossible. However, the larger the constant C is, the more compensation we achieve and the closer the two values can be to each other—C can be viewed as the open loop gain of the feedback system. Increasing the proxy transistor size, the current mirror gain and the last stage output resistance are all possible ways to maximize C. While this opens up optimization opportunities for power and area, these 'knobs' are *not* independent of each other, and the optimization *cannot* be carried out separately, due to the analog nature of the circuit. An important consideration is that the design should always guarantee the correct working range of the current mirrors. How to maximize the gain and quantify the tradeoff of parameters given an area or power budget is our ongoing work.

Finally, notice that although the above analysis assumes a constant reference current I_B, a similar derivation can be carried out in case when I_B is also a variable. We will see an example in the temperature aware design in the next section.

In the following sections, we exploit this adaptive circuit design technique for two example applications, one for reducing temperature sensitivity and the other for mitigating the impact of circuit aging. Both of these examples demonstrate how the proposed adaptive circuit design can help the system achieve its optimum operating point and maximize the system computation efficiency. While temperature- and reliability-aware designs are in themselves important topics for reliable sustainable computing, we mainly choose these two examples to show the ability and versatility of the proposed scheme to adapt to different undesirable environmental factors and mechanisms, thus enabling typical case-based design. One should always remember that *green computing is not necessarily equivalent to low power computing*. The amount of consumed *energy* (or the produced carbon footprint for a given computation load) is the ultimate metric for measuring the 'green' part. Therefore, maintaining a circuit or system at its optimal operating point is the key to exploit every bit of the consumed energy for useful computation.

THRESHOLD COMPENSATION FOR TEMPERATURE VARIABILITY

Now we demonstrate how the proposed circuit technique can be used for maintaining an optimal I_{ON} to I_{OFF} ratio for MOS transistors in the presence of temperature variation. While energy, power, temperature, and temperature variations are all important issues for a system built from semiconductor chips, which in turn are built from transistors, it is important to distinguish among these concepts since the design challenges and issues are not always the same, thus cannot always be tackled together. As we will show in the next section, distinguishing these concepts is critical in identifying and directly targeting the challenge for reducing carbon footprint of computation and bringing forth green computing.

Temperature Variation and Why It Is Important

Thanks to the increase in circuit density and clock speed, power and thermal issues have been upgraded to first tier concerns in modern VLSI design, from chips in high performance servers to low power handheld devices (Chandrakasan, Sheng, & Brodersen, 1992). The first thought that usually comes to mind when thinking about thermal issues is probably power consumption, which is indeed a critical concern especially for battery supported, mobile and handheld consumer electronics and devices. The most popular examples are smart phones, tablets, laptops, portable media players, GPS (global positioning system) devices, etc. This concern about power motivated the whole low power design research initiative in both academia and industry, for good reasons.

However, more precisely speaking, for the above applications what we really need should be called ‘low energy’ design. Recall that energy is the product of power and time. For the given amount of computation (or device usage), simply lowering power certainly helps in reducing thermal hazards, but does not necessarily reduce energy consumption (or the battery usage). In reality, most low power designs or temperature-aware techniques involve lowering circuit speed and performance, thus increase the operation time for a given user task (Lu, Lach, Stan, & Skadron, 2005). For example, the most common and conceptually simple low power technique that has been long known in academia but has only been slowly adopted by industry in recent years, DVFS (Dynamic Voltage and Frequency Scaling), directly plays with this tradeoff between power and time by dynamically increasing or decreasing voltage and frequency at runtime for different applications. Since lower voltage and frequency immediately reduces power, but also decreases circuit speed (equivalently increasing computation time), therefore applying low power techniques like DVFS blindly does not necessarily reduce the energy consumption and increase battery time, but may actually exhaust their battery faster due the extra area and power overhead from the added DVFS management circuitry, in addition to possibly resulting in an unfriendly user experience due to the slower response time. As another example, parallelism can bring back the performance loss due to voltage scaling in low power design (Chandrakasan, Sheng, & Brodersen, 1992), but with leakage power rising rapidly in modern semiconductor technologies, the total energy consumption may still increase due to the extra transistors and area. Therefore, designers should always double check if they are using the right metric for their purpose, and if the metric is indeed improved after everything is considered. In the circuit design community, the Energy-Delay Product (EDP) is often used to evaluate the optimality, since it takes into consideration both energy consumption and system performance.

In this section, we focus on a less obvious, yet equivalently important, challenge hidden in the ‘power wall’ (a terminology from Asanovic, et al., 2006) temperature. Temperature is closely related to circuit performance and power. On one hand, the temperature is among the most important environmental factors, which can impact both the performance and power consumption (including dynamic runtime power and static leakage power) of integrated circuits. On the other hand, the temperature can also be affected by the power consumption of the circuit itself since all the power consumed by the circuit ultimately transforms into heat, according to the low of conservation of energy. In fact, since an elevated temperature not only hurts circuit performance but may also lead to a phenomenon called 'thermal runaway' (caused by a positive feedback of temperature and leakage power), which permanently destroy a semiconductor microchip, keeping circuit operational temperature in the specified range has become a critical concern, from integrated circuit packaging to IT facility maintenance, and is very cost-sensitive. At the macroscale level, the cooling facility is a significant portion of IT expense. The old cooling method through ventilation is no longer effective. Nowadays, high performance servers or compute farms need to use sophisticated air-conditioning schemes. At the microscale, the on-chip cooling systems like heat sink and spreader designs are getting fancier and more complicated, at the expense of cost that goes to every single chip, and has become a significant portion of the cost of chip manufacturing. Therefore, it is very important to distinguish between the two related concepts, i.e., low power design and temperature aware design.

While keeping the circuit out of dangerous temperature zones is vital for its health, keeping the circuit at optimal temperature can maximize its efficiency, since the variation of temperature can change the optimal operating point of a circuit. Unfortunately, while it may be possible to maintain the ambient or average temperature, it is almost impossible to maintain the temperature for every transistor on the circuit at a certain value, because of on-chip temperature variations. On-chip temperature variations can happen both spatially across different function blocks of the die, and temporally over time when the system runs different applications. Spatial temperature variations occur when some parts of the circuit consume more power, leading to 'hot spots' on the die while other parts are less active and their temperature is relatively lower. Temporal temperature variations occur when the function of the units on the die are switched on or off, changing the power consumption of the processor, thus changing the temperature of the chip over the time. The sources of temperature variations include ambient temperature and heat generated by circuit itself. Temperature variations are usually defined using 'temperature maps' (temporal and spatial distribution of temperature) which are either directly measured or indirectly derived from 'power maps' (temporal and spatial distribution of power). The calculation of temperature maps from power maps has been investigated by many research groups and various thermal simulators have been proposed for this purpose. On the other hand, temperature variation is also a good indicator of power distribution (Qi, Meyer, Huang, Ribando, Skadron, & Stan, 2010). In practice, circuits on a microprocessor die can experience a wide temperature range of 0-70°C for commercial applications and –55-125°C for military applications.

Due to the importance of temperature and the difficulty to control the temperature for every transistor because of on-chip temperature variations, researchers have proposed different techniques to compensate for temperature variation to reduce its impact (Park, et al., 1995). Most of them focus on scaling and exploiting the "design knobs" of V_{TH} and $V_{DD.}$ For example, using fixed-voltage and scaled-V_{TH} techniques, two sub-1V MOS-based reference current generators were proposed in (Tang, Narendra, & De, 2003) to provide immunity against both temperature and process variations. A dynamic voltage scaling technique based on the temperature variation was proposed in Shakeri and Meindl (2003) to reduce power consumption. In the following, we present the design of a temperature-aware circuit using the proposed threshold compensation technique to dynamically track temperature variations and reduce its impact on circuit performance.

Dependence of I_{ON} and I_{OFF} Current on Temperature

To explain the effect of temperature variation on circuit performance, we first show the dependence of the I_{ON} and I_{OFF} current on temperature. Here we are mainly concerned with digital circuits, which form the dominant portion of modern VLSI system and consume most energy and chip area. The input voltage is either close to V_{DD} (called '1' or ON state) or close to ground (called '0' or OFF state). When in the 'ON' state, a transistor operates in the saturation region. When in the 'OFF' state, a transistor operates in the subthreshold region).

In the ON state, the drain current of a transistor I_{ON} can be expressed by the α power law model (Sakurai & Newton, 1991) as shown in Equation (1). For simplicity we rewrite Equation (1) as:

$$I_{ON} \propto \mu(T)(V_{DD} - V_{TH}(T)) \quad (10)$$

where α is velocity saturation index whose typical value is 2 for long channel MOSFETs and approaches 1 for short channel MOSFET. For current technology α is around 1.3. Notice that the threshold voltage $V_{TH}(T)$ and the mobility $\mu(T)$ themselves also have temperature dependence that can be expressed as follows (Bellaouar, Fridi, Elmasry, & Itoh, 1998):

$$V_{TH}(T) = V_{TH}(T_0) - K(T - T_0) \quad (11)$$

$$\mu(T) = \mu(T_0)\left(\frac{T}{T_0}\right)^{-m} \quad (12)$$

Here T_0 is room temperature (300 Kelvin); K is a threshold voltage temperature coefficient whose typical value is 2.5mV/K and m is mobility temperature exponent whose typical value is 1.5.

According to (11) and (12), it can be seen that both mobility μ and threshold voltage V_{TH} has negative dependence on temperature. Moreover, from (10) we can see that μ and V_{TH} have the opposite impacts on the I_{ON}, thus it is not immediately obvious how I_{ON} changes across a range of temperature values. Figure 2 shows the temperature dependence of I_{ON} for a NMOS transistor with different supply voltage. Based on the analysis in (Park, et al., 1995), if the supply voltage $V_{DD} >> V_{TH}$, I_{ON} is dominantly controlled by the carrier mobility μ and the I_{ON} decreases as temperature increases; However, as V_{DD} approaches V_{TH}, the effect of the V_{TH} shift with temperature becomes stronger and I_{ON} increases with temperature. At a certain V_{DD} value (V_{DD} =0.7 in our chosen technology node as shown in Figure 2), I_{ON} does not vary with temperature. This voltage is called Zero-Temperature Coefficient (ZTC) supply voltage. In current technologies, V_{DD} is still much larger than V_{TH}, therefore temperature has a negative impact on I_{ON} current, and circuit performance deteriorates at higher temperatures.

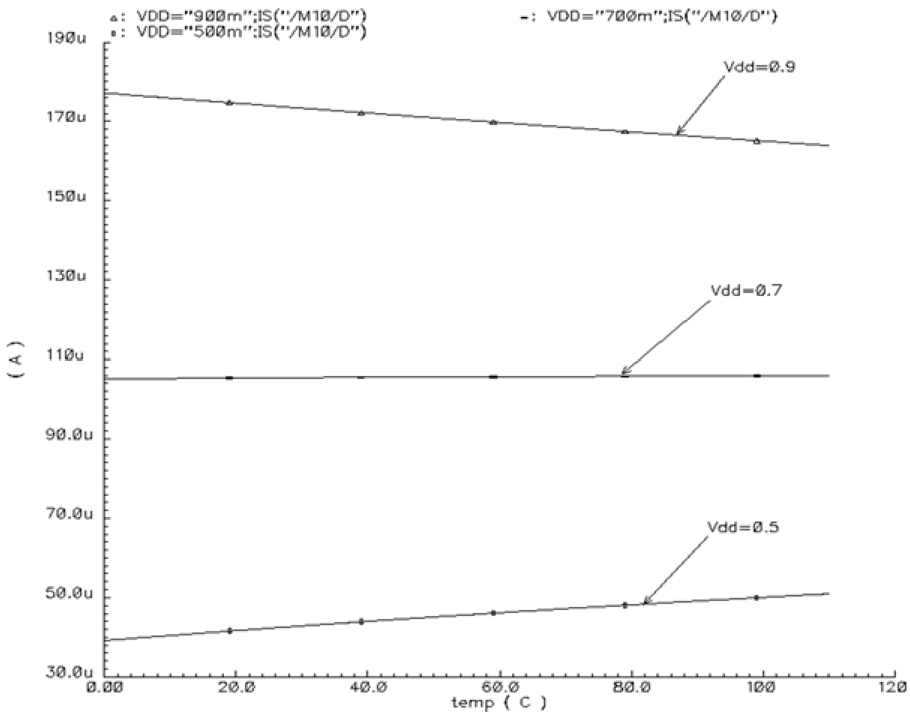
When a transistor is turned off, the drain current I_{OFF} is essentially the subthreshold current or leakage current, which can be expressed as:

$$I_{OFF} \propto \mu(T)\exp\frac{V_{GS} - V_{TH}(T)}{nV_t}\left(1 - \exp\left(-\frac{V_{DS}}{V_t}\right)\right) \quad (13)$$

Here n called the subthreshold slope coefficient and V_t=kT/q is the thermal voltage (which is about 26mV at room temperature). Equation (13) shows that I_{OFF} has an exponential dependence on V_t, so I_{OFF} increases exponentially as temperature increases.

Therefore, the effect of temperature variations on I_{OFF} is more significant than its effect on I_{ON}. This leads to a wide range of I_{ON} to I_{OFF} ratio values across the specified temperature range. The I_{ON} to I_{OFF} ratio characterizes the difference between the 'ON' state and the 'OFF' state, thus this value directly affects the robustness of a circuit (for example, a large I_{ON} to I_{OFF} ratio leads to a large noise margin, and a small I_{ON} to I_{OFF} ratio means more susceptibility to power noises and soft errors). This difference

Figure 2. Temperature dependence of I_{ON} with different supply voltages (Zhang & Stan, 2007 ©2007, ACM, Inc. Used with permission)



must be kept greater than a certain minimum, and the system must be designed to operate at the worst case I_{ON} to I_{OFF} ratio (which in turn implicates the upper bound of the operating temperature range). In a worst case-based design, the circuit will have to be over-designed to accommodate for the worst case. The over-designed circuit will not only incur power and area overhead, but also operate at non-optimal points whenever and wherever the temperature is lower than the upper-bound temperature. For this reason, we adapt the aforementioned threshold compensation scheme to dynamically track the on chip temperature variations and reduce the I_{ON} to I_{OFF} ratio variations across a wide temperature range.

Temperature-Aware Adaptive-Biasing Technique

In order to keep the ratio of I_{ON} to I_{OFF} constant across the temperature range, we can apply the threshold compensation scheme. Recall from Equation (5), positive bias voltage (or forward body bias) decreases the V_{TH} while negative bias voltage (or reverse body bias) increases V_{TH}. The key of the design is to adaptively bias the body voltage so that it tracks the circuit temperature thus produce a relatively constant I_{ON} to I_{OFF} ratio. There are two points we need to consider in the circuit implementation of the general compensation scheme.

First, as we have seen from the analysis in the last section, the temperature variations affect both I_{ON} and I_{OFF}, and their dependence on temperature is quite different. Therefore, here it is not enough to simply design the I_A from upper part of the circuit to follow a constant current I_B in the lower part, as shown in Figure 1. Instead, both I_A and I_B are changing with temperature and at different rates, and we need to design for the I_A to I_B ratio (or effectively, I_{ON} to I_{OFF} ratio). Therefore, we need to carefully design the parameters for both the upper and lower portions of the circuit to obtain a dynamic balance of the two, and produce appropriate output body bias voltages to achieve the temperature compensation for the I_{ON} to I_{OFF} ratio.

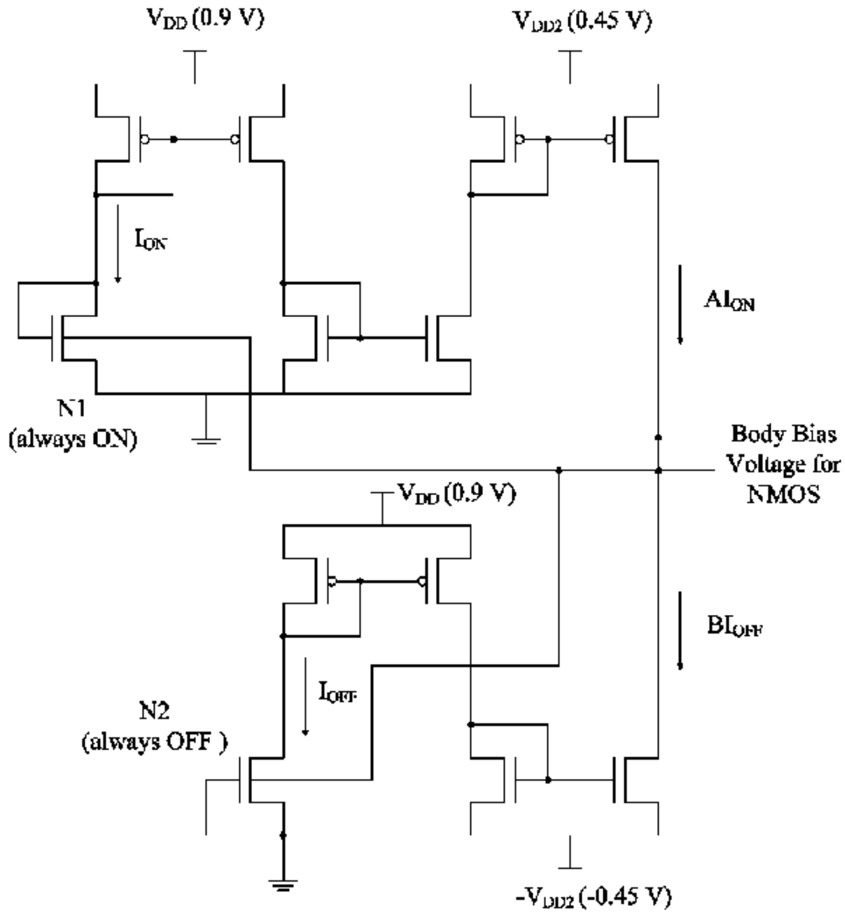
Second, the most common CMOS (Complementary MOS) based digital circuits have a pull up network comprised of solely PMOS transistors and a pull down network comprised of solely NMOS transistors. The strength of the pull up network affects the rising edge of the output signal, while the pull down network affects the falling edge of the output signal. To reduce the temperature variation induced slew rate changes, both pull up and pull down network need adaptive body biasing to reduce their current change due to the temperature variations. Since NMOS and PMOS transistors have different body bias voltages (the body of NMOS transistor is usually close to '0' or ground, while the body of PMOS transistor is usually close to '1' or power supply voltage), we need to design two sets of body bias circuits to supply different body bias voltages to both transistor types to adjust their drain currents separately.

Figure 3 shows the adaptive body biasing circuit implementation for NMOS transistor temperature compensation. To understand the circuit, we can first view it in two parts, i.e., the upper and lower branches. These two parts monitor *ION* and *IOFF* respectively. In the upper part, N_1 is ON (since its gate is connected to drain) and thus its current is a proxy for I_{ON}. In the lower part, NMOS transistor N_2 is OFF (since its gate is connected to the source) and thus its current is a proxy for I_{OFF}. Then for each part, current mirrors are sized with fixed gains *A* and *B* to separately amplify the *ION* and *IOFF* currents. At the final output the circuit is in equilibrium when $A \times I_{ON} = B \times I_{OFF}$ (again, *A* and *B* are the gains for the ON and OFF branches). The circuit is designed such that when the temperature equals a certain value, the output voltage in the equilibrium state is close to zero, thus the circuit does not provide any bias voltage to the NMOS transistors in the system at this temperature. Then, when the temperature changes due to various reasons including ambient environmental change or on chip power dissipation, the circuit will output a non-zero bias voltage to balance the *ION* and *IOFF* currents and reduce the temperature sensitivity of I_{ON} to I_{OFF} ratio. In this work this zero biasing temperature is set at the middle point of the specified temperature range, but it could also be set to other values, e.g. to the expected working temperature.

To see how the temperature sensitivity can be reduced, first consider the case when the temperature becomes lower than the zero biasing temperature. Since I_{OFF} decreases much faster than I_{ON}, this leads to an imbalance of $A \times I_{ON} > B \times I_{OFF}$. This imbalance will move the output voltage to be more positive, thus providing a positive bias or forward body bias voltage for NMOS. The forward bias in turn reduces *VTH* and increases I_{OFF} to bring the circuit back to equilibrium. On the other hand, if the temperature is larger than the zero biasing temperature, the faster increase in I_{OFF} leads to an imbalance $A \times ION < B \times I_{OFF}$, which results in a negative output (or reverse body bias for NMOS) which increases *VTH* and decreases I_{OFF} to bring the circuit back to equilibrium.

We note that the threshold compensation circuit requires two additional supply voltages (+0.45V and -0.45V in the implementation shown in Figure 3, but may vary depending on technology and design parameters) to generate the output bias voltage, which would be implemented either through external power pads or internal charge pumps. Moreoever, the value of the output voltage can be used as an indication of the temperature. In other words, each value of V_{OUT} corresponds to a certain temperature value, so with a look up table this circuit can also acts as an on-chip temperature sensor. Finally, implementing the threshold compensation for the PMOS transistor to reduce the temperature sensitivity of its I_{ON} to I_{OFF} ratio is very similar (mirror) to the NMOS one.

Figure 3. Threshold compensation circuit for NMOS to reduce temperature sensitvity of I_{ON} to I_{OFF} ratio (Adatepd from Zhang & Stan, 2007)

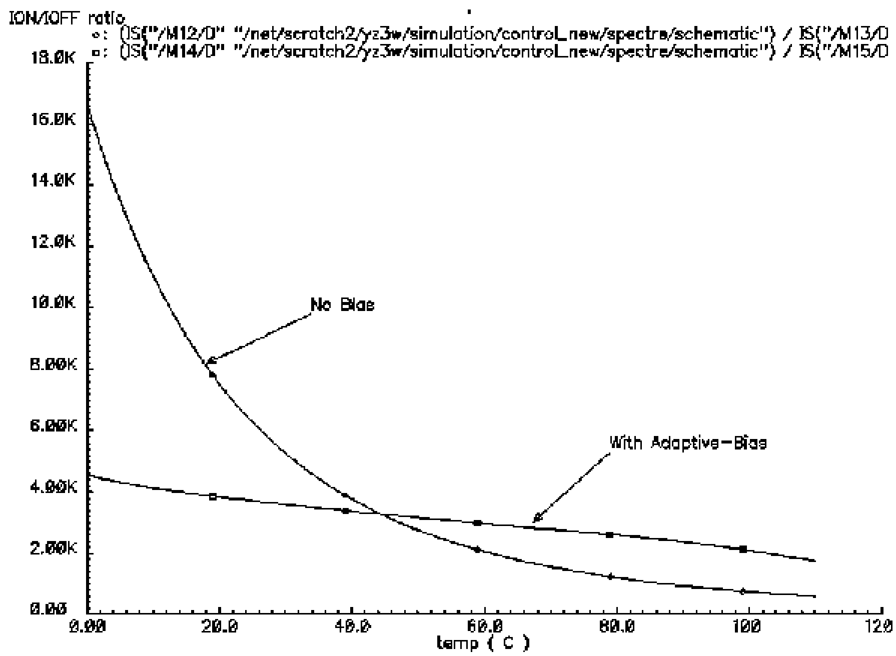


Temperature Sensitivity Reduction of I_{ON} to I_{OFF} Ratio

The threshold compensation circuit shown in Figure 3 has been designed in the openly downloadable 70nm Predictive Technology (PTM) (Zhao & Cao, 2006) with the nominal supply voltage of 0.9V. All the simulations in the following sections are also performed with this technology. The output biasing voltage varies from 320mV to –280mV across the temperature range (0 to 110°C). The zero point is set in the middle of the operation temperature range (55°C). We also run Monte Carlo simulations to see the impact of parameter variations. The result shows ~10% standard deviations at high bound and low bound range of output bias voltage.

Figure 4 shows the I_{ON} to I_{OFF} ratios for a single NMOS with and without threshold compensation. The ratio varies from 16600 to 500 without biasing when the temperature varies from 0°C to 110°C. As can be seen, at low temperatures *IOFF* is reduced significantly and circuits operate at a larger *ION/IOFF* ratio than necessary. This leads to sub-optimal performance. By applying forward body biasing to reduce the threshold voltage, the *ION/IOFF* ratio can be brought back to the nominal value. As can be seen from Figure 4, with the proposed compensation scheme the ratio is kept within a much narrower range and only

Figure 4. ION/IOFF ratio for a NMOS transistor with and without threshold compensation



varies from 4500 to 1800. Also, due to the smaller threshold voltage at low temperature, the circuits operate at higher speed. Therefore, in this case the performance can actually be improved with a scheme like Dynamic Voltage and Frequency Scaling (DVFS), which takes advantage of higher circuit speed to reduce computation time with equal or less energy consumption for a given task.

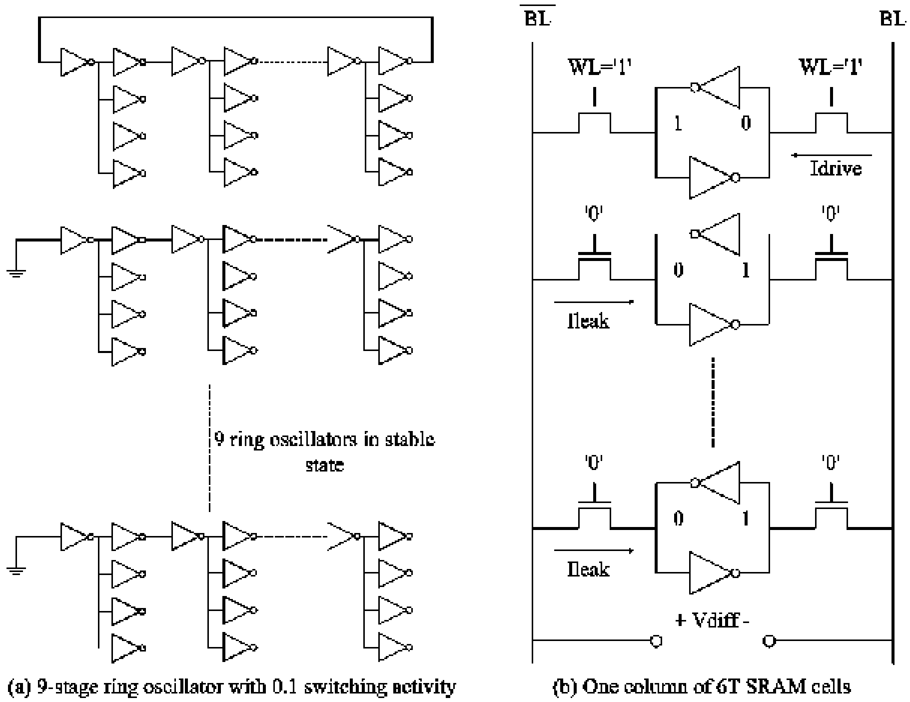
Temperature Compensation for Combinational Circuitry

We first apply the compensation scheme for logic circuitry. A circuit that represents a generic logic circuit is shown in Figure 5(a). The first block in the test circuit is a nine-stage, Fan-Out of 4 (FO4) ring oscillator. Then other nine identical inverter chains are constructed and put in a static state. Together they form a system with an equivalent switching activity factor of 0.1. Since at different supply voltages I_{ON} has a different temperature dependence, two sets of simulations are run at V_{DD}=0.9V (negative dependence) and V_{DD}=0.5V (positive dependence).

The simulation results are shown in Figure 6. There are two other baseline settings in our simulation. "NO BIAS 1" represents test circuit without threshold compensation. "NO BIAS 2" represents a test circuit without threshold compensation but still achieving the same worst-case I_{ON}/I_{OFF} ratio at 110°C (in order to do this we have to increase default threshold voltage to match the actual threshold voltage with threshold compensation at 110°C). Finally, "TAC-ABB" represents the temperature aware circuit with adaptive body biasing circuitry for threshold compensation.

Figure 6a shows the comparison of I_{ON}/I_{OFF} ratio between the three settings for different supply voltages. Here I_{ON} current is the average drain current in the ON state and I_{OFF} the average leakage current in the OFF state. With threshold compensation, the ratio has much less temperature sensitivity and remains almost constant across the temperature range for both supply voltages. Furthermore, "NO BIAS 1" has lower worst-case $I_{ON}/$

Figure 5. Two tests circuit for temperature variability compensation: (a) represents a combinational circuit and (b) represents a memory circuit (figures from Zhang & Stan, 2007)

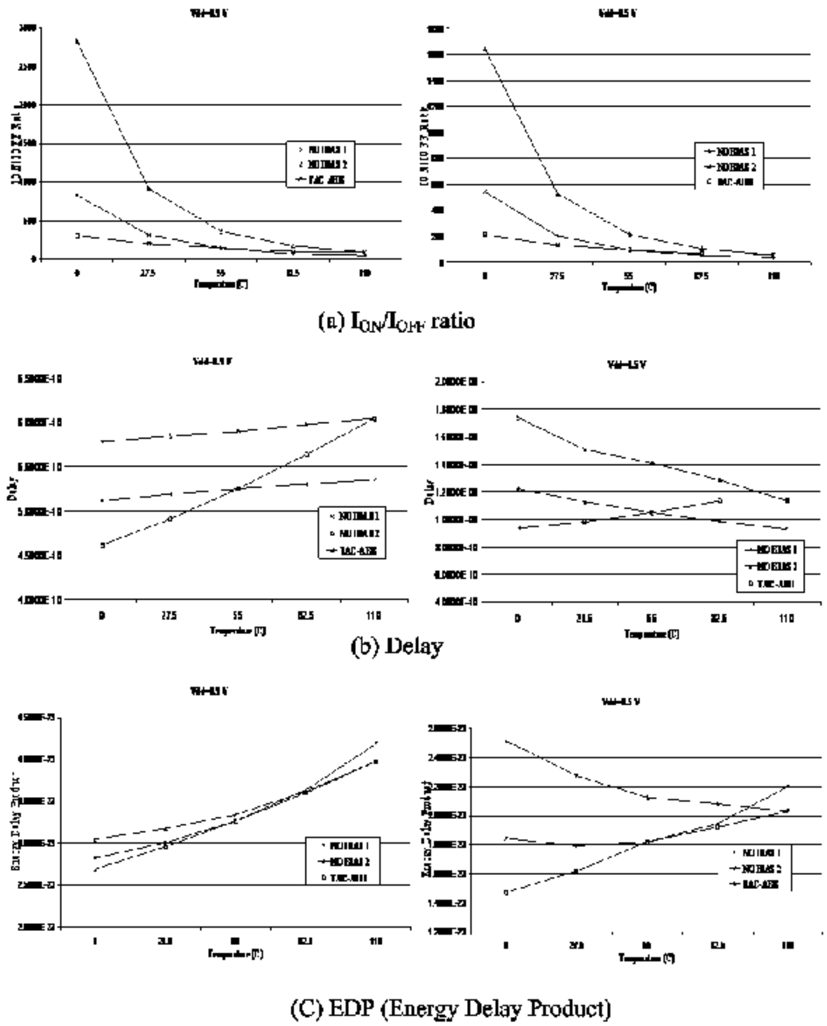


I_{OFF} ratio compared to other two settings. "NO BIAS 2" has the same worst-case I_{ON}/I_{OFF} ratio as the "TAC-ABB" but the ratio at lower temperatures is significantly higher than the other two settings.

Figure 6b shows the comparison of delay between three settings for different supply voltages. At low temperatures, the system with threshold compensation operates at a higher frequency and lower delay thus offering a higher performance compared with both "NO BIAS 1" and "NO BIAS 2." At high temperatures, the worst case-based "NO BIAS 2" design offers the same I_{ON}/I_{OFF} ratio. However, this comes at the expense of longer delay at other temperatures since it has higher V_{TH} value than the other designs. For non-temperature-aware designs like "NO BIAS 1," the leakage current increases drastically, which can cause reduced noise margins, potential thermal hazards and increased leakage power. With the proposed threshold compensation scheme, the system operates at a lower frequency at high temperatures to retain the system's reliability and stability. By operating at lower speed, the circuit also generates less power, which can help cool down the system. Moreover, with reverse bias, the NMOS transistors have higher V_{TH}, which further cuts down the leakage power. Therefore, the threshold compensation scheme can indeed help reliable and green computing.

On the other hand, the right hand side of Figure 6b shows that for lower values (here V_{DD}=0.5 V), the circuit speed could have a positive temperature dependence, i.e., the circuit becomes faster at higher temperature. This reverse temperature dependence usually happens for low power supply voltages (Park, et al., 1995). This phenomenon can lead to a positive feedback, in which the circuit runs faster at higher temperatures, and generates more power to further increase the temperature. This positive feedback loop may cause serious reliability problem. Again, the dynamic threshold

Figure 6. Comparing I_{ON}/I_{OFF} ratio, delay and energy delay product in three scenarios across the temperature range 0 °C - 110 °C. Each coomparison is done for both (figure from Zhang & Stan, 2007).



compensation technique can throttle this mechanism to prevent potential thermal runaway.

Figure 6c shows the comparison of Energy Delay Product (EDP) between the three settings for different supply voltages. Overall EDP is improved with the threshold voltage for both high and low supply voltages. Compared to "NO BIAS 1," about 5% improvement is achieved at both 0°C and 110°C when V_{DD} = 0.9V; about 20% and 8% improvements are achieved at 0°C and 110°C respectively when V_{DD}=0.5. Compared with "NO BIAS 2" which by design has the same V_{TH} as the threshold compensation circuit, even larger improvements are achieved across all the temperature values. At 0°C EDP is reduced by 11.6% and 41.5% for V_{DD} =0.9V and 0.5V, respectively.

From the above simulation results, it can be observed that by reducing the temperature sensitivity of I_{ON}/I_{OFF} ratio, the threshold compensation scheme offers high performance and reliability. The scheme also achieves a smaller energy-delay product, which means that for the same task, it can reduce the energy without posing a penalty on performance. This is achieved by dynamically tracking the temperature and exploiting higher performance at low temperatures and reducing leakage power at high temperatures. When reverse temperature dependence happens, the same circuit can also throttle the system to prevent potential thermal runaway and unreliable conditions. In summary, the threshold compensation circuit helps the system remain in the optimal and most energy efficient condition.

Threshold Compensation for Memory Circuitry

Due to the large capacity and low switching activity, leakage is a much more critical metric in memory design than in combinational circuit design. However, leakage is important not only because it determines the static power consumption, but it can also affect SRAM stability. In this section, we show how the threshold compensation scheme also helps memory circuits. We implemented a 64-row × 32-column, standard 6T (six-transistor) SRAM array in the 70nm PTM model with 0.9 V supply voltage as an example. Figure 5b shows one column of the SRAM memory.

Assume the top cell which stores a "0" is being read. After both bit lines BL and $\overline{BL}$ are pre-charged to "1," the top access transistors are selected. BL is discharged while $\overline{BL}$ keeps its pre-charged value. After some time a certain amount of differential voltage (100mV in this example) is built up between the two bit lines and the sense amplifier for this column is activated to poll the stored value. Notice that the above description does not consider the influence of other cells in this column which all share the same bit lines. In the worst case, a "0" is stored in the top cell while all other cells are storing "1," therefore the leakage current from these cells results in a voltage drop on $\overline{BL}$. This voltage drop not only deteriorates the access time (thus memory performance) but also has an impact on the cell stability and noise margin.

At high temperatures, the leakage current *IOFF* increases faster than *ION*, thus by reverse body biasing and increasing *VTH*, *IOFF* can be reduced, thereby decreasing access time and increasing noise margin. At low temperatures, *IOFF* decreases quickly and the read current (*ION*) becomes the dominant factor of the read speed. Forward body biasing can reduce V_{TH}, increase *ION* and reduce the access time. Therefore threshold compensation can improve SRAM performance across whole temperature range. Notice that this is different from the combinational circuit case, where reverse body bias increases delay and throttles circuit speed.

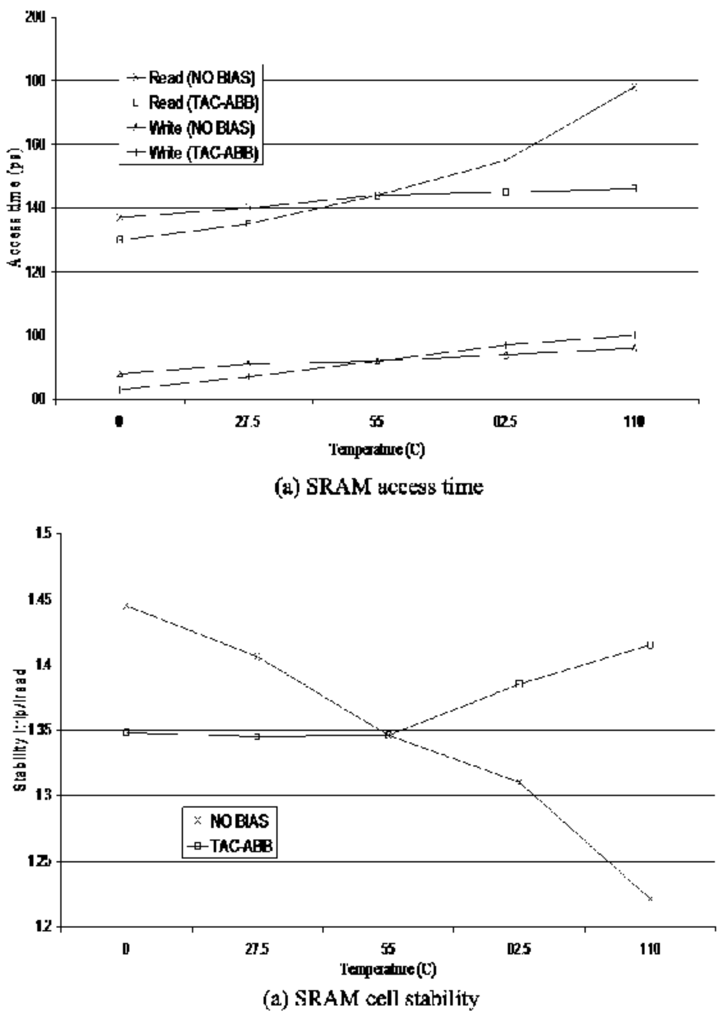
Figure 7a shows the performance comparison for SRAM. By applying threshold compensation, 5.1% and 18% read time improvement are achieved at low and high temperatures respectively. Write time increases slightly at high temperatures, but write is not a critical operation for memory access since it has a large noise margin, so this penalty is usually acceptable.

We use the method proposed in Hamzaoglu, et al. (2002) to measure the 6T SRAM cell stability. Figure 7(b) shows the stability comparison. At high temperature with threshold compensation, the SRAM cell stability is improved by 15.8% and worst-case cell stability is improved by 10%. This comes with a penalty of less stability at low temperatures. However, this penalty can be easily justified since most reliability problems happen in high temperatures. This increasing stability with rising of the temperature is especially suitable for high performance applications, which usually suffer from degraded performance and stability in elevated temperatures.

THRESHOLD COMPENSATION FOR NBTI

The previous examples have demonstrated how the threshold compensation circuits can be used to improve circuit performance, energy efficiency

Figure 7. Improvement of both performance and stability for SRAM cells by threshold compensation (figure from Zhang & Stan, 2007)



and thermal reliability by reducing temperature variability for both combinational and memory circuits. In this section, we show another area where the threshold compensation scheme can find applications.

The Circuit Also Ages

Even as it continues unabated, technology scaling hardly comes for free any more. Reliability has become a major concern and poses hefty penalties on future scaling (Borkar, 2005). Reliability is usually measured by MTTF (Mean Time to Failure), or failure rate (Hennessy & Patterson, 2003). However, different reliability hazards impact circuits in very different ways and need different ways of handling. For example, soft errors (also called single event upsets or SEU) occur almost purely randomly and cause random transient failures. Aging mechanisms like NBTI (Negative Bias Temperature Instability), HCI (Hot Carrier Injection), EM (Electro-Migration), TDDB (Time Dependent Dielectric Breakdown), and thermal cycling are more tractable, as they usually appear as a result of a certain amount of circuit functioning, and ultimately limit the system lifetime. Interestingly some aging effects are reversible. For instance, 'healing effects' exist for both NBTI (Bhardwaj, Wang, Vattikonda, Cao, & Vrudhula, 2006) and EM (Blaauw, Oh, Zolotov, & Dasgupta, 2003).

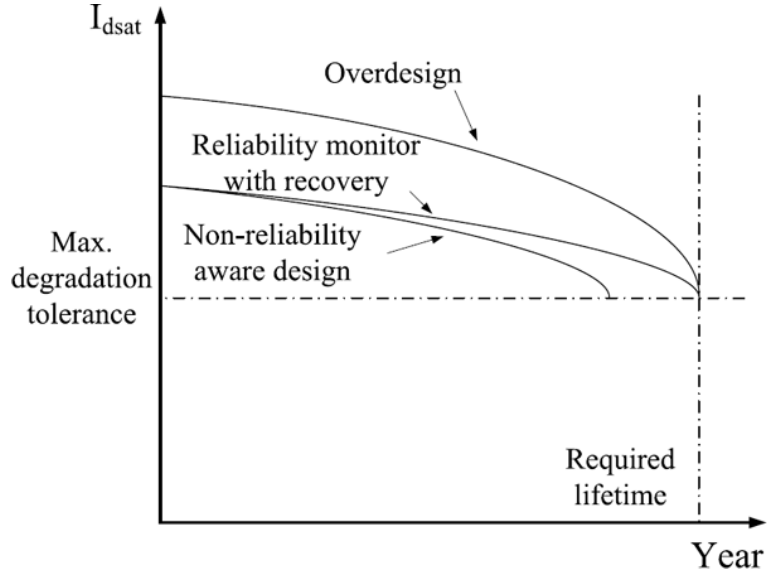
At the system level, reliability-aware design schemes, including Dynamic Reliability Management (DRM) and reliability banking, have been proposed (Karl, Blaauw, Sylvester, & Mudge, 2006; Lu, Lach, Stan, & Skadron, 2005). In a general sense, Dynamic Thermal Management (DTM) is also a reliability aware design method that targets temperature cycling (thermal shock). At the circuit level, redundancy based designs like TMR (Triple Modular Redundancy) and Razor (Ernst, et al., 2005) were introduced to prevent local circuit failures from propagating in the system. 'Circuit hardening' (Zhou & Mohanram, 2006), among other techniques that provide extra margin by overdesigning, is often adopted as well. Redundancy and overdesigning are general methods to deal with most reliability problems, but they could also lead to large area and power overhead by duplicating, triplicating, or upsizing transistors by a significant portion. Accurate reliability models and time consuming reliability simulations, which are not commonly found in current design kits and design tools, may also be needed. In addition, it can be difficult to calculate the required margin for desired lifetime if the realistic input signal pattern is unknown, since the switching activity directly decides the amount of NBTI stress for each PMOS.

It has been suggested that online monitoring with in-situ sensors might be more effective in dealing with reliability problems (Mishra, Pecht, & Goodman, 2002; Mitra, 2007). The idea is to track circuit degradation in real time and issue advance 'warnings' before the system starts to malfunction. A warning indicates either maintenance ('healing,' if possible) or replacement is required. Figure 8 compares the different impact of in-situ sensors and overdesigning on circuit lifetime. In contrast to the above worst-case design with excessive margins, reliability monitors enable typical-case designs. In this chapter, we propose a reliability monitor for NBTI that not only tracks the degradation online, but also *adaptively* heals the degradation and prevents it from harming normal system functioning. In advanced technologies with thin gate oxide, NBTI is predicted to dominate other reliability mechanisms like HCI in system lifetime (Bhardwaj, Wang, Vattikonda, Cao, & Vrudhula, 2006). Although the monitor here is designed specifically for NBTI, it could also be adapted for other reliability hazards as long as they can be monitored or mitigated through transistor threshold voltage, e.g. HCI and thermal hazards.

NBTI Modeling

NBTI becomes a major concern in modern CMOS technologies with thin gate oxide due to its exponential dependence on oxide thickness and temperature (Chen, et al., 2003). NBTI stress occurs in PMOS transistors with negative gate to source voltages, which is often the case in CMOS circuits where PMOS serves as the header device. The most notable aging effect from NBTI is the increase in absolute value of the threshold voltage V_{TH} for PMOS, which contributes to decreased transconductance and weaker driving capability. Although similar mechanisms exist for NMOS, i.e., PBTI (Positive Body Bias Temperature Instability), NBTI imposes a much shorter lifetime compared to PBTI and other major reliability concerns, and has becomes a very active research topic recently (Bhardwaj, Wang, Vattikonda, Cao, & Vrudhula, 2006; Kang, Kim, Islam, Alam, & Roy, 2007; Kang, Kufluoglu, Alam, & Roy, 2007; Paul, Kang, Kufluoglu, Alam, & Roy, 2006; Vattikonda, Wang, & Cao, 2006; Wang, et al., 2007). While this phenomenon has been known for more than 40 years in the device area, the underlying physics is still being studied under various circuit operating conditions (Massey, 2004), and can be

Figure 8. Circuit performance degradation comparison with different reliability aware designs (Qi & Stan, 2008 ©2008, ACM, Inc. Used with permission.)



more complicated when coupled with process variation (Agostinelli, et al., 2005).

Nonetheless, it is well understood that NBTI stress and recovery phases involve the diffusion and back-diffusion of H and H_2 in the oxide, the Poly-Si and Si. The following equations are from the newest NBTI model from PTM (Zhao & Cao, 2006), also explained in Bhardwaj, Wang, Vattikonda, Cao, and Vrudhula (2006):

$$\Delta V_{th} = \begin{cases} \sqrt{K_v^2 (t-t_0)^{0.5} + \Delta V_{th1}^2} + \delta_v & \text{(stress)} \\ (\Delta \mathrm{V}_{th2} - \delta_v)\left[1 - \sqrt{\eta (t-t_0)/t}\right] & \text{(recovery)} \end{cases} \tag{14}$$

where:

$$K_v = A\,T_{ox}\sqrt{C_{ox}(V_{gs}-V_{th})}\exp\left(\frac{E_{ox}}{E_0}\right) \left[1 - \frac{V_{ds}}{\alpha(V_{gs}-V_{th})}\right]\exp\left(-\frac{E_{ox}}{E_0}\right)$$

and:

$$E_{ox} = (V_{gs} - V_{th}) / T_{ox} \tag{15}$$

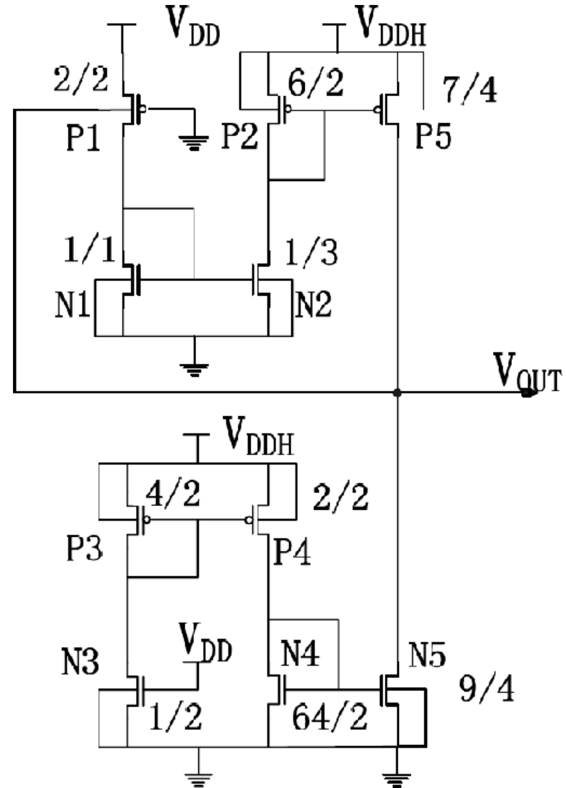
Default values for different PTM technology nodes can be found on the PTM website (PTM Technology). In the above model ΔV_{TH} is proportional to $t^{1/4}$, where t denotes time. Depending on whether H or H_2 dominates the diffusion, the dependence of ΔV_{TH} and t could vary from $t^{1/4}$ to $t^{1/6}$ in Bhardwaj, Wang, Vattikonda, Cao, and Vrudhula (2006), Kang, Kufluoglu, Alam, and Roy (2007), and Kumar, Kim, and Sapatnekar (2006).

Body Bias Circuit

Figure 9 shows the proposed threshold compensation scheme adapted for NBTI monitoring and mitigation. This circuit shares many similarities with the one used for reducing temperature variability shown in Figure 3. The circuit also can also be divided into an upper part and a lower part. In the upper part, transistor $P1$ is acting as a proxy for PMOS transistors experiencing NBTI stress. Transistors *N*1 and *N*2 serve as a current mirror which track the drain current of *P*1 and also provides some current gain. Similarly, *P*2 and *P*5 form the second current mirror that further tracks and amplifies the drain current. The lower part of the circuit also consists of current mirror circuits, except that now the current in the first stage is determined by the NMOS transistor *N*3, whose gate is constantly tied to V_{DD} and is always on. After two stages of current amplification through current mirror pairs *P*3/*P*4 and *N*4/*N*5, the amplified drain current of *N*3 eventually becomes the drain current of *N*5. Since the drain currents of *N*5 and *P*5 have to be the same, this balance will decide the output voltage V_{OUT}, which is then used to body-bias PMOS transistors of the actual circuit. The output is also fed back to *P*1 to form a closed loop amplifier. Similar as the circuit used for temperature variability, the magnitude of the biasing voltage can also be used as a metric to characterize the NBTI stress amount and the circuit can act as an on chip NBTI monitor.

However, there are some important differences between the design for NBTI in Figure 9 and the design for temperature variability in Figure 3. First, the gate of transistor *P*1 is tied to ground so V_{GS} = - V_{DD} for *P*1 all the time. V_{DD} is a voltage equal to the power supply voltage in the actual circuit to be monitored. Since each PMOS transistor will have its own switching activity, and most of them usually have some periods of stress relaxation when the input gate voltage turns high and shuts off the PMOS, this connection makes *P*1 subjected to the most severe NBTI stress compared to PMOS transistors in the actual circuit. The introduced pessimistic assumption can be dealt with at the circuit level, as will be discussed later. This is different from the case of temperature variability, where temperatures of transistors in the same area are usually quite close, and the proxy transistor could either see a higher or lower temperature than the actual circuit it is monitoring.

Figure 9. Threshold compensation circuit for monitoring and mitigating NBTI. Sizing is shown for PTM 65nm technology with V_{DD} =1V. Feature size (65nm) is taken as unit length (Qi & Stan, 2008 ©2008, ACM, Inc. Used with permission.).



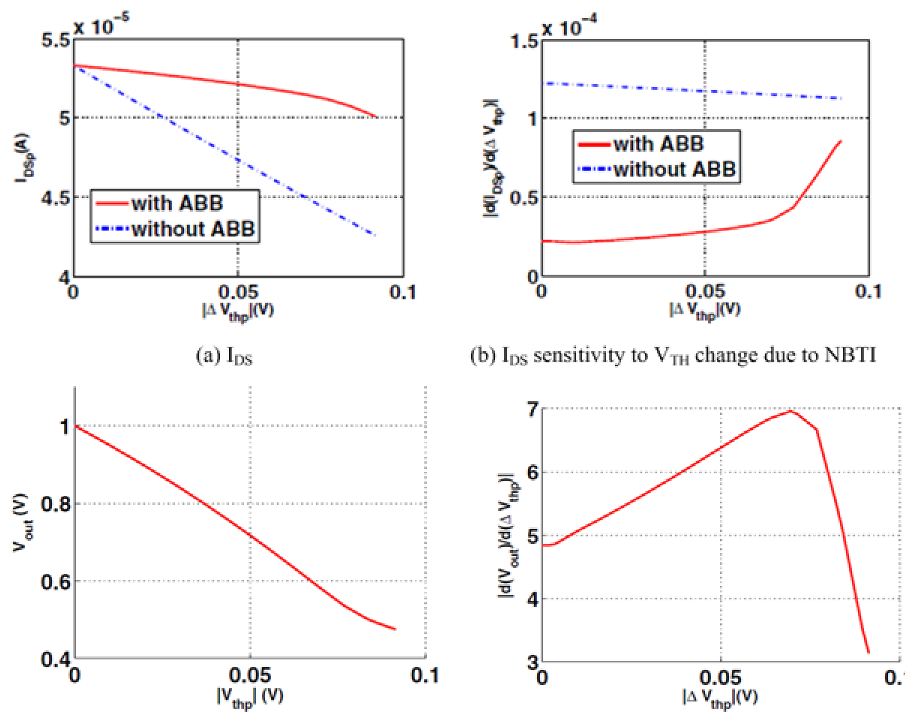
Second, there is only one power supply V_{DDH} in the last stage. In the temperature variability case, both positive and negative voltage supplies are needed since the starting point is at the middle and temperature can both rise and fall. On the other hand NBTI degradation only moves PMOS threshold voltage more negative. Therefore, only forward body biasing will be applied to mitigate this change. Since V_{OUT} should equal V_{DD} when no NBTI stress is applied, V_{DDH} needs to be higher than V_{DD} to provide full swing to the output body bias voltage. While this may pose extra design challenges and potential reliability problems, multi- V_{DD} design is not new in today's IC design flows and is well supported by CAD tools. Furthermore, body biasing (both forward and backward) has been adopted as a standard method to systematically reduce the impact of process variation (Tschanz, et al., 2002), which also implies that voltages higher than V_{DD} can be made available.

Finally, it is worth mentioning that at least on the first order ΔV_{TH} is independent of transistor sizing, as can be seen from Equation (14). On the other hand, the drain voltage will affect NBTI degradation. For PMOS stacks in the pull-up network in CMOS gates, the degradation of each PMOS gate can be different. However, the V_{DS} impact on ΔV_{TH} is rather insignificant, and stacks of PMOS gates are not recommended anyhow due to the slow speed.

Experimental Results

Just as in the temperature-aware design, we start from a simple test case. We first examine the drive current I_{DS} of two PMOS transistors to see how device degradation due to NBTI can be mitigated with the proposed scheme. The following simulation results are obtained with PTM 65nm models, $1V\ V_{DD}$ and $2V\ V_{DDH}$. The NBTI monitor circuit is sized as shown in Figure 9. Figure 10(a) shows how the I_{DS} of each transistor decreases as $|V_{TH}|$ increases. Here we assume that NBTI imposes exactly the same V_{TH} degradation on all PMOS. The reduced I_{DS} amounts to a larger time constant, weaker driving capability and longer charging time, which can eat-up timing margins and eventually lead to timing violations. Although typically NBTI lifetime can be mapped to ΔV_{TH}, what we would like to find out is how lifetime is extended by the reliability monitor. Therefore, we take a 5% I_{DS} reduction as the cut-off point for lifetime estimation and the ΔV_{TH} shown in all the figures does not take body biasing into account in order to isolate ΔV_{TH} caused by NBTI. This is

Figure 10. Current and output voltage change with threshold voltage drift, as well as their sensitivity to threshold voltage drift (Qi & Stan, 2008 ©2008, ACM, Inc. Used with permission.).



(a) I_{DS} (b) I_{DS} sensitivity to V_{TH} change due to NBTI

(c) V_{OUT} (d) V_{TH} sensitivity to V_{TH} change due to NBTI achieved by modifying parameters in the PTM model file during simulation.

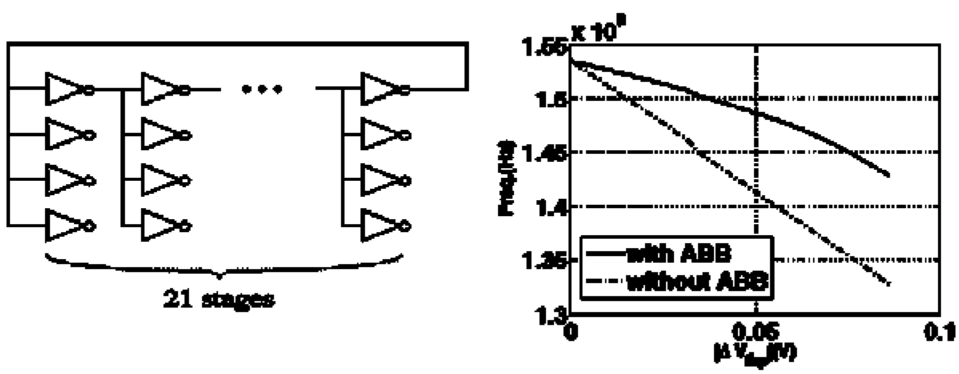
From Figure 10b, it can seen that with ABB, I_{DS} reduction in $P2$ is much slower than $P1$, which means P2 tolerates more NBTI stress and has longer lifetime. Indeed, the 5% ΔI_{DS} for $P2$ is reached when V_{TH} degrades almost 100mV from the unstressed value. In contrast I_{DS} in $P1$ drops 5% as soon as V_{TH} changes by only 25mV. Figure 10b compares the sensitivities of I_{DS} in both transistors. It can be seen that body biasing essentially reduces the sensitivity, especially in the range where the maximum reliability tolerance is not violated and the device is supposed to meet the performance requirement set by timing analysis.

Referring to the NBTI model from earlier sections, ΔV_{TH} depends on $t^{1/n}$ where n varies from 1/4 to 1/6. With the reliability monitor, the tolerance of ΔV_{TH} increases four times from 25mv to 100mv, which in turn is equivalent to a prolonged device lifetime 256 to 1296 times the original depending the effective n value in the NBTI model. However, notice that the above values are *not* representative of the actual circuit lifetime due to the assumed constant static stress. The above analysis is for static stress with no recovery phase during the whole lifetime. In practice very rarely will a PMOS gate be tied constantly to ground, which is the worst-case scenario. Moreover, device lifetime is also limited by temperature and other reliability hazards. Nonetheless, the improvement in lifetime demonstrates the effectiveness of the proposed NBTI monitor.

Figure 10c and 10d show the output voltage and the small signal gain of V_{OUT} to V_{TH}. The circuit is sized such that this gain is maximized within the lifetime requirement. This is an important guideline for this design. Another constraint is that the PMOS body bias voltage must equal V_{DD} at the beginning when any NBTI stress is applied, as it would be if the monitor did not exist. For different technologies, the circuit in Figure 9 needs to be resized accordingly to these requirements.

To show the effectiveness of the NBTI compensation for general circuits, we again resort to the ring oscillator structure. This time we use a twenty-one stage FO4 ring oscillator designed in PTM 65nm technology. Again, with the assumption that all PMOS transistors have the same NBTI stress and thus the same ΔV_{TH}, we monitor the frequency degradation. As shown in Figure 11, with the NBTI monitor, the circuit can tolerate almost twice ΔV_{TH}. However, in this case the lifetime cannot be simply translated from $t^{1/4}$ or $t^{1/6}$, since this is dynamic NBTI stress with relaxation and 'healing' within every clock period.

Figure 11. Threshold compensation slows down the frequency degradation of a 21 stage oscillator as PMOS threshold voltage being degraded by NBTI (Qi & Stan, 2008 ©2008, ACM, Inc. Used with permission.).



Actual energy savings from employing the proposed scheme relate to a number of factors, including the system specification, usage model, circuit-switching activity, operating environment, deployment of the proposed circuit, and the alternative approach when the proposed scheme is not adopted, etc. To make our analysis more straightforward, we still resort to the simple but representative ring oscillator in Figure 11. With a specification that states that the frequency cannot fall below 900MHz, this results in about 5% guardband, which translates to 0.08V threshold degradation. Without the proposed scheme, at 0.08V threshold degradation the circuit would be operating at 830MHz, thus violating the specification. Ignoring all second order factors, the maximum frequency is inversely proportional to the lesser of the charging and discharging cycles of the circuit. Since NBTI only affects PMOS, the charging cycle becomes the limiting factor. The charging cycle is proportional to the maximum of the current that a PMOS can supply. Therefore:

$$f \propto \frac{1}{t_{charging}} \propto I_{PMOS} \propto W_{PMOS} \qquad (16)$$

It is immediately clear that in order to maintain 900MHz when NBTI degrades the V_{TH} by 0.08V, one needs to add an up-front guarband of (900-830)/830 = 8.4% on the PMOS width, which translates to 8.4% extra energy consumption and area overhead.

Notice that the above is an over-simplistic first order estimation. First, overdesign doesn't need to be applied on every path. However, one cannot overdesign only the critical paths either. Identifying which paths to overdesign is a big challenge and requires extensive low-level circuit simulation based on accurate models from device-level to system-level (Saluja, Vijayakumar, Sootkaneung, & Yang, 2008). Second, the actual energy savings will be offset a little by the energy consumption of the threshold compensation circuit itself. The overhead incurred by the proposed circuit is largely affected by its deployment, which is discussed in the next section.

It should also be emphasized that the benefits of the proposed scheme go far beyond the immediate energy saving from the above guardband reduction. In fact, the more implicit energy savings can actually be more significant. By tolerating more aging degradation, the circuit improves the efficiency of analog circuits which often rely on precise matching and voltage biasing. It also improves noise characteristics and soft error immunity in memory systems. In contrast, without adaptive threshold compensation and merely adding guardband disrupts the normal design. For example, upsized PMOS transistors form a stronger pull-up network than the pull-down network, thus reducing noise margins. With the adaptive compensation scheme, the reduction of excessive noise and probability of failure lead to potential energy savings which would otherwise be incurred from engaging error correction systems or replacing failure part. For example, in a recent paper (Mostafa, et al., 2011) which proposes an alternative body bias scheme, our circuit is shown to improve write margins by 4.6%, and reduces the read and write failure probablity by 0.28% and 0.14% respectively for standard 6T SRAM banks. In fact the proposed circuit is also shown to be 1.2X smaller in area, and leads to 5.5% less leakage power than the ABB circuit proposed in Mostafa, et al. (2011).

DEPLOYMENT OF PROPOSED CIRCUIT

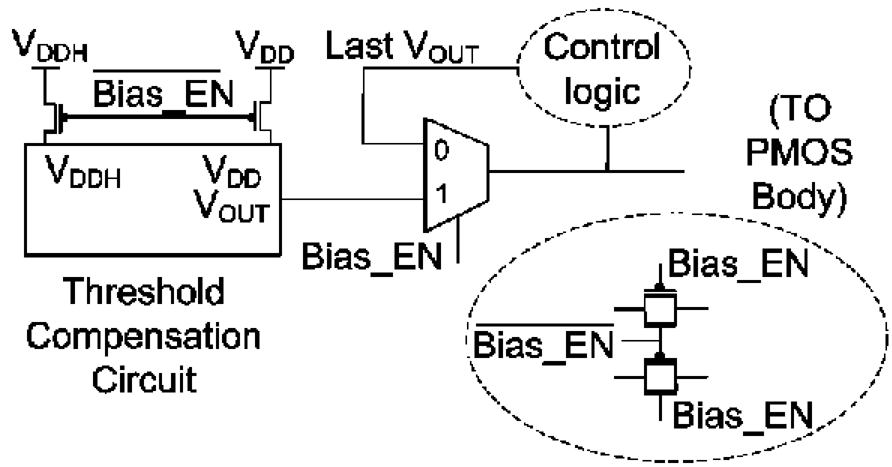
As shown in both applications, the proposed threshold compensation circuit serves dual purposes. It can act as an on chip sensor to monitor temperature or reliability effects, and at the same time reduce their impact on the system by compensating the threshold voltage change via adaptive body biasing. A common issue with on chip sensors is how to let them see the same environmental variables (temperature, NBTI, etc.) of the actual devices that they are monitoring. Each individual device can experience different temperature or stress, and it is impossible to assign one sensor to each device for the whole circuit. Process variations further complicate the problem. A more realistic and practical way is to allocate a sensor to a group of devices in their neighborhood in order to reduce the overhead and the impact of local process variation. The granularity at which the sensors are deployed reflects a tradeoff between overhead and accuracy, and the optimization can be assisted with a-priori knowledge of temperature or failure distribution.

As mentioned above, compensating for aging effects is more challenging than for temperature variability, since the former is based on switching activity which differs from device to device and ideally the compensation should have much finer granularity than for temperature variability. In the following we use the NBTI application as an example and provide some analysis and insight. In Figure 9 $P1$ is under constant NBTI stress, thus only representing the worst stress case. This pessimism may result in a situation where a PMOS is over-biased. However, in this case the PMOS, threshold compensation may provide a larger drive current than the nominal value used in timing analysis. While this may cause matching problems in analog circuits, for digital circuits it actually helps setup mode timing, as long as the hold mode timing margin is not very stringent. This is usually the case for most designs and most paths even in a design with a tight hold time margin. Recall that NBTI becomes a concern because it causes timing problems by slowing down the critical paths and causing timing violations after a certain amount of stress time. For circuits like shift registers, where hold timing is critical, NBTI is most likely not an issue anyway and we simply do not deploy any compensation for them. Furthermore, Figure 10 and Figure 11 both show that even with the NBTI monitor the V_{TH} degradation is still not fully removed, so some extra amount of forward biasing still helps recover the lost margin.

If one really wants to remove the pessimism, there are at least two compatible approaches to choose from, or combine. The first is to identify the most critical paths whose timing analysis result is extremely sensitive to NBTI degradation. This can be achieved with reliability simulations, either by commercial tools supported by foundry-provided device reliability parameters (Liu & McGaughy, 2006) or implementing one's own device reliability models and incorporating them in the simulation (Wang, et al., 2007). An NBTI-aware design scheme that only upsizes those PMOS on critical paths is also presented in Yang and Saluja (2007). The difference is that, for overdesigning, accurate sizing for each transistor directly depends on modeling and simulation precision which may even reply on a correct assumption of input signal switching activity, while for monitor deployment we only need to identify the most vulnerable portions of the circuit.

The second scheme, as illustrated in Figure 12, is to only selectively turn on the monitor when NBTI degradation is large enough and a degradation constraint either on I_{DS} or V_{TH} is violated. The violation detection can be done either off-line in a special testing mode enabled at preset time points, or online with error detection structures as in the Razor architecture (Ernst, et al., 2005). Notice that when the body bias output is selected by the multiplexer, the reliability monitor should also be turned off to prevent the proxy ($P1$ in Figure 9) from being over-stressed. In addition, the pass transistor logic multiplexer needs to pass an analog output V_{OUT}, and cannot be replaced by a standard cell implementation. Pass transistor logic can be used here because V_{OUT} is connected to the body with small current and feedback; power savings can be achieved by being able to turn off the NBTI monitors.

Figure 12. Selectively power on/off the monitor to prevent over-stressing and save power (adapted from Qi & Stan, 2008)



SUMMARY

In this chapter, we proposed a threshold compensation scheme that can optimize the system energy efficiency. We demonstrated that the design can effectively mitigate the transistor threshold voltage shift due to non-ideal factors, like temperature variability and reliability degradation, and prevent the system drifting far away from its optimal operation condition. A detailed analysis of the proposed scheme shows that although ideal compensation is physically impossible, several design parameters can be tuned to maximize the compensation capability. Two example applications are demonstrated for temperature variation and NBTI-caused threshold shifts. In these examples the proposed scheme is shown to improve circuit performance, reliability and lifetime for both combinational and memory circuitry.

With little modification, the proposed scheme can be adapted for a wide range of applications. For example, compensating the threshold shift by HCI (Hot Carrier Injection) or PBTI (Positive Bias Temperature Instability) can be done very similarly as for NBTI. The scheme can also be applied to adjust shifted threshold voltages due to manufacturing process variation. Intra-die or inter-die variation can be mitigated through an on-chip proxy transistor and an off-chip reference current (I_B in Figure 1). Depending on the actual application, possible simplifications may be made, as in the case of NBTI sensor, which exploits the fact that only forward biasing is needed.

We believe adaptive and distributed computing are two viable approaches for making future computing systems more sustainable. Adaptive and distributed computing can be implemented across all the levels from the bottom circuit level to the top system level. The proposed scheme can be viewed as one such example at the circuit level. The ability to adapt to the runtime usage and environmental variations is critical to maximize the system efficiency. Distributing such compensation blocks across the whole chip can achieve more aggressive savings at a finer granularity. By adaptively compensating for both short time variation and long time shifting of transistor threshold voltages, the proposed scheme enables typical case-based design, thus effectively reducing design margins and associated chip area and power consumption. The two different example applications, i.e., compensating for short time temperature and long time NBTI aging induced threshold voltage instability, demonstrate its versatility.

KEY TERMS AND DEFINITIONS

Design Margin/Guardband: The extra capability designed into a circuit system slightly beyond the minimum requirement from design specification in terms of performance, reliability, power, etc, to compensate for all kinds of variations or uncertainties. This can translate to extra circuit area, extra power consumption, etc.

Feedback: Used in the context of control theory, meaning the system output is fed back into as part of the input to control the system. Feedback improves stability of a system.

Hot Carrier Injection (HCI): A phenomenon in which high energy ("hot") electrons tunnel through the gate dioxide of a transistor, causing threshold voltage drift and degraded transistor performance.

NBTI/PBTI: Negative/Positive Bias Temperature Instability. NBTI happens in PMOS with negative voltage bias between gate and source terminal. The effect is increased threshold voltage and larger transimpedance. The degradation increases with the biasing time and elevated temperature, but can partially recover when the bias is removed. PBTI is the symmetric mechanism for NMOS.

Open/Closed Loop: Systems with/without feedback mechanism

Reliability Degradation/Aging: The performance of a transistor can change (usually resulting in inferior performance, e.g., slower transition, reduced noise margin, or even failure to turn on) after it is turned on and passes currents for some time. Mechanisms include NBTI (Negative Bias Temperature Instability), HCI (Hot Carrier Injection), TDDB (Time Dependent Dioxide Breakdown), etc.

Threshold Voltage: The gate voltage needed for forming a low-resistance channel (inversion layer) between the source and drain of a transistor. In oversimplified terms, it can be considered a point beyond which the transistor is "turned on" (passing current) and below which "turned off" (open circuit).

Transimpedance/Transconductance: For a two-port circuit, transimpedance is the ratio of the output voltage change to the input current change, and transconductance is the ratio of the output current change to the input voltage change.

Transistor/NMOS/PMOS: A transistor (also called MOS or MOSFET) is the basic building element for modern integrated circuits. There are two types of transistors: NMOS (N-type MOS transistor, also called NFET) and PMOS (P-type MOS transistor, also called PFET).

Variation: Circuit uncertainty and drift from the values designed for in all aspects of design specifications. Variation can come from many sources including manufacturing process (process variation), power supply instability (power variation), circuit operating temperature (thermal variation), aging degradation (aging variation), etc.

Chapter 19
Modeling Closed Loop Supply Chain Systems

Roberto Poles
University of Melbourne, Australia

ABSTRACT

In the past, many companies were concerned with managing activities primarily along the traditional supply chain to optimize operational processes and thereby economic benefits, without considering new economic or environmental opportunities in relation to the reverse supply chain and the use of used or reclaimed products. In contrast, companies are now showing increased interest in reverse logistics and closed loop supply chains (CLSCs) and their economic benefits and environmental impacts. In this chapter, our focus is the study of remanufacturing activity, which is one of the main recovery methods applied to closed loop supply chains. Specifically, the authors investigate and evaluate strategies for effective management of inventory control and production planning of a remanufacturing system. To pursue this objective, they model a production and inventory system for remanufacturing using the System Dynamics (SD) simulation modeling approach. The authors primary interest is in the returns process of such a system. Case studies will be referred to in this chapter to support some of the findings and to further validate the developed model.

INTRODUCTION

Industry in general, and society more broadly, have come to recognize the limited availability of natural resources and are moving towards the manufacture of more environmentally friendly products and the recovery of resources. For this reason, the modern trend, particularly in developed countries, is to use fewer environmental resources such as water, air and raw materials to manufacture products. Moreover, interest in strategic sustainability is growing among multinational companies, some of whom are developing sustainability reports to demonstrate both their concern for the environment and their commitment to conducting socio-ecological activities in business. In addi-

DOI: 10.4018/978-1-4666-1945-6.ch019

tion, sustainability can be used as a competitive strategy to create company branding, comply with government regulations on the environment and optimize the cost of operational processes.

This emerging economic and environmental consciousness within business has increased the focus on reverse logistics activity (company processes that recapture value from product returns) over the last decade (Blumberg, 2005). Indeed, this reverse logistics activity, particularly remanufacturing (the process of reusing returned products in production), can play an important role in sustainability, as well as in developing competitive strategies aimed at reducing the use of natural resources and recovering value from used products. However, several factors make the development of reverse logistics processes difficult. In particular, the complex integration between the forward (from the producer to the consumer) and the reverse (from the consumer to the producer) supply chains can negatively affect operations and logistics management activities such as production planning, inventory control and distribution planning.

According to the Reverse Logistics Executive Council, reverse logistics is the process of moving goods from the point of consumption to the point of origin for the purpose of either recapturing value or proper disposal. Stock (2001) has defined reverse logistics as "the term most often used to refer to the role of logistics in product returns, source reduction, recycling, material substitution, reuse of material, waste disposal, and refurbishing, repair and remanufacturing" (p. 5).

Companies can pursue several methods of recapturing value from returns, and carry out a range of recovery methods (Kulwiec, 2006). For example, products can be reused directly after cleaning or reconstruction. This is a common practice for items such as used pallets, bottles/glass or containers. However, products whose parts or materials need to be repaired or replaced can be reused after repair as rebuilt or used products. Another method of recovery is remanufacturing, a process in which parts and materials from returned products are reused for production. Remanufacturing requires more extensive work, since the returned product must be completely disassembled, its parts and modules examined and either repaired or replaced, and then reassembled into a new product. Remanufacturing is practiced in many industries, including for photocopiers, computers, telecommunications equipment, automotive parts, office furniture and tires. A final recovery option is recycling. In this case, some or all of the parts and materials from returned products can be processed to make different products (Kulwiec, 2006).

The concept of reverse logistics has changed in recent years (Dekker, Fleischmann, Inderfurth, & Wassenhove, 2004). More specifically, the concept of a closed loop supply chain (CLSC) has been developed to refer to the complete loop from the customer, back to the plant, through a reprocessing operation, and then back to the customer (French & LaForge, 2006). Closed loops consist of two integrated supply chains—a forward and a reverse chain—through which a recovered product re-enters the original forward chain (Wells & Seitz, 2005). CLSC is sometimes treated as an extension of the traditional concept of supply chain management. In this case, reverse logistics is not managed independently of forward logistics, but rather both processes form part of a complete supply chain process whereby products start with the manufacturer to reach the customer, then come back to the plant and return to the customer once more. This process has been defined by this new concept of the closed loop supply chain (Eoksu, Sungwon, Haejoong, & Jinwoo, 2004).

The integration of reverse logistics activities within the structure of the original production and distribution systems leads to additional complexity in the closed loop supply chain system. This complexity, which can hinder the integration process, comes from the significant differences between the forward and reverse supply chains. The latter are characterized by operational and business factors that disrupt the traditional approach to dealing with supply chain management, such as: (1) the complexity of forecasting returns; (2) a lack of uniformity in returns quality; (3) reverse logistics costs being less directly visible; and (4) production and inventory management being affected by the flow of returns. These factors make it necessary to rethink and re-plan the original supply chain. In particular, in the context of the remanufacturing process, production and inventory management entail the added complexity of coordination between the remanufacturing and production activity in terms of size of orders and lead times. Moreover, such coordination must account for the new kind of inventory generated by the additional flow of collected returns to be integrated into the remanufacturing process. However, this additional flow is not directly available to the manufacturer because of the unpredictability of the quantity, timing and quality of the products returned by customers.

The uncertainty around the quantity and timing of returns is one of the main factors that make the implementation of closed loop supply chain processes difficult, particularly in the case of integration between the forward and reverse supply chains. For example, the difficulty of determining the quantity of used products that will be returned by customers negatively affects remanufacturing and traditional production planning. Moreover, the lack of tools and guidelines on planning, controlling and managing remanufacturing operations has limited the growth of the remanufacturing sector (Guide, 2000). If not well designed, closed loop supply chain activities such as remanufacturing and disposal can increase company costs (Inderfurth, 2005). For this reason, a company objective is to integrate the reverse and forward supply chains so as to minimize the total cost and consequently obtain economic benefits.

Mindful that these problems add complexity to this field of research, in this chapter we aim primarily to model the factors affecting a production and inventory system that combines returns and remanufacturing, and to evaluate effective control strategies that address dynamic production and inventory management issues in order to improve the performance of the system. For this purpose, the System Dynamics (SD) simulation modeling approach (Forrester, 1958, 1961)—a methodology used for studying and managing complex feedback systems, particularly business and social systems—is adopted to model a production and inventory system for remanufacturing within the context of closed loop supply chains in order to understand the complex and dynamic interaction of factors that affect the behavior of the system. Our primary interest is the returns process in the context of closed loop supply chains. Moreover, this model is used to evaluate strategies for the effective management of remanufacturing and returns processes.

In order to assess some of the findings and to further validate the developed model, the methodological approach taken in this chapter is based on case study research. The selection of companies employed as case studies was based on their engagement in remanufacturing and returns processes, which made them useful for our study. The companies studied are: (1) the Australian Mobile Telecommunications Association (AMTA), which has commenced a national recycling program for mobile phones; and (2) Fuji Xerox Australia, which is involved in the remanufacturing of assemblies and sub-assemblies of printers and copiers.

BACKGROUND

The introduction of new environmental legislation in recent years has strengthened the need to focus on reverse logistics and CLSC among logistics operators. While legislation introduced in Europe, North America and Japan encourages this awareness, many corporations have proactively taken measures in anticipation of evolving environmental performance requirements (Savaskan, Bhattacharya, & Wassenhove, 2004). Several examples of government regulations can be considered. In Japan any products purchased by the government must contain recycled materials and the European Union (EU) has issued a directive for producer responsibility to collect, process and recycle waste from both "white goods" (e.g. refrigerators, washing machines and freezers) and "brown goods" (e.g. TVs and speakers) (Kulwiec, 2006). In Europe, many countries have forced industry to develop collection and recycling systems in order to reduce waste. This has led to the issuing of several environmental regulations such as the EU Directive 2000/53/EC (Blanc, Fleuren, & Krikke, 2004) for responsibility in taking care of used products, the EU Directive 2002/96/EC and 2003/108/EC for electrical and electronic equipment, and the EU Directive 2002/525/EC for end-of-life vehicles (Tang, Grubbström, & Zanoni, 2007). According to the US Environmental Protection Agency (EPA), in the United States (US) the amount of waste generated has increased from 88 million tons in the 1960s to 196 million tons in 1990 alone. Consequently, companies need to develop techniques for product recovery and waste management (Gungor & Grupta, 1999). Furthermore, hundreds of environmental laws and regulations for recycling operations and responsibility for packaging recovery have been developed (Kulwiec, 2006). Local governments in North America promote the reduction of landfill use, which is the main driver of non-toxic solid waste, pushing companies towards improving and innovating in their manufacturing activities (Biehl, Prater, & Realff, 2007). This places an onus on manufacturing firms to use reverse logistics activities as a form of extended producer responsibility (EPR), which makes them responsible for their products throughout their life cycles (Klausner & Hendrickson, 2000).

In the US, the precise extent of reverse logistics activities is difficult to determine because most companies have not quantified them (Reverse Logistics Executive Council, 2007). However, reverse logistics activities account for a significant portion of logistics costs in the US. These are estimated to account for approximately 10.7% of the US economy and approximately 4% of the total logistics costs (Reverse Logistics Executive Council, 2007). Reverse logistics costs are estimated to be approximately 0.5% of total US gross domestic product (GDP), which equated to around US$58.34 billion in 2004. In 1999 the total value of returned merchandise in the US, with an estimated handling cost of $40 billion, was $62 billion (ReturnBuy, 2000). The US is not the only country where reverse logistics activities are increasing. In Europe, the annual production of remanufactured automotive parts was approximately 20,000,000 units in 2005, and is expected to increase to 30,000,000 units in 2015 (Automotive Parts Rebuilders Association, 2007). In Australia, the Eco Manufacturing Centre of Fuji Xerox, a company that continually adopts new remanufacturing programs, has aimed for zero waste discharge and has achieved 90% reuse and recycling (Environment Protection Authority, 2002).

Based on these data, it is evident that many companies have realized that reverse logistics/CLSC, particularly remanufacturing, is an important competitive and strategic component of their business mission. Indeed, the use of reverse logistics in the business sector is increasing not only because of the implementation of more stringent environmental regulations, but also for reasons related to competition. The results of a survey involving 1,200 logistics managers and more than 150 managers with reverse logistics responsibilities in the US found that 65% of companies believe that returns management is an important strategic tool for their business (Rogers & Tibben-Lembke, 2001). Indeed, through reverse logistics and closed loop supply chain activities companies can fulfill the environmental responsibilities stipulated by government regulations and at the same time optimize operational processes. Such optimization can be achieved both by reducing operating expenses, and by improving company image through a reduced use of resources. The cost of remanufacturing, for example, is typically 40–60% of the cost of manufacturing, and remanufactured products are of the same quality as new products, and sold with the same warranties (Mitra, 2007). Moreover, customers have become more environmentally conscious, which in recent years has led to an increase to over US$2,000 billion worth of environmentally friendly products on the global market (Mitra, 2007). This growing pressure to improve the market competitiveness of companies through the reverse logistics process has pushed researchers to analyze, model and explain why and how reverse logistics can lead to economic and environmental benefits. A number of studies describe the role of reverse logistics in economic and environmental activities during the product development process. In particular, several models have been developed to support managerial decision-making and to optimize processes in different reverse logistics areas. The scope of these models is mostly to minimize costs and optimize profits through analysis of the parameters and variables as defined in the modeling method.

However, the characteristic of variability in the quality, quantity and timing of returned products and the integration of the returns flow within the original forward supply chain make reverse logistics activities, particularly remanufacturing, difficult to plan, control and manage (Guide & Wassenhove, 2001). For this reason, systems that are not appropriate for dealing with returns could increase operating expenses. In a study by Guide (2000), 61.5% of the firms under study were found to have no control over the timing or quantity of returns. He discusses several characteristics of recoverable manufacturing systems that complicate production planning and points out that there is a significant lack of specific technologies and techniques for remanufacturing logistics. These include: uncertainty around the timing and quantity of returns; balancing returns with demands; disassembly of returned products; and materials recovery uncertainty, which are all factors that require considerable research. These characteristics could be addressed by focusing on several issues, such as the methods (e.g. leasing, deposits) used to reduce uncertainty around timing and quantity of returns; forecasting models; aggregate production planning models that consider returns; and models that support material recovery planning and prediction based on the age and usage rate of products.

Production and inventory management requires appropriate control mechanisms to integrate the return flow of used products within the material planning for the forward flow (Fleischmann et al., 1997). This can vary for different reverse logistics situations. For example, for companies whose business is recycling, returns are the only inventory resources for the forward production process and used products or materials are the only raw materials. Traditional inventory control methods might be satisfactory in this context. However, the mechanism is different for remanufacturing or reuse where used products are returned for introduction into the main production stream. In this case, returned goods consist of an additional inventory source to the usual inventory procured from outside. Moreover, this additional flow is not directly available to the manufacturer because of the unpredictable factors of quantity, time and quality of the products returned. Hence, inventory management can be made particularly complicated by remanufacturing activities since key information such as that related to on-hand inventory, lead time and yield is not clearly known (Toktay, Wein, & Zenios, 2000).

For these reasons, in this study we model a production and inventory system in which production is integrated with remanufacturing activity. Several authors have conducted research into such a system. They have focused mainly on: production and remanufacturing lead times (Inderfurth & van der Laan, 2001; Kiesmuller, 2003; Kiesmuller & Minner, 2003; van der Laan, Salomon, & Dekker, 1999); optimization procedures for inventory levels and economic order quantity (Kiesmuller & van der Laan, 2001; Koh, Hwang, Sohn, & Ko, 2002; Teunter, 2001; van der Laan, Dekker, & Salomon, 1996; van der Laan, Dekker, Salomon, & Ridder, 1996); comparisons between pull and push strategies (van der Laan & Salomon, 1997; van der Laan, Salomon, Dekker, & Wassenhove, 1999; van der Laan & Teunter, 2006); and capacity planning (Georgiadis, Vlachos, & Tagaras, 2006; Kleber, 2006; Vlachos, Georgiadis, & Iakovou, 2007). However, to our knowledge no previous study has examined a system in which the returns process is modeled and analyzed in relation to the particular system variables involved in our research. Several inventory models for the remanufacturing process have been developed where returns are included as exogenous variables, without any or with only simple correlation between demand and returns. Many of these have adopted simple assumptions regarding the returns process such as the homogeneous Poisson Process for demand and/or return flow, or that returns are independent of the demand (de Brito & Dekker, 2003).

MODEL BUILDING

The modeling process undertaken in this research was characterized by a sequence of iterative activities and stages that involved continuous revisions and changes. Indeed, this modeling can be defined as a continual process of iteration among problem articulation, the generation of hypotheses, data collection, model formulation, testing and analysis (Sterman, 2000). In this section, the final results of this process of iteration, which led to the model building for the production and inventory system for remanufacturing, are presented.

Description of the System under Study

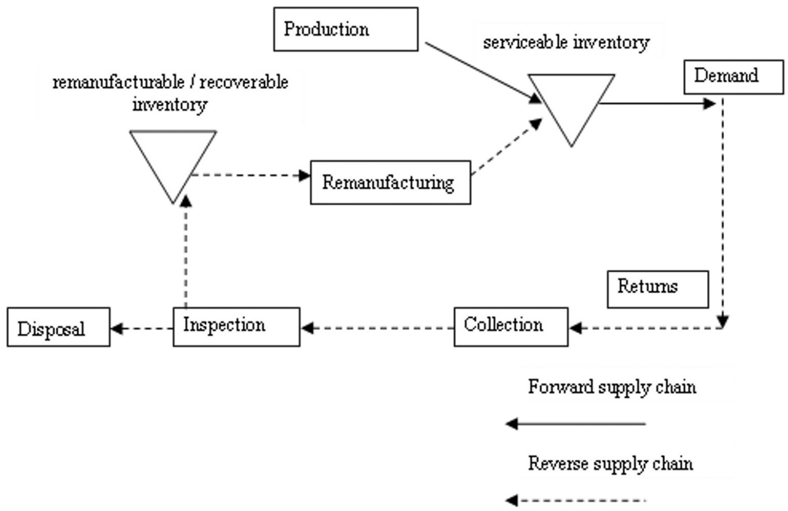
The purpose of this chapter is to model the factors affecting a production and inventory system that combines returns and remanufacturing within the context of closed loop supply chains, and to evaluate effective control strategies aimed at improving the performance of the system, focusing particularly on the returns process. For this purpose, we model and simulate a single-product production and inventory system for remanufacturing within the context of closed loop supply chains. The system involves several operations including: production of new products; collection and inspection of used products; remanufacturing; and disposal. Our focus in this study is on the return of products by customers/product users at the end of the products' useful life; other returns such as product recalls and B2B commercial returns are excluded from examination.

The system under consideration is depicted in Figure 1. The forward supply chain involves the production of new products to meet customer demand. After product use, returns are collected, inspected and either stored as remanufacturable/recoverable inventory or disposed of depending on whether the quality of returns is deemed suitable for remanufacturing according to the company's policy on quality standards. The serviceable inventory, used to fulfill external demands, is fed by the production of new or remanufactured products which are as good as new. Production and remanufacturing activities are important components of any production and inventory system for remanufacturing. Equally important to the process is analysis and decision-making regarding inventory, operational and marketing activities.

The following assumptions are adopted throughout this analysis in order to simplify the system and facilitate the modeling process by focusing on the most important factors:

- Uncontrollable disposal is not considered, whereby instead of the product returning to the remanufacturer, it is disposed of in an uncontrolled manner, sometimes in opposition to the manufacturer's instructions or environmental regulations.

Figure 1. Production and inventory system for remanufacturing



- The planned disposal of recoverable inventory is not considered.
- The capacity of several activities such as collection, inspection, remanufacturing and production are considered infinite.
- Backordering and lead times are not considered.

In our model, the returns rate incorporates the uncertainty around the quantity and timing of returns and a pull inventory control policy is applied. This policy is implemented through reorder point inventory replenishment policies, which are basic features of several industries in the context of supply chain/inventory planning. The returns rate, which is used to calculate the number of returns after the time of use, is represented as the ratio between the probable returns flow of sold products and the demand. The probable returns flow and the time of use are calculated on the basis of the relationship between two factors: the *return index* and the *residence time*. The latter is the factor defined in the study of Georgiadis et al. (2006), and represents the average time for which a product stays with its customer before it is returned.

The ways in which companies manage the returns process for products sold to customers, through service agreements and sales contracts with retailers or the customers themselves, can influence the returns rate and particularly the quantity of returns. For example, leasing contracts ensure that almost all products are returned after the residence time. In our model, the *service agreement with customer* factor is used to relate the quantity of returns with the demand for different products in different industries. *Customer behavior* is another factor that can influence this relationship. The attitude of the customer in terms of their return activity and their response to a company's returns process incentives can affect the returns rate and in particular the likelihood of a particular product being returned. Hence, the *return index* is obtained by considering the relationship between company incentives/service agreements aimed at recovering used products and actual customer behavior in returning products. Put simply, the return index is the tendency of the product to be returned by the customer during its lifetime, which varies across different products and industries. This is explained in more detail in the next section.

Quantitative Modeling

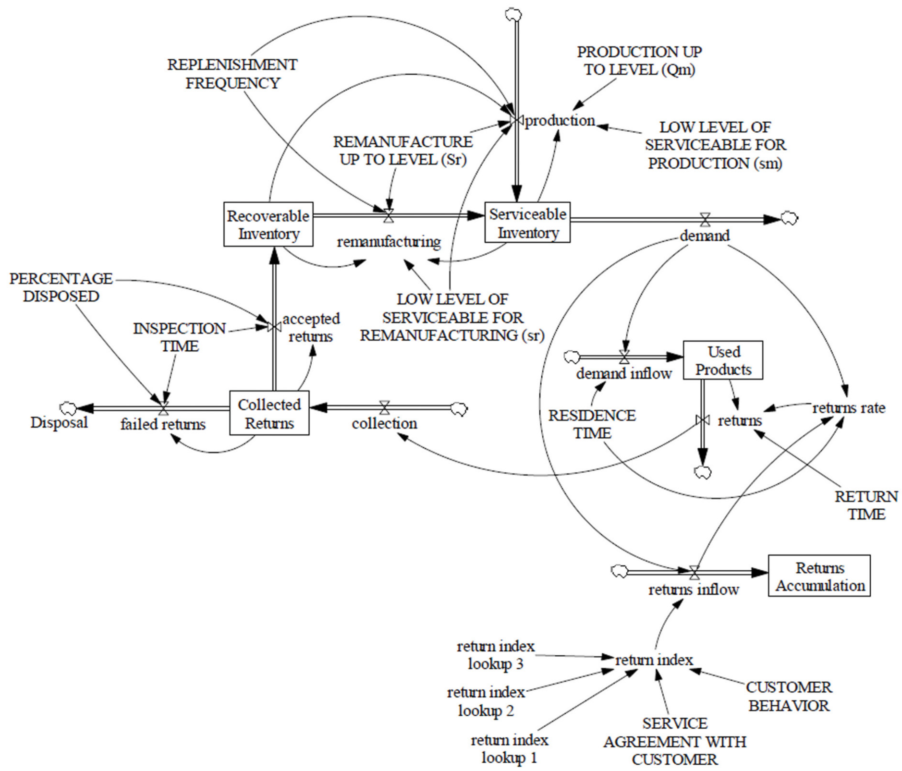
A System Dynamics (SD) simulation modeling approach is adopted in this research. SD was introduced in the early 1960s by Jay Forrester (1958, 1961) as a modeling and simulation methodology aimed at dealing with the dynamics and controllability of management systems (Coyle, 1996). The SD method is commonly used to analyze how the dynamic behavior patterns of system variables change in response to dynamic inputs. Controllability refers to the "control systems" (Coyle, 1996) by which the policies employed and applied in the system structure control system behavior over time. The objective of using SD is to identify strategies to improve system performance (Sterman, 2000). For these reasons, SD has become a computer-aided method of analyzing and solving complex problems, particularly in the area of policy analysis and design. It is applied in a number of fields, including: corporate planning and policy design; economic behavior; public management; biological and medical modeling; energy and environmental studies; social science; dynamic decision-making; complex nonlinear dynamics; software engineering; and supply chain management (Angerhofer & Angelides, 2000). The choice of a simulation approach, in particular the SD approach, rather than other methods such as analytical approaches was based on the recognition that SD can model an entire system in which several policies and factors can be used to evaluate strategies aimed at improving system performance. Moreover, SD can handle the issues arising from models in which dynamic forces and nonlinear relationships play a significant role.

All business and social systems contain a host of different asset stocks or accumulation of resources which change according to their physical inflows and outflows (Morecroft, 2007). According to Morecroft, this stock and flow structure of systems reveals the operations behind the causal influences or relationships among system variables. In SD, the stock and flow structure of systems is represented by the Stock and Flow Diagram (SFD). Such a diagram is obtained by identifying the stock, flow and auxiliary variables among the variables used to model a system. The stock variables determine the state of the system and are represented by an accumulation of the difference between the inflow to a process and its outflow (Sterman, 2000), while the flow variables determine the physical flows in the system and generate change in the stocks, which is then used to make decisions. The auxiliary variables can be useful for clarifying the structure and process of the model. They represent constants or exogenous inputs into the model, as well as converters or intermediate variables used in the mathematical equations of the model (Kirkwood, 1998; Sterman, 2000). The objective in developing an SFD is to analyze and define the dynamic relationships among stock, flow and auxiliary variables through mathematical equations in order to run simulations of the model.

The SFD for the production and inventory system for remanufacturing is presented in Figure 2. The rectangles represent stock variables which equate with accumulations of items, while the valves represent flow variables which correspond to the physical flow of items feeding or depleting the stocks. The physical flow of items is represented by a double line with arrows, while the flow of information (i.e. connections among variables and their relationships used for mathematical formulations) is represented by a single line with arrows. The auxiliary variables shown in upper case letters represent constants or exogenous inputs, while those in lower case letters represent the converters used in calculations.

In the diagram above, an increase/decrease in *returns* increases/decreases the rate of *collection*, which in turn increases/decreases the level of *Collected Returns*. At this stage of the process, returned products are inspected in order to check their quality and remanufacturability. Failed items decrease the level of *Collected Returns*, through a *failed returns* flow, and at the same time increase

Figure 2. Stock and flow diagram



the level of *Disposal* which represents the quantity of non-reusable items that are disposed of. The flow rate of failed items depends on the value of *percentage disposED* and *inspection time*. The former affects the flow rate as any change in the percentage leads to a change in the quantity of failures. For example, an increase in the percentage value of disposal leads to an increase in the flow of failed items for a given time period. *Percentage disposED* also represents the quality standards policy of the company and is affected by several parameters and techniques used to check returned items. It is defined as an average percentage of collected returns that are disposed of, and differs for different products and different quality standard policies adopted (Vlachos et al., 2007). *Inspection time* represents the period of time required to inspect collected items. This affects the inspection flow, as a faster/slower inspection time leads to an increase/decrease in the flow.

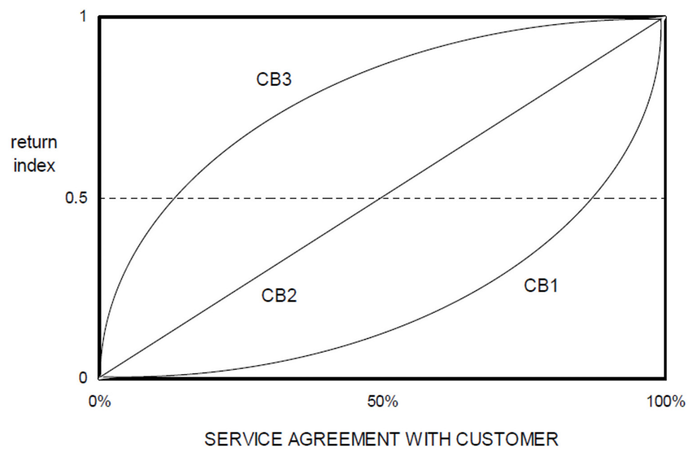
Accepted items increase the level of *Recoverable Inventory* that is ready to be remanufactured through the *accepted returns* flow. The flow rate of accepted items depends inversely on the value of *percentage disposED*, as a lower percentage of disposed items leads to a higher number of remanufacturable items.

Remanufacturable items are stored as *Recoverable Inventory* from which items are used for remanufacturing purposes when necessary and stored as *Serviceable Inventory* in order to fulfill customer *demand*. In this system, remanufacturing, which is preferred to the more expensive production activity, occurs when necessary as a pull inventory policy is applied. Several studies have previously modeled push and pull inventory policies in a production and inventory system for remanufacturing (Kiesmuller, 2003; van der Laan & Salomon, 1997; van der Laan, Salomon, & Dekker, 1999). A more detailed picture of the inventory pull policy was provided in a study by van der Laan, Salomon and Dekker (1999), who similarly did not consider the disposal of recoverable inventory in their model. According to these authors, *REMANUFACTURE UP TO LEVEL* (*Sr*) and *LOW LEVEL OF SERVICEABLE FOR REMANUFACTURING* (*sr*) are two variables that affect the *remanufacturing* rate and are used to implement a pull policy in the system. *Sr* represents the upper value limit for remanufactured batches, while *sr* represents the lower value for remanufactured batches as well as the level of a *Serviceable Inventory* at which a remanufacturing batch is required. *Sr* - *sr* represents the level of *Recoverable Inventory* for which it is possible to produce a remanufacturing batch. The pull policy is represented by the *Recoverable Inventory* level. Only when this level reaches the difference (*Sr* - *sr*), and the *Serviceable Inventory* level is lower than *sr*, is it possible to produce a remanufacturing batch. Two additional variables that affect production flow are incorporated to implement the pull inventory policy: *PRODUCTION UP TO LEVEL* (*Qm*), which is the upper value for production batches; and *LOW LEVEL OF SERVICEABLE FOR PRODUCTION* (*sm*). Production activity is only used to increase the *Serviceable Inventory* level when the *Recoverable Inventory* level is lower than (*Sr* - *sr*) and the *Serviceable Inventory* level is lower than *sm* (the *Serviceable Inventory* level at which a production batch is required). However, production flow is mainly affected by *Sr* and *sr*, because it is only when the *Recoverable Inventory* level is lower than *Sr* - *sr* and the *Serviceable Inventory* level reaches *sm* that a production batch is manufactured and stored in *Serviceable Inventory*. This strategy increases the cost of the *Recoverable Inventory* but reduces the cost of the *Serviceable Inventory* which is usually more expensive. Moreover, remanufacturing is preferred to production activity, as *sm* is lower than *sr*. *Remanufacturing* flow is also affected by the *replenishment frequency* of the inventory. *Replenishment frequency* represents the time taken to replenish remanufacturing orders and an increase/decrease in its value generally leads to a decrease/increase in the order size.

The returns process starts with customer demand, which depletes the *Serviceable Inventory* level. Product demand is considered equal to sales. After a period of time or *RESIDENCE TIME*, products in use can be considered to be used products. This is represented by the flow between the rate of the variable *demand inflow* and the level of *Used Products*. The variability of *RESIDENCE TIME* represents the uncertainty that affects the timing of returns in a closed loop supply chain. For this reason, in this model not all used products are considered to be returns but rather as possible returns after an average period of use that is dependent on the type of product. A portion of these used products become *returns*, which are consequently collected. This is represented by the physical flow in which *returns* deplete the *Used Products* level and the information flow between *returns* and *collection*.

Uncertainty around the quantity of used products returned by customers negatively affects collection, remanufacturing, production planning and inventory control. For this reason, several variables are used to reduce the effect of this uncertainty and set the quantity of returns. The *return index* is used to set the number of returns based on customer demand. The number of returns is represented by the *returns inflow*, which is influenced by both *returns index* and *demand*. Two parameters influence the *return index*: *SERVICE AGREEMENT WITH CUSTOMER* and *CUSTOMER BEHAVIOR*. The former defines the level of the service agreement or incentives that the company offers to the customer at the end or during the use of the product in order to stimulate the returns process. However, it also represents the level of responsibility the company has towards the recovery of its own products. The latter parameter, *CUSTOMER BEHAVIOR*, defines the attitude of the customers towards returning used products and their response to company incentives aimed

Figure 3. Relationship between SERVICE AGREEMENT WITH CUSTOMER and return index for various CUSTOMER BEHAVIORS



at increasing the number of returns. The relationships among these three factors are shown in Figure 3. The difficulty in obtaining and documenting real data has led to the use of a distributional form constructed on intuitive grounds. However, a similar approach to the analysis of influences was adopted by Georgiadis and Vlachos (2004), who analyzed different parameters such as market behavior and the "green image" factor in relation to products in different industries.

In Figure 3 *return index* for a particular product is obtained based on the level of service that a company offers to its customers to encourage the return of the product after its use. In this regard, the values given to *SERVICE AGREEMENT WITH CUSTOMER* lie between 0 and 100%, which correspond to 0 and 1 of the *return index*, respectively. High values of service agreement are obtained for companies that offer incentives for the full return of sold products, such as through leasing contracts (e.g. cars and photocopiers) or service at the end of the useful life of a product/component (e.g. single-use cameras and toner cartridges). Also included are companies that maintain full responsibility for product recovery to abide by government environmental regulations. High values of service agreement correspond to high values of the *return index*, for which it is assumed that almost all sold products are returned by customers. The minimum value of service agreement corresponds to the kinds of products not involved in reverse logistics activity, particularly remanufacturing, resulting in a zero *return index* and no efforts by companies to generate product recovery. For all values in between, the relation between the index and service agreement depends on *CUSTOMER BEHAVIOR* (CB).

A range of company incentives are used in practice to stimulate a desired customer behavior in the area of product recovery (de Brito, Dekker, & Flapper, 2004), including: a deposit that must be paid when purchasing the product; free collection or repurchase of used products; a monetary incentive paid upon return of used products; and a trade-in that involves the possibility of obtaining a newer version of a product when the original product is returned. Currently, products designed for easier disassembly and clear information/advertising about reverse logistics activities and environmental responsibilities are being developed by companies to encourage the return of used products. However, the reaction to such incentives depends on individual customer behavior. To incorporate various possible customer behaviors into this study, three alternative relationships are assumed, which are represented in Figure 3. CB2 corresponds to a proportional relationship between *service agreement with customer* and *return index*. In this case, it is assumed that customers respond proportionally to incentives and services offered by companies attempting to recover used products. The symmetric curves CB3 and CB1 correspond to a quicker and a slower response from customers, respectively. Particularly in relation to CB3, it is assumed that the response of customers and consequently the associated *return index* changes quickly for low values of *service agreement with customer* while it is almost the same for higher values. This is different for CB1 which becomes more acute for higher values of *service agreement with customer*. This influence analysis is used to account for the relationship between customer behavior and quantity of returns, as much as is possible.

Mathematical Formulation

The dynamic relationships among the variables of the developed SFD for the production and inventory system for remanufacturing are defined by a set of mathematical equations. The symbology and the form used for the equations follow the conventions of the simulation software used to build the model: Vensim PLE v5.6d (Ventana Systems, Inc.). This provides a simple and flexible means of building simulation models from Stock and Flow Diagrams (Ventana Systems, Inc., 1999). The mathematical equations include several constant parameters or inputs. The latter correspond to the exogenous inputs of the SFD, which were represented in upper case letters, as well as to the initial values of the stock variables. Usually, when modeling a specific real system the values of these parameters are finetuned in order to reproduce the behavior of the system. However, because in this study we are developing a generic SD model of a production and inventory system for remanufacturing, assumptions are adopted for the value of the parameters. Indeed, given the objective of running a simulation of this generic model to evaluate strategies with a particular focus on the returns process, to improve the performance of the system we believe that an intuitive understanding regarding the impacts of the structure of the model on its dynamic behavior is more important than determining the exact value of the parameters. However, the assumptions used for the values of these parameters, which will be provided for the simulation analysis of the model, are set to correspond as far as possible to a meaningful concept based on real-world situations.

The mathematical meaning of an SFD results from the conventions used by Forrester (1961) to define this particular diagram based on the hydraulic metaphor of the flow of water into and out of reservoirs (Sterman, 2000). Specifically, stocks (reservoirs) accumulate material (water), which changes dynamically in response to the flow variables (inflow and outflow of water). For this reason, stocks can be represented mathematically through a differential equation (Sterman, 2000) or an equivalent integral equation. Thus, the stock variable *Collected Returns* is defined by a time integral of the net inflow (*collection*) minus the net outflows (*accepted returns* and *failed returns*):

$$\textit{Collected Returns}\ (t) = \int_{t_0}^{t} (\textit{collection}(t) - \textit{accepted returns}(t) - \textit{failed returns}(t))dt + \textit{Collected Returns}\ (t_0).$$

The *collection* flow is equal to the *returns* flow. This means that at time t, all returns follow a collection process: *collection (t) = returns (t)*. Infinite collection capacity is assumed as all possible returns are collected. *Failed returns* at time t are equal to total *Collected Returns* times the *PERCENTAGE DISPOSED* divided by the *INSPECTION TIME* (Vlachos et al., 2007). The percentage of disposed returns and the inspection time are assumed to be constant due to the difficulty of representing and modeling the real dynamic variance for this factor which depends on product characteristics, company quality policies and inspection strategies; and this particular issue is not within the scope of this study. *Accepted returns* at time *t* are the *Collected Returns* that pass the inspection process. For this reason, the percentage of returns accepted for remanufacturing is 1 – disposal percentage. Equations can thus be formulated as:

$$accepted\ returns(t) = \frac{\text{Collected Returns(t) * (1- PERCENTAGE DISPOSED)}}{\text{INSPECTION TIME}}$$

$$failed\ returns(t) = \frac{\text{Collected Returns(t) * PERCENTAGE DISPOSED}}{\text{INSPECTION TIME}}$$

An *IF THEN ELSE* function and the logical operator *AND* are used to define the production quantity in the system. In particular, they provide the number of production orders during the simulation period. The logical expression defines the condition when the *Serviceable Inventory* level is less than or equal to the *low level of serviceable for production* and also when the *Recoverable Inventory* level is less than the *remanufacture up to level* minus *low level of serviceable for remanufacturing*. If the condition is true, the expression returns a production order value equal to the ratio between *production up to level* minus the serviceable inventory on hand and the *replenishment frequency*; otherwise the returned value is zero. A similar equation defines the remanufacturing quantity and the number of remanufacturing orders in the model. In this case, the condition requires that the *Serviceable Inventory* level is less than or equal to *low level of serviceable for remanufacturing* and that *Recoverable Inventory* is greater than or equal to *remanufacture up to level* minus *low level of serviceable for remanufacturing*. The possible returned values are a remanufacturing order that is equal to the ratio between *remanufacture up to level* minus *low level of serviceable for remanufacturing* and *replenishment frequency* if the condition is true, or zero otherwise. *Recoverable* and *Serviceable Inventory* levels are defined in the equations below:

$$Recoverable\ Inventory(t) = \int_{t_0}^{t} (\text{acceptedreturns}(t) - remanufacturing(t))d + Recoverable\ Inventory(t_0)$$

The assumed values for the product demand are set in order to generalize the model for different kinds of products. Specifically, *demand* is set to a uniformly distributed random number. The random values are set at between 300 and 2,000 items with a fixed noise seed, in order to have the same sequence of random values for every simulation, which equals 2. The formulation of *demand* is thus represented as: *demand = RANDOM UNIFORM (300, 2,000, 2)*. *Demand inflow* represents the flow of previously sold products currently in use which are now used products and possible returns after the *residence time* has elapsed. In order to model this process the function *DELAY FIXED* is used. This function returns the value of the input *demand* delayed by the delay time, which in this case is the *residence time*. Zero is the initial value of *demand inflow* at the start of the delay process: *demand inflow = DELAY FIXED (demand, residence time, 0)*.

The flow of actual returned items that are collected is represented as a dynamic ratio between the proportion of *Used Products* through the use of *a returns rate* and the time required to return and collect the items:

$$returns(t) = \frac{\text{(Used Products(t) * returns rate(t))}}{\text{RETURN TIME}}$$

The variable *Used Products* is defined as:

$$Used\ Products(t) = \int_{t_0}^{t} (\text{demandinflow}(t) - returns(t))dt + Used\ Products(t_0)$$

Returns rate represents the proportion or percentage of used products that are returned during the time period under consideration. Several authors, such as Kiesmuller (2003), Kiesmuller and Minner (2003) and Inderfurth (2005), use the returns rate variable in their models. In order to define the quantity of returns, they consider a returns rate to be the ratio between the average returns and the average demands. Consequently, the *returns rate* in this model is represented as a dynamic ratio between *returns inflow* and *demand*:

$$\text{Returns rate (t)}\ \frac{\text{returns inflow(t)}}{\text{demand(t)}}$$

The function *DELAY FIXED* is used to identify the value of the input given by the previous ratio delayed by the *residence time* plus one time period. The reason for this delay is due to the necessary time equivalence between the variables *returns* and *returns rate*, as the accumulation of used products and the actual returns flow start one time period after the residence time. *Returns inflow* represents the expected returns of demand. A forecast of returns is obtained using the *return index*: *returns inflow (t) = demand (t) * return index (t)*.

A functional relationship between two variables is used for the formulation of the *return index* at time *t*. This is obtained by using a lookup function which allows the definition of a customized relationship between a variable and its causes. Specifically, an equation gives the value of *return index* at any value of *SERVICE AGREEMENT WITH CUSTOMER* through a linear interpolation between the values specified in *return index lookup* (Figure 2) as: *return index = return index lookup (SERVICE AGREEMENT WITH CUSTOMER)*. *Return index lookup* defines the lookup function that expresses the relationship between *return index* (dependent variable) and *SERVICE AGREEMENT WITH CUSTOMER* (independent variable), as shown in Figure 3. For this reason, the variable *return index* is formulated through a combination of *IF THEN ELSE* and lookup functions: *return index (t) = IF THEN ELSE (CUSTOMER BEHAVIOR = 3, return index lookup 3 (SERVICE AGREEMENT WITH CUSTOMER), IF THEN ELSE (CUSTOMER BEHAVIOR = 2, return index lookup 2 (SERVICE AGREEMENT WITH CUSTOMER), return index lookup 1 (SERVICE AGREEMENT WITH CUSTOMER)))*. This equation represents the tendency of a particular product to be returned by customers, considering individual customer behaviors and differing levels of service agreement or company incentives. The constant *CUSTOMER BEHAVIOR* can assume three values, 1, 2 or 3, represented by the three different curves in Figure 3. In the function of value assumed for *CUSTOMER BEHAVIOR*, *return index* is calculated through one of the lookup functions.

Finally, the accumulation of returns from *returns inflow* is defined through the time integral of the flow:

$$Returns\,Accumulation(t) = \int_{t_0}^{t} (\text{returnsinflow(t)})\,\text{dt} + Returns\ Accumulation\ (t_0)$$

Validation Analysis

Before we can run a simulation of the model for evaluating and investigating strategies to improve the performance of the system, a validation analysis must be performed to determine whether the model is suitable for this objective. In SD theory, model validation primarily involves the assessment of the structure and behavior of the model in terms of its consistency with the available facts and descriptive knowledge of a real-world system (Morecroft, 2007; Sterman, 2000). Such assessment, as Sterman states, is useful to build confidence that a model is appropriate for its purpose.

Although the theoretical basis of the quantitative modeling in this study was obtained from the existing literature as well as from some of the information and data collected from the companies employed as case studies, in order to develop a model that corresponds to a meaningful concept representing the real world (Sterman, 2000), we deemed it necessary to perform validation tests to define its capacity to reflect the structure and behavior of a real process model.

The validation tests were the *direct structure tests* and *structure-oriented behavior tests* (Barlas, 1996). Specifically, for the *direct structure tests*, in which simulation was not involved, we engaged extreme condition tests in order to check whether each mathematical equation of the model made sense and was reasonable given the available knowledge of the real system. For the *structure-oriented behavior tests*, which involved simulation of the entire model, we undertook behavior sensitivity tests. These involved sensitivity analysis on particular parameters of the model aimed at comparing the high sensitivity of these parameters between the model and a real system.

Based on the outcome of the validation analysis we determined that the developed model of the production and inventory system for remanufacturing is suitable for evaluating and investigating strategies aimed at improving the performance of the system through a simulation of scenarios. Specifically, through the direct structure validation we confirmed the capacity of the model equations to be logically and dimensionally consistent with the available knowledge of real-world scenarios. Through the sensitivity analysis, we also identified that the changes in the behavior patterns of the model, due to particular assumptions regarding the changes in value for particular parameters, are consistent with a real system.

Another outcome of the sensitivity analysis was the identification of those parameters to which the model showed sensitivity. In particular, in line with the purpose of the model, it was found that the model showed sensitivity to the changes or joint changes in the values of the main parameters involved in the returns process (*RESIDENCE TIME*, *SERVICE AGREEMENT WITH CUSTOMER* and *CUSTOMER BEHAVIOR)*. Thus, these parameters can be used for the simulation analysis of scenarios to achieve the aims of the model.

SIMULATION OF SCENARIOS

The development of the model, and its validation, led to the final stage of SD simulation modeling, which involved simulation of scenarios focusing on the main parameters of the returns process in order to reach conclusions, specifically to identify and evaluate the best policy and strategy to adopt, and what occurs in the system if factors change or events intervene. In particular, the main purpose of the simulation is not to create predictions or forecasts of a future event, but rather to evaluate scenarios or alternative futures that could occur given certain assumptions or conditions (Morecroft, 2007).

Before the various scenarios can be designed and simulated, we must first identify and present the measure of performance and the base scenario used for the simulation analysis. We then discuss the various scenarios employed in the analysis and present the results of the simulations from which an evaluation can be undertaken of the best strategies to adopt to improve system performance.

Performance Measure

The measure of performance for this simulation analysis represents the output variable the value changes of which under different scenarios and given certain values of the parameters enhance our understanding of the conditions that might arise in the system. These conditions which represent the simulation results lead to an evaluation of strategies, which in turn provide guidelines as to how to improve the performance of the system.

As was found in the existing literature, for most production and inventory systems for remanufacturing the objective is to minimize the total inventory cost; therefore, the latter will be considered as a measure of performance for the simulation analysis. However, the analysis is not aimed at determining the optimal order quantity or reorder inventory level. Rather, the objective is to identify the effects on the system of the main factors involved in the returns process, in particular residence time, service agreements offered by companies and customer behavior. Changes in these factors are considered to be events that intervene in a production and inventory system for remanufacturing where the returns process is characterized by uncertainty around the quantity and timing of returns.

The value of the total inventory cost for the analysis is obtained by adding a number of operational costs. These are the set-up costs for each production order and remanufacturing order, the cost of stockout for each out-of-stock sale, and the holding costs for recoverable and serviceable inventory. The choice of this particular sum of total cost in which the remanufacturing and production costs are excluded is based on several observations. First, one of the assumptions previously mentioned in the description of the system under study determines that the model posits a disposal activity resulting from the inspection process rather than a planned disposal in recoverable inventory. This means that all accepted returns from the inspection are stored as recoverable inventory and used for the remanufacturing activity. Therefore, there are no inventory decisions that affect the remanufacturing and production activity in terms of quantity of items to be remanufactured and produced (van der Laan & Teunter, 2006). Moreover, the mathematical formulation of the model considers the number of remanufacturing orders and production orders rather than production and remanufacturing rates. These observations render the system independent of the remanufacturing and production activity, and consequently it excludes the production and remanufacturing costs. However, in order to potentially consider cheaper remanufacturing in place of production activity (remembering that the cost of remanufacturing is typically 40–60% of the cost of production), different set-up costs are assumed for production orders and remanufacturing orders. Moreover, this analysis focuses on the total inventory costs which exclude the collection and inspection/disposal costs.

Base Scenario

The base scenario represents and determines the values of the parameters that we initially set in order to run the simulation of scenarios. Specifically, these scenarios are obtained by changing the value of the main parameters under study while at the same time keeping the other parameters at the value of the base scenario.

The base scenario used for this simulation analysis involved the use of several assumptions aimed at ensuring the model corresponds as much as possible to a meaningful representation of the real world. Such assumptions reflect the theoretical basis drawn from the existing literature and to a degree information obtained from the companies employed as case studies. Indeed, the generic models based on remanufacturing and closed loop supply chains presented in the literature use several assumptions in relation to the values of the model parameters. For this reason, we deemed it appropriate to adopt similar assumptions for the purposes of the simulation analysis.

In setting the values of the model parameters, *INSPECTION TIME*, *REPLENISHMENT FREQUENCY* and *RETURN TIME* were set to one month. It was assumed that all returns collected in a given month are inspected within that same month, that the remanufacturing and production orders are replenished monthly, and that there is a monthly collection of returns. The initial values at the beginning of the simulation horizon for the stock variables were set to zero (Georgiadis & Vlachos, 2004) for *Collected Returns*, *Recoverable Inventory* and *Used Products*, while 2,000 items were set for the *Serviceable Inventory*. *PERCENTAGE DISPOSED* was set at 0.1 (10%), 500 items for *low level of serviceable for remanufacturing* (*sr*), 4,000 items for *REMANUFACTURE UP TO LEVEL* (*Sr*), 4,000 items for *PRODUCTION UP TO LEVEL* (*Qm*), 300 items for *low level of serviceable for production* (*sm*) and 12 months for the *RESIDENCE TIME*. *CUSTOMER BEHAVIOR* was set at 2, with a proportional relationship between *return index* and *SERVICE AGREEMENT WITH CUSTOMER*, which in turn assumed a value equal to 50%. In defining the values of the parameters related to the measure of performance, set-up costs were set at $20 per remanufacturing order and $50 per production order. The cost of stockout was set at $10 per out-of-stock sale, with $0.5 and $0.8 per unit recoverable and serviceable inventory holding cost, respectively. However, the generality of the model provides the opportunity to finetune and customize the values chosen for the basic scenario for different kinds of products and different industries.

Scenarios Derived from the Returns Process

The simulation of scenarios focused on the main parameters considered for the returns process. Thus, the scenarios were obtained through the combination of a range of values for those parameters related to the system policies defined for the returns process. Moreover, the model was sensitive to these parameters during the sensitivity analysis. Specifically, these parameters are *RESIDENCE TIME* (RT), *SERVICE AGREEMENT WITH CUSTOMER* (SAWC) and *CUSTOMER BEHAVIOR* (CB).

The analysis focused on the effect of the three parameters on the total inventory cost during the planning horizon, which was set at 60 months. Specifically, through this measure of performance changes in the behavior of the modeled production and inventory system for remanufacturing were examined using 6 levels of *residence time*, 5 levels of *SERVICE AGREEMENT WITH CUSTOMER* and 3 levels of *CUSTOMER BEHAVIOR*. Figure 4 lists the values of the parameters used for the analysis, which involved a total of 90 scenarios. The selection of the assumed values for the parameters was intended to correspond as much as possible to a meaningful reflection of the real world for a broad range of products. However, following the purpose of this simulation analysis to evaluate strategies aimed at improving the performance of the system, we believe that the exact value of the parameters is not as important as an understanding of the changes in the behavior of the system under different scenarios.

The various scenarios are characterized by low and high *residence times*, which correspond with *fast-used products* and *slow-used products*, respectively. The choice of this table structure was based on the relationship between *residence time* and type of product. *service agreement with customer* is considered to be the policies/incentives that companies use to retrieve used products and *customer behavior* the customer tendency to return them, respectively. The parameter values used to set the residence time are realistic as they can be associated with several remanufacturable products (Georgiadis et al., 2006). The assumed values for *service agreement with customer* represent a broad range of company policies and incentive types that develop a relationship between companies and their customers in the returns process. In the same way, the different levels of *customer behavior* are representative of a broad range of responsive aptitudes.

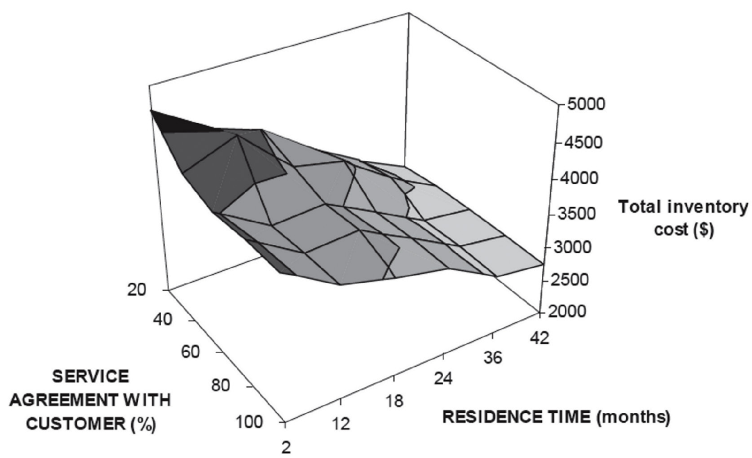
Figure 5 represents the evolution of the total inventory cost for various simultaneously simulated levels of *residence time* and *service agreement with customer*, given a *customer behavior* level equal to 3.

The first observation shows a decrease in the total inventory cost for a high level of *residence*

Figure 4. Parameter values used for returns process scenarios

Scenarios	RESIDENCE TIME (months)	SERVICE AGREEMENT WITH CUSTOMER	CUSTOMER BEHAVIOR
Base scenario	12	50%	2
Fast-used products	2	20%, 40%, 60%, 80%, 100%	1, 2, 3
	12	20%, 40%, 60%, 80%, 100%	1, 2, 3
	18	20%, 40%, 60%, 80%, 100%	1, 2, 3
Slow-used products	24	20%, 40%, 60%, 80%, 100%	1, 2, 3
	36	20%, 40%, 60%, 80%, 100%	1, 2, 3
	42	20%, 40%, 60%, 80%, 100%	1, 2, 3

Figure 5. Evolution of total inventory cost changing RT and SAWC



time. This is due to the reduced cyclic nature of returns for *slow-used products*, which remain with customers for longer. In the model the reduced cyclic nature of the return of a product is represented by the long time period between the product sale and its possible return. Specifically, a portion of products sold at time 0 of the planning horizon become remanufacturable returns only after a long residence time, and during this residence time they do not affect the recoverable inventory and its associated cost. Conversely, products with a short residence time engender a fast cyclic nature of return and are quickly involved in recoverable inventory and remanufacturing activity. Therefore, in the short time period, s*low-used products* lead to a reduced use of recoverable inventory and remanufacturing activity with a consequent reduction in the total inventory cost. This reduction is also due to the serviceable holding costs, which, according to our analysis, resulted indifferent to the remanufacturing or production of the product and consequently of the residence time, and stockout costs were often special events.

Our aim is not to reveal that *slow-used products* are promising candidates for profitable remanufacturing systems. On the contrary, in the context of a closed loop supply chain, examples of profitable remanufacturing processes include *fast-used products* such as single-use cameras and assemblies or sub-assemblies of copiers/printers. These kinds of products generate high levels of return and recoverable inventory with a subsequent increase in the total inventory costs. At the same time, cheaper remanufacturing activity can then be adopted as a substitute for more expensive production activity, as was shown by the reduction of the total set-up cost during the simulation analysis. As the structure of the model does not involve remanufacturing and production costs then it is not possible to draw any conclusions regarding the profitability of remanufacturing. However, several examples have been provided in the literature of products with low residence times or short lifecycles and high returns rates for which high stock levels increase inventory costs. At the same time, in the long run these products generate a more profitable remanufacturing activity due to reduced production costs such as purchasing and service costs (Flapper, Van Nunen, & Van Wassenhove, 2005).

The second observation obtained through the scenarios simulation reinforces the possibility that a high returns rate can generate a more profitable remanufacturability in closed loop supply chains. From Figure 5 it is possible to observe a decrease in the total inventory cost for each level of *residence time* except for the highest one, by increasing the *service agreement with customer* from 20% to 100%. The cost variation is not as significant as that which occurs when increasing the *residence time*. However, it can improve efficiency in managing inventory in the remanufacturing process. High incentives for product recovery and consequently a high returns rate and quantity of remanufacturable returns can increase the level of recoverable inventory, which can be used to generate remanufacturing orders faster as a substitute for production. This reduces the average level of recoverable inventory and consequently the total inventory cost, as was shown by the reduction of the recoverable holding costs during the simulation analysis. Moreover, increasing remanufacturing activity does not negatively impact the effectiveness of the system, as stockout quantity and costs showed a reduction for a higher returns rate.

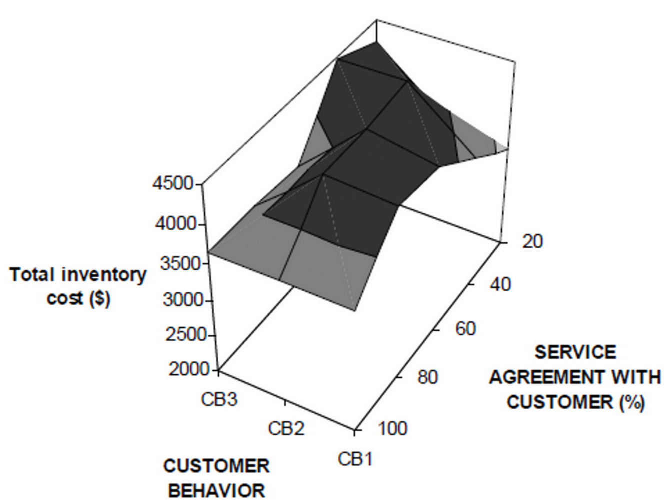
The simulation analysis showed a higher reduction of the total inventory cost, increasing the *service agreement with customer* from 20% to 100%, for *fast-used products* than for *slow-used products* for which an increase in cost characterizes the highest residence time (42 months). This difference in cost trend is due to the lesser influence of *slow-used products* on recoverable holding costs and recoverable inventory, as noticed in the first observation. In this case, an increase in the service agreement or incentives increases the quantity of recoverable inventory but only after a long residence time. This surplus of recoverable inventory does not affect remanufacturing as a substitute for production activity in the short term. Therefore, an increase in service agreement for product recovery could have a reduced or negative effect on total inventory cost for *slow-used products* over a short time period. This is different for *fast-used products*, where an increase in incentives affects the quantity of recoverable inventory in a shorter time period, which can then be used sooner in remanufacturing activity with subsequent benefits in recoverable inventory and production activity reduction. However, in the long term the return of *slow-used products* can be improved by a percentage increase in the service agreement. Increasing the planning horizon from 60 to 120 months, the total inventory cost for *slow-used products* with a *residence time* equal to 42 months decreases from $3,834 for 20% of *service agreement with customer* to $3,601 for 100% of *service agreement with customer*. Examples of closed loop supply chains for *slow-used products* such as white goods are presented in the literature (Flapper et al., 2005). The main driver of the reverse logistics process for such products is government legislation, which stipulates the responsibilities of producers to recover their end-of-life products. However, incentives to the customer and several other factors involved in the process are given in order to increase the returns rate and improve economic and environmental benefits.

Simulations, using the same values for the parameters *RESIDENCE TIME* and *SERVICE AGREEMENT WITH CUSTOMER* presented in Figure 4, were undertaken by setting *CUSTOMER BEHAVIOR* at equal to 2 and 1. Figure 6 shows the evolution of the total inventory cost for changes in *customer behavior* and percentage of *service agreement with customer,* with a *residence time* equal to the base value of 12 months.

A reduction in the value of *customer behavior* from 3 to 1 decreases the returns rate and consequently the average number of returns. This applies to every percentage value of *service agreement with customer* except for 100%, for which the *return index* and consequently the returns rate is found to be independent of customer behavior. These simulation results correspond with and are thus representative of real-world scenarios, as a lower response from customers to company incentives for the recovery of used products in a closed loop supply chain system can reduce the quantity of returns. However, this does not tend to occur for products for which companies maintain ownership such as products under leasing contracts, or have recovery responsibilities as determined by government legislation.

This reduction in returns quantity resulting from changes in customer behavior has several consequences on the system and its total inventory cost. From Figure 6 it is possible to observe that for higher percentages of *service agreement with customer*, such as 60% and 80%, the total inventory cost increases if the customer response (and returns rate) is lower. This is due to the lower level of recoverable returns in the short term. Higher levels of service agreement or incentives coupled with higher response levels from customers to these incentives increase the level of remanufacturable returns. Therefore, in a shorter timeframe it is possible to use remanufacturing as a substitute for production activity with subsequent economic benefits obtained from the reduction of recoverable inventory and holding costs and the cheaper manufacturing processes. This observation was confirmed by lower recoverable holding costs obtained in a shorter period

Figure 6. Evolution of total inventory cost changing SAWC and CB



within the simulation analysis. Specifically, it was observed that when the remanufacturable returns start to accumulate, the recoverable holding costs are higher for the higher value of *customer behavior* due to the greater quantity of recoverable inventory. However, the latter allows for a prompt remanufacturing activity, which in turn reduces the recoverable inventory level and the costs. The same observation has been previously noted for an increase in *service agreement with customer*.

From Figure 6 it is evident that for lower percentages of *service agreement with customer*, such as 20% and 40%, the total inventory cost decreases if the *customer behavior* value decreases. In this case, as the analysis revealed, the low quantity of returns due to low incentives and low customer response leads to a low level of recoverable inventory, which is almost always lower than the level of recoverable inventory for higher values of *customer behavior*. The latter involves more remanufacturing activity but not enough to reduce the recoverable inventory level. Therefore, in the case of low values for *customer behavior* the level of recoverable inventory involves lower holding costs but at the same time lower remanufacturing activity. This scenario could negatively impact companies involved in remanufacturing activity for closed loop supply chain systems which require a sufficient quantity of returns to increase remanufacturing as a substitute for production activity. However, the analysis showed that in the case of low *customer behavior* the increased percentage in the service agreement might not generate an expected reduction in cost. As already mentioned, this is due to the insufficient level of remanufacturing activity needed to reduce and lower recoverable holding costs.

Evaluation and Recommendations

Remanufacturing activity in closed loop supply chain systems requires an adequate quantity of remanufacturable returns in order to establish a manufacturing process in which cheaper remanufacturing can be used as a substitute for production activity. This process leads to economic and environmental benefits in reducing the reliance on the more costly production activity. Remanufacturing uses 85% less energy than production, and reduces landfill, pollution and raw material usage (Gray & Charter, 2007). Moreover, the simulation analysis revealed that an increase in remanufacturing activity can optimize the inventory system and its costs through enhanced efficiency in the management of recoverable inventory. *Slow-used products* with a longer residence time in the short term present a reduced use of recoverable inventory due to their slower cyclic nature of return and consequently lower inventory cost compared to *fast-used products*. However, in the short run this could negatively affect remanufacturing as a substitute for production activity due to a shortage of remanufacturable returns. On the other hand, *fast-used products* can be used within a shorter time period and therefore prompt remanufacturing activity, which reduces the inventory cost through greater efficiency in recoverable inventory management. A prompt remanufacturing activity depends on the recoverable inventory on hand which, as the simulation analysis showed, is also influenced by *SERVICE AGREEMENT WITH CUSTOMER* and *CUSTOMER BEHAVIOR*. An increase in both these parameters leads to a higher returns rate, which in turn generates a higher level of recoverable inventory on hand and increases the possibility of prompt remanufacturing activity. For these reasons, the evaluation suggests that, for companies involved in remanufacturing activity as a substitute for the more expensive production activity, a shorter residence time combined with an increased level of service agreement or incentives for product recovery and a higher response from customers to these incentives can generate economic benefits through an increase in the quantity of remanufacturable returns.

However, uncertainty around the returns flow, particularly related to the timing and quantity of returns, could influence the results of the previous analysis of the inventory system. Some companies manage this uncertainty around the quantity of remanufacturable returns stored in the recoverable inventory without attempting to balance returns with demands, preferring instead to dispose of excess inventories on a periodic basis (Guide, 2000). In the same way, several authors incorporate a planned disposal of recoverable inventory in their models and posit a simple probabilistic returns quantity or define all demands as returns (van der Laan, Dekker, & Salomon, 1996; van der Laan & Salomon, 1997; Vlachos et al., 2007). In our model, planned disposal of recoverable inventory is not considered, which could add a new inventory cost and be more profitable, following the reverse logistics *preponement* concept (Blackburn, Guide, Souza, & Wassenhove, 2004), during or prior to the inspection stage. However, uncertainty around the timing and quantity of returns is specifically tackled in this study through the use of parameters such as *Residence time*, *SERVICE AGREEMENT WITH CUSTOMER* and *CUSTOMER BEHAVIOR*. Analysis of their interrelationships in the returns process can provide a forecasted returns rate and a possible time of return for used products with different product characteristics and in different industries. Knowledge of a product's residence time coupled with combinations of incentives in product recovery such as trade-in and leasing contracts can also assist in estimating the time and quantity of returns. Moreover, incentives, particularly leasing contracts and changes in product design for easier disassembly and recovery of product/components, can result in a reduction of the residence time, and subsequent benefits as those previously mentioned in connection to *fast-used products*. For example, the introduction of leasing contracts, or changes in product design that enable customers to easily disassemble and return used products/components, can fix or reduce the residence time. Through such incentives, companies can influence customer behavior in returning used products. By adopting policies such as the introduction of deposit fees, free collection or repurchase of used products, fees paid upon the return of used products, and improving product design, alongside providing clear information/advertising about reverse logistics activities and environmental responsibilities, can assist in enhancing customer behavior in relation to the returns process.

CASE STUDIES

In this section we assess the robustness of the findings obtained through the simulation analysis, which leads to the evaluation of the strategies aimed at improving the performance of the system. For this purpose, we use the data and information collected from the two companies employed as case studies: the Australian Mobile Telecommunications Association (AMTA) and Fuji Xerox Australia. These companies are involved respectively in reverse logistics and remanufacturing activity, and in particular are engaged in returns process activities, which meant they were appropriate cases for our study.

The findings were obtained from a generic model of the production and inventory system for remanufacturing. For this reason, the assessment involves a comparison between the findings and the data and information collected from these companies in order to find similarities and to verify the former by referring to the actual real-world practices of these companies. Specifically, the quantitative data and information collected from AMTA are employed first. Then the similarities between the AMTA data and both the qualitative data and the information collected from Fuji Xerox Australia are identified and discussed.

Australian Mobile Telecommunications Association (AMTA)

The first Australian company case is examined to assess the findings that revealed that an increase in the service agreement or incentives for product recovery, which in turn increases the likelihood of customers to engage in the returns process, leads to a higher returns rate.

AMTA is the national body of the mobile telecommunications industry in Australia and is currently supporting the official national recycling program of the mobile phone industry (KPMG, 2008). This program is a free recycling project for mobile phone users, which avoids landfill activity and recovers material from used mobile phones, bringing environmental and economical benefits. Project managers were contacted in order to obtain data and information, not about the recycling program (which is not directly relevant to this study) but about the influence of incentives on customers to return used products, and on customer behavior and returns rates in general. Data and information were obtained from the organization's 2007–2008 annual report (KPMG, 2008).

According to the report, the company has developed numerous incentives and service agreements with customers, retailers and other reverse logistics actors such as local councils and recyclers in order to increase returns/collection rates and improve customer behavior in relation to the returns process. In particular, the focus of the program is on free used product collection from customers. This has been achieved by distributing reply paid recycling satchels available in selected mobile phone packs and by setting up public collection points nationwide in retailers and Australia Post outlets. Other incentives include customer communications and environmental campaigns about the program published in catalogues, on websites, through direct marketing and television advertising presented by mobile manufacturers, service centers and retailers. These activities have achieved varying results. In particular, it was interesting to notice the evolution of particular key performance indicators for the program for the years 2005 to 2008. Since 2005, awareness of the recycling program, which represents consumer attitudes towards the reverse logistics program, has increased from 46% to 75% and at the same time collection and collection rates have increased from 42 tons to 97 tons and from 15% to 19%, respectively. The latter two factors are representative of the quantity of returns and the returns rate of used mobile phones. Moreover, the disposal to landfill rate has decreased from 9% to 4%.

Therefore, similar to our findings, these company incentives have enhanced customer behavior in relation to the returns process, which in turn has led to an increased returns rate.

Fuji Xerox Australia

The case study of Fuji Xerox Australia is presented in this section in order to assess two of the findings obtained from the simulation analysis. The first regards our belief that benefits can be obtained from remanufacturing activity through the combination of a shorter residence time and an increased level of service agreement or incentives for product recovery. The second regards the significant influence of service agreement or incentives for product recovery on the uncertainty around the quantity and timing of returns.

This case study employs qualitative data and information on this world leader in remanufacturing processes, obtained from the company management and drawn from the existing literature. Specifically, the qualitative data and information refer mainly to the Eco Manufacturing Centre located in Sydney.

The Eco Manufacturing Centre is the distribution center for remanufactured printer and copier assemblies or sub-assemblies, which would otherwise be landfill for the Asia-Pacific Region (Fuji Xerox Australia, 2007). Assemblies and sub-assemblies, removed from equipment during maintenance service calls, are remanufactured at this center. According to the managers, the Eco Manufacturing Centre focuses on and deals only with remanufacturing activity. For this reason, returns are an essential element in its remanufacturing activity, and predicting the quantity and timing of returns is essential to ensuring an efficient inventory and planning/scheduling for remanufacturing.

The information obtained from the managers is used to assess the first research finding. Specifically, the introduction of changes in product design as an incentive for product recovery through the easier disassembly and recovery of components rather than the whole machine, which in turn leads to faster recovery of returns or shorter residence times, has been strongly supported by the Fuji Xerox managers. Indeed, new machines are built for easier and faster disassembly, recovery and remanufacturing processes. In this way, remanufacturing activity can focus on modules that have shorter residence times and easier remanufacturability. The company's aim is to increase the number of remanufacturable returns and maximize engagement in the more profitable remanufacturing activity as a substitute for production activity. The work of the Eco Manufacturing Centre, which deals only with remanufacturing activity, supports this aim.

In terms of the second research finding, Fuji Xerox managers believe that a *full service agreement with customer* is an important strategy in the remanufacturing process. Fuji Xerox draws up a full service and maintenance agreement with its customers, whose preference is usually to lease the products. The full service agreement has a number of targets, including a marketing strategy aimed at increasing service levels for the customer. However, from the remanufacturing activity point of view the full service agreement is also a returns process strategy which functions to increase control of the quantity and timing of returns and to improve remanufacturing activity. The service is conducted by engineering teams, who provide service and repairs for breakdowns or when customers find the product is not working satisfactorily, as well as preventive maintenance of products. Using diagnostic tools, this maintenance service identifies the reasons for failure and opportunities to extend the product life (Fuji Xerox, 2007). This process involves two main analyses:

- **Failure Mode Analysis:** to identify the reasons for the failure of assemblies and sub-assemblies.
- **Signature Analysis:** to determine the remaining life of the assemblies and sub-assemblies through an examination of their critical performance parameters.

Data collection on these processes has led to continuous improvement of the basic product design and has resulted in a number of improvements. The durability of main assemblies and sub-assemblies, which is usually measured on the basis of the possible maximum number of copies to be completed, is designed so as to enable replacement of all of the components at the same time. In this way, during preventive maintenance it is possible to predict when it will be necessary to replace the assemblies to improve product performance, and when it will be necessary to replace them altogether. This process is guided by computer systems that identify whether or not there is a remanufacturing program for an assembly. During the breakdown and preventive maintenance, assemblies and sub-assemblies are replaced, and information on problems, solutions and forecasts for future replacement is provided. If the replacement is not possible at the maintenance stage because there is no ready availability of new assemblies, an order is submitted to the local warehouse. Used assemblies and sub-assemblies are collected by the service engineers, valet service staff or dealers to be returned and stored at the local warehouse. From the local warehouses, they are transported to the Eco Manufacturing Centre to be re-engineered and remanufactured as products that are good as new. Finally, they are packaged and stored in the surrounding warehouse as new products, awaiting transportation to the central distribution center of Fuji Xerox Australia.

From the information collected we can conclude that one of the reasons why the Fuji Xerox managers at the Eco Manufacturing Centre strongly support the introduction of a full service and maintenance agreement with customers is that it will increase control of the quantity and timing of returns. Indeed, the use of leasing contracts for products, combined with a service agreement that can generate a forecast regarding the quantity and timing of returns, allows the company to keep track of the quantity and location of equipment and maintain a degree of control over the returns rate.

FUTURE RESEARCH DIRECTIONS

The study described in this chapter explored a series of issues relevant to the field of reverse supply chains and in particular closed loop supply chains. However, we believe there is scope for further lines of enquiry in this area, to be considered by future researchers.

The findings of this study were obtained through the modeling and simulation of a generic production and inventory system for remanufacturing which is generally in line with those used in previous studies. In order to simplify the analysis and interpretation of such a system, a number of assumptions were made. However, an opportunity for further research lies in the evaluation of system performance by relaxing the remaining assumptions. This could be achieved by remodeling the structure of the system and incorporating the factors and their influence relationships that affect the system activities/processes.

Improving the model structure and its applicability to the real world might also be achieved through an extension of the meaning of the existing factors. Specifically, several exogenous factors such as service agreement with customers, customer behavior and residence time were defined in a generic way without considering their social, economic or management backgrounds. An exploration of the origins and roles of these factors could expand the models to cover new areas of research focusing on different fields of study. For example, in the returns process the factors residence time and service agreement with customers could be connected with perspectives from the social, legislative and marketing disciplines. Therefore, this study could be the starting point for further research aimed at analyzing the impact that such perspectives and considerations may have on a reverse supply chain system.

CONCLUSION

In this research, we developed an SD simulation model of the production and inventory system for remanufacturing within the context of closed loop supply chains. Our focus, particularly for the simulation analysis, was on the returns process within the system in which the returns rate was modeled by manipulating the relationships between particular factors that affect the system. The selected factors identify the time period for which products stay with customers, or residence time, and the quantity of possible returns based on customer demand or the return index. In particular, the return index was obtained by considering the relationship between the company incentives or service agreement with the customer aimed at encouraging used products recovery, and the customer behavior in terms of product return. The remanufacturing process was also modeled and a pull inventory control policy was applied to the process.

By analyzing the total inventory cost as a measure of the performance of the system, several findings were obtained regarding the effects of residence time and changes in the level of company incentives and the resulting customer behavior. The main finding is that companies engaged in remanufacturing activity can enhance their efficiency in managing inventory through shorter residence times and an increased level of company incentives, which results in improved customer behavior. This leads to a higher level of recoverable inventory on hand and consequently the possibility of prompt remanufacturing as a substitute for the more costly production activity, which in turn reduces the recoverable inventory level and its related holding cost.

Moreover, company incentives for the recovery of used products have significant influences on the uncertainty around the quantity and timing of returns and ultimately on total inventory costs. Increasing company incentives or enhancing service agreements with customers, which in turn improves customer behavior in returning used products, can improve the control of returns. Two company case studies (the Australian Mobile Telecommunications Association and Fuji Xerox Australia) were employed to assess the findings. It was found that Fuji Xerox Australia in particular offers incentives such as changes in product characteristics, full service and maintenance agreements with customers, and leasing contracts that function to reduce the product residence time and improve the company's control over returns.

Following our purpose to model a production and inventory system for remanufacturing within the context of closed loop supply chains and to evaluate effective control strategies aimed at improving system performance, this chapter made several contributions in different research areas. Specifically, the modeled returns process can be linked to specific product categories using the knowledge of the distinctive elements of particular products, which in this case was the average residence time. The latter characterizes different types of products depending on their variable time of use and recovery time, which in turn affects the system through the timing of returns. Service agreements with customers can influence customer behavior in relation to returning used products, and consequently affect the quantity of returns within the system. The variability of customer behavior, which generates uncertainty around the quantity of returns within the system, has been modeled and analyzed through three different customer behavior patterns. Our contribution in this area is to extend the current research with an approach to product recovery in which the correlation between demand and returns is identified through the use of these particular factors.

On the basis of the findings obtained from the simulation analysis, our contribution is to offer observations regarding efficiency in managing inventory activities for this particular system, and to provide guidelines for determining the quantity and timing of the return of used products by customers in order to reduce the uncertainty surrounding the timing and quantity of returns.

KEY TERMS AND DEFINITIONS

Closed Loop Supply Chain: Integration between a forward and reverse supply chain in reverse logistics processes.

Customer Relationship Management: Company strategies/policies for managing relationships with customers and organizing business processes.

Remanufacturing: A sustainable method applied particularly in closed loop supply chains to recapture value from product returns.

Reverse Logistics: A sustainable process applied in returns management in order to reuse, remanufacture, and recycle or properly dispose of product returns.

Sustainable Production: A production process that creates goods and services and is aimed at minimizing the usage of energy and natural resources.

System Dynamics: A modeling and simulation approach aimed at understanding the dynamic behavior of complex systems in order to analyze and solve complex problems with a focus on policy analysis and design.

Systems Modeling: Representation and construction of business systems through the use of models which correspond as much as possible to a meaningful concept based on real-world situations.

Chapter 20
A Production Planning Optimization Model for Maximizing Battery Manufacturing Profitability

Hesham K. Alfares
King Fahd University of Petroleum & Minerals, Saudi Arabia

ABSTRACT

This paper presents an integer programming (IP) model for production planning, which is used to maximize the profitability of battery manufacturing in a mid-size company. Battery production is a complicated multi-stage process. The formation stage, during which the batteries are filled with acid and charged with electricity, is considered to be the bottleneck of this process. The IP model maximizes the total profit of batteries produced in the formation stage, subject to limited manufacturing resources as well as time limitations and demand restrictions. The IP model is able to accommodate a large variety of battery models and sizes, and also different charging circuit capacities and speeds. The model is formulated and optimally solved using Microsoft Excel Solver. Compared to the current manual production planning approach, the optimum IP-generated production plans lead to an average increase of 12% in daily profits.

INTRODUCTION

Battery production requires a special manufacturing process that involves several distinctive steps such as chemical curing, acid filling, and electrical charging. Due to the unique characteristics of the battery manufacturing process, battery production planning has its own distinguishing features. In this paper, an integer programming model is presented for maximizing the profitability of battery production at the formation stage of manufacturing for the Middle East Battery Company (MEBCO) in Saudi Arabia. The model is formulated and applied to real production data, showing significant

DOI: 10.4018/978-1-4666-1945-6.ch020

advantages over the current manual production planning approach.

The Middle East Battery Company (MEBCO) is a joint venture between a group of Saudi industrialists and Johnson Control International (JCI). MEBCO produces AC Delco, JCI and Toyota branded maintenance-free batteries. As an equity partner in MEBCO, JCI has management responsibility for the plant operation. MEBCO plant, which is located in Dammam, Saudi Arabia, started commercial production in 1998. The production has been steadily growing and it has exceeded 2.5 million batteries since 2006. The plant produces batteries for all vehicle types, as well as marine, commercial and industrial applications. MEBCO's primary market is the Middle East, but it also has growing markets in Asia, Europe, and North America.

MEBCO's battery manufacturing plant is divided into 4 main areas; X-Met, Green Group, Formation, and Final Assembly. The Formation area's main function is the electrical charging of batteries for periods that range from 14.5 hours to 24 hours, depending on the type of battery. Because of the limited time per day, and also because of space limitations that restrict the number of charging circuits, the Formation area is considered to be the bottleneck of the battery production capacity.

According to the theory of constraints, the throughput rate of any multi-component system is controlled by the slowest component (called the constraint or the bottleneck). In order to maximize the productivity (profitability) of the battery production line, the company needs to optimize the production planning output in the formation stage. As shown in the following section, a variety of optimization and heuristic techniques have been used to solve battery production planning problems. In this paper, an integer programming (IP) model is used to maximize the profitability of the formation area. This IP model has been practically applied to optimally schedule the daily production of 74 battery models. The model considers different battery sizes, charging times, and daily demands, as well as limitations on times, capacities, and numbers of different types of charging circuits. Compared to manually generated production plans, the IP-optimized production plans increase daily profits by 12% on average.

The remaining sections of this paper are arranged as follows. First, previous literature on battery production planning is reviewed. Next, the manufacturing process, especially in the formation step, is described in more detail. Subsequently, the integer programming model for battery production planning is presented, and then the model's performance is compared to the current manual approach. Finally, results are analyzed, and conclusions are drawn.

LITERATURE REVIEW

Previous approaches to battery production planning include simulation, network flow models, EOQ-type techniques, mathematical programming, and various heuristics. Turnquist (1991) described a software system for battery production planning developed by Cornell University for the Battery Strategic Business Unit of Delco Remy. The PC-based system includes three main components: (1) a forecasting module, (2) a multi-plant product allocations module, and (3) a scheduling module. The production scheduling module employs a network flow model to dynamically balance inventory and overtime costs given limited capacities and fluctuating demands for each plant.

Yenradeea (1994) combines simulation, the optimized production technology (OPT), and simple scheduling rules to schedule a four-stage battery production line. The OPT production plans successfully minimize inventory while maximizing the throughput rate. Using simulation experiments, these plans are shown to outperform both the push and the pull policies. Khadem and Ali (2008) develop a simulation model to optimize the cost effectiveness of a car battery manufacturer.

The model is used to represent and analyze the dynamics of the battery assembly line, and also to make several recommendations for improving the line's cycle time, productivity, and quality.

Sharma (2003) integrated the principles of lean production with the practices of Six Sigma to improve daily work life in a battery company on a continuing basis. The advantages realized by the company included significant cost reduction, more efficient manufacturing process, and higher customer satisfaction. Al-Turki (2000) presented a heuristic multi-product batch scheduling algorithm to schedule battery batch production with the minimum set-up time. The effects of set-up time/frequency and batch size on the production performance were investigated in a real-life battery manufacturing company. César et al. (2007) described a case study implementation of intermediate stock management in the production process for automotive batteries, highlighting the main positive aspects and the deficiencies.

Huston (1996) used a three-stage process for production planning at the International Fuel Cell Corporation (IFC) in the US. First, a spread-sheet model determines daily production and workforce size. Next, an EOQ model determines optimal lot sizes. Finally, a process improvement model increases bottleneck production by reducing setup time and/or cycle time. Elimam and Udayabhanu (1999) presented two procedures for planning the production of lead-acid batteries: a simple MRP-based heuristic and a mixed integer programming optimization model. In a later paper, Elimam and Udayabhanu (2001) modeled battery production as a multi-product, multi-period, and multi-component supply chain process. The trade-offs in this process – including the costs of holding, ordering, and defects – were tested in a small battery manufacturing plant.

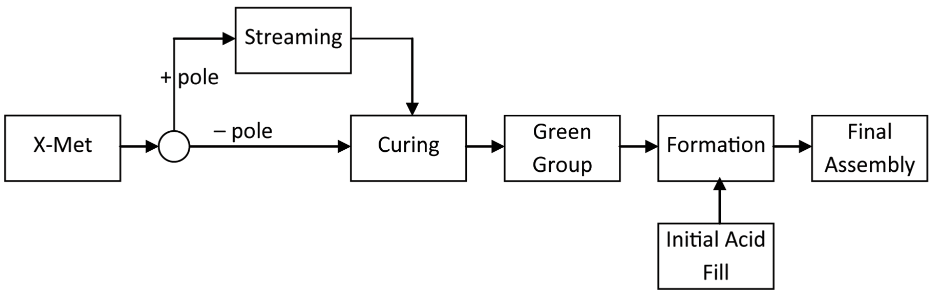
Dunstall and Mills (2002) presented a mixed-integer programming (MIP) model to optimally schedule cyclic production of batteries for Exide Technologies in Australia. A production schedule is developed for 42 periods in a cyclic workweek. The objective is to maximize throughout of a multi-product battery charging and finishing facility while maintaining a given product mix. Dunstall and Mills (2007) slightly modified their earlier MIP model and then used simulation experiments to evaluate its performance compared to two simple scheduling rules: shortest processing time (SPT), and random sequencing (RND). The simulation results confirmed that the optimal MIP schedules consistently yield higher throughputs than simple on-line dispatching rules.

The formation-stage production planning problem at MEBCO, which is described in detail later, does not involve any stochastic or nonlinear aspects. Although the problem has integer variables, it is fairly small and thus easy to solve. Therefore, optimization by integer linear programming is the most suitable approach for this problem. Compared to Dunstall and Mills (2002) MIP model, this paper presents a pure-integer programming model with substantially different decision variables, objective function, and constraints. Before introducing the model, the battery manufacturing process is described in the following section.

BATTERY MANUFACTURING PROCESS

The manufacturing space in the plant is divided into 4 main areas; X-Met, Green Group, Formation, and Final Assembly. The main processes in the X-Met area are lead strip manufacturing, oxide manufacturing, paste mixing, X-Met line, steaming, and curing. The Green Group main sections are encapsulation/collation, case preparation, battery assembly, cast-on-strap, side terminal weld, extrusion fusion weld, heat seal, and top terminal weld. The main processes in the Formation stage, which is described in more detail later in this section, are initial acid fill and formation. The Final Assembly's main processes are formation acid dump, final acid fill, final heat seal, labeling,

Figure 1. Flow chart of the manufacturing process



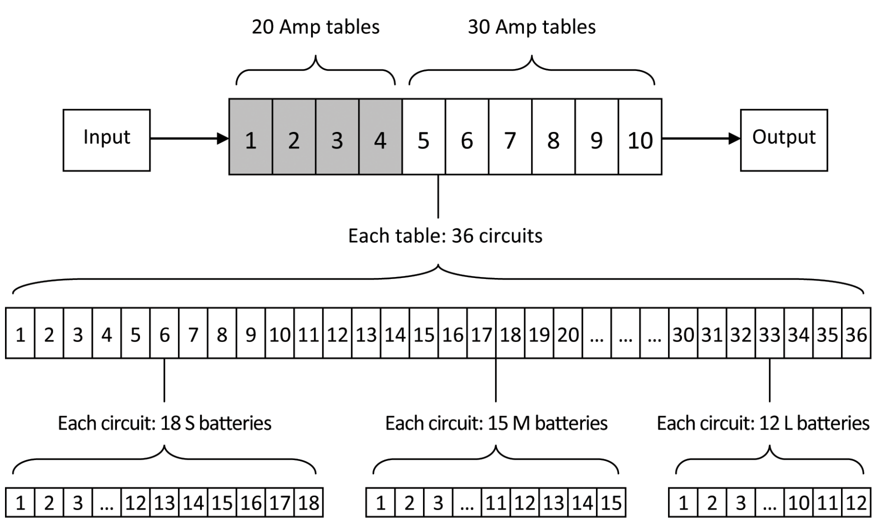
and packing. Figure 1 illustrates the flow of the manufacturing process.

The first operation in the formation area is filling the batteries with a lower-specific-gravity acid called the forming acid. This weak acid contains more water than acid to facilitate and promote the chemical conversion of the plates. This forming acid also contains a specific ingredient called formax. Controlling the amount of formax, acid gravity, and acid volume in the acid mixing process is very important in attaining proper battery formation and performance.

Once the Green Group batteries have been filled with forming acid, they are transferred by conveyors to the charging area, whose layout is shown in Figure 2. The charging area has 10 tables, 4 of which have 20-Ampere chargers while the remaining 6 have 30-Ampere chargers. On the charging tables, batteries are arranged in groups (known as circuits) to match the circuit output points of the chargers. Each charger has 36 output points (circuits), with up to 18 small-size batteries per circuit. However, due to space limitations, only 15 medium-size or 12 large-size batteries can be connected to each circuit. Within each circuit, the individual batteries are hooked together (positive of one battery attached to negative of next battery) by the use of charging straps.

Once the batteries are loaded on to tables in different circuits, they are subjected to a one-hour rest or pickling time. During this one-hour time frame, strap and circuit connections are com-

Figure 2. Layout of the charging tables in the formation area



pleted and the batteries are spaced apart to attain proper air flow cooling. Subsequently, they are given two steps of electrical charges for a specific duration and ampere rates. Between two steps, a rest time of 3 hours is provided. The electrical charges are applied in order to turn the green sulfated plate material into formed plates capable of storing and delivering electrical charge.

The electrical charging cycle of the batteries varies with the size of the battery. Smaller automotive batteries require less Ampere-hour (Amps-charger output multiplied by time on charge) charging than larger automotive batteries. Extra-large heavy duty batteries tend to have the longest charging cycles. Once the formation is completed, the batteries are unstrapped from each other and from the charging circuits. Finally, the batteries are off loaded from the charging rows onto conveyors that transfer the units to the finishing line. The steps of the formation process are depicted in Figure 3.

Sometimes during the peak season, the formation stage becomes a bottleneck that limits the battery production capacity because it involves many constraints and obstacles. These include long formation times, capacity constraints, lack of scheduling system, and inexact demand forecasting. In the following section, an integer programming optimization model for production planning is formulated for maximizing the productivity (profitability) of the formation stage.

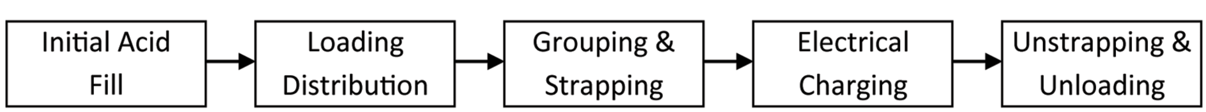
FORMATION CAPACITY OPTIMIZATION MODEL

In this section, we present the assumptions, decision variables, objective function, and constraints of an integer programming production planning model that is formulated to maximize the profitability of batteries produced from the formation area.

Assumptions of the Model

1. There are 10 tables for charging batteries. The number of tables is currently limited due to scarce space availability in the formation area.
2. There are six 30-Amps and four 20-Amps charging tables. This is probably a sub-optimum allocation of the 10 tables among the two types, because more battery models can be charged on 20-Amps circuits than on 30-Amps circuits.
3. Each table has 36 charging circuits. This number is fixed by the table size and the space requirements of the different battery models and charging circuits.
4. Each circuit consists of 18, 15 or 12 batteries, depending on battery size.
5. There are three battery sizes:
   - Size 1 (small): 18 batteries per circuit.
   - Size 2 (medium): 15 batteries per circuit.
   - Size 3 (large): 12 batteries per circuit.
6. In any charging circuit, we cannot have any mix among the three battery sizes.
7. Some batteries can be charged only on 20-Amps circuits, some others can be charged on 30-Amps, while the rest can be charged on both.
8. If a battery can be charged on either 20-Amps or 30-Amps circuits, then the charging time is shorter on the 30-Amps.

Figure 3. Detailed flow chart of the formation stage



9. The larger the battery size, the longer the charging time required.
10. The total number of battery models produced by the company is 74. Out of these, 35 models can be charged on 20-Amps circuits, 31 models can be charged on 30-Amps circuits, while 8 models can be charged on both types of circuits.
11. The maximum demand for each battery model is given per day, based on the overall weekly demand.

In reality, there are several other considerations that are not explicitly included in the model because they do not affect the model's output. For example, storage time constraints require batteries are not kept for more than 96 hours after formation. In addition, batteries taking longer times are not loaded when there is an urgent need for finishing certain quantities of other models. Finally, where demand is normal, batteries with longer charging duration will be put on charge first.

Given Parameters

d_i = demand of model i battery, i = 1,..., 74
p_i = profit per unit of model i battery, i = 1,..., 74
t_{ia} = formation time of model i battery if charged on a 20-Amps table
t_{ib} = formation time of model i battery if charged on a 30-Amps table
S_k = set of indices (model numbers) of batteries of size k, k = 1,..., 3

Decision Variables

X_i = number of model i batteries charged on 20-Amps tables per day, i = 1,..., 74
Y_i = number of model i batteries charged on 30-Amps tables per day, i = 1,..., 74
A_k = number of 20-Amps circuits assigned to batteries of size k, k = 1,..., 3
B_k = number of 30-Amps circuits assigned to batteries of size k, k = 1,..., 3

Objective Function

The objective of the integer programming model is to maximize the total daily profit of batteries processed in the formation stage of the battery manufacturing process:

$$\text{Maximize } Z = \sum_{i=1}^{74} p_i (X_i + Y_i) \quad (1)$$

Constraints

The maximum daily demand for each battery model cannot be exceeded:

$$X_i + Y_i \le d_i,\ i = 1,..., 74 \quad (2)$$

The number of batteries charged in the 20-Amps (30-Amps) tables is limited by the available respective circuit capacity:

$$A_1 + A_2 + A_3 \le 4(36) \quad (3)$$

$$B_1 + B_2 + B_3 \le 6(36) \quad (4)$$

For each of the three sizes, the total number of hours used for charging 20-Amps batteries cannot exceed the total available circuit-hours per day:

$$\sum_{i \in S_1} t_{ia} X_i \le 18(24) A_1 \quad (5)$$

$$\sum_{i \in S_2} t_{ia} X_i \le 15(24) A_2 \quad (6)$$

$$\sum_{i \in S_3} t_{ia} X_i \le 12(24) A_3 \quad (7)$$

For each of the three sizes, the total number of hours used for charging 30-Amps batteries cannot exceed the total available circuit-hours per day:

$$\sum_{i \in S_1} t_{ib} Y_i \le 18(24) B_1 \quad (8)$$

$$\sum_{i \in S_2} t_{ib} Y_i \le 15(24) B_2 \quad (9)$$

$$\sum_{i \in S_3} t_{ib} Y_i \le 12(24) B_3 \quad (10)$$

X_i, Y_i, A_k, $B_k \ge 0$ and integer, $i = 1,..., 74$, $k = 1,..., 3$ (11)

MODEL APPLICATION AT MEBCO

All of the data required for the model were collected from the MEBCO Product Standards Manual for all 74 battery models produced by MEBCO. Some of these models can be charged either on 20-Amps or on 30-Amps charging circuits. Table 1 shows standard data (formation time, charge table type, and battery size) for a sample of 15 battery models. In addition, current unit profits and typical daily demands are shown for these 15 battery models.

For each work day, the above integer programming model was solved for different daily demands d_i, $i = 1,..., 74$, using the Solver optimization tool in Microsoft Excel. Compared to the current manual schedules, the optimum solutions found by the model produced significantly higher daily profits. The increase in daily profit ranged from \$3,500 to \$6,200, and averaged around \$4,600. In relative terms, the increase in daily profit ranged from 8% to 16%, and averaged around 12%. Table 2 compares the daily profits of the model's optimum solution and the company's manual solutions for 5 typical work days.

Table 1. Typical data for a sample of 15 battery models

Model	Formation time (Hr)	Table type	Battery size	Profit ($)	Daily demand
1	17.5	20 Amps	1	3.52	748
4	21	20 Amps	1	4.59	218
	17	30 Amps			
5	24	30 Amps	2	6.72	4
20	22.5	30 Amps	3	6.72	180
21	23.5	20 Amps	2	5.28	75
22	23.5	20 Amps	2	5.28	225
28	24	20 Amps	1	5.23	0
29	24	30 Amps	2	11.12	0
30	21	30 Amps	3	7.15	72
31	16	20 Amps	1	3.52	192
	15.5	30 Amps			
32	23	30 Amps	3	7.87	0
33	15.5	20 Amps	1	3.52	256
	16	30 Amps			
34	24	30 Amps	3	10.40	9
35	18	20 Amps	1	3.04	0
36	16.5	20 Amps	1	3.04	0
37	20.5	30 Amps	2	9.20	144

Table 2. Optimal solution profit vs. company schedules' profits for five work days

Day	Company profit ($)	Optimum Profit ($)	% Profit Increase
1	37,387	43,200	**15.55**
2	41,605	46,160	**10.95**
3	32,803	37,099	**13.10**
4	41,369	45,077	**8.97**
5	35,973	39,767	**10.54**

CONCLUSION

An optimum production planning model has been formulated and used to maximize the profitability of battery production for a real-life battery manufacturer. The integer programming model is specifically designed to determine the production plan at the formation stage (i.e., quantities of each battery model allocated to each type of charging table). The constraints of the model include demand for each battery model, availability of charging tables, and charging time limitations.

The IP model has several advantages. First, the model produced significant improvements (averaging 12%) in daily profit. Second, the model is flexible to changes in input parameters such as daily demands, or to changes in decision variables (e.g., new battery models). Another advantage is the use of standard Microsoft Excel Solver, which makes the model a very convenient low-cost tool to find the optimal battery production plan under a variety of scenarios. Limitations of the model are imposed by the given assumptions and constraints, reflecting the company's current practice. These include space and time constraints and the number of charging tables of each type.

Several opportunities for future research could be pursued in order to improve performance further. First, daily demands for different battery types could be estimated more carefully in order to take full advantage of the model. Second, the optimum number of 20-Amps and 30-Amps tables could be determined under space and budget constraints, subject to varying daily demands for individual battery types. Third, mixing different battery sizes on the same charging circuit could be allowed to increase the flexibility to meet demands. Finally, the IP model could be combined with facility layout techniques in order to maximize the space utilization and increase the number of charging tables.

Chapter 21
Multi-Objective Optimization of Manufacturing Processes Using Evolutionary Algorithms

M. Kanthababu
Anna University, India

ABSTRACT

Recently evolutionary algorithms have created more interest among researchers and manufacturing engineers for solving multiple-objective problems. The objective of this chapter is to give readers a comprehensive understanding and also to give a better insight into the applications of solving multi-objective problems using evolutionary algorithms for manufacturing processes. The most important feature of evolutionary algorithms is that it can successfully find globally optimal solutions without getting restricted to local optima. This chapter introduces the reader with the basic concepts of single-objective optimization, multi-objective optimization, as well as evolutionary algorithms, and also gives an overview of its salient features. Some of the evolutionary algorithms widely used by researchers for solving multiple objectives have been presented and compared. Among the evolutionary algorithms, the Non-dominated Sorting Genetic Algorithm (NSGA) and Non-dominated Sorting Genetic Algorithm-II (NSGA-II) have emerged as most efficient algorithms for solving multi-objective problems in manufacturing processes. The NSGA method applied to a complex manufacturing process, namely plateau honing process, considering multiple objectives, has been detailed with a case study. The chapter concludes by suggesting implementation of evolutionary algorithms in different research areas which hold promise for future applications.

1. INTRODUCTION

Optimization refers to determining one or more feasible solutions from a set of available alternatives which may correspond to the maximum or minimum value of one or more objective functions. It implies choosing values for a variable from a set of real numbers such that the desired function takes one of the values. Finding an optimal solution for a given problem, which involves only one objective function is called single-objective optimization. Single-objective optimization generally attempts to find one good solution that is better than any

DOI: 10.4018/978-1-4666-1945-6.ch021

other feasible solutions in a set or search space. The input process parameters corresponding to such solution are called optimal parameters. For a single-objective problem, varieties of optimization methods ranging from classical to search methods have been used. Researchers have used the single-objective optimization techniques in several fields such as routing, scheduling, salesman, image processing, engineering design, parameter fitting, computer game playing, transportation, etc. (Goldberg, 1989; Srinivas and Deb, 1995).

A single-objective optimization involves maximizing or minimizing a chosen objective function without considering its effects on any other objective functions. Consider a hypothetical case, where the customer wants a product with the best possible surface finish irrespective of the cost/material removal rate. In such a scenario, the manufacturing engineer can choose the input process parameters that can yield the fine surface finish without considering the productivity or costs. On the other hand, if the desired outputs are more than one, for example when a customer demands for fine surface finish at lower cost, then it is considered as a multi-objective optimization problem. Therefore, the manufacturing engineer has to optimize two conflicting objectives i.e., fine surface finish and high material removal rate. If the manufacturing engineer chooses the first option based on the single-objective optimization considering only fine surface finish, then the productivity will suffer. Since, the fine surface finish results from lower material removal rate. If the manufacturing engineer chooses the input process parameters which provides only higher material removal rate, then it is very difficult to achieve the fine surface finish. Now the question arises, which is the best possible solution/solutions to achieve both fine surface finish and higher material removal rate together. In such a scenario, there is no single optimum solution or they cannot be solved through single-objective optimization techniques. Therefore, such problem is considered under the preview of multi-objective optimization.

Researchers made several attempts to solve multi-objective problems through different methods such as classical optimization, weighted sum, goal programming, min-max, etc. But these methods are not able to find multiple solutions in a single run. These methods change the multi-objective problem into a single-objective problem with the corresponding weights based on their relative importance and also suffer from a drawback that the decision maker must have a thorough knowledge of ranking of objective functions. These methods also fail when the objective functions become discontinuous. In contrast, evolutionary algorithms have been proved successfully for solving multi-objective problems because they operate with a population of individuals and also well suited to search for multiple solutions simultaneously. It is well proven that evolutionary algorithms can solve several conflicting objectives and also able to approximate the optimal solutions in a single run. Therefore, evolutionary algorithms have attracted a lot of research during the last two decades and it is still one of the hottest research areas in the field of evolutionary computation (Fonseca and Fleming, 1995; Sbalzariniy et al., 2000; Deb, 2001; Deb et al., 2002; Zitzler et al., 2004; Konak et al., 2006; Zhou et al., 2011).

In the view of the above, the following sections present the basic principles of multi-objective optimization as well as evolutionary algorithms and the working mechanisms of one of the efficient evolutionary algorithm has been detailed with a case study for ease in understanding. Finally the chapter is concluded with some potential directions for future research.

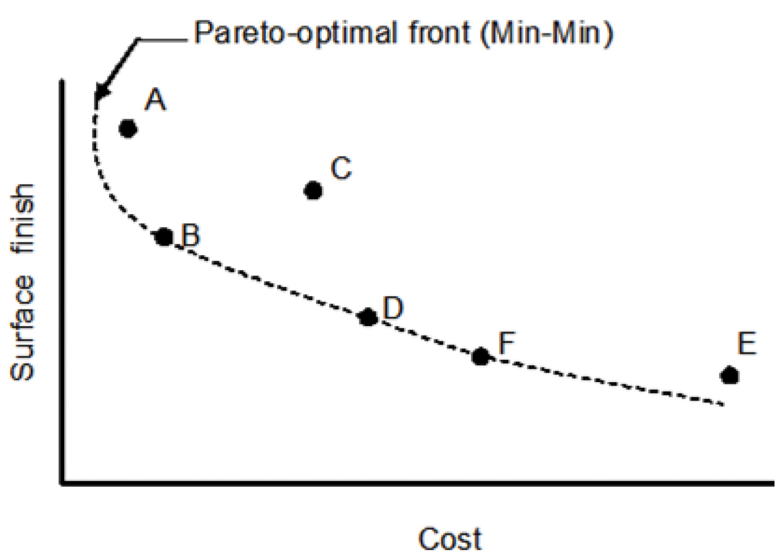
2. MULTI-OBJECTIVE OPTIMIZATION

In a multi-objective optimization problem there are more than one objective functions. The objective functions are often conflicting to each other and there is no single combination of optimal parameters, which can provide the best performance. Therefore, multi-objective optimization results in set of solutions in the search space. Among the set of solutions, no solution can be said to be inferior or superior over the other solutions in the set. Such solutions are known as Pareto-optimal solutions or Pareto-set or non-dominated solutions. The rest are called dominated solutions. The dominated solutions are not important for us. Therefore, in the multi-objective optimization, Pareto-optimal solutions are obtained by capturing number of feasible solutions simultaneously. Pareto-optimal solutions are often preferred than single solution because they are found to be practical while considering real life problems, since the final solution of the decision maker is always a trade-off. Almost, all real world problems can be accurately modelled by considering it as a multi-objective problem. Let us see Pareto-optimal solutions with a typical example as shown in Figure 1.

The example shown in Figure 1 has two objectives namely cost and surface finish, both of which are to be minimized (Min-Min) for productivity. In Figure 1, the point A represents a solution which incurs minimal cost but results in higher surface finish. On the other hand, the point E represents a solution which is costly, but it result in lower surface finish comparatively to point A. If both objectives i.e cost and surface finish are important goals and have to be considered simultaneously by the manufacturing engineer, one cannot really say whether solution A is better than solution E, or vice versa. i.e. Solution A is better than other in one objective (cost), but it is worse in the other objective (surface finish). But, there exists many solutions like B, D and F, which belong to the Pareto-optimal solutions. The Pareto-optimal solutions are shown as Pareto-optimal front marked as dashed line in Figure 1. From Figure 1, we can also observe that there exist non-Pareto-optimal solutions or dominated solution like point A, C and E. If we compare solution A with solution C, it is difficult to conclude which one is better than the other considering both the objectives. This is because there is another solution namely B in the search space, which is better than the solutions A and C.

The location of the Pareto-optimal front of the Pareto-optimal solutions in the search space

Figure 1. Pareto-optimal solutions

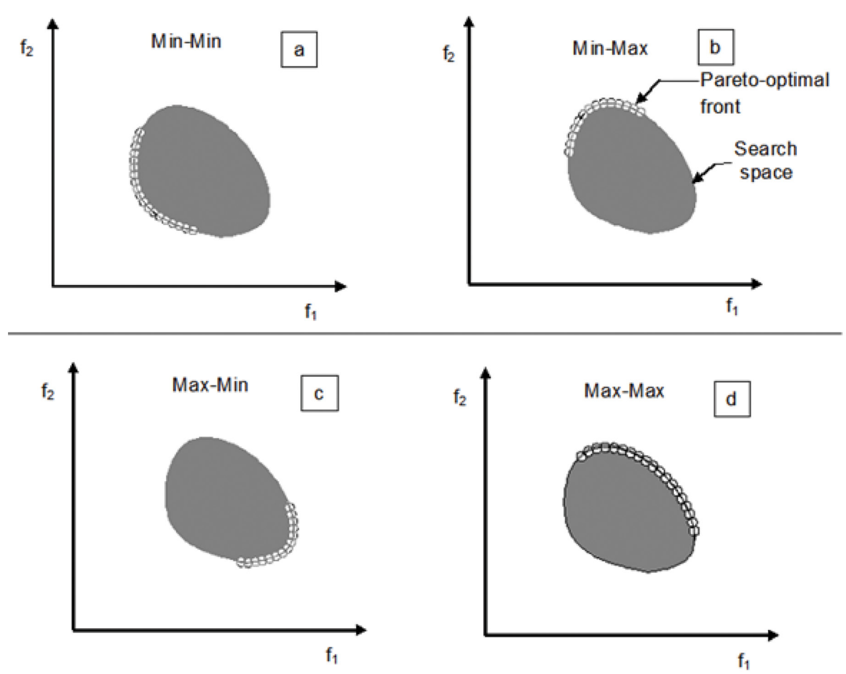


is based on the constraints of the objective functions, whether the objective functions have to be minimized or vice versa or opposite in nature (Figure 2). Consider the problem in Figure 2a, in which both objective functions f_1 and f_2 have to be minimized (Min-Min). The Pareto-optimal front (Pareto-optimal solutions) is shown with smaller circles in the search space. The search space is shown as shaded area in the Figure 2. The Pareto-optimal solutions in the front is a set of solution indicated that no one solution dominates the others and each solution is equally good for the given optimization problem and constraints. Figure 2b shows the Pareto-optimal front for a problem involving minimizing f_1 and maximizing f_2 (Min-Max) and Figure 2c shows the Pareto-optimal front corresponds to the problem of maximizing f_1 and minimizing f_2 (Max-Min). Figure 2d corresponds to the Pareto-optimal front for maximization of both objectives f_1 and f_2 (Max-Max).

The ultimate goal of the multi-objective algorithms for solving multi-objective problems is to identify solutions with in the Pareto-optimal solutions or Pareto-optimal front. However, it is practically difficult to identify the entire Pareto-optimal solutions due to its size or computational infeasibility. Therefore, a practical approach is to investigate a set of solutions (the best-known Pareto-set) that represent the Pareto-optimal set. Therefore, any multi-objective algorithms should achieve the following three important conflicting goals (Konak et al., 2006):

1. The best known Pareto-front should be as close as possible to the true Pareto-front. Ideally, the best known Pareto-set should be a subset of the Pareto-optimal set.
2. Solutions in the best known Pareto-set should be uniformly distributed and diverse over the Pareto-front in order to provide the decision maker a true picture of trade-offs.
3. The best known Pareto-front should capture the whole spectrum of the Pareto-front. This requires investigating solutions at the extreme ends of the objective function space.

Figure 2. Pareto-optimal front for different combinations of maximization and minimization problems



A typical multi-objective optimization problem consists of a number of objectives and is associated with a number of inequality and equality constraints. Mathematically, the multi-objective optimization problem can be expressed as follows:

Minimize / Maximize

f_i (x) i = 1, 2,....., N (1)

Subject to

$g_i(x) \leq 0$ j = 1, 2,....., J

$h_k(x)=0$ k=1, 2, ….., K

The parameter x is a p dimensional vector having p design or decision variables. Solutions to a multi-objective optimization problem are mathematically expressed in terms of Pareto-optimal solutions or non-dominated or superior points. In a minimization problem, a vector $x^{(1)}$ is less than another vector $x^{(2)}$, ($x^{(1)} < x^{(2)}$), when no value of $x^{(2)}$ is less than $x^{(1)}$ and at least one value of $x^{(2)}$ is strictly greater than $x^{(1)}$. If $x^{(1)}$ is partially less than $x^{(2)}$, we say that the solution $x^{(1)}$ dominates $x^{(2)}$ or the solution $x^{(2)}$ is inferior to the $x^{(1)}$. Any member of such vectors which is not dominated by any other member is said to be non-dominated or non-inferior. Similarly if the objective is to maximize a function, we define a dominated point if the corresponding component is greater than that of a non-dominated point (Rao, 1984).

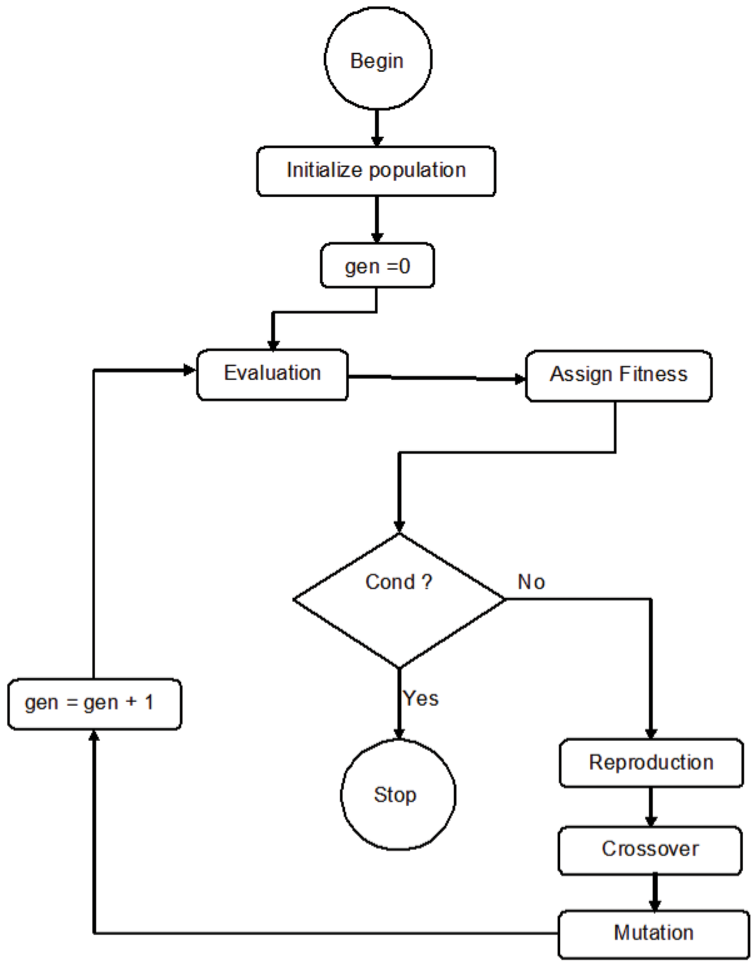
Mathematically, an optimization algorithm should terminate if any one of the Pareto-optimal solutions is obtained. But in practice, since there could be a number of Pareto-optimal solutions and the suitability of one solution depends on a number of factors. Hence, a multi-objective optimization algorithm must successfully find a globally optimal solution without getting restricted to local optima. Therefore, researchers are increasingly focussing on solving the multi-objective optimization problems using evolutionary algorithms due to its effectiveness and efficiency (Deb, 1995; Deb, 1999; Deb, 2001). Considering the importance of evolutionary algorithms for solving multiple objectives, the following are discussed in detail.

3. EVOLUTIONARY ALGORITHMS

The following sections deals with the different types of evolutionary algorithms starting with Genetic Algorithm (GA). GA is one of the widely used evolutionary algorithms. The procedure of a GA is given in Figure 3.

The concept of GA was developed by Holland and his colleagues in the 1960s (Goldberg, 1989). GA is a search and optimization tool developed by mimicking the evolutionary principles and chromosomal processing in natural genetics based on the concept of Darwinian theory of evolution. According to this theory, in nature, weak and unfit species within their environment are faced with extinction by natural selection. The strong ones have greater opportunity to pass their genes to future generations via. reproduction. In the long run, species carrying the correct combination in their genes become dominant in their population. Sometimes, during the slow process of evolution, random changes may occur in genes. Random changes provide additional advantages for survival (i.e) new species evolve from the old ones. Unsuccessful changes are eliminated by natural selection. The basics and working principles of GAs are detailed by Deb (1995) and Deb (2001). GA and its variations such as ant colony optimization, particle swarm optimization, simulated annealing, etc. are used by researchers for optimization. However, GA is mostly limited to single-objective optimisation. For addressing multi-objective optimization, several multi-objective evolutionary algorithms are formulated by different researchers to solve multi-objective problems (Fonseca and Fleming, 1995; Sbalzariniy et al., 2000; Deb 2001; Deb et al., 2002; Zitzler et al., 2004; Konak et al., 2006; Zhou et al., 2011).

Figure 3. Flowchart of GA (Deb, 2001)



3.1 Multi-Objective Optimization Algorithms

Multi-objective optimization algorithms differ from single objective optimization algorithms in terms of their fitness assignment procedure, elitism or diversification approaches and it can overcome the shortcomings encountered in single-objective optimization algorithms. The first multi-objective evolutionary algorithm called Vector Evaluated GA (or VEGA) was proposed by Schaffer (1985). Afterwards, several multi-objective evolutionary algorithms were developed including Multi-objective Genetic Algorithm (MOGA), Niched Pareto Genetic Algorithm (NPGA), Weight-based Genetic Algorithm (WBGA), Random Weighted Genetic Algorithm (RWGA), Non-dominated Sorting Genetic Algorithm (NSGA), Strength Pareto Evolutionary Algorithm (SPEA), improved SPEA (SPEA2), Pareto-Archived Evolution Strategy (PAES), Pareto Envelope-based Selection Algorithm (PESA), Region-based Selection in Evolutionary Multi-objective Optimization (PESA-II), Non-dominated Sorting Genetic Algorithm-II (NSGA-II), Multi-objective Evolutionary Algorithm (MEA), Micro-GA, Rank-Density Based Genetic Algorithm (RDGA), Dynamic Multi-objective Evolutionary Algorithm (DMOEA), etc (Fonseca and Fleming, 1993; Deb, 2001; Valenzuela, 2002; Konak et al., 2006). The summary of applications of multi-objective evolutionary algorithms for real world problems has been detailed by Zhoua et al. (2011). Although several algorithms exist, many researchers applied strategies from various multi-objective GAs and their performances were tested in several studies (Zitzler et al., 2000; Konak et al., 2006). The advantages and disadvantages of different evolutionary algorithms are briefly summarized and presented in Table 1.

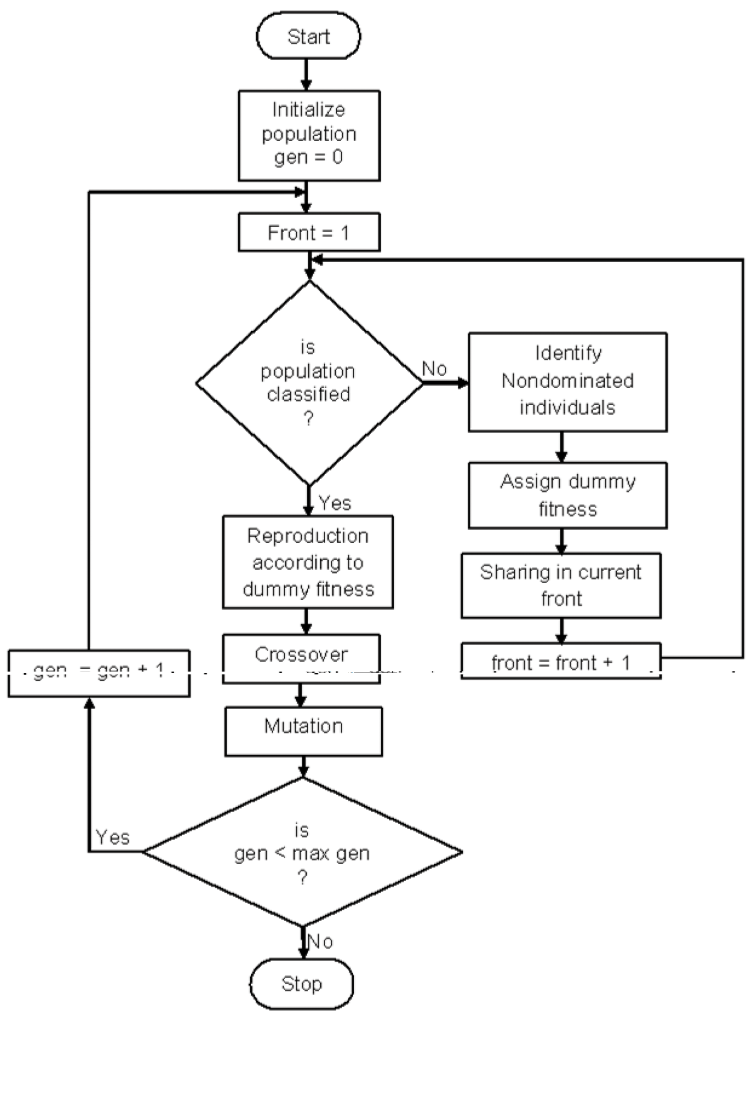
Though many evolutionary algorithms exist, only few researchers made an attempt to optimise multiple objectives using evolutionary algorithms especially in manufacturing process. Literature related to the application of evolutionary algorithms in manufacturing processes is briefly presented here. Kuriakose and Shunmugam (2005) made an attempt to optimise conflicting multiple objectives such as maximizing cutting velocity and minimising surface finish in wire electric discharge machining using NSGA. Sardiňas et al. (2006) made an attempt to optimise two mutually conflicting multiple objectives such as maximizing metal removal rate (to increase productivity) and minimising the delamination factor (improving surface quality) for drilling composite materials. Wang et al. (2006) made an attempt to optimise the multi-pass milling process considering multiple objectives such as minimising machining time as well as minimising production cost using parallel genetic simulated annealing, in which the fitness assignment is used based on

Table 1. Comparisons of evolutionary algorithms (Konak et al., 2006)

S. No	Multi-objective evolutionary algorithm	Advantages	Disadvantages
1	Vector Evaluated Genetic Algorithm (VEGA)	Straightforward for implementation	Tend to converge to the extreme for each objective
2	Multi objective Genetic Algorithm (MOGA)	Simple extension of single objective GA	Slow convergence
3	Weight Based Genetic Algorithm (WBGA)	Simple extension of single objective GA	Difficulties in non-convex objective function space
4	Niched Pareto Genetic Algorithm (NPGA)	Very simple selection process with tournament selection	Requires extra parameters for tournament selection
5	Random Weighted genetic Algorithm (RWGA)	Efficient and easy to implement	Difficulties in non-convex objective function space
6	Pareto Envelope based Selection Algorithm (PESA)	Easy to implement and computationally efficient	However, performance is depends on the cell sizes
7	Pareto Archived Selection Strategy (PAES)	Easy to implement and computationally efficient	Not a population based approach and the performance is depends on the cell sizes
8	Non-dominated Sorting Genetic Algorithm (NSGA)	Fast convergence	Problems related to niche size parameter
9	Non-dominated Sorting Genetic Algorithm-II (NSGA-II)	Single parameter, well tested and efficient	Crowding distance works in objective space only
10	Strength Pareto Evolutionary Algorithm (SPEA)	Well tested and no parameter for clustering	Complex clustering algorithm
11	SPEA II	Ensures extreme points are preserved	Computationally expensive fitness and density calculations
12	Rank Density based Genetic Algorithm (RDGA)	Dynamic cell update and robust with respect to number of objectives	Difficulty to implement
13	Dynamic Multi-objective Genetic Algorithm (DMOEA)	Efficient techniques to update cell densities and adaptive approaches to set GA parameters	Difficulty to implement

the concept of NSGA. Mandal et al. (2007) made an attempt to optimize multi-objectives such as maximizing metal removal rate and minimizing tool wear (to maintain accuracy) in an electrical discharge machining process using NSGA-II. Yang and Natarajan (2010) made an attempt to optimize conflicting multi-objectives (i.e) to minimise tool wear and maximize metal removal rate in turning process by using multi-objective differential evolution (MODE) algorithm and NSGA-II. From the literature, it is observed that among the evolutionary algorithms, NSGA and NSGA-II methods are found to be advantageous than other algorithms, especially for selecting optimal parameters for manufacturing processes. It is also observed that NSGA and NSGA-II methods resulted in wider solutions for the manufacturing engineers to select the appropriate input process parameters in various manufacturing processes. They are also found to be stable and have uniform reproductive potential across non-dominated individuals (Srinivas and Deb, 1995; Nandasana et al., 2003; Konak et al., 2006; Yang and Natarajan, 2010). Hence, the principles of NSGA and NSGA-II are briefly presented in the following sections.

Figure 4. Flowchart of NSGA (Srinivas and Deb, 1995)



3.2 Non-Dominated Sorting Genetic Algorithm (NSGA)

Figure 4 shows a flowchart of NSGA.

NSGA was developed by Srinivas and Deb (1995) based on the limitations of VEGA. It is similar to a simple GA except the classification of non-dominated fronts and the sharing operation. Thus the NSGA varies from a simple GA only in the way the selection operator is used. The crossover and mutation operators remain as usual. In NSGA, ranking selection method is used to emphasize current non-dominated points and a niching method is used to maintain diversity in the population. Before the ranking selection is performed, the population is ranked on the basis of an individual's non-dominated. The non-dominated individuals are assumed to constitute the first non-dominated front in the population and assigned a large dummy fitness value. The same fitness value is assigned to give an equal reproductive potential to all these non-dominated individuals. In order to maintain diversity in the population, these classified individuals are then shared with their dummy fitness values. Sharing is achieved by performing selection operation using degraded fitness values which are obtained by a quantity proportional to the number of individuals around it. This causes multiple optimal points to co-exist in the population. After sharing, these non-dominated individuals for the second non-dominated front are obtained. These new set of points are then assigned a new dummy fitness value which is kept smaller than the minimum shared dummy fitness of the previous front. This process is continued until the entire population is classified into several fronts. The population is then reproduced according to the dummy fitness values. Since individuals in the first front have the maximum fitness value, they always get more copies than the rest of population. This was intended to search for non-dominated regions or Pareto-optimal fronts. This results in quick convergence of the population towards non-dominated regions or Pareto-optimal fronts and sharing helps to distribute it over this region. By emphasizing non-dominated points, NSGA is actually processing the Pareto-optimal regions. The efficiency of NSGA lies in the way multiple objectives are reduced to a dummy fitness function using non-dominated sorting procedure. Another aspect of NSGA is that it can practically compute any number of objectives. Both minimization and maximization problems can also be handled by this algorithm. The only place of change required for above two cases is in the way the non-dominated points are identified. Further details on NSGA can be obtained from Srinivas and Deb (1995) and Deb (2001).

3.3 Honing Process

The following sections deals with working principles of honing process and its surface topography. The importance of bearing area parameters and its influences on the performance has been discussed. Typical application of one of the most efficient evolutionary algorithm namely NSGA to plateau honing process for solving multiple objectives has been described.

3.3.1 Basics of Honing Process

Honing is a type of super-finishing process generally applied to internal cylindrical surfaces, but sometimes on few external surfaces also as a finishing operation. Honing operation is carried out with bonded abrasives sticks/stones (known as honing tool) fitted on the honing shoe of a mandrel (honing head). The honing tool is subjected to simultaneous action of rotation, reciprocation (oscillation) and expansion in radial direction resulting in grooves with crosshatch lay surface texture (Davis, 1989).

In the case of manufacturing of cylinder liners, the cylinder liners are subjected to rough honing, finish honing and plateau honing operations. Rough honing is performed on the bored surface with coarse abrasives to control the dimension of the cylinder liner. Finish honing is performed with medium size abrasives to improve the finish. Finally plateau honing is performed with fine size abrasives to remove only the peaks on the finish honed surface (in the order of few microns) to achieve desired surface topography. The valleys of the profiles of the cylinder liner surface obtained after finish honing is remains and untouched. Hence, the surface generated in the final component has texture from two processes (finish and plateau honing). Plateau honing is carried out in order to generate surface that resemble run-in surfaces. Therefore, the final liner surface texture has proper plateau portion at the top to resist wear and grooves at desired honing angle to retain lubricant during engine operation. However, the use of the traditional surface parameters such as R_a, in the analysis of multi-process texture is found to be not adequate to characterize the surface texture of the cylinder liners. Therefore, the engine manufacturers and researchers have established alternative procedures to accept the cylinder liners based on the bearing area parameters in the final finished component (after plateau honing) (Pawlus, 1994; Pawlus, 1997; Feng et al., 2003; Kanthababu et al., 2009a; Kanthababu et al., 2009b; Kanthababu et al., 2010).

3.3.2 Bearing Area Parameters

The surface topography of honed cylinder liner is characterized by the bearing area parameters using the bearing area curve. The bearing area curve is obtained by double-step filtering in accordance with ISO 13565-1:1996 from the surface roughness measuring instrument. The procedure is briefly presented here. Initially, a mean line is obtained by filtering the primary profile with phase-corrected Gaussian filter (ISO 11562:1996) with a selected cut-off (say 0.8 mm) (Figure 5a). During the double-step filtering, the entire valley portion which lies below the mean line obtained from the phase-corrected Gaussian filter are suppressed and the same filter is used once again on this suppressed profile (Figure 5b (i, ii and iii)). The mean line obtained on the suppressed profile is the final mean line, which is taken as final reference line. This reference line is transferred to the original primary profile and subtracted to get the roughness profile (Figure 5b (iv)). Then the bearing area curve is obtained from this roughness profile (Figure 6).

Figure 6 shows a typical roughness profile and its bearing area curve along with methods for their evaluation. Though definition of R_a is clear from Figure 6, a brief description of the bearing area parameters is given here to understand their nature. The bearing area parameters consist of reduced peak height (R_{pk}), depth of the core roughness (R_k), reduced valley height (R_{vk}), material portion corresponding to the upper limit position of the roughness core (M_{r1}) and material portion corresponding to the lower limit position of the roughness core (M_{r2}). A line segment representing 40% material ratio is moved over the curve starting from extreme left point. The slope of the line, when it matches first with the curve, is taken as slope of an equivalent straight line. This equivalent straight line is extended to meet 0% and 100% lines and difference in height denotes R_k, namely core roughness. Horizontal lines drawn through these intersection points at 0% and 100% lines meet the curve at M_{r1} and M_{r2} respectively. Points corresponding to R_{pk} and R_{vk} are determined such that shaded triangular areas represent area of the curve above and below the core roughness respectively. Further details can be obtained from ISO 13565-2:1996. It may be noted that the equivalent straight line influences the bearing area parameters (Pawlus, 1998).

Among the bearing area parameters, M_{r2} and $R_{k,}$ have been assigned with higher weightage of 50% and 30% respectively based on their impact of engine performance, while $R_{vk,}$ $R_{pk,}$ and M_{r1} are assigned with 15%, 4%, and 1% weightage respectively (Feng et al., 2003). A plateau honed surface with M_{r2} and R_k values within the specified range

Figure 5. Schematic of filtering process using phase-corrected filter

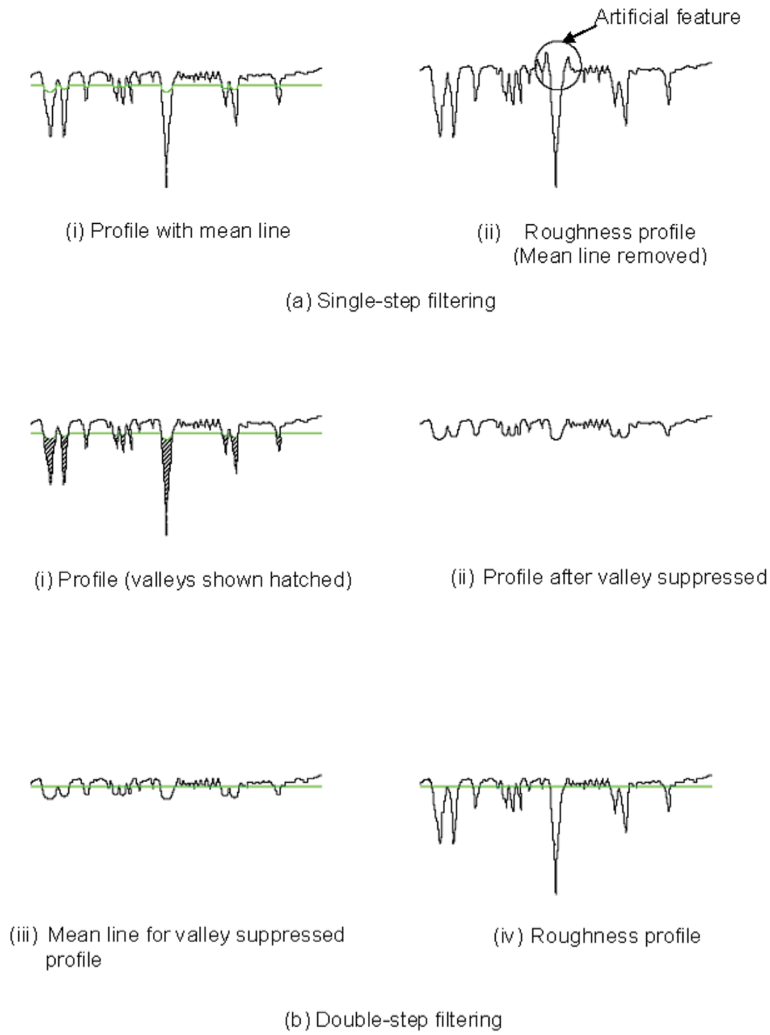


Figure 6. Roughness average (R_a) and bearing area parameters

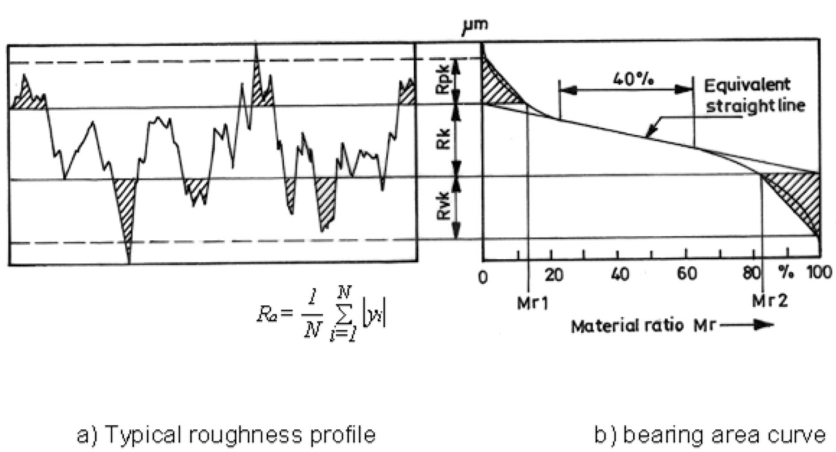

ensures good sliding properties of smooth surfaces (characterized by R_k) and has greater ability to retain oil in the grooves (characterized by M_{r2}) for effective lubrication. It can be noticed that both R_k and M_{r2} are conflicting in nature. Therefore, achieving required M_{r2} and R_k within range 75-85% and 0.6-1.8 µm respectively as prescribed by the engine manufacturers in the final cylinder liners are important in plateau honing operation. If the honing parameters are not properly selected from the manufacturing point of view, it is very difficult to achieve the bearing area parameters within the specified range in the final components. Therefore, these constraints leaves very difficult for the manufacturing engineers to select the appropriate plateau honing process parameters. Though different techniques are available, there are only a limited attempts made by researchers to select suitable honing parameters considering the surface topography, especially the bearing area parameters. Since the NSGA has emerged as one of the most efficient multi-objective evolutionary algorithm for solving multi-obective problems, the NSGA applied to a plateau honing process has been detailed in the next section.

3.4 Application of NSGA for Plateau Honing Process

The following sections deals with the selection of Pareto-optimal solutions using NSGA for plateau honing process considering it as a multi-objective problem. The input honing parameters considered are rotary speed (RS) reciprocating speed (ST), pressure (PR) and honing time (HT) (Table 2). The output parameters considered are M_{r2} and R_k. The procedure of NSGA applied to plateau honing process is given in Figures 7 and 8 for easier understanding. The results obtained through NSGA of the 200th iteration are given in Table 3.

3.4.1 Selection of Chromosome and Coding

Initially, the chromosomes for the entire population are randomly generated to allow different solutions to be scattered in the search space. A typical chromosome obtained from the selected population is shown in Figure 7a and also in Table 3a (S.No.1). The input honing parameters used in the trials have different lower and upper limits with different step lengths (Table 2). Therefore, a binary coding with '0' and '1' is used to represent the variable honing parameters. The total length of the string is 16, in which first 4 bits represent rotary speed (RS), the second 4 bits represent reciprocating speed (ST), the third 4 bits represent honing pressure (PR) and fourth 4 bits represents honing time (HT) (Figure 7a).

The binary numbers are decoded using the formula

$$X_A = X_L + \frac{X_U - X_L}{2_n - 1}(Decoded\ \ value) \tag{2}$$

where X_A is the actual value of honing parameters, X_U and X_L are the upper and lower limits of the individual honing parameters and *n* is the sub-

Table 2. Honing parameters, limits, step, and bit length used for NSGA

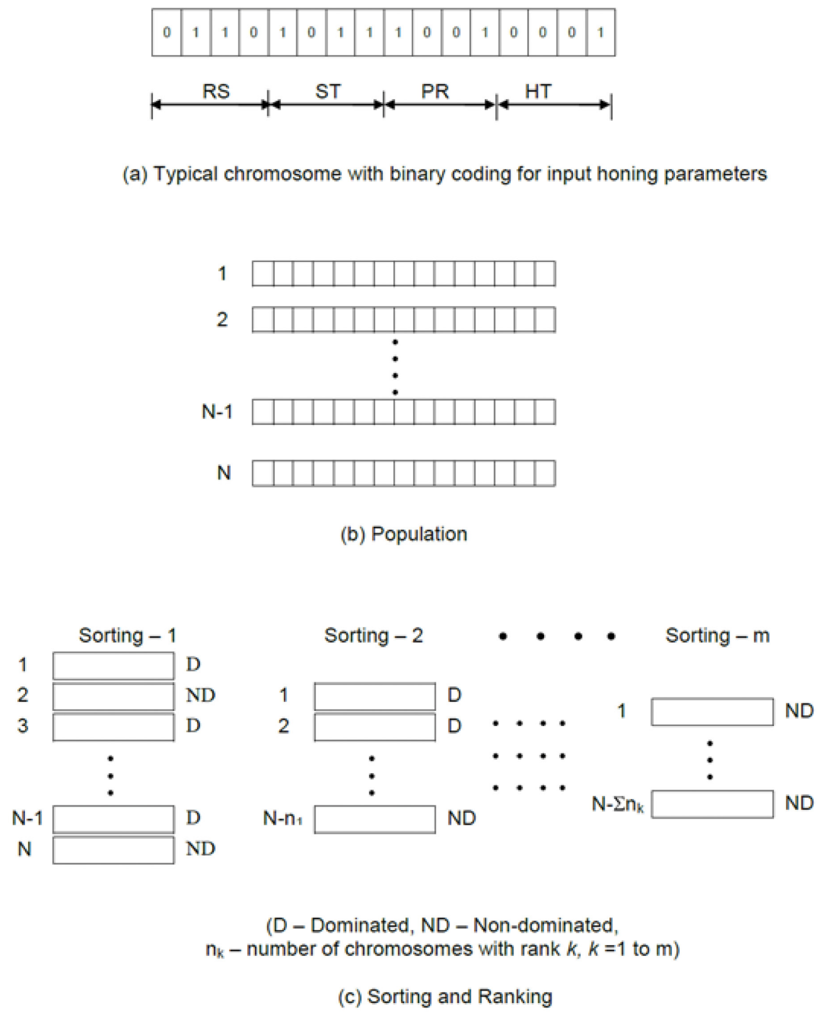
2	Rec. speed (ST), m/min.	10.4	14.4	0.266	4
3	Pressure (PR), MPa	0.5	0.7	0.013	4
4	Honing time (HT), s	8	16	0.533	4

Figure 7. The procedure of NSGA (Part 1)



string length. Typical decoded and actual values of the 200th generation are shown in Table 3, Col. (a) and Col.(b) respectively.

3.4.2 Sorting and Ranking

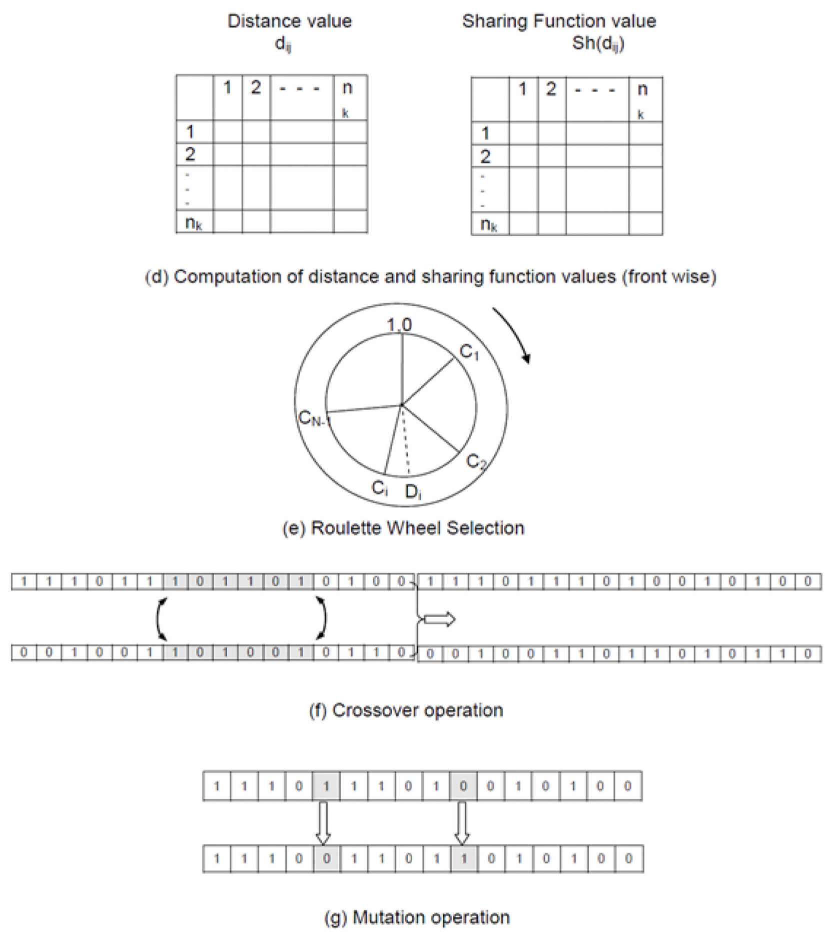
After generating number of populations (N=80) (Figure 7b and Table 3a), the chromosomes are sorted to assign ranks. The ranking is done based on its closeness towards optimizing both the fitness (objective) functions. The fitness functions used in this work are as follows.

$$Fn.1 = 1/|M_{r2(min)} - M_{r2}| + |M_{r2} - M_{r2(max)}| \quad (3)$$

$$Fn.2 = 1/|R_{k(min)} - R_{k}| + |R_{k} - R_{k(max)}| \quad (4)$$

The values of the fitness functions are computed for each string in the population (Table 3 Col.(c)). The M_{r2} and R_k values for the fitness Equations 3 and 4 are obtained from the multiple linear regression Equations 5 and 6 respectively. The multiple regression equations are obtained from the experimental data (Kanthababu et al., 2009a)

Figure 8. The procedure of NSGA (Part 2)



$$M_{r2} = ST^{0.2170}\, PR^{-0.1648}\, HT^{0.0493}\, RS^{1.0083} \quad (5)$$

$$R_k = ST^{0.0303}\, PR^{-0.6805}\, HT^{-1.0651}\, RS^{0.6503} \quad (6)$$

The objective of sorting and ranking is to find a string with maximum fitness function value of Fn. 1 and Fn. 2. The denominator in the Equations 3 and 4 represents transformed parameters. By such transformation, denominator reaches a minimum value when the parameter is within the specified range. The minimum value is equal to the range itself. For example, if the range for M_{r2} (Table 4) is used in the Equation 3, i.e. $M_{r2(min)}$ is 75% and $M_{r2(max)}$ is 85%, then M_{r2} of 80% results in a denominator value of 10 and the therefore the maximum value of Fn.1 is 0.1. If any value of M_{r2} less than 75% or greater than 85% gives a denominator value greater than 10 and as a result, the maximum value of Fn.1 will be less than 0.1. Similarly, if the range for R_k (Table 4) is used in the Equation 4 i.e. $R_{k(min)}$ is 0.8 and $R_{k(max)}$ is 1.6 µm, then it results in maximum value of 1.25 for Fn.2 (Table 4). The maximum and minimum values for M_{r2} and R_k have been fixed based on the recommendations of the engine manufacturers for effective performance of the engine (Table 4).

In order to maximize both the fitness functions, the ranking is done based on Equation 7 as given.

Max. Fn. 1	0.1	
Max. Fn. 2	1.25	

$$\text{Fn.1}[i] < \text{Fn.1}[j] \text{ and } \text{Fn.2}[i] < \text{Fn.2}[j],\ i \neq j \quad (7)$$

where i and j are chromosome numbers. The procedure for sorting and ranking are detailed below.

In the first sorting, each set is checked whether it satisfies the rules as per Equation 7 with respect to the other set in the population. If the above rules are satisfied for any one of the remaining values, then the set is marked as dominated, otherwise it is marked as non-dominated (Figure 7c). All the non-dominated sets obtained in the first sorting are ranked as 1. The remaining (dominated) sets are again sorted out and rank 2 set is obtained. This procedure is repeated until all sets are ranked (Table 3, Col.(d)). The non-dominated solutions of rank 1 are better than non-dominated solutions of rank 2 and so on. The input parameters corresponding to rank 1 are the best in terms of their closeness to the Pareto-optimal solutions in the population.

3.4.3 Shared Fitness

In order to ensure that less crowded regions in the front are adequately emphasized, sharing fitness method is used. For calculating the shared fitness, the distances and a sharing function of each chromosome with respect to the other chromosomes are calculated front wise. Then, a niche value for each chromosome is calculated based on the sharing function values. The calculation of shared fitness is as follows: The population in the first front set (rank 1) is initially assigned a temporary (dummy) fitness value of 80 (equal to population size) (Table 3, Col.(g)). Then the normalized Euclidean distance (d_{ij}) (Equation 8) of each chromosome is calculated with respect to all other chromosomes within the first front set using the formula

$$d_{ij} = \sqrt{\sum_{s=1}^{p_1} \left(\frac{x_s^{(i)} - x_s^{(j)}}{x_s^{\max} - x_s^{\min}} \right)^2} \quad (8)$$

where p_1 is total number of input parameters, x_s is the value of s^{th} input parameter with upper and lower bound values, while *i* and *j* are chromosome numbers (Figure 7d). Then the sharing function values ($Sh(d_{ij})$) of all the first front chromosomes are calculated using the formula

$$Sh(d_{ij}) = \begin{cases} 1 - \left(\dfrac{d_{ij}}{\sigma_{share}} \right)^2, & if\ d_{ij} < \sigma_{share} \\ 0, & otherwise \end{cases} \quad (9)$$

where σ_{share} is the maximum distance allowed between any two chromosomes to become members of a niche (Figure 7d). The σ_{share} value in the Equation 9 is chosen as 0.5. The sharing function takes a value between zero and one depending on the distance d_{ij}. Then niche count (nc_i) (Table 3, Col.(f)) provides an estimate of the extent of crowding near a chromosome and is calculated using the Equation 10.

$$nc_i = \sum_{j=1}^{N} Sh(d_{ij}) \quad (10)$$

where *N* is the total population. If there is no solution within a radius of σ_{share} then the niche count for that solution is taken as one. Then the shared fitness values (F_i') (Table 3, Col.(h)) are calculated by dividing the temporary fitness values by the niche count, which is given by

$$F_i' = \frac{F_i}{nc_i} \quad (11)$$

After calculating the shared fitness values for the first front, a smaller value of 0.2 is subtracted from the minimum shared fitness value of the population in the first front and the resultant value is assigned as the temporary fitness value for all the second front (rank 2) chromosomes. The above procedure is adopted for calculating also the shared fitness value for the second front. This has been done to make sure that no solution in the first front has been assigned with fitness value worse than the second front. This procedure is continued to find the shared fitness values for all the fronts (Table 3, Col.(h)).

3.4.4 Roulette Wheel Selection

After calculating the shared fitness values for all the chromosomes, a new mating pool (Table 5, Col.(n)) is selected from the given population based on the shared fitness values using roulette wheel selection operator (Figure 7e). The roulette wheel selection procedure is as follows:

First, the expected count A_i (Table 3, Col.(i)) is calculated by

$$A_i = \frac{F_i'}{\bar{F}_i'} \quad (12)$$

$\bar{F}_i'$ is the average fitness value given by

$$\bar{F}_i' = \frac{\sum F_i'}{N} \quad (13)$$

where N is the total population. Then the probability of selection (Table 3, Col.(j)) and cumulative probability (Table 3, Col.(k)) are calculated by

$$B_i = \frac{A_i}{N} \text{ and } C_i = \sum B_i \quad (14)$$

The cumulative probability will add up to 1 for the N^{th} (80^{th}) chromosome. To find mating chromosome, random numbers between 0 and 1 are generated N times (Table 3, Col.(l)). Each random number is checked for the range of cumulative probability within which it is lying. Then the chromosome corresponding to the next

upper bound of the cumulative probability range is selected for the mating pool (Table 3, Col.(m)). Thus a population of N^{th} chromosomes is obtained for the mating pool (Table 3, Col.(n)). Therefore, each solution in the first rank has a better chance of surviving in the mating pool than that of the second front and so on.

3.4.5 Crossover and Mutation

After selecting chromosomes for the mating pool, a randomly generated two-point crossover (Table 3, Col.(p) and Col.(q)) is adopted for crossing with a crossover probability of 0.8 (Figure 7f). The crossover probability has usually a higher value, as generation of new chromosomes is to be encouraged. Then bitwise mutation is performed subsequently with a mutation probability of 0.1, which is commonly taken to be a smaller value (Table 3, Col.(s) and Figure 7g). The chromosomes obtained after mutation in the first generations are used as input for next generations and so on (Table 3, Col.(t)).

The above procedure is continued until the termination criterion (200 generation) is over. The values shown in Table 3 are obtained after the 200th generation. The finally generated chromosome is expected to have better solutions than that of the previous generations (Table 3, Col.(t)). The chromosomes obtained in the final generation with rank 1 are considered as Pareto-optimal solutions. Typical results of the Pareto-optimal solutions (1st rank) obtained at the 200th iteration is shown in Table 5. The NSGA algorithm is implemented using TurboC and run on Pentium IV PC.

The Pareto-optimal set or non-dominated solutions (Table 5) obtained through NSGA will serve as a ready reference for the manufacturer of cylinder liners to implement in plateau honing operation in order to achieve the multiple objectives M_{r2} and R_k values within certain limits. The same procedure could be used for any manufacturing processes by clearly defining the objective functions.

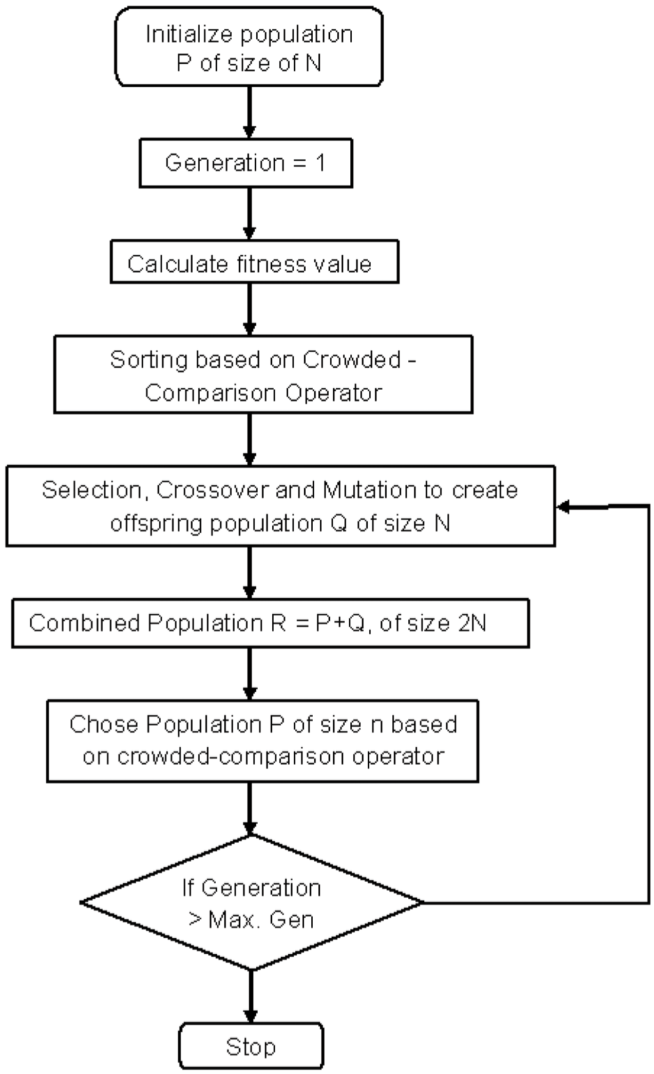
3.5 Non-Dominated Sorting Genetic Algorithm-II (NSGA-II)

NSGA-II is proposed by Deb et al. (2002). It is fast and further advancement of simple NSGA and addresses certain issues like high computational complexity of non-dominated sorting, lack of elitism, need for specifying the sharing parameter, etc. The flowchart of NSGA-II is given in Figure 9. In NSGA-II, the crossover and mutation operators remain same but the selection operator works differently from simple GA. In this algorithm, selection is carried out with the help of crowded-comparison operator based on the ranking and crowding distance. The offspring population is first created by using the parent population. Instead of finding the non-dominated front, the two populations are combined to form of size 2N. Then, a non-dominated sorting is used to classify the entire population. The main advantage of maintaining non-dominated solutions in the population is straightforward implementation. In this strategy, the population size is an important GA parameter, since no external archive is used. Although this requires more effort, however it allows a global non-dominance check among the parent and offspring solutions. Once the non-dominated sorting is over, the new population is filled by solutions of different non-dominated front, one at a time, starting with the best non-dominated front, followed by the next best non-dominated front and so on. Since the population size is 2N, not all fronts may be accommodated in the new population. All fronts which could not be accommodated are deleted. The detailed procedure of NSGA-II is given in Deb et al. (2002) and Konak et al. (2006).

4. FUTURE DIRECTIONS OF EVOLUTIONARY ALGORITHMS

Many engineering problems have multiple objectives including engineering system design, reli-

Figure 9. Flowchart of NSGA-II (Mandal et al., 2007)



ability optimization, telecommunication networks, etc. Therefore, evolutionary algorithms created interest among researchers and manufacturing engineers to solve multi-objective problems in real world applications. As the interests grow, there is a need for a focused research and application. The following are some of the immediate research directions that may help to develop better evolutionary algorithms for multi-objective optimization problems.

1. Comparison of existing multi-objective GAs
2. Understand the dynamics of GA populations
3. Multi-objective GAs with number of objectives
4. Convergence to Pareto-optimal front
5. Hybrid multi-objective GAs
6. Real-world application problems

5. CONCLUSION

In this chapter, the importances of evolutionary algorithms which have been evolved as useful tool to solve real world multi-objective problems have been discussed. By evolving a population of solutions, evolutionary algorithms are able to approximate the Pareto-optimal set in a single run without restricting to local optimal solution. Different evolutionary algorithms which have been developed in order to optimize conflicting multiple objectives by researchers for a variety of applications have been detailed by focusing on their components and their salient issues encountered while implementing. Among the multi-objectives evolutionary algorithms, the NSGA and NSGA-II have been found to possess many advantages and successfully applied to optimize different manufacturing processes with conflicting objectives. The concepts and working mechanisms of NSGA have been elucidated with a case study for optimizing multiple objectives in plateau honing process. The future scope for the research and the areas in which it can be applied have been discussed.

ACKNOWLEDGMENT

The author would like to acknowledge the services of Mr. R. Venkataraman, Mr. M. Prakash, Mr. A. Gopikrishna, Mr. D. Sathish Kumar, Department of Manufacturing Engineering, Anna University, Chennai, India for the preparation of this chapter and special thanks to my dear friend Dr. S. Arivazhagan for his constant source of encouragements, valuable guidance and suggestions.

KEY TERMS AND DEFINITIONS

Chromosome: In genetic algorithms, a chromosome (also sometimes called a genome) is a set of parameters which define a proposed solution to the problem that the genetic algorithm is trying to solve.

Crossover: In genetic algorithms of computing, crossover is a genetic operator used to vary the programming of chromosome from one generation to the next. It is analogous to reproduction and biological crossover, upon which genetic algorithms are based.

Evolutionary Algorithm: It is a subset of evolutionary computation, a generic population-based metaheuristic optimization algorithm. An Evolutionary algorithm uses mechanisms inspired by biological evolution such as reproduction, mutation, recombination and selection.

Fitness Function: The objective function where the user wants to minimize or maximize. For standard optimization algorithms this is known as the objective function.

Genetic Algorithm: It is a method for solving both constrained and unconstrained optimization problems that is based on natural selection.

Multi-objective Optimization: It is the process of simultaneously optimizing two or more conflicting objectives subject to certain constraints.

Mutation: In genetic algorithms of computing, mutation is a genetic operator used to maintain genetic diversity from one generation of a population of algorithm chromosomes to the next. It is analogous to biological mutation.

Pareto-optimal Solution: Pareto-optimal solutions are optimal compromises of the two criteria in the sense that any improvement of one criterion implies an impairment to the other.

Plateau Honing: It is super-finishing process that generates a surface texture that has the benefits of both smooth surface and rough surface (grooves with cross hatch lay).

Roulette-wheel Selection: It is also known as fitness proportionate selection. It is a genetic operator used in genetic algorithms for selecting potentially useful solutions for recombination.

Surface Texture: It is the characteristics of a surface and also known as surface finish. It has three components namely lay, surface roughness, and waviness.

Chapter 22
Decision Support Framework for the Selection of a Layout Type

Jannes Slomp
University of Groningen, The Netherlands

Jos A.C. Bokhorst
University of Groningen, The Netherlands

ABSTRACT

One of the most important design decisions in a firm is the choice for a manufacturing layout type. This chapter shows which aspects have to be taken into account and suggests a systematic method for the decision problem. The method can be seen as a decision support framework, which links the various aspects. The framework is based on the AHP (Analytic Hierarchy Process) approach. A case study, concerning a Dutch firm, illustrates the applicability of the framework in a practical instance.

INTRODUCTION

The choice for a manufacturing layout is a strategic issue and has a significant impact on the performance of the operations function of a company (Meijers and Stephens, 2004, Francis et al. 1992). A variety of manufacturing layout types may be applicable in a practical situation. Table 1 presents some alternative layout types for high-variety/low-volume situations. The most dominant layout type in practice is the process-oriented functional layout, where machines of the same type are located in the same area (Slomp et al., 1995). An important alternative is the socalled Cellular Layout type, where machines are grouped in cells and each cell is responsible for the complete manufacturing of a part family. This product-oriented layout type has gained substantial attention in literature and in practice (Wemmerlöv and Hyer, 1989, and Wemmerlöv and Johnson, 1997). Both types of manufacturing layout have their advantages and disadvantages. Several authors present alternative layout types to cope with the disadvantages of the functional and/or cellular layout type. Rosenblatt (1986) suggested a dynamic plant layout where cellular configurations periodically change depending on the demand in each period. Balankrishnan and

DOI: 10.4018/978-1-4666-1945-6.ch022

Cheng (1998) present a review on the dynamic plant layout problem. Venkatadri et al. (1997) and Montreuil et al. (1999) propose a socalled fractal layout for job shop environments in order to gain the flow time advantages of Cellular Manufacturing and the flexibility of a functional layout. This type of layout is robust with respect to changes in demand and product mix. Another robust design, the socalled holographic or holonic layout, is proposed by Montreuil et al. (1993). Here individual machines, or machines types, are strategically distributed through the facility. Production orders are assigned to available machines which are located in the same area of the plant. A special case of the holonic layout is the socalled distributed layout (Benjaafar and Sheikhzdeh, 2000 and Benjaafar et al., 2002) where machine replicates are strategically distributed across physical space. Some researchers stress the need for a hybrid layout system which combines several layout types (e.g. Irani, 1993). Irani and Huang (2000) and Benjaafar et al. (2002) define a modular layout in which products have to be manufactured by one or more modules. Each module may have its own internal layout. A modular layout is an example of a hybrid layout. Wemmerlöv and Hyer (1989) show that many companies apply a hybrid layout.

Table 1. Layout types and some major advantages and disadvantages

Type of Layout	Explanation	Major advantages	Major disadvantages
Process Layout or Functional Layout	Machines of the same type are located in the same area.	Routing Flexibility. Specialization in process type.	Complexity of coordination between departments.
Cellular Layout	Machines are grouped in cells and each cell is responsible for the complete manufacturing of a part family.	Short setup times because of the dedication of families to cells.	Sensitive for unbalance in the load of identical machines in different cells. Inflexible for the introduction of new products.
Dynamic Cellular Layout	A reconfigurable cellular layout.	Enables the cell layout to respond to product changes.	Costs of reallocating machines in case of product changes
Fractal Layout	Machines are grouped in various fractals, which are (more or less) identical cells able to produce all products.	Enables the cell layout to deal with changes in product mix.	Limited specialization of workers and machines.
Holonic Layout or Holographic Layout	Each machine (type) is an autonomous entity (holons) and is seemingly random (=random or based upon transition probabilities) located throughout the plant.	Provides efficient process routes for any production order. As orders arrive, routings are constructed by searching for compatibility between order requirements and machine availability, location, and capability.	Complexity of coordination between machine requirements of the various production orders
Distributed Layout or Scattered Layout. (Distributed or scattered layouts can be seen as special cases of the holonic layout)	Distributed or scattered layouts are those where machine replicates are strategically distributed across physical space.	Flexibility of assigning manufacturing orders to available machines which are located in the same area.	Limited specialization of workers and machines. Complexity of coordination.
Hybrid layout	Several layout types exist within one department	Fit between the various characteristics of the product types of a company and the various layout options.	Complexity of planning and control
Modular layout (Modular layouts can be seen as a special case of a hybrid layout)	Machines are clustered in modules. Each module has its own layout and is responsible for a number of operations to be performed on a product	Recognizes the layout needs of the various operations needed per product.	Complexity of the linkage of the various modules

This chapter presents a general decision support framework for the selection of a manufacturing layout type. Our focus lies on the selection of objectives, aspects and contributing elements for the selection problem. The framework applies the AHP (Analytic Hierarchy Process) approach (Saaty, 1980). This approach is useful for multi-criteria decisions where intuitive, qualitative and quantitative aspects play a role. The approach includes a hierarchical decomposition of the decision problem and a further decomposition of each decision level into pairwise comparisons of decision elements. Next, the "eigenvalue" method is used to estimate the relative weights of the decision elements. For a further explanation of the AHP method, we refer to Saaty (1980) or Zahedi (1986). As will be made clear in the remainder of this chapter, the AHP method offers several advantages in the layout type selection problem.

The next section will provide some further background to the selection problem. We will make clear that it is important to approach the layout type selection problem from a strategic viewpoint. In a subsequent section, we will discuss how layout types influence generic objectives of a company. We will then show how various aspects of layouts have an impact on manufacturing performance. The performance objectives and the various aspects are presented in the form of a decision hierarchy, according the AHP approach. After specifying the AHP approach, we present a case study to indicate the generic value of the defined decision hierarchy. The last section of this chapter is meant to reflect on the proposed selection methodology and to draw conclusions.

BACKGROUND

Literature on layout design problems falls into two major categories, algorithmic and procedural approaches (Yang and Kuo, 2003). Algorithmic approaches make use of simplified design constraints and objectives and can be used to generate layout alternatives efficiently (Meller and Gau, 1996). Algorithmic approaches are useful as a step in the design of a detailed layout. They assume the choice of a layout type. Procedural approaches may incorporate the choice of layout type and take care of both qualitative and quantitative objectives in the whole design process (Muther, 1973). A major disadvantage of a procedural approach is its dependence on the subjective judgement of one ore more experienced designers. Furthermore, procedural approaches divide the design problem in several steps which may lead to suboptimality. In order to overcome this suboptimality, designers may develop alternative layouts, based upon different layout types, and a well-working methodology may support the selection of the best layout. This chapter is devoted to the presentation of such a methodology. The methodology recognizes major differences between layout types.

Several authors propose methodologies to simultaneously cope with qualitative and quantitative objectives in the selection of a layout. Cambron and Evans (1991) applied Saaty's Analytic Hierarchy Process (AHP) to consider the problem's multiple objectives. The approach is illustrated by means of a problem involving the layout of a commercial printing and binding facility. Partove and Burton (1992) also propose AHP for layout selection. Yang and Kuo (2002) and Ertay et. al (2006) apply AHP and combine this with the data envelopment analysis (DEA) approach to solve the layout selection problem. Qualitative performance measures were weighted by AHP. DEA was then used to solve the multiple-objective layout problem. Yang and Kuo (2002) used a practical case study, an IC packaging company, to illustrate the efficiency and effectiveness of their methodology. Ertay et. al (2006) illustrate the applicability by means of a case study in which a choice has to be made between 17 alternative layouts for a company producing plastic profiles. Abdi and Labib (2003) apply AHP for the selection of a reconfigurable manufacturing system. Yang and Hung (2007) explore the use of multiple-attribute decision making (MADM) in the selection of an appropriate layout design. Two methods were proposed in solving the case study problem: the technique for order preference by similarity to ideal solution (TOPSIS) and fuzzy TOPSIS. The methodologies for layout selection, as presented in literature, focus on the methods to deal with conflicting quantitative and/or qualitative objectives. Limited attention is devoted to the selection of appropriate objectives and criteria. This chapter pays substantial attention to the choice of objectives and the specification of criteria.

Objectives and criteria in the layout literature are usually just a listing of some relevant elements. Researchers do not link the elements to the various strategic objectives of a company. The evaluation of layout alternatives is based on objectives such as (i) minimizing material handling costs, (ii) improving flexibility for arrangement and operation, (iii) utilising the available area most effectively, and (iv) minimising overall production time (Francis et al, 1992). Raman et. al (2009) distinguish three layout effectiveness factors—facilities layout flexibility (FLF), productive area utilisation (PAU) and closeness gap (CG). They claim that the measurement of these factors enables the decision-maker of a manufacturing enterprise to analyse a layout, based on which they can make decisions towards productivity improvement. They do not link the three factors to generic performance objectives of manufacturing companies. In this chapter we stress the importance of clarifying the link between layout decision criteria and the performance objectives of the company. This is needed to place the layout decision in its strategic context.

A major decision in many companies is the choice between a product-oriented and a process-oriented design philosophy. In a product-oriented design philosophy, machines and workers are grouped according to manufacturing needs of product types. A group of machines and workers is responsible for the complete manufacturing of (a set of) product types. The various groups in a product layout are relatively independent from each other. In a process-oriented design philosophy, machines and workers are grouped according the various functions needed to perform all product types. The functionally based groups are highly dependent on each other. Products flow from group to group. Most studies on the selection of a manufacturing layout implicitly assume a functional, or process-oriented, layout and are concerned with the allocation of the different functional groups. This chapter explicitly recognizes that companies may select a process-oriented or a product-oriented layout type, or a mix of both types. Table 1 gives an overview of possible layout types in a high-variety/low-volume environment. In our viewpoint, the type of layout has an important impact on the various performance objectives of a company.

The choice between a product- and a process-oriented layout is, many times, not an obvious decision. Case studies and survey articles (see e.g. Wemmerlöv and Hyer 1989, Burbidge et al. 1992) illustrate the enormous advantages of the introduction of a product-oriented, cellular manufacturing layout (CML). Other case studies indicate that several firms move from a cellular manufacturing layout towards a process-oriented, functional layout (FL) (see e.g. Slomp 1998, Molleman *et al.* 2002). Numerous simulation studies have been performed in order to compare the performance of a CML and a FL in various situations (for an overview, see Johnson and Wemmerlöv 1996, Argarwal and Sarkis, 1998, or Shambu et al., 1996). These studies indicate important factors, which have to play a role in the layout choice. Johnson and Wemmerlöv (1996), however, state that the simulation studies cannot assist practitioners in making specific choices between existing layouts and alternative cell systems. They indicate various mismatches between the model world and reality and suggest that decisions to change the existing layout should be made on a case-by-case basis for each potential cell application. A general framework, as presented in this chapter, may support managers in the selection of an appropriate layout type. The case study in this paper shows how the framework has supported the managers involved.

THE LINK BETWEEN STRATEGIC OBJECTIVES AND LAYOUT TYPE

An essential condition in the selection of a layout is the ability of decision makers to link the strengths and weaknesses of each layout alternative with the market demands, or performance objectives, with which the firm has to deal. Slack *et al.* (2001) distinguish five major performance objectives: price, quality, speed, flexibility, and dependability. The flexibility objective can be further split in product/service flexibility, mix flexibility and volume/demand flexibility. These objectives have to play an essential role in the selection of a manufacturing layout. We have added the objective "quality of work" to the set of objectives. This criterion is especially important in environments where labor is scarce. In the next subsections, we link the various performance objectives with aspects of the manufacturing layout type. We will refer to the functional (process-oriented) and cellular (product-oriented) layout type, as described in Table 1, in the discussion of the various aspects. Important words in the next subsections are written in italics. These words concern the aspects and elements which need to be dealt with in the layout selection problem. They are summarized in Table 2.

The Impact of Layout Type on the Price of a Product

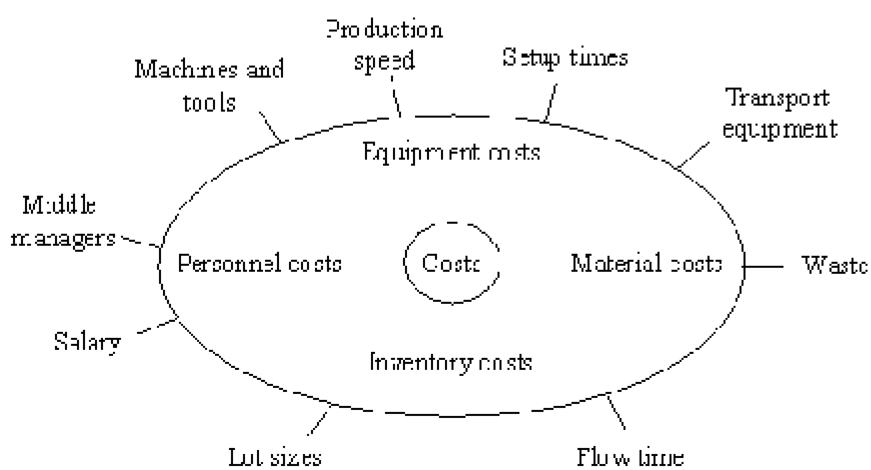
From the perspective of a production manager, the price of a product has to be related to the manufacturing costs. A reduction of the manufacturing costs can be a reason to lower the price of products. Elements of the manufacturing costs are *equipment costs*, *personnel costs*, *material costs* and *inventory costs*. Several aspects of a manufacturing layout will have impact on these

Table 2. Objectives, aspects and elements in the selection of a manufacturing layout

Objectives	aspects	elements
price	costs	• equipment costs • personnel costs • material costs • inventory costs
quality	• specialization of workers • advanced machinery • control loops	
speed	throughput time	• transport time • machining time • waiting time
flexibility • product/service • mix • volume/demand	• response • range	
dependability	• interchangeability of workers • interchangeability of equipment • control capacity	
quality of labor	• skill variety • task identity • task significance • autonomy • feedback	

costs (see Figure 1). More *machines and tools* may be needed in a product-oriented cell layout in order to create independent, autonomous groups of workers and machines. A survey of 32 U.S. firms involved with cellular manufacturing, reported in Wemmerlöv and Hyer (1989), showed that new equipment and machine duplication was a major expense category for cell implementation. Specialization in a process layout may lead to a higher *production speed*, which may reduce equipment and personnel costs. On the other hand, *setup times* are usually lower in a product layout (see e.g. Flynn and Jacobs 1986, Wemmerlöv and Hyer 1989, Wemmerlöv and Johnson 1997) and reduce equipment and personnel costs in this type of layout. Furthermore, less *transport equipment* is usually required in a product layout because of the shorter transport distances. All these aspects have to be considered in order to estimate the impact on the equipment costs by the various types of layout. Personnel costs are, as mentioned above, related to the factors that have impact on equipment costs. Personnel costs in a product layout can also be lower than in a process layout because of a reduced need of *middle managers*. Farrington and Nazemetz (1998) indicate, by means of simulation studies, that a cellular system is easier to manage than a job shop. Empirical studies show the reduced need for indirect labor where firms convert from a functional layout to a cellular layout (Wemmerlöv and Hyer 1989, Burbidge 1992, Slomp *et al.* 1993). On the other hand, the *salaries* in a product-oriented layout may be higher, since more tasks are, probably, decentralized to the autonomous groups and workers need higher qualifications. These aspects of personnel costs should be taken into account when assessing the various layout alternatives. Material costs can be influenced by the layout through the effect of layout choice on *waste*. It is conceivable that workers in a product layout feel more responsibility for the reduction of the amount of waste. On the other hand, more advanced equipment and more specialized workers in a process layout may also reduce waste. Inventory costs can be lower in a product layout because of the smaller *lot sizes* that can be produced efficiently in this type of layout. This efficiency is due to the smaller setup times in a product layout. Further, *flow times* in a product layout are often lower than in a process layout and this reduces the work-in-process inventory. Reductions in throughput time and work-in-process inventory have been reported in surveys of plants that implemented cellular manufacturing (Wemmerlöv and Hyer 1989, Wemmerlöv and Johnson 1997).

Figure 1. Impact of layout factors on manufacturing costs



The Impact of Layout Type on the Quality of a Product

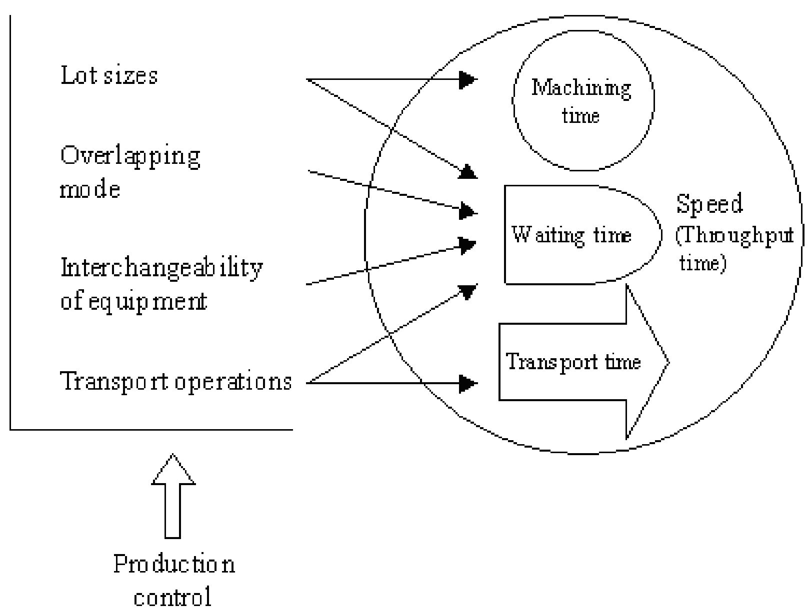
The type of manufacturing layout can also influence the quality of products. In a process layout, workers are probably more *specialized* and will provide for a better product quality. In a product layout, experts are divided among the various groups and the best worker will not always be assigned to the most complex task. Furthermore, a process layout may apply more *advanced machinery*, which has a positive effect on the quality of products. On the other hand, the *control loops* in a product layout are short and may, in comparison to a process layout, have a positive effect on product quality.

The Impact of Layout Type on the Speed to Serve Customers

Speed concerns the time needed to fulfill the needs of internal or external customers. The throughput time of an average job is a measure for speed. This throughput time consists of *transport*, *machining* and *waiting times* (see Figure 2).

A product layout usually involves less *transport operations* for manufacturing jobs because of the proximity of the required machines. It may also be possible to produce in an *overlapping mode* (Shafer and Charnes 1993, Shafer and Meredith 1993), which reduces the "lot size" waiting times. This is more easily realized in a product layout. Problematic for the waiting times in a product layout may be the lack of pooling synergy (Suresh and Meredith 1994). Identical machines are probably split over more than one group and the *interchangeability of equipment* is less than in a process layout. The throughput time will also be influenced by the *lot sizes.* Reduced setup time, which can be realized in a CM environment, may make smaller lot sizes acceptable. This may have a positive impact on the throughput time (Suresh, 1991). *Production control*, finally, plays an important role in the ability to realize short throughput times. An inflexible control system, for instance, may frustrate the production in an overlapping mode. When assessing the effect of

Figure 2. Impact of layout factors on speed



different manufacturing layouts on speed, it is important to consider the requirements with respect to the production control system.

The Impact of Layout Type on the Flexibility to Serve Customer

As mentioned earlier, the flexibility objective can be further split in product/service flexibility, mix flexibility and volume/demand flexibility (Slack *et al.* 2001). The importance of these types of flexibility for a particular instance may differ substantially. Therefore, these types of flexibility have to be seen as different performance objectives. Flexibility, in general, can be defined as the ease (time, effort and/or money) by which changes can be realized. Two aspects determine the flexibility of a manufacturing layout: (i) *range* and (ii) *response*. "Range" refers to the scope of a layout and indicates the variety of situations that can be dealt with without a serious change of the production layout. "Response" indicates the speed by which the layout can be adapted to changing circumstances. Slack (1987) and Upton (1994) have observed that managers think along these lines with respect to the term flexibility.

Product flexibility indicates the ease by which new products can be introduced in a firm. This type of flexibility is higher in a product layout if the new product can be assigned to a single existing product group (quicker response). If a new product has impact on the design of the manufacturing cells, then a process layout is more stable and has more product flexibility (larger range).

Mix flexibility indicates the ease by which a firm can vary the mix of products. Important for the assessment of mix flexibility is insight in the effect of mix changes on the need of various manufacturing processes. A process layout is more range-flexible if the impact of mix changes on the need for manufacturing processes is limited. A product layout is range-flexible if work can be reallocated between the various groups. An important advantage of a product layout concerns the multi-functionality of workers: there are more capabilities at the work floor to deal with changes in the product mix.

Volume/demand flexibility concerns the ease by which the production volume can be increased or decreased. Temporary workers and the extension of working time are possibilities to increase the production volume. It is conceivable that autonomous teams in a product layout can respond more quickly to the need for additional capacity than functional groups in a process layout (i.e. response flexibility). The need for additional capacity is localized and only one group is involved in the need for more capacity for a particular product family. On the other hand, extension of capacity can be realized more easily in a process layout, because more workers with the same capabilities are eligible to work overtime (i.e. range flexibility). Also, temporary workers can probably best be integrated in a process layout.

The Impact of Layout Type on the Dependability to Deliver on Time

The performance objective "dependability" points to the importance of being dependable with respect to delivery times, the quality of the products, and such. To be dependable, it is important that the manufacturing activities can be buffered from all kinds of disturbances. Machine breakdowns and unexpected absenteeism of workers may complicate the dependability of a manufacturing system. *Interchangeability of machines* (or the ability to subcontract) and the *possibility to replace workers* (or increase the working times of some workers) indicate to what extent a manufacturing system can be reliable in various circumstances. The interchangeability and the possibility to replace workers are probably higher in a process layout because of the clustering of identical capacities. Another aspect of dependability concerns the ability to *control* the flow of products. It is likely that the throughput times in a product layout can be controlled better; the control responsibility can be decentralized to autonomous groups which are able to respond quickly to disturbances.

The Impact of Layout Type on the Quality of Work

Quality of work can be investigated in several ways. A well-known approach concerns the job characteristics model of Hackman and Oldham (1980). This model is used by Huber and Hyer (1985) and Shafer *et* al. (1995) to investigate human issues in cellular manufacturing. The job characteristics model distinguishes five task characteristics that have impact on quality of labor: (i) *skill variety*, (ii) *task identity*, (iii) *task significance*, (iv) *autonomy*, and v) *feedback*. Skill variety refers to the extent to which the work requires a variety of activities involving different skills and talents of the workers. Task identity concerns the extent to which the work enables the worker to complete a whole task from start to finish. Task significance relates to the impact of the work on other people within or outside of the organization. Autonomy indicates to what extent a worker has the freedom to plan, to organize, and to perform the tasks in his/her own way. Finally, feedback refers to the extent to which the worker receives information on the effectiveness of his/her performance.

A product layout likely supports a higher/better skill variety, more autonomy, and a better feedback mechanism: workers can perform a variety of tasks, they are responsible for the internal organization of the group, and they get a quick feedback on their activities. The task identity and task significance in a process layout is probably better: the tasks to be performed are clear for all workers and they will be respected because of their specialization.

DECISION SUPPORT FRAMEWORK

The previous section presented major performance objectives of a manufacturing system and indicated which layout-related aspects play an important role. Table 2 summarizes these aspects. As can be seen, the performance objectives price and speed consist of several elements. These elements together constitute the related performance indicators. We do not distinguish aspects for these two performance objectives.

The ultimate goal is to select the best layout out of a set of alternative layouts. Based upon the scheme of Table 2, the selection problem can be split in three sets of questions:

1. What are the relative scores of the various alternative layouts on the aspects mentioned in Table 2? This question involves a comparison of the alternative layouts with respect to the various aspects. Answering this question requires knowledge of operational issues on the work floor and the ability to assess the impact of an alternative layout on the aspects. The answer to this question determines value $\pi(i,j)$, see Table 3.
2. What is the relative importance of the various aspects for the performance objectives? Table 2 gives an overview of all the aspects. The answer to this question determines value $\pi(j,k)$. The sum of the elements, mentioned in column 3 of Table 2, forms an indication for the performance of respectively the price and speed objective.
3. What is the relative importance of the various performance objectives for the firm? This is basically a strategic question, which has to be answered by the management of the firm. It requires knowledge about customers and competitors. The answer to this question determines value $\pi(k)$.

Table 3. Notation

$\pi(k)$ = relative importance of performance objective k for the firm, $\sum_k \pi(k) = 1$;
$\pi(j,k)$ = relative importance of aspects j on performance objective k, $\sum_j \pi(j,k) = 1$;
$\pi(i,j)$ = relative scores of the layout i on aspect j, $\sum_i \pi(i,j) = 1$;
$R(i)$ = relative performance of alternative *i*, $\sum_i R(i) = 1$.

The answers to these sets of questions enable the calculation of the relative performance of the alternatives:

$$R(i) = \sum_j \sum_k \pi(i,j)\ \pi(j,k)\ \pi(k) \qquad (1)$$

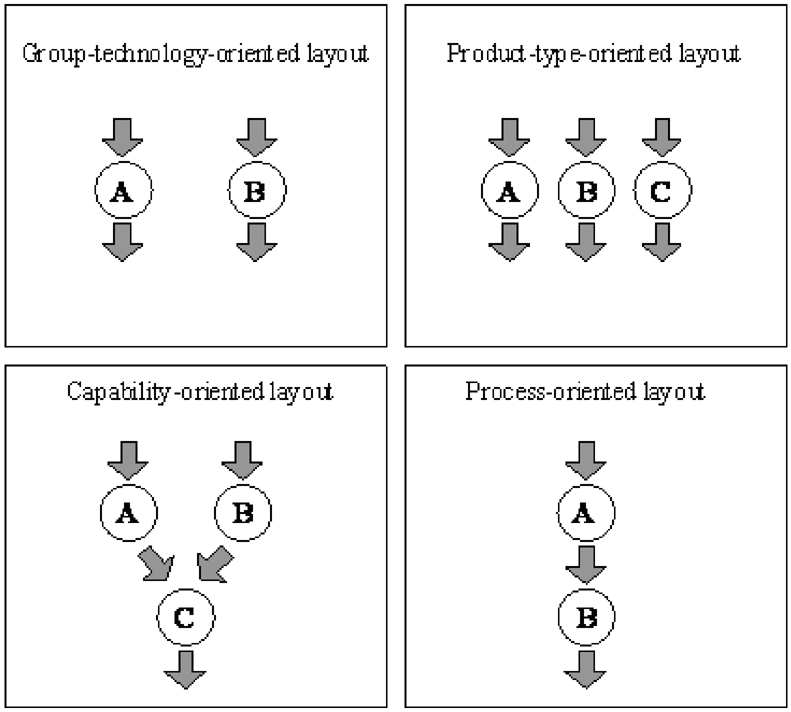
The three sets of questions and the way in which the relative performance of the alternatives are calculated can be seen as an example of using the weighted-score method (see e.g. Slack *et al.* 2001, p. 166). A major issue is the difficulty to "determine" the values of $\pi(k)$, $\pi(j,k)$, $\pi(i,j)$, and $R(i)$. It requires the ability to weight different types of issues.

The three sets of questions and the issue of weighting different types of issues fits in the AHP-approach of Saaty (1980). AHP forces the decision maker(s) to make all assessments explicit. The decomposition of the main problem in several smaller problems also enables an effective participation of employees in the decision problem, using their specific expertise and responsibilities. In the next section, we will illustrate the use of the AHP-approach for layout selection on hand of a practical instance.

CASE STUDY

The case study presented here concerns the sheet metal processing department of the firm Holec Algemene Toelevering B.V., a supplier of parts, tools, and services for the electro-mechanical industry. Before the layout study started, the sheet metal processing department consisted of four autonomous manufacturing cells with some exchangeability between the cells: (i) an automated flexible system for sheet metal working (<3 mm), (ii) numerical sheet metal working (>3mm), (iii) sheet metal construction processing (>5 mm), and (iv) conventional sheet metal processing. Basic processes to be performed in the cells are sawing, punching, cutting, tapping, squaring, welding, and bench work. The firm started to produce in manufacturing cells in 1987. This has led to significant improvements in manufacturing throughput time and efficiency. In the course of years, however, there were several reasons to move back to a more functional layout, such as the complexity and productivity of new equipment, the possibility of workers to operate more than one machine simultaneously, and the increased variety of part types. Other parts of the manufacturing facility of the firm were already transformed to a more process-oriented layout (see Molleman *et al.* 2002). A layout study at the sheet metal processing department started in 2000. Four alternative layouts were generated on the basis of a production flow analysis (Burbidge 1991, Slomp 1998): (i) a group-technology-oriented alternative, (ii) a product-type-oriented alternative, (iii) a capability-oriented alternative, and (iv) a process-oriented alternative. These alternatives are schematically depicted in Figure 3.

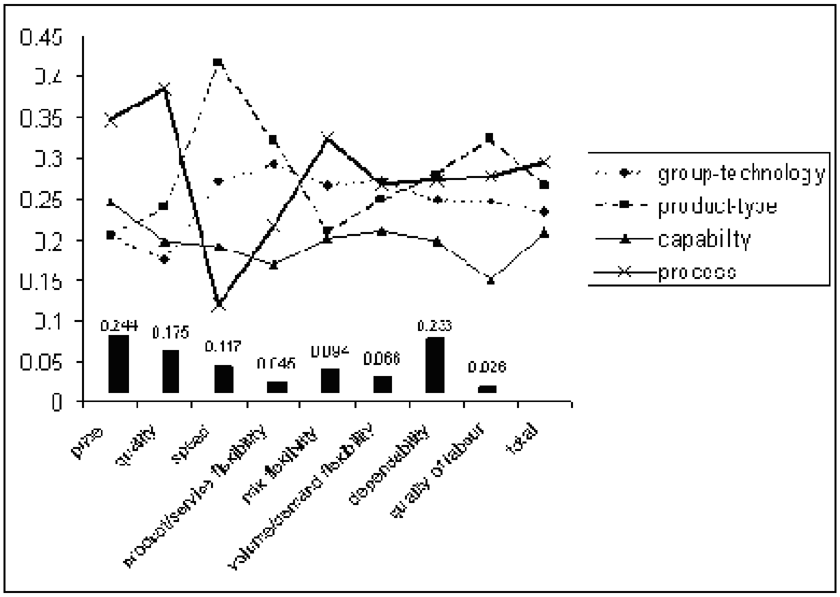
Figure 3. Layout type alternatives for the sheet metal processing



In the group-technology-oriented alternative, the department is divided in two relatively autonomous cells with minimal intercell movements. Some part types can be produced in both groups, which simplifies the balancing of the workload. The product-type-oriented alternative consists of three manufacturing cells, each responsible for a particular type of product. Two cells are responsible for the production of repetitive part types, while one cell is mainly focused on the production of quick orders. An important advantage of this layout is that the production of repetitive part types is not disturbed by quick orders. This may simplify the production control. On the other hand, the cell that is responsible for the quick orders may face undesirable fluctuations of demand. The capability-oriented alternative consists of three manufacturing cells. Basic viewpoint of this alternative is that all assembly work (welding and bench work) needs to be performed in one manufacturing cell (C). The other cells (A and B) are autonomous cells, which have their own product-oriented capabilities. Therefore, intercell movements are minimal. The process-oriented alternative consists of two manufacturing cells. Sawing, punching and cutting is performed in cell A, while tapping, squaring, welding, and bench work is done in cell B. Each cell consists of small groups of identical machines.

The four alternatives are compared by means of the decision framework of Table 2 and by using the AHP methodology. We used the software package Expert Choice. Figure 4 presents the results of the comparisons of the four alternatives. The bars in Figure 4 indicate the relative importance of the various performance objectives. The four lines in the figure show the relative scores of each alternative on the performance objectives. The position of the alternatives at “total” shows the final judgment of the alternatives. As can be seen, the process-oriented layout is preferred because of its positive effect on price, quality,

Figure 4. Scores of the four alternatives



mix flexibility and, to less extent, dependability. Especially price and quality are important reasons to select the process-oriented layout.

It is interesting to see the almost equal end scores of the product-type-oriented and the process-oriented layout, despite their completely different orientation. The product-type-oriented layout performs well with respect to the performance objective speed. In the assessment of the speed factors of Table 2, the managers of the firm assumed that the production control in the process-oriented layout is more complex and will perform worse than in the product-type-oriented layout. At that moment, the firm did not have a good registration system (bar-coding system) on the work floor that is connected with the production control system. A better shop floor control system, which was under study at the firm at the moment of deciding for a new manufacturing layout, would likely improve the score of the process-oriented layout on the performance objective speed. This kind of sensitivity analysis is also useful for the assessment of the scores on the performance objectives quality and price. In this particular case, the impact of shorter control loops on the quality of the products is assessed as being minimal. This assessment has a negative impact on the final score of the product-type-oriented layout. The software package Expert Choice supports sensitivity analysis. It appears that if short control loops do have a major impact on the quality of the products, the product-type-oriented layout performs better than the process-oriented alternative.

Based upon the results of the analysis, the firm changed the layout of the sheet-metal processing department into a process-oriented layout, see also Molleman *et al.* (2002). The systematic approach of the selection problem is seen at the firm as a major help to canalize the discussions about the required layout of manufacturing departments.

CONCLUSION AND REFLECTIONS

This chapter presents a systematic approach for the selection of a manufacturing layout type. The approach includes the use of the AHP-methodology. An important element of the approach is the construction of a decision hierarchy and the pairwise comparisons of decision elements. In this section we will first reflect on the AHP methodology and next we will draw conclusions on the use of AHP for the layout selection type problem.

As in all Multi-Criteria-Decision-Methods, AHP is sensitive for issues such as the specification of the selection problem, its decomposition, and the scales used for the pairwise comparisons (see Pöyhönen *et al.* 1997). The quality of the outcome of an AHP analysis is largely determined by the quality of the problem specification. For instance, adding aspects or regrouping decision elements may lead to different outcomes. A particular problem concerns the issue of "rank reversal". This means that the priority of alternatives may change if alternatives are removed from and/or other alternatives are added to the selection problem (see e.g. Belton and Gear 1983). The problem of rank reversal plays a role if almost identical alternatives are taken into consideration. Finally, the number of pairwise comparisons may be problematic and may lead to unreliable results. Employees who have to make the pairwise comparisons may get tired and lose the required concentration. Another issue, which has to be taken into consideration when applying the AHP approach, is the translation of verbal or graphical assessments in numerical figures. Pöyhönen *et al.* (1997) show that it is not advisable to mix different types of assessment within the levels of the AHP hierarchy.

This chapter has presented a decision support framework based on the AHP approach for the selection of a manufacturing layout. The value of the framework is illustrated by means of a case application. Important advantages of using the AHP approach are (1) the ability to decompose the complex decision problem in smaller problems, (2) the possibility of an efficient and effective employee participation, and (3) the detailed assessment of the selected layout alternative, which helps to define further improvement actions. These advantages of using the AHP approach are also illustrated by Abdi and Labid (2003).

Interesting point in the case study, as presented in this chapter, is that opposite alternatives do have the best scores. This illustrates the group technology debate, as it takes place in practice. Both alternatives appear to be acceptable and have their pros and cons. The proposed approach has the advantage that it gives insight in whether the two alternatives do have similar scores. A debate about the differences on the scores of the various aspects will help the decision process and the acceptability of the final decision.

The systematic approach as presented in this chapter is developed around 1999 (see also Slomp *et al.* 1999a, b) and is applied in several practical situations, mostly master projects of Industrial Engineering students. The evaluation criteria (see Table 2) and the use of AHP has proven to be a robust framework for the selection of a layout in many situations.

Chapter 23

Petri Net Model Based Design and Control of Robotic Manufacturing Cells

Gen'ichi Yasuda
Nagasaki Institute of Applied Science, Japan

ABSTRACT

The methods of modeling and control of discrete event robotic manufacturing cells using Petri nets are considered, and a methodology of decomposition and coordination is presented for hierarchical and distributed control. Based on task specification, a conceptual Petri net model is transformed into the detailed Petri net model, and then decomposed into constituent local Petri net based controller tasks. The local controllers are coordinated by the coordinator through communication between the coordinator and the controllers. Simulation and implementation of the control system for a robotic workcell are described. By the proposed method, modeling, simulation, and control of large and complex manufacturing systems can be performed consistently using Petri nets.

INTRODUCTION

Manufacturing systems, where the materials which are handled are mainly composed of discrete entities, for example parts that are machined and/or assembled, are called discrete manufacturing systems. Due to its complexity, manufacturing system control is commonly decomposed into a hierarchy of abstraction levels: planning, scheduling, coordination and local control. Each level operates on a certain time horizon. The planning level determines at which time each product will be introduced in the manufacturing system. The scheduling level produces a sequence of times for the execution of each operation on each machine or a total ordering of all the operations. The coordination level updates the state representation of the manufacturing system in real-time, supervises it and makes real-time decisions. The local control level implements the real-time

DOI: 10.4018/978-1-4666-1945-6.ch023

control of machines and devices etc., interacting directly with the sensors and actuators. All the emergency procedures are implemented at this level, so real-time constraints may be very hard. At each level, any modeling has to be based on the concepts of discrete events and states, where an event corresponds to a state change (Martinez, 1986), (Silva, 1990).

A flexible manufacturing system is formed of a set of flexible machines, an automatic transport system, and a sophisticated decision making system to decide at each instant what has to be done and on which machine. A manufacturing cell is an elementary manufacturing system consisting of some flexible machines (machine tools, assembly devices, or any complex devices dedicated to complex manufacturing operations), some local storage facilities for tools and parts and some handling devices such as robots in order to transfer parts and tools. Elementary manufacturing cells are called workstations. At the local control level of manufacturing cells many different kinds of machines can be controlled, and specific languages for different application domains are provided; for example, block diagrams for continuous process control and special purpose languages for CNC or robot programming. For common sequential control, special purpose real-time computers named Programmable Logic Controllers (PLCs) are used. PLCs are replacements for relays, but they incorporate many additional and complex functions, such as supervisory and alarm functions and start-up and shut-down operations, approaching the functionalities of general purpose process computers. The most frequent programming languages are based on ladder or logic diagrams and boolean algebra. However, when the local control is of greater complexity, the above kinds of languages may not be well adapted. The development of industrial techniques makes a sequential control system for manufacturing cells more large and complicated one, in which some subsystems operate concurrently and cooperatively. Conventional representation methods based on flowcharts, time diagrams, state machine diagrams, etc. cannot be used for such systems.

To realize control systems for flexible manufacturing cells, it is necessary to provide effective tools for describing process specifications and developing control algorithms in a clear and consistent manner. In the area of real-time control of discrete event manufacturing cells the main problems that the system designer has to deal with are concurrency, synchronization, and resource sharing problems. For this class of problems, Petri nets have intrinsic favorable qualities and it is very easy to model sequences, choices between alternatives, rendezvous and concurrent activities by means of Petri nets (Reisig, 1985). When using Petri nets, events are associated with transitions. Activities are associated to the firing of transitions and to the markings of places which represent the states of the system. The network model can describe the execution order of sequential and parallel tasks directly without ambiguity (Murata, et al. 1986), (Crockett, et al. 1987). Moreover, the formalism allowing a validation of the main properties of the Petri net control structure (liveness, boundedness, etc.) guarantees that the control system will not fall immediately in a deadlocked situation. In the field of flexible manufacturing cells, the last aspect is essential because the sequences of control are complex and change very often. Furthermore, a real-time implementation of the Petri net specification by software called a token player can avoid implementation errors, because the specification is directly executed by the token player and the implementation of these control sequences preserves the properties of the model (Bruno, 1986). In this approach, the Petri net model is stored in a database and the token player updates the state of the database according to the operation rules of the model. For control purposes, this solution is very well suited to the need of flexibility, because, when the control sequences change, only the database needs to be changed(Silva, et al. 1982), (Valette, et al. 1983).

In addition to its graphic representation differentiating events and states, Petri nets allows the modeling of true parallelism and the possibility of progressive modeling by using stepwise refinements or modular composition. Libraries of well-tested subnets allow components reusability leading to significant reductions in the modeling effort. The possibility of progressive modeling is absolutely necessary for flexible manufacturing cells because they are usually large and complex systems. The refinement mechanism allows the building of hierarchically structured net models.

Some techniques derived from Petri nets have been successfully introduced as an effective tool for describing control specifications and realizing the control in a uniform manner. However, in the field of flexible manufacturing cells, the network model becomes complicated and it lacks the readability and comprehensibility. Therefore, the flexibility and expandability are not satisfactory in order to deal with the specification change of the control system. Despite the advantages offered by Petri nets, the synthesis, correction, updating, etc. of the system model and programming of the controllers are not simple tasks (Desrochers, et al. 1995), (Lee, et al. 2006).

In this chapter, a Petri net based specification and real-time control method for large and complex manufacturing cells is presented. Based on the hierarchical and distributed structure of the manufacturing cell, the specification procedure is a top-down approach from the conceptual level to the detailed level such that the macro representation of the system is broken down to generate the detailed Petri nets at the local machine control level. Then the Petri nets are decomposed and assigned to the machine controllers to perform distributed control using Petri net based multitask processing. An algorithm is proposed for coordination of machine controllers. By the proposed method, modeling, simulation and control of large and complex manufacturing cells can be performed consistently using Petri nets.

MODELING OF MANUFACTURING CELLS USING MODIFIED PETRI NETS

A manufacturing process is characterized by the flow of workpieces or parts, which pass in ordered form through subsystems and receive appropriate operations. Each subsystem executes manufacturing operations, that is, physical transformations such as machining, assembling, or transfer operations such as loading and unloading.

From the viewpoint of discrete event process control, an overall manufacturing process can be decomposed into a set of distinct activities (or events) and conditions mutually interrelated in a complex form. An activity is a single operation of a manufacturing process executed by a subsystem. A condition is a state in the process such as machine operation mode.

Considering the nature of discrete event manufacturing cells which are characterized by the occurrence of events and changing conditions, the condition-event net based specification method has been investigated. The Petri net is one of the effective means to represent condition-event systems. The specification method is a graphical model used as a tool to identify types of activities, conditions, and their mutual interrelation. It describes explicitly the concept of the manufacturing process to be carried out in the discrete event manufacturing cells.

Considering not only the modeling of the systems but also the actual well-designed control, the guarantee of safeness and the capability to represent input and output signals from and to the machines are required. In the condition-event systems, deadlock occurs when the system enters into a state that is not possible for any event to occur. Further bumping occurs when, despite the holding of a condition, the preceding event occurs. This can result in the multiple holding of that condition. Therefore, the basic Petri net which is called Place/Transition-net should be modified and extended in order to represent the activity contents and control strategies for the manufacturing system control in detail.

The extended Petri net consists of the following six elements: (1) Place, (2) Transition, (3) Directed arc, (4) Token, (5) Gate arc, (6) Output signal arc (Hasegawa, et al. 1984). A place represents a condition of a system element or action. A transition represents an event of the system. A directed arc connects from a place to a transition or from a transition to a place, and its direction shows the input and output relation between them. Places and transitions are alternately connected using directed arcs. The number of directed arcs connected with places or transitions is not restricted. A token is placed in a place to indicate that the condition corresponding to the place is holding.

A gate arc connects a transition with a signal source, and depending on the signal, it either permits or inhibits the occurrence of the event which corresponds to the connected transition. Gate arcs are classified as permissive or inhibitive, and internal or external. An output signal arc sends the signal from a place to an external machine. Thus a transition is enabled if and only if it satisfies all the following conditions:

1. It does not have any output place filled with a token.
2. It does not have any empty input place.
3. It does not have any internal permissive arc signaling 0.
4. It does not have any internal inhibitive arc signaling 1.

Figure 1 shows the place and gate variables for transition firing test.

Formally, the enabling condition and the external gate condition of a transition j are described using the logical place and gate variables as follows:

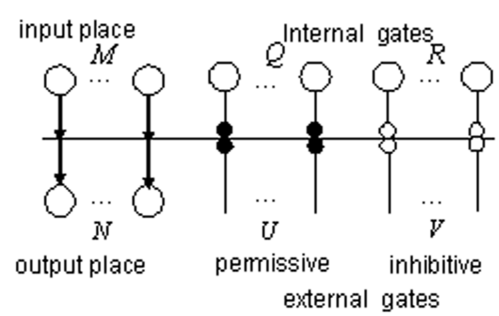
$$t_j(k) = \bigcap_{m=1}^{M} p_{j,m}^{I}(k) \wedge \bigcap_{n=1}^{N} \overline{p_{j,n}^{O}(k)} \wedge \bigcap_{q=1}^{Q} g_{j,q}^{IP}(k) \wedge \bigcap_{r=1}^{R} \overline{g_{j,r}^{II}(k)} \quad (1)$$

$$g_j^{E}(k) = \bigcap_{u=1}^{U} g_{j,u}^{EP}(k) \wedge \bigcap_{v=1}^{V} \overline{g_{j,v}^{EI}(k)} \quad (2)$$

where,

- M: set of input places of transition j
- $p_{j,m}^{I}(k)$: state of input place m of transition j at time sequence k
- N: set of output places of transition j
- $p_{j,n}^{O}(k)$: state of output place n of transition j at time sequence k
- Q: set of internal permissive gate signals of transition j
- $g_{j,q}^{IP}(k)$: internal permissive gate signal variable q of transition j at time sequence k
- R: set of internal inhibitive gate signals of transition j
- $g_{j,r}^{II}(k)$: internal inhibitive gate signal variable r of transition j at time sequence k
- U: set of external permissive gate signals of transition j
- $g_{j,u}^{EP}(k)$: external permissive gate signal variable u of transition j at time sequence k

Figure 1. Place and gate variables for transition firing test



- V: set of external inhibitive gate signals of transition j
- $g_{j,v}^{EI}(k)$: external inhibitive gate signal variable v of transition j at time sequence k

The state (marking) change, that is, the addition or removal of a token of an input or output place, is described as follows:

$$p_{j,m}^{I}(k+1) = p_{j,m}^{I}(k) \wedge \overline{(t_j(k) \wedge g_j^E(k))} \qquad (3)$$

$$p_{j,n}^{O}(k+1) = p_{j,n}^{O}(k) \vee (t_j(k) \wedge g_j^E(k)) \qquad (4)$$

An enabled transition may fire when it does not have any external permissive arc signaling 0 nor any external inhibitive arc signaling 1. The firing of a transition removes a token from each input place and put a token in each output place connected to it. The assignment of tokens into the places of a Petri net is called marking and it represents the system state. In any initial marking, there must not exist more than one token in a place. According to these rules, the number of tokens in a place never exceeds one, thus the Petri net is essentially a safe graph; the system is free from the bumping phenomenon.

For the actual control, the operations of each machine are broken down into a series of unit motions, which is represented by mutual connection between places and transitions. A place means a concrete unit motion of a machine. From these places, output signal arcs are connected to the machines, and external gate arcs from the machines are connected to the transitions of the Petri net when needed, for example, to synchronize and coordinate operations. When a token enters a place that represents a subtask, the machine defined by a machine code is informed to execute a specified subtask with positional data and control parameters; all the code and data are defined as the place parameters.

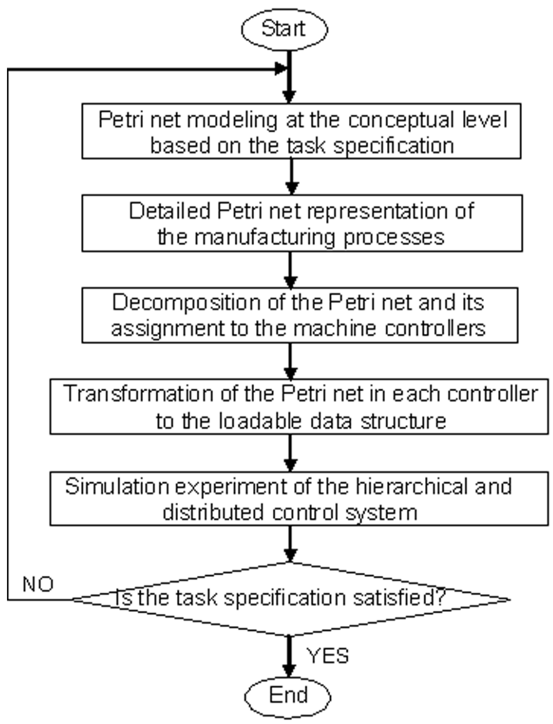
If a place has two or more input or output transitions, these transitions may be in conflict for firing. When two or more transitions are enabled only one transition should fire using gate arcs or some arbitration rule. The Petri net described in detail by such a procedure mentioned above can be used as a program for the system control, while features of discrete event manufacturing cells such as ordering, parallelism, asynchronism, concurrency and conflict can be concretely described through the extended Petri net.

The extended Petri net is a tool for the study of condition-event systems and used to model condition-event systems through its graphical representation. Analysis of the net reveals important information about the structure and the dynamic behavior of the modeled condition-event system. This information can then be used to evaluate the modeled condition-event system and suggest improvements or changes.

DESIGN OF HIERARCHICAL AND DISTRIBUTED CONTROL SYSTEM

A specification procedure for discrete event manufacturing cells based on Petri nets is as follows. First, the conceptual level activities of the discrete event manufacturing cells are defined through a Petri net model considering the task specification corresponding to the manufacturing process. A conceptual Petri net model describes the aggregate manufacturing process. At the level, each subtask composing the task specification is represented as a place of the Petri net, where the activity of each equipment is also represented as a place. Then, the detailed Petri nets describing the activities are deduced based on activity specification and required control strategies. The macro representation of the manufacturing process is effectively used for achieving a top-down interpretation down to the concrete lower level activities using Petri nets. Based on the hierarchical approach, the Petri net is translated into the detailed Petri net by

Figure 2. Flow chart of Petri net based implementation of hierarchical and distributed control system



stepwise refinements from the highest conceptual level to the lowest machine control level. This procedure is repeated up to an appropriate level corresponding to the control level of the equipment responsible for the activity execution. At each step of detailed specification, places of the Petri net are substituted by a subnet in a manner which maintains the structural properties (Miyagi, 1988). The overall procedure of the Petri net based implementation of hierarchical and distributed control for robotic manufacturing cells is summarized as shown in Figure 2.

It is natural to implement a hierarchical and distributed control system, where one controller is allocated to each control layer or block. For the robotic manufacturing cells composed of robots, machine tools, and conveyors, an example structure of hierarchical and distributed control is composed of one station controller and three machine controllers as shown in Figure 3, although each robot may be controlled by one robot controller. The detailed Petri net is decomposed into subnets, which are assigned to machine controllers.

In the decomposition procedure, a transition may be divided and distributed into different machine controllers as shown in Figure 4. The machine controllers should be coordinated so that these transitions fire simultaneously, that is, the aggregate behavior of decomposed subnets should be the same as that of the original Petri net. Decomposed transitions are called global transitions, and other transitions are called local transitions.

By the Petri net model, the state of the discrete event system is represented as the marking of tokens, and firing of any transition brings about change to the next state. So the firing condition and state (marking) change before decomposition should be the same as those after decomposition. If transition j is divided into s transitions $j1$, $j2$,,,

Figure 3. Example structure of distributed control system

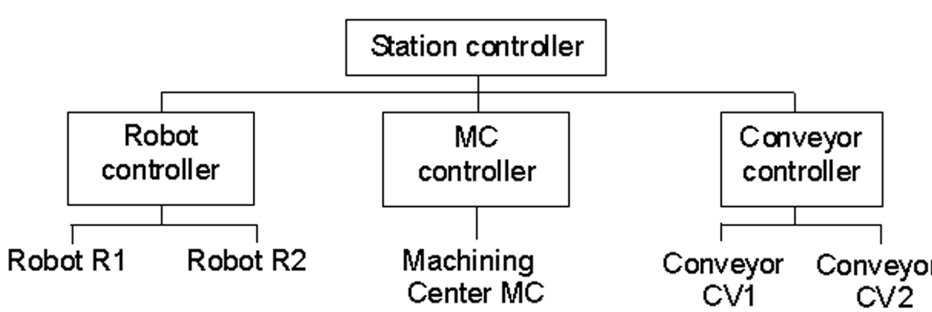


Figure 4. Decomposition of transitions

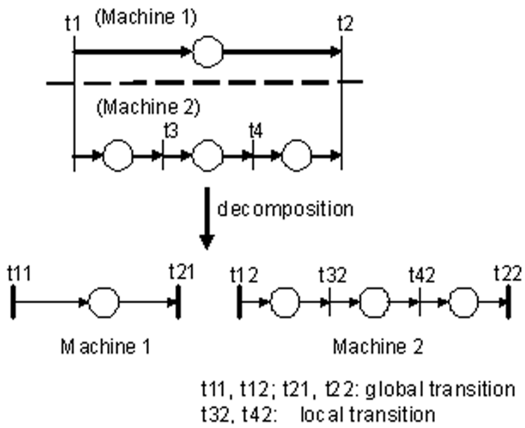


js, as shown in Figure 5, the firability condition of the transition after decomposition is described as follows:

$$t_{jsub}(k) = \bigcap_{m=1}^{Msub} p^{I}_{jsub,m}(k) \wedge \bigcap_{n=1}^{Nsub} \overline{p^{O}_{jsub,n}(k)} \wedge \bigcap_{q=1}^{Qsub} g^{IP}_{jsub,q}(k) \wedge \bigcap_{r=1}^{Rsub} \overline{g^{II}_{jsub,r}(k)} \tag{5}$$

$$g^{E}_{jsub}(k) = \bigcap_{u=1}^{Usub} g^{EP}_{jsub,u}(k) \wedge \bigcap_{v=1}^{Vsub} \overline{g^{EI}_{jsub,v}(k)} \tag{6}$$

From Equation 1 and Equation 5,

$$t_{j}(k) = \bigcap_{sub=1}^{S} t_{jsub}\ (k) \tag{7}$$

From Equation 2 and Equation 6,

$$g^{E}_{j}(k) = \bigcap_{sub=1}^{S} g^{E}_{jsub}(k) \tag{8}$$

where,

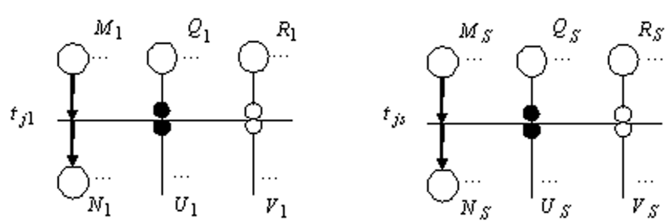
- *S*: total number of subnets
- *Msub*: set of input places of transition *jsub* of subnet *sub*
- $p^{I}_{jsub,m}(k)$: state of input place *m* of transition *jsub* of subnet *sub* at time sequence *k*
- *Nsub*: set of output places of transition *jsub* of subnet *sub*
- $p^{O}_{jsub,n}(k)$: state of output place *n* of transition *jsub* of subnet *sub* at time sequence *k*
- *Qsub*: set of internal permissive gate signals of transition *jsub* of subnet *sub*
- *Rsub*: set of internal inhibitive gate signals of transition *jsub* of subnet *sub*
- *Usub*: set of external permissive gate signals of transition *jsub* of subnet *sub*
- *Vsub*: set of external permissive gate signals of transition *jsub* of subnet *sub*

The addition or removal of a token of a place connected to a decomposed transition is described as follows:

$$p^{I}_{jsub,m}(k+1) = p^{I}_{jsub,m}(k) \wedge \overline{(t_{j}(k) \wedge g^{E}_{j}(k))} \tag{9}$$

$$p^{O}_{jsub,n}(k+1) = p^{O}_{jsub,n}(k) \vee (t_{j}(k) \wedge g^{E}_{j}(k)) \tag{10}$$

Figure 5. Place and gate variables after decomposition of transition

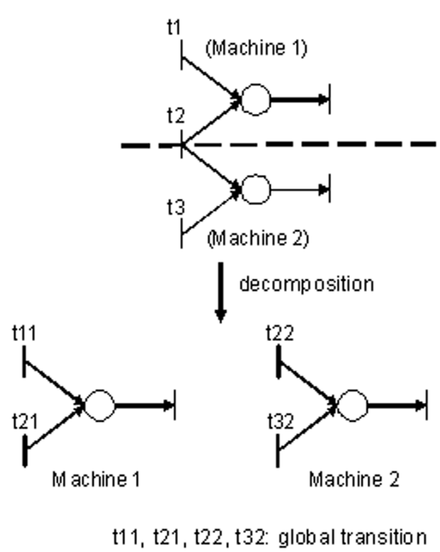


Consequently it is proven that the firability condition of the original transition is equal to AND operation of firability conditions of decomposed transitions. If and only if all of the decomposed transitions are firable, then the global transitions are firable. To utilize the above results, the coordinator program has been introduced to coordinate the decomposed subnets so that the aggregate behavior of decomposed subnets is the same as that of the original Petri net.

There may exist a place which has several input transitions and/or several output transitions. This place is called a conflict place. The transitions connected to a conflict place are in conflict when some of them are firable at the same time. In this case, only one of them can be fired and the others become disabled. The selection of firing transition is done arbitrarily using an arbiter program.

In case that a transition in conflict with other transitions is decomposed as shown in Figure 6, these transitions should be coordinated by the system controller. If arbitrations of the transitions are performed independently in separate subnets, the results may be inconsistent with the original rule of arbitration. Therefore the transitions should be arbitrated together as a group. On the other hand, arbitration of local transitions in conflict is performed by local machine controllers.

Figure 6. Decomposition of transition in conflict

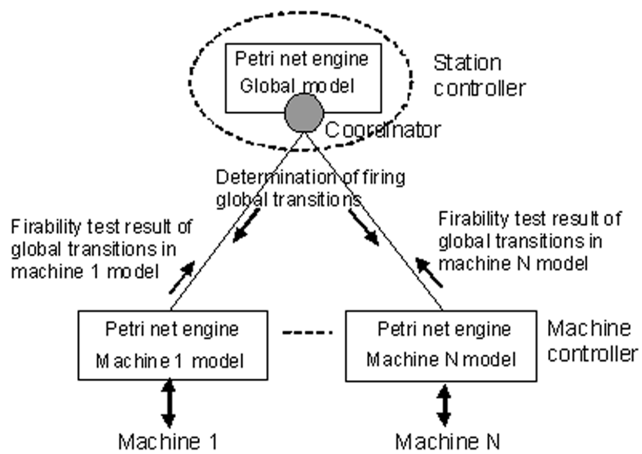


The hierarchical and distributed control system composed of one station controller and several machine controllers has been implemented. The conceptual Petri net model is allocated to the Petri net based controller for management of the overall system. The detailed Petri net models are allocated to the Petri net based controllers in the machine controllers. Each machine controller directly monitors and controls the sensors and actuators of its machine.

The control of the overall system is achieved by coordinating these Petri net based controllers. Figure 7 shows the Petri net based control structure with the coordinator. System coordination is performed through communication between the coordinator in the station controller and the Petri net based controllers in the machine controllers as the following steps.

1. When each machine controller receives the start signal from the coordinator, it tests the firability of all transitions in its own Petri net, and sends the information on the global transitions and the end signal to the coordinator.
2. The coordinator tests the firability of the global transitions, arbitrates conflicts among global transitions, and sends the names of firing global transitions and the end signal to the machine controllers.
3. Each machine controller arbitrates conflicts among local transitions using the information from the coordinator, generates a new marking, and sends the end signal to the coordinator.
4. When the coordinator receives the end signal from all the machine controllers, it sends the output command to the machine controllers.
5. Each machine controller outputs the control signals to its actuators simultaneously.

Figure 7. Petri net based control structure with coordinator

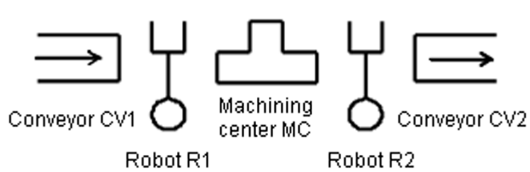


REAL-TIME CONTROL OF A MANUFACTURING CELL

The example manufacturing system has two robots, one machining center, and two conveyors, where one is for carrying in and the other is for carrying out, as shown in Figure 8. The main execution of the system is indicated as the following task specification:

1. A workpiece is carried in by the conveyor CV1.
2. The robot R1 loads the workpiece to the machining center MC.
3. The machining center MC processes the workpiece.
4. The robot R2 unloads the workpiece from the machining center and places it on the conveyor CV2.

Figure 8. Example of robotic manufacturing system



5. The workpiece is carried out by the conveyor CV2.

A conceptual Petri net model is first chosen, which describes the aggregate manufacturing process. The places which represent the subtasks indicated as the task specification are connected by arcs via transitions in the specified order corresponding to the flow of subtasks and a workpiece. The places representing the machines are also added to connect transitions which correspond to the beginning and ending of their subtasks. Thus at the conceptual level the manufacturing process is represented as shown in Figure 9. In this step, if necessary, control conditions such as the capacity of the system between the respective subtasks must be connected to regulate the execution of the Petri net. For the cell with one robot, the place "Robot" has two input transitions and two output transitions, but these transitions are not firable at the same time, so they are not in conflict for firing. The firing of only one of these transitions is permitted using gate arcs (Yasuda, 2008). Next, each place representing a subtask at the conceptual level is translated into a detailed subnet. Figure 10 shows the detailed Petri net representation of loading, processing and unloading in Figure 9.

Figure 9. Petri net representation of the example system at the conceptual level

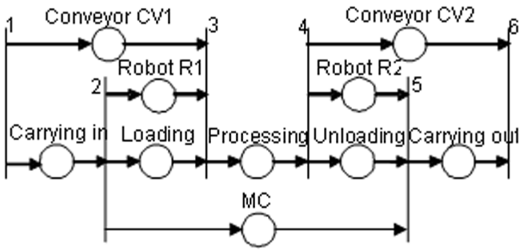


Figure 10. Detailed Petri net representation of subtasks

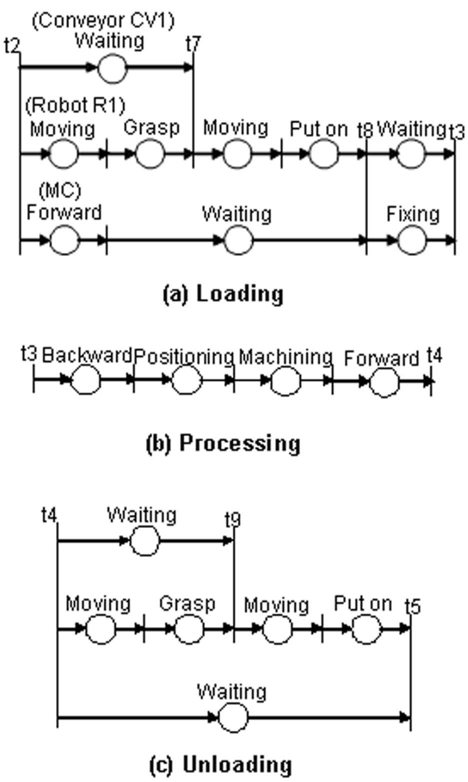

For the example system, the hierarchical and distributed control system has been realized using a set of PCs. Each machine controller is implemented on a dedicated PC. The station controller is implemented on another PC. Communications among the controllers are performed using serial communication interfaces.

The names of global transitions and their conflict relations are loaded into the coordinator in the station controller. The connection structure of a decomposed Petri net model and conflict relations among local transitions are loaded into the Petri net based controller in the corresponding machine controller. In the connection structure, a transition of a Petri net model is defined using the names of its input places and output places; for example, t1-1=p1-1, -p1-11, where the transition no.1 (t1-1) of Robot controller (subsystem no.1) is connected to the input place no.1 and the output place no.11. For the distributed control system shown in Figure 3, the Petri net representations assigned to the machine controllers are shown in Figure 11. Structural information for the robot controller inputted to the loader is shown in Table 1.

Using the names of transitions in the subsystems, global transitions are defined; for example, G2: t0-2, t1-21, t2-22, t3-23 indicates that the global transition G2 is composed of the transition

Figure 11. Petri net representation of machine controllers (: global transition, : local transition)

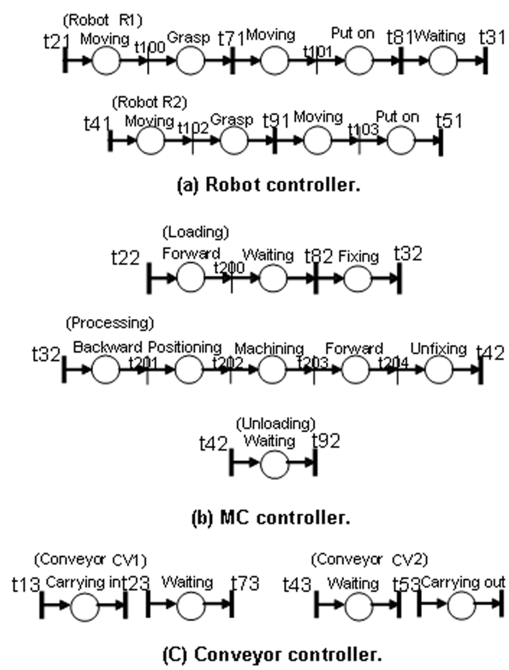

Table 1. Structural information for the robot controller, as inputted to the loader

t1-21=-p1-11	t1-41=-p1-21
t1-100=p1-11, -p1-12	t1-102=p1-21, -p1-22
t1-71=p1-12, -p1-13	t1-91=p1-22, -p1-23
t1-101=p1-13, -p1-14	t1-103=p1-23, -p1-24
t1-81=p1-14, -p1-15	t1-51=p1-24
t1-31=p1-15	

no.2 of Station controller (subsystem no.0), the transition no.21 of Robot controller, the transition no.22 of MC controller (subsystem no.2), and the transition no.23 of Conveyor controller (subsystem no.3). Then, the coordinator information for the example distributed control system is shown in Table 2.

By executing the coordinator and Petri net based controllers algorithms based on loaded information, simulation experiments have been performed. The robot controller executes robot motion control through the transmission of command. The MC controller and the conveyor controller communicate with a dedicated PLC. The Petri net simulator initiates the execution of the subtasks attached to the fired transitions through the serial interface to the robot or other external machine. When a task ends its activity, it informs the simulator to proceed with the next activations by the external permissive gate arc (Yasuda, 2010). The detailed Petri net representation for real-time external machine control is shown in Figure 12. External permissive gate arcs from sensors for detecting the completion of work handling are employed as shown in Figure 13.

Table 2. Coordinator information for the example distributed control system

G2: t0-2, t1-21, t2-22, t3-23	start of loading from CV1
G3: t1-71, t3-73	end of grasp on CV1
G4: t1-81, t2-82	end of putting on MC
G5: t0-3, t1-31, t2-32	end of loading into MC
G6: t0-4, t1-41, t2-42, t3-43	start of unloading from MC
G7: t1-91, t2-92	end of grasp on MC
G8: t0-5, t1-51, t3-53	end of putting on CV2
G9: t0-6, t3-63	end of carrying out

The machine controllers control two conveyors or robots, so control software on each PC is written using multithreaded programming. Petri net simulation and task execution program through serial interface are implemented as threads in each machine controller. Real-time task execution using multithreaded programming is shown in Figure 14.

In multithreaded system a thread is an independent flow of execution. All threads share code, data, stack, and system memory areas. So, all threads can access to all global data. Further, because each thread has a separate CPU state and its own stack memory, all local variables and function arguments are private to a specific thread. Context switching between threads involves simply saving the CPU state for the current thread and loading the CPU state for the new thread. It's easy for threads to interact with each other by way of synchronization objects and intertask communications, because they have some shared memory. Memory management data structures do not need to be changed, because the threads share the same memory areas (Grehan, et al. 1998).

In the implementation both the Petri net simulation and task execution threads access to the external gate variables as shared variables; the task execution thread writes the new values of the gate variables and the Petri net simulation thread reads them. Mutual exclusive access control is implemented, so that, while one thread accesses to the shared variables, the other thread can not access to them. Control software using multithreaded programming was written in Visual C# under OS Windows XP SP3 on a general PC. Experiments using a real industrial robot show that the Petri net simulation thread and the task execution threads proceed concurrently with even

Figure 12. Detailed Petri net representation of real-time machine control

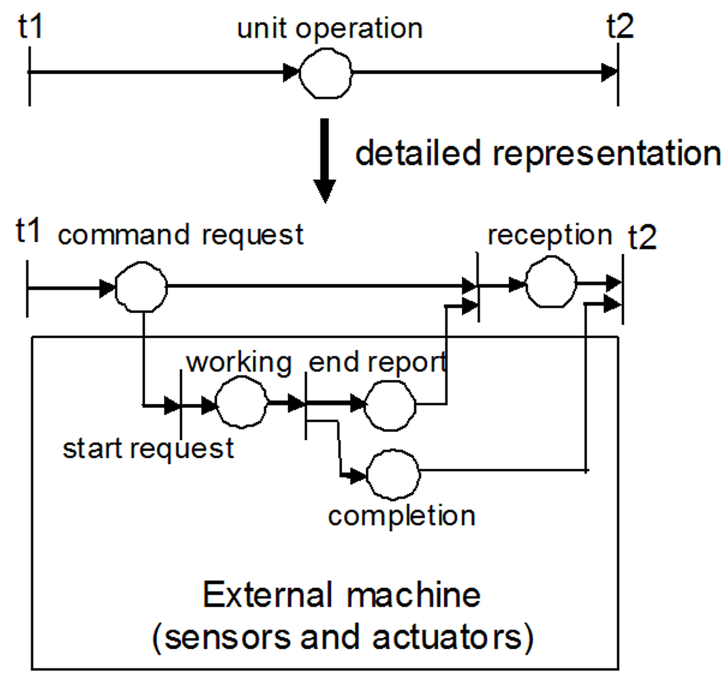

Figure 13. External permissive gate arcs from sensors for work handling

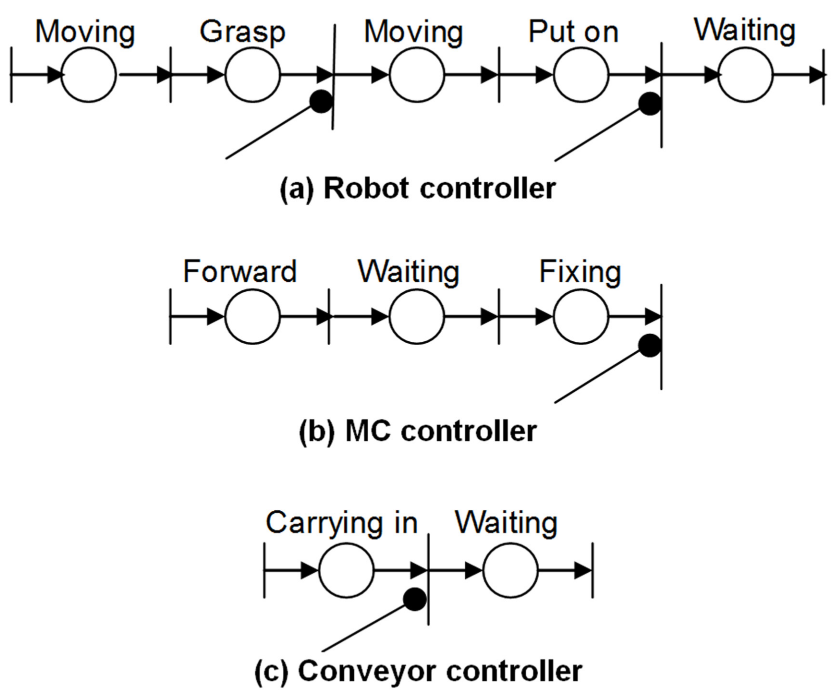

Figure 14. Real-time execution of subtasks using multithreaded programming

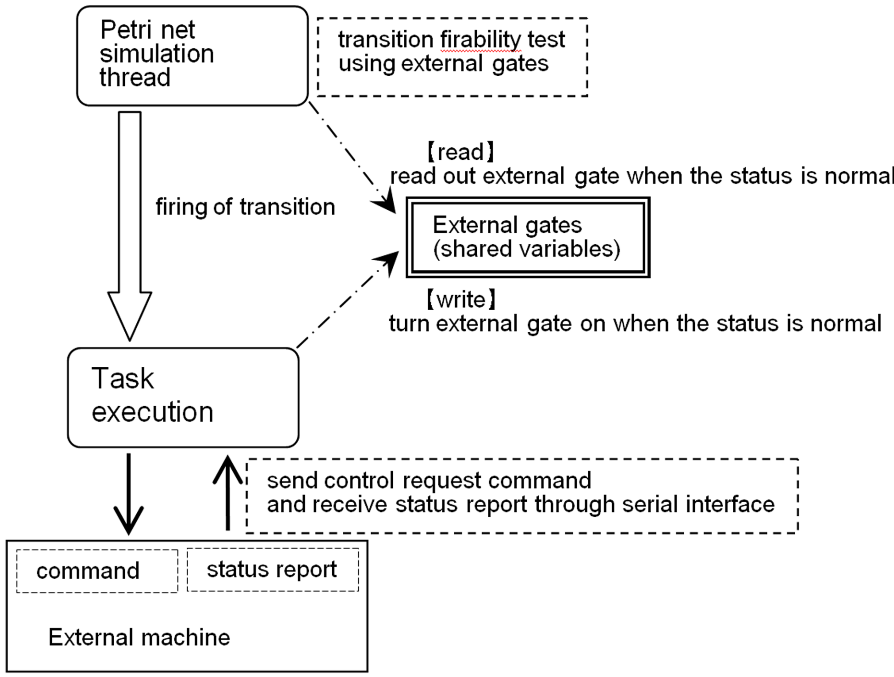


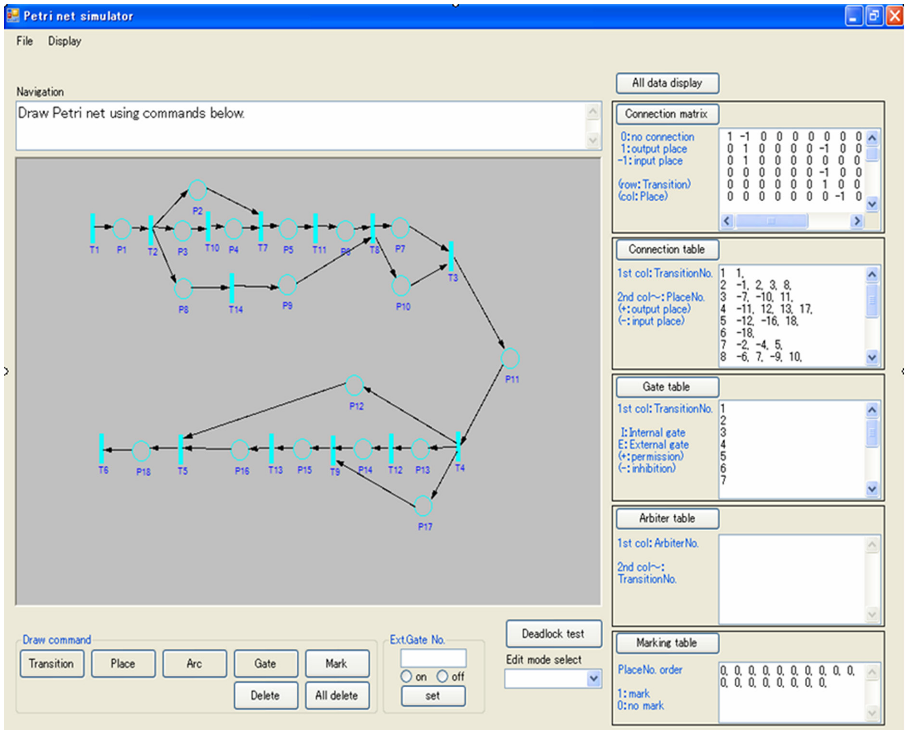
priority, and the values of external gate variables are changed successfully; after the task execution threads write the new values, the Petri net simulator thread reads them immediately.

Experimental results show that the decomposed transitions fire simultaneously as the original transition of the detailed Petri net of the whole system task. The robots cooperated with the conveyors and the machining center, and the example manufacturing cell performed the task specification successfully. Firing transitions and marking of tokens can be directly observed on the display at each time sequence using the simulator on each PC (Yasuda, 2009), as shown in Figure 15. The Petri net modeling thread is executed as the main thread to perform the modeling, drawing and modification of the overall system control net model based on task specification. When the transformation of graphic data of the Petri net model into internal structural data is finished, the Petri net simulation thread starts. During simulation and task execution, liveness or deadlock is possibly decided, and the user can stop the task execution at any time.

CONCLUSION

A methodology to construct hierarchical and distributed control systems, which correspond to the hardware structure of manufacturing cells, has been proposed. By introduction of the coordinator, the Petri net based controllers are arranged according to the hierarchical and distributed nature of the overall manufacturing system; the coordination mechanism is implemented in each layer repeatedly. The Petri net model in each Petri net based machine controller is not so large and easily manageable. The overall control structure of the example robotic manufacturing cell was implemented on a communication network of PCs using multithreaded programming. In accordance with the implementation using multithreaded programming, hierarchical and distributed implementation

Figure 15. View of Petri net simulator



under a real-time operating system on a network of microcomputers connected via a serial bus is also possible, where each microcomputer is dedicated to the local Petri net model of a subsystem in the manufacturing cell. Thus, modeling, simulation and control of large and complex manufacturing systems can be performed consistently using Petri nets.

The proposed methodology has the following advantages especially for manufacturing cells composed of several parallel processes.

1. Because of decomposition of detailed Petri net model, design and implementation of lower level controllers can be performed efficiently for each subsystem. Modification or breakdown in a lower level controller is restricted to the corresponding controller. Machine controllers can be realized using conventional relay circuits, PLCs, or microcomputers. From the practical point of view, transformation Petri nets into ladder diagrams, PLC or microcomputer programs, and inversely transformation them into Petri nets, are desirable.
2. By monitoring the flow of token in the upper level controller, the global state of the system can be conceptually understood.
3. By realizing the upper level controller using a general PLC or computer, the Petri net model (places and transitions) can be easily changed according to task specification.

From the proposed coordinator algorithm the coordination mechanism is performed with the master-slave multicomputer architecture; the upper level controller is the master and the lower level controllers are slaves. So access conflict and lock out do not occur, and both hardware and software structures can be simply realized, especially including non-homogeneous system. Although in the master-slave architecture of operating systems the performance of the upper level controller is required to be sufficiently high, there is no problem because robotic arms, conveyors and machine tools are very slow in comparison with the controller. In case of an accident or breakdown of the upper level controller, manual operation modes must be provided for the lower level controllers. In order to improve the Petri net based control system for manufacturing cells, future works include the following:

1. The number of token is increased and some kinds of tokens are provided in a place.
2. The time required for transition firing condition in a place is provided.

The above extensions of the Petri net is necessary to optimize the process control in a manufacturing cell using simulations without real machines. It is also possible to analyze deadlock phenomena in Petri net models based on detailed simulations.

Chapter 24
Lean Thinking Based Investment Planning at Design Stage of Cellular/Hybrid Manufacturing Systems

M. Bulent Durmusoglu
Istanbul Technical University, Turkey

Goksu Kaya
Istanbul Technical University, Turkey

ABSTRACT

This chapter focuses on providing a methodology for lean thinking based investment planning from the perspective of cellular or hybrid manufacturing systems. The chapter has been divided into three parts. First part provides a general explanation of why lean thinking is so beneficial for managing manufacturing processes and obtaining sustained improvement. This part then moves to the aim of cell formation, and then uses value stream mapping to map current state for visualizing material-information flow and to design a desired future state for examining economic aspects of new machine investment decisions aligned with lean manufacturing principles. The purpose of second part is to explore axiomatic design approach; it provides an overall view of what to do. The third part presents the actual use of the methodology with implementation of hybrid system at a furniture factory; it helps to see application results of this methodology as part of a lean manufacturing program.

INTRODUCTION

Traditional manufacturing systems are built on a functional layout or an assembly line with the principle of economies of scale. This point of view causes much capital investments in high-volume operations and large work-in-process inventories. As an alternative to traditional manufacturing, the principles of the Toyota Production System (TPS) have been widely adopted in recent years. Application of TPS principles have led to lean manufacturing (Sullivan *et al.*, 2002). Womack & Jones (1996) used the term lean thinking as the thinking process of Taiichi Ohno and the set of

DOI: 10.4018/978-1-4666-1945-6.ch024

methods describing the Toyota Production System (Womack & Jones, 1996; Monden, 1993). Lean manufacturing emerged as a global approach that uses different tools to focus on waste elimination and to manufacture products that meet customer's needs (Hines & Taylor, 2000). Lean manufacturing has been increasingly adopted as a potential solution for many organizations, particularly within the automotive industries (Womack, *et al.*, 1990; Day, 1998; Jones, 1999) and aerospace industries (Abbett *et al.*, 1999; Womack & Fitzpatrick, 1999).

Lean production requires the analysis of the "value stream". A value stream is defined as all the value-added and non-value-added operations required manufacturing specific products and services to a customer (Womack & Jones, 1996; Rother & Shook, 1998). Value Stream Map is an enterprise improvement technique to visualize entire production process, representing information and material flows, to improve the production process by identifying waste and its sources (Rother & Shook, 1998).

Lean manufacturing focuses on the waste elimination and produces products that meet customer expectations. Lean production uses production and assembly cells consisting of product focused resources. The aims of the cell formation are smoothing work flow with flexible operation across a wide variety of low cost and high quality products by means of waste elimination. Economic benefits of lean manufacturing include smaller floor space requirements, lower work-in process, reduced lead-times and higher throughput (Sullivan, *et al.*, 2002). Lean production focuses on value pulled from the next upstream activity as customer. As value is specified, value streams are identified eliminating steps that do not create value, so the product will flow smoothly toward the customer. A value stream mapping is an enterprise improvement technique to visualize an entire production process by identifying waste (Braglia *et al.,* 2006).

Cellular manufacturing is an important technique in the planning and controlling of manufacturing system. Cellular manufacturing offers three groups of benefits. These benefits are: human related factors facilitated by empowerment in smaller cells; improved flow and supervisory control in cells to deal with smaller number of parts and facilities; improved operational efficiency, obtainable due to similarity; setup reduction; batch size reduction; improvement in performance related to productivity, quality and agility (Babu *et al.*, 2000). In practice, it is usually hard to partition all machines into independent cells. So, a functional layout generally becomes necessary. Because of this fact, hybrid cellular manufacturing systems (HMS) are required (Suresh 1991).

Hybrid manufacturing system (HMS) is the system where manufacturing cells and functional layout coexist (Shambu & Suresh, 2000), and also it has an advantage of more product flexibility (Satoglu *et al.,* 2009) and less capital investment for machines. Utilization of alternative machines in the HMS reduces additional machine purchasing requirements, and therefore it is beneficial (Satoglu *et al.,* 2009).Empirical evidences also show that hybrid manufacturing system is common for practice (Marsh *et al.,* 1999).

Lean manufacturing tools and techniques provide economical basis to managers for investment planning decisions. Value stream mapping creates a common language about a production process, enabling more purposeful decisions to improve the production system. Value stream map of the system should be taken into account for the design of future state to examine the economic aspects of new machine investment decisions (Sullivan, *et al.*, 2002).This chapter attempts to provide insight as to the choice and use of appropriate tools for designing a successful lean manufacturing system. Although it does not cover every lean manufacturing aspect, it does offer a road map that can guide a company for effective new machine investment decisions toward the development of a lean manufacturing environment.

Investment planning is the determination of suitable machines for manufacturing of part families within the cell. Investment planning for cellular manufacturing can enhance the operating characteristics of the system. After equipment purchases are decided, it is necessary to measure the effectiveness of this decision by evaluating the effects of the new equipment on the system (Gosh, 1989). In existing factories, investment decisions for purchasing new machines in favor of cellular or hybrid manufacturing systems can be troublesome to managers. Many of investment decisions in manufacturing industry are not beneficial and economical (Sullivan, *et al.*, 2002). For this reason, this chapter aims to be a guideline to managers for effective new machine investment decisions in implementation of cellular or hybrid manufacturing layout. This chapter focuses on providing a methodology for lean thinking based investment planning in restructuring manufacturing environment from the perspective of cellular or hybrid manufacturing layout. To do this, we used axiomatic design methodology for creating a systematic perspective.

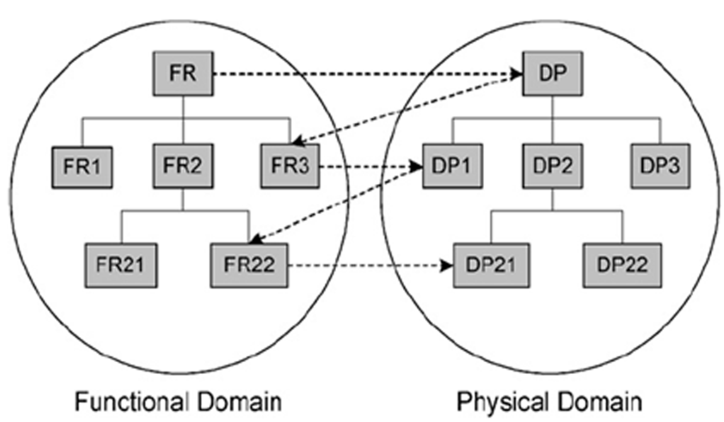
Axiomatic design (AD) is a design theory that was created by Professor Nam Pyo Suh of the Massachusetts Institute of Technology (Suh 1990). The goal of AD is to establish a scientific basis for design and to improve design activities by providing logical and rational processes and tools to designer. In accomplishing this goal, AD provides a systematic search process through the design space to minimize the random search process and determines the best design solution among many alternatives (Kulak *et al.*, 2005).

Some of algorithmic methods can be effective if the design has to satisfy only one functional requirement, but when many functional requirements must be satisfied at the same time, they are less effective. Axioms provide the boundaries within which these algorithms are valid, in addition to providing the general principles. AD includes four domains: customer domain, functional domain, physical domain and process domain. In the customer domain, there are customers' needs or attributes (CAs) from a product, service or system. The functional domain includes customer needs transformed into functional requirements (FRs). To answer FRs, physical domain has design parameters (DPs). Finally, process domain is characterized by the process variables (PVs) to develop a process for production (Suh, 2001). These functional domain and physical domain and mapping between them are illustrated in Figure 1.

The most important concept in axiomatic design is the existence of the design axioms. These axioms are (Suh, 2001):

1. **Axiom:** Independence axiom: The FRs are defined as the minimum set of independent

Figure 1. Hierarchical structure of axiomatic design (Durmusoglu & Kulak, 2008)



requirements that the design must satisfy. A set of FRs is the description of design goals. The independence axiom states that when there are two or more FRs, the design solution must be such that each one of the FRs can be satisfied without affecting the other FRs. That means we have to choose a correct set of DPs to be able to satisfy the FRs and maintain their independence (Suh, 2001).

Axiom: Information axiom: The design that has the smallest information content is the best design. The information content is defined in terms of probability; this axiom also states that the design that has the highest probability of success is the best design (Suh, 2001).

$$\{FR\} = [A]\ \{DP\} \tag{1}$$

Here, {FR} is the functional requirement vector, {DP} is the design parameter vector, and [A] is the design matrix that characterizes the design. The structure of [A] matrix defines the type of design being considered. In order to satisfy the independence axiom, [A] matrix should be an uncoupled (a diagonal matrix) or decoupled design (a triangular matrix) (Suh, 2001).

The design of an ideal manufacturing system depends on the selection of functional requirements (FRs) the system must satisfy within a given set of constraints (Cs). Therefore, an ideal manufacturing system design is not time invariant. It changes with the selection of specific sets of FRs and Cs. An efficient manufacturing system must utilize things, people and information in a rational manner, consistent with basic principles (Suh, 2001).

BACKGROUND

There have been many publications on lean manufacturing and cellular manufacturing systems. Some subsequent steps need for a complete cell formation as Durmusoglu and Nomak (2005) observed in their CMS design implementation. Nancy and Wemmerlöv (2002), published a paper for defining part families and related machine groups, and Sarher and Mondal (1999) studied the evaluation of grouping efficiency measures. Aneke and Carrie (1986) studied on designing of multi product flow lines on the basis of one piece flow.

Many AD applications in designing products, systems, organizations and software have appeared in the literature so far. AD theory and principles have been introduced first time by Suh (1990). Suh (1997) described a conceptual approach for designing of the systems using AD methodology. Suh *et al.* (1998) provided an AD-based model for an ideal production system based on lean principles. Cochran, Eversheim *et al.* (2000) used lean principles to structure smaller production segments by AD. Houshmand & Jamshidnezhad (2002) also provided a lean manufacturing based production system design model using AD approach. In this model, organizational capabilities, technological capabilities and value stream analysis are used as the basis. Kulak *et al.* (2005) published a paper for a complete cellular manufacturing system design methodology based on axiomatic design principles.

Sullivan *et al.* (2002) illustrated an equipment replacement decision problem within the context of lean manufacturing implementation. In particular, they demonstrated how the value stream mapping (VSM) tools can be used to map the current state of a production line and design a desired future state. Further, they provided a roadmap for how VSM can provide necessary information for analysis of equipment replacement decision problems encountered in lean manufacturing implementation.

Considering the literature mentioned above, a road map including a systematic design model for equipment investments in cellular/hybrid manufacturing system is not found. In this study, a methodology is developed using AD principles in order to fill this gap.

LEAN THINKING BASED INVESTMENT PLANNING BY AXIOMATIC DESIGN FOR CMS OR HMS

Main focus of the chapter is giving a systematic methodology by axiomatic design principles to design a desired future state aligned with lean manufacturing principles by using value stream mapping and its associated tools and to provide a roadmap for investment decisions in cellular/hybrid manufacturing.

The first step of axiomatic design is defining the functional requirement at the highest level of the system hierarchy of functional domain (Suh *et al.*, 1998).

Step 1. Defining Functional Requirements (FR1): The design goal of the production system (functional requirement at the highest level) was defined as;

FR1= Improve the system performance

The companies, focusing on lean, aim eliminating wastes and improving system for responding quickly to customer needs.

Step 2. Mapping of FRs in the Physical Domain (DP1): Design parameter (DP), which satisfies the FRs established in the previous step, is selected as below.

DP1= Design of a lean manufacturing system

Step 3. Decomposition of FR (FR1): If the DPs can not be implemented without further clarification, the AD principles recommend returning to the functional domain for decomposing the FRs into their lower functional requirement set (Suh, 2001). The following functional requirements are defined for decomposing the FR determined in the first step.

- FR11= Define customer requirements and expectations
- FR12= Make experts and employees conscious on lean thinking
- FR13= Divide production system into sub-systems for simplification of the system
- FR14= Visualize wastes
- FR15= Apply the proposed plan to eliminate waste in production processes and offices

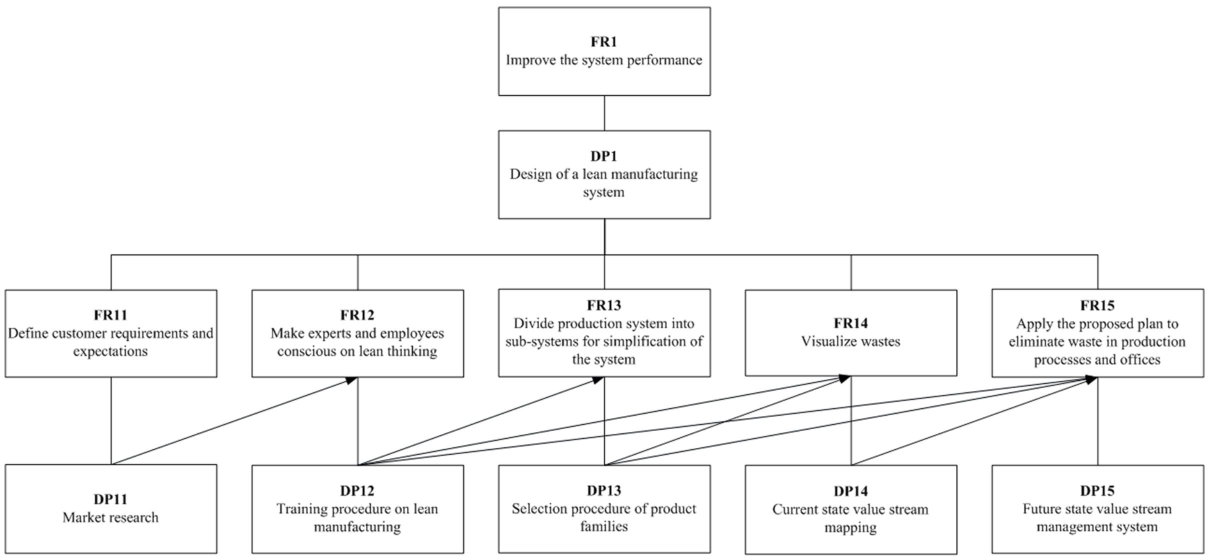
Step 4. Defining the Corresponding DPs of FRs (DP1): We move from the functional domain to the physical domain. The following DPs in response to satisfy the five FR1ns defined in step 3 are listed below.

- DP11= Market research
- DP12= Training procedure on lean manufacturing
- DP13= Selection procedure of product families
- DP14= Current state value stream mapping
- DP15= Future state value stream management system

Step 5. Structuring of Design Matrix (FR1-DP1): The FR-DP sets are defined in Step 3 and Step 4, and the corresponding design matrix (DM) providing the relationship between the FR and DP elements is structured. In the design matrix, a symbol X represents a strong relationship between the corresponding FR-DP pair. It is important to ensure that this DM satisfies the Independence Axiom (IA) of the AD principles. If the DM matrix is uncoupled or decoupled, then it satisfies the Independence Axiom of AD principles (Suh, 2001). The design equation and the DM corresponding to the FR-DP sets are as follows and depicted in Figure 2. Equation 2 is a decoupled design, and satisfies the IA.

$$\begin{bmatrix} FR11 \\ FR12 \\ FR13 \\ FR14 \\ FR15 \end{bmatrix} = \begin{bmatrix} X & 0 & 0 & 0 & 0 \\ X & X & 0 & 0 & 0 \\ 0 & X & X & 0 & 0 \\ 0 & X & X & X & 0 \\ 0 & X & X & X & X \end{bmatrix} * \begin{bmatrix} DP11 \\ DP12 \\ DP13 \\ DP14 \\ DP15 \end{bmatrix} \tag{2}$$

Figure 2. The decomposition FR1-DP1



Defining Customer Requirements and Expectations (FR11-DP11): Making market research is one of the effective working criteria for companies. The companies not giving importance to the research face various risks. Market research is collecting and analyzing of systematic and objective information about products, market and consumers (Megep, 2008). Market research is very important for defining customer demands, sales forecasting in production planning and new product developments.

Making Experts and Employees Conscious on Lean Thinking (FR12-DP12): Employee training is the most efficient method for using human resource effectively in a company. Employee training directly affects company's profitability and decreasing employee turnover by increasing employee satisfaction. Applying of lean thinking and making it company's culture are possible with by training program which makes employees conscious about lean.

Dividing Production System into Sub-systems for Simplification of the System (FR13-DP13): The products should be classified up to the similarities based on production system's characteristics. So, the first step consists of identification of product families and in the selection of one with its production sub-system as the pilot application for improvement. This step continues until all of the product families have been selected.

Pareto Analysis (ABC analysis) is used for separating the vital few from trivial many. Pareto analysis is essential for visualizing volume of the product families in total production. By doing this analysis, it is possible to see how the customer demand is distributed among different product types (Durmusoglu & Kulak 2008). High volume products are responsible for the largest amount of waste's costs (work in process, material handling, other operational costs, etc.). Focusing on these high volume products affects overall performance of the company.

Product family could be a group of high volume products, which pass through the similar operational steps at common machines. Another example of product families is to divide products into catalogued products and specific-project type products. Therefore determining product families depends on production system's characteristics. In order to determine product family, the relationship matrix, including products, production volume, processes, production functions and customers is needed (Durmusoglu & Kulak 2008).

Visualizing Wastes (FR14-DP14): Value stream mapping (VSM) visualizes value and waste resources through the production processes for a defined product family. Therefore, it is used for understanding how the process flow must be, and then, it combines lean tools.

Value stream mapping is a tool, which was created for redesigning production system (Rother & Shook 1998; Womack & Jones, 2002; Pavnaskar *et al.*, 2003). To find causes of waste, it is useful to show parameters for each production processes in detail (Braglia *et al.*, 2006).

Applying the Proposed Plan to Eliminate Waste in Manufacturing Processes and Offices (FR15-DP15): The last step of the proposed methodology is the future state value stream management. For future state, applied for developing the system in redesign stage, the initial aim must be performing a plan that is proposed without any investment. Before the application stage, several scenarios can be tried for deciding new machine investment(s) is needed or not, and finally the cost analysis must be performed based on lead time for decision making. Initial aim of the axiomatic design model is designing cells for products families processed in current machine resources on hand. As seen in the industry, new machine investments to solve bottlenecks of the system are dominated point of view as the key solution. Whereas the majority of new machinery purchasing decisions may create new unnecessary waste resources. This systematic study underlines the necessity of value stream mapping for new investment decisions.

For future state value stream management plan, cell design, kaizen plans, poka-yoke applications, total productive maintenance, heijunka boxes for leveling of production and pull/hybrid system design must be done as lean manufacturing tools with using current resources. Supporting lean manufacturing practices to increase overall performance is possible by lean transition within the whole organization. Therefore, lean office applications have been planned for other units that support production. After the determination of the pilot study group for lean office applications, designing new processes and office cells, and applying visual management practices are aimed to be strengthening with the help of value stream maps and new process flow charts.

Step 6. Decomposition of FR12: FR12 (Make experts and employees conscious on lean thinking) and DP12 (Training procedure on lean manufacturing) are decomposed below:

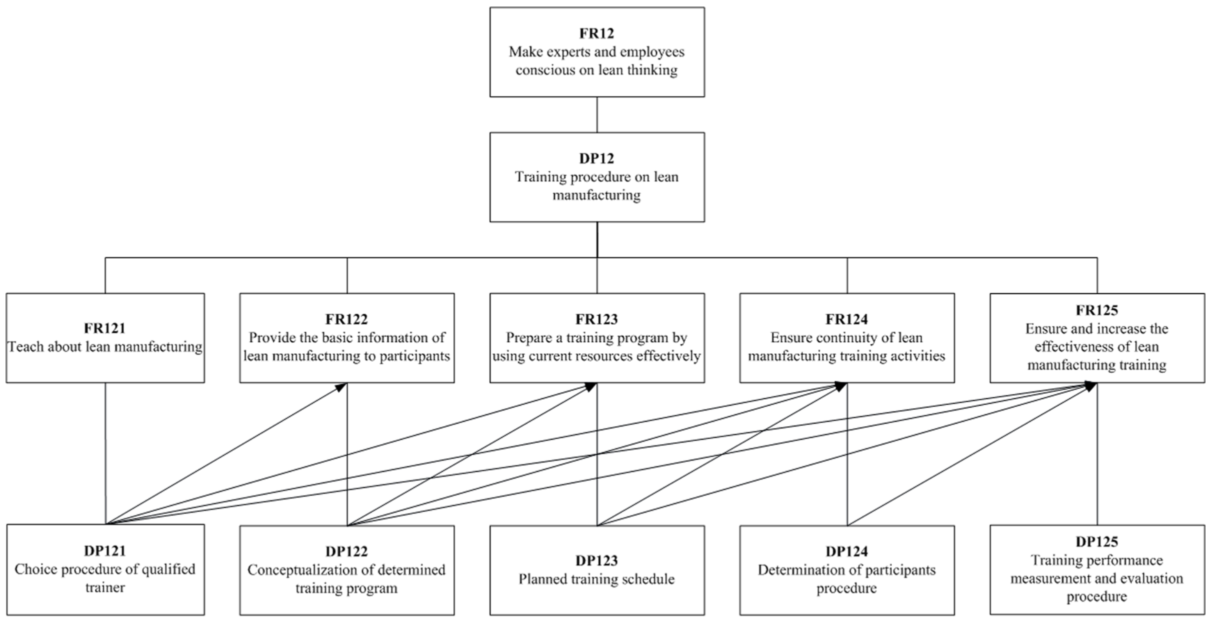
- ◦ FR121= Teach about lean manufacturing
- ◦ FR122= Provide the basic information of lean manufacturing to participants
- ◦ FR123= Prepare a training program by using current resources effectively
- ◦ FR124= Ensure continuity of lean manufacturing training activities
- ◦ FR125= Ensure and increase the effectiveness of lean manufacturing training

Design parameters satisfying the five FRs defined above are as follows;

- DP121= Choice procedure of qualified trainer
- DP122= Conceptualization of determined training program
- DP123= Planned training schedule
- DP124= Determination of participants procedure
- DP125= Training performance measurement and evaluation procedure

The design equation and the DM corresponding to the FR-DP sets are as followed and depicted in Figure 3. This is a decoupled design, and satisfies the IA.

Figure 3. The decomposition FR12-DP12



$$\begin{bmatrix} FR121 \\ FR122 \\ FR123 \\ FR124 \\ FR125 \end{bmatrix} = \begin{bmatrix} X & 0 & 0 & 0 & 0 \\ X & X & 0 & 0 & 0 \\ X & X & X & 0 & 0 \\ X & X & X & X & 0 \\ X & X & X & X & X \end{bmatrix} * \begin{bmatrix} DP121 \\ DP122 \\ DP123 \\ DP124 \\ DP125 \end{bmatrix} \tag{3}$$

Teaching about Lean Manufacturing (FR121-DP121): To increase the efficiency of lean manufacturing and to ensure continuity, employees should be educated on this issue. Planned training program for this purpose is required to be updated continuously to ensure the continuity. Therefore, the experienced instructors from outside or inside the company must be determined for contributing to the preparation and implementation of training programs.

Providing the Basic Information of Lean Manufacturing to Participants (FR122-DP122): Lean manufacturing system, considered to be implemented, brings all the principles of new business culture understanding. To achieve the success of the designed system, employee resistance to new ideas must be eliminated, and then, the new philosophy must be adapted to all employees. Training needs of all employees must be determined and after this, preparation of multi-purpose training programs that meet these needs is necessary.

Preparing a Training Program by Using Current Resources Effectively (FR123-DP123): A timetable for trainers and participants should be identified in parallel with the implementation steps of designed system, and all staff should be informed about lean tools by training programs.

Ensuring Continuity of Lean Manufacturing Training Activities (FR124-DP124): Participants have to be determined according to the company's planned training program and schedule. Selected instructor(s) should determine the training periods and the number of employees to participate in training with a balanced planning in order to ensure the effectiveness of training.

Ensuring and Increasing the Effectiveness of Lean Manufacturing Training (FR125-DP125): At the end of the training, questionnaires should be distributed to evaluate the content of training program. Performances of instructors and training program's content should be reviewed according to the evaluation results obtained from questionnaires. Finally, the scope of further training programs should be revised according to the evaluation results.

Step 7. Decomposition of FR13: FR13 (Divide production system into sub-systems for simplification of the system) and DP13 (Selection procedure of product families) are decomposed as below:

- FR131= Classify products based on customer demand
- FR132= Determine product families based on production system's characteristics

The corresponding DPs satisfying FRs at this step are stated as:

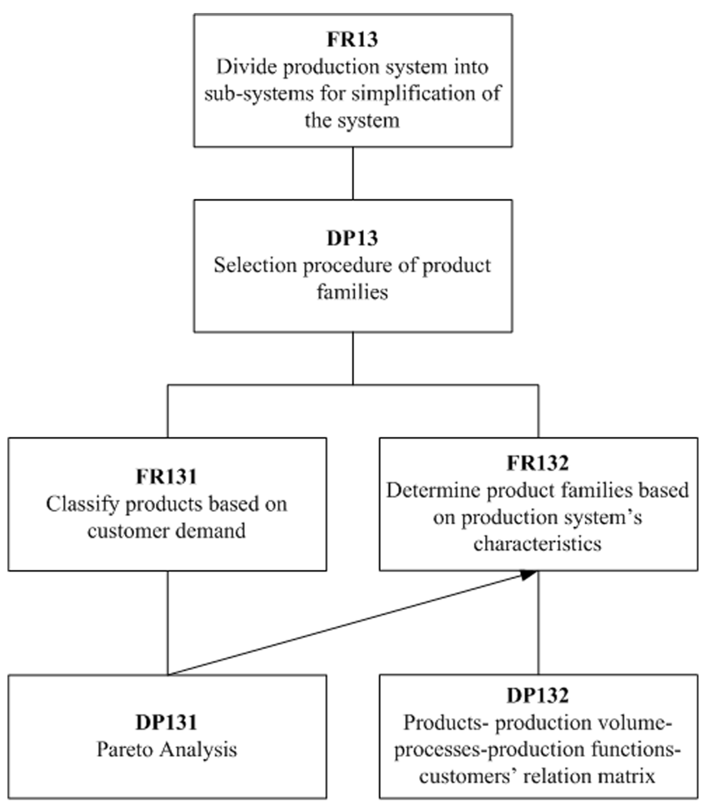
- DP131= Pareto Analysis
- DP132= Products- production volume-processes-production functions-customers' relation matrix

The design matrix for the above set of FRs and DPs are as followed and depicted in Figure 4. This is a decoupled design, and satisfies the IA.

$$\begin{bmatrix} FR131 \\ FR132 \end{bmatrix} = \begin{bmatrix} X & 0 \\ X & X \end{bmatrix} * \begin{bmatrix} DP131 \\ DP132 \end{bmatrix} \quad (4)$$

Classify Products Based on Customer Demand (FR132-DP132): In order to simplify the production system for analysis, products should

Figure 4. The decomposition FR13-DP13



be classified based on customer demand. Pareto (ABC) analysis is used for this classification and it is essential for visualizing volume of the product families. High volume products are responsible for the largest amount of waste's costs (work in process, material handling, other operational costs, etc.). Focusing on these high volume products affects overall performance of the company. So, pareto analysis is used for determining which product families should be selected first for pilot applications.

Determine Product Families Based on Production System's Characteristics (FR131-DP131): Products based on production systems characteristics are grouped as families. For example, products belonging to "A" class, which pass through the similar operations, are grouped as a family. In order to determine product families, constructing a relationship matrix, including products, production volume, processes, production functions and customers, is needed.

Step 8. Decomposition of FR14: FR14 (Visualize wastes) and DP14 (Current state value stream mapping) are decomposed as below:

- FR141= Define process parameters in proposed processes and collect information in response to these parameters
- FR142= Define relations between operations and knowledge processes

The corresponding DP14s satisfying FR14s at this step are stated as followed:

- DP141= Information collecting procedure
- DP142= Value stream mapping procedure

The design equation and the DM corresponding to the FR14-DP14 sets are as followed and depicted in Figure 5. This is a decoupled design, and satisfies the IA.

$$\begin{bmatrix} FR141 \\ FR142 \end{bmatrix} = \begin{bmatrix} X & 0 \\ X & X \end{bmatrix} * \begin{bmatrix} DP141 \\ DP142 \end{bmatrix} \quad (5)$$

Defining Process Parameters in Proposed Processes and Collect Information in Response to These Parameters (FR141-DP141): The first step for the implementation of lean manufacturing tools is visualization of wastes. Before drawing the current state value stream mapping, necessary information such as the process routes, the daily product demands, supplier delivery schedules, available production time, cycle times, setup times, uptime, scrap rates, number of employees, number of shifts, inventory locations and quantities, times between processes, should be collected, and then, should be transferred to value stream maps.

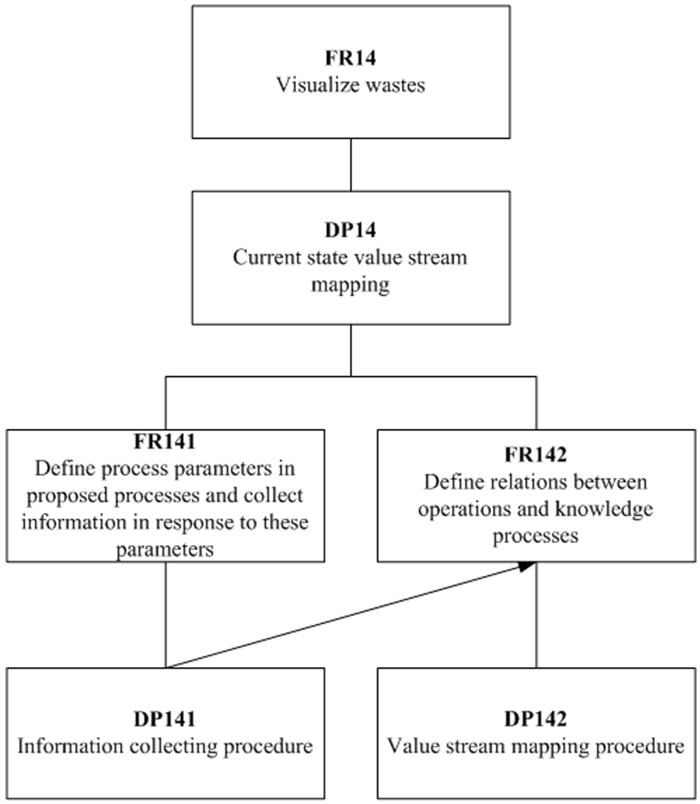
Defining Relations between Operations and Knowledge Processes (FR142-DP142): Drawing current state value stream map helps to visualize the whole system through operation steps by the representation of information and material flow. It also helps to eliminate the non-value added activities. By the use of value stream map, purposeful decisions can be made for the selection of necessary lean tools to eliminate wastes in the system.

Value stream mapping has two parts: big picture mapping and detailed mapping. Before starting detailed mapping of any core process, it is useful to develop an overview of the key features of that entire process. This will (Hines & Taylor, 2000):

- help you to visualize the flows,
- help you to see where waste is,
- pull together the lean thinking principles,
- help you to decide who should be in the implementation teams,
- show relationships between information and physical flows.

Big picture mapping makes easier to understand current state of the system. Big picture mapping consists of five basic steps (Hines & Taylor, 2000):

Figure 5. The decomposition FR14-DP14



Phase 1: Record customer requirements
Phase 2: Add information flows
Phase 3: Add physical flows
Phase 4: Linking physical and information flows
Phase 5: Complete mapping

After big picture mapping, detailed mapping should be done for drawing value stream map to visualize whole system. Collected information should be reflected to the map by value stream mapping symbols.

Step 9. Decomposition of FR15: FR15 (Apply the proposed plan to eliminate waste in manufacturing processes and offices) and DP15 (Future state value stream management system) are decomposed as below:

- FR151= Ensure production pace based on customer demand
- FR152= Ensure the part family flows in product families in the system
- FR153= Ensure one-piece flow
- FR154= Visualize the planned system
- FR155= Increase performance on the systems supporting manufacturing
- FR156= Define other parameters needed for improvement
- FR157= Eliminate the rest trouble bottlenecks
- FR158= Visualize the system with investment
- FR159= Evaluate the system performance with investment
- FR1510= Decrease the excessive volume fluctuations and variations in production
- FR1511= Provide pulling between inter cell flows

The corresponding DP15s satisfying FR15s at this step are stated as:

- DP151= Calculated takt time
- DP152= Clustered machine groups based on part families
- DP153= Cell(s) design procedure
- DP154= Future state value stream mapping procedure
- DP155= Lean office design
- DP156= Kaizen procedures correspondent to parameter

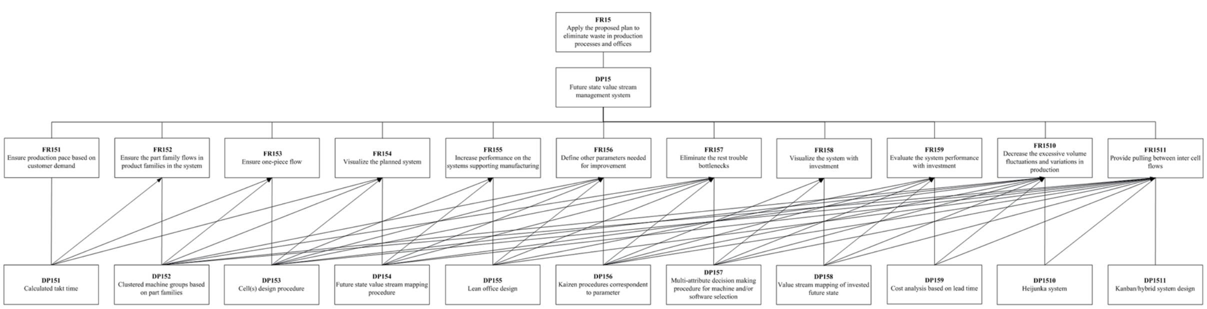
The design equation and the DM corresponding to the FR15-DP15 sets are shown in Equation 6 and depicted in Figure 6. This is a decoupled design, and satisfies the IA.

The stage after drawing the current state value stream map is put into practice the lean principles and lean tools by focusing on waste points. Primarily aim at this point will be making planning for elimination of wastes without any investment

Figure 6. The decomposition of FR15-DP15



Equation 6.

in equipment. At this stage, if equipment investment is needed, the system should be re-planned in accordance to the new situation. The starting point is making a decision to focus on which specific areas (the price reduction request from customers, lead time reduction demand, presence of competing products on the market, product quality problems, etc.). For the purpose of waste elimination plan without any investment, workflow should be simplified, takt time should be calculated to determine the production pace according to customer demand, cell designs should be done, and later other parameters should be taken into account for developing. After configuration plan of the cells, Heijunka and pull system should be established in accordance with the lean principles for reduction of work in process inventories and performing manufacturing just in time according to the customer demand. After this planning stage, the value stream map should be drawn by visualization of the developed system without investment.

After elimination of wastes in production environment, lean office working must be performed in order to increase the performance of systems, supporting manufacturing. By the result of all these activities, if there are still bottlenecks in the system, software or machinery investment decisions were taken into account and the future state value stream map must be revised. Cost analysis based on lead time is recommended for the system's performance evaluation before any investment.

Ensuring Production Pace based on Customer Demand (FR151-DP151): Rather than producing at high-speed, producing according to takt time is preferred (Byrne, 1995). In accordance with the competitiveness conditions, enterprises have to build production systems that will produce the amount that customer demands. Takt time is the cycle time that customers request. Takt time that is calculated by dividing daily operating time to daily customer demand is used to determine the pace of production.

Ensuring the Part Family Flows in Product Families in the System (FR152-DP152): In a manufacturing system for a product family, determination of parts and manufacturing processes/machines assigned to the cell(s) is needed.

For this purpose, there are three approaches:

- Intuitive and Visual Analysis
- Classification & Coding
- Analysis of Routings, Part-Machine Clustering Procedures

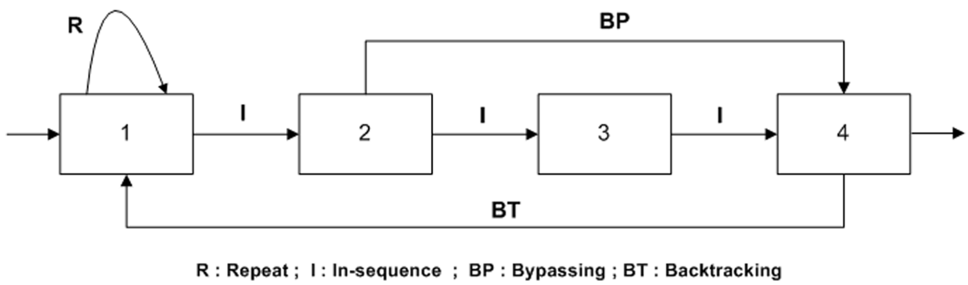
If the system is complex, the clustering procedure is necessary. Using clustering method is more practical and appropriate than alternative classification and coding methods for configurations of cells (Gallagher & Knight 1973).

Ensuring One-Piece Flow (FR153-DP153): Cellular manufacturing system leads to one-piece flow (Miltenburg, 2001). The one-piece flow principle stipulates that parts in a batch travel between machines or processes as single pieces, and do not wait for the rest of the batch to be completed. In other words, part operations on different machines are overlapped and carried out in parallel, which reduces part waiting times, and therefore manufacturing lead-times (Satoglu *et al.*, 2009).

Creating a cellular layout helps to achieve the targeted one-piece flow without repeat and backtracking movements between machines and/or work stations (Satoglu *et al.*, 2009). Figure 7 shows all possible parts movements. If the workflow is complex within the cell, an algorithm, for example, developed by Aneke & Carrie, (1986) would be useful for the design of intra-cell movements.

After using of multi product flow line algorithm developed by Aneke & Carrie, (1986), one piece flow in the cells is ensured. Following the determination of relative positions of the work stations in the cell, the work station layout, preferably U-shaped layout, must be decided. While planning the layout of work stations, transport of materials within the cell and transportation distance should

Figure 7. Four types of product flow (Aneke & Carrie, 1986)



be minimized. Material handling costs in total production costs are ranged from 30% to 75% (Sule,1994). Also, the cells, which have high material transportation traffic between each other, should be placed as close to each other for reducing the number and size of stock area.

Visualizing the Planned System (FR154-DP154): Primary goal is performing the future state plan without any equipment investment. For this purpose, implementation of improvement methods (Kaizen applications, heijunka boxes for production leveling and pull/hybrid system design, reduction of setup times, total productive maintenance, etc.) should be planned. If these improvement methods are not sufficient and there are still some bottlenecks in the production system, new machine investment should be considered. For visualization of the planned system, drawing of future state value stream map is necessary.

Drawing of future state value stream map includes customer demand, workflow and distribution of operations to machines by reducing of work in process inventory, etc.. Moving from the current state value stream map, future state is designed by using lean metrics and tools (Tapping, *et al.*, 2002).

Increasing Performance on the Systems Supporting Manufacturing (FR155-DP155): One of the reasons for long respond time to customer inquiries can be long lead time related to office operations (Suri, 1998). An important method for solving this problem should be lean office. Lean office is elimination of waste from workplace to provide better service to internal and external customers. For reducing non-value added activities and decreasing lead times, the organizational structure should be reconfigured into office cells. At the same time, office cells create a good environment for teamwork. For office cell design, product/service/project families must be determined (with clustering), accordingly the team members should be selected and relevant skill development planning should be done (team building), then the physical office layout should be configured. Moreover, an effective management model should be developed for team work within cells (Durmusoglu & Kulak, 2008).

Defining Other Parameters Needed for Improvement (FR156-DP156): To increase the success in implementation of the planned future state value stream map, Kaizen plans (continuous improvement plans) are recommended (Tapping, *et al.*, 2002). For parameters decided to develop, kaizen tools as 5S for work environment, Single Minute Exchange of Die (SMED) for setup time reduction, Poka-Yokes for reduction of defects, Total Productive Maintenance (TPM) for reduction of potential equipment breakdowns and process kaizens should be applied.

Eliminating the Rest Trouble Bottlenecks (FR157-DP157): After application of kaizen plans, there are still bottlenecks in the system, new investments can be considered. The selection of appropriate machines is very important for prevention of problems caused by production quality, delivery and cost. Many of the decision variables in selection of machines between alternatives make decision making process difficult for managers. In the literature, there are many decision making methods (analytic hierarchy process, second axiom in axiomatic design, etc.) related to machine selection (Saaty, 1990; Babic 1999). On the other side, in the previous step of the axiomatic design model for lean office operations, software investment can be made for accelerating office works, easier information sharing and keeping up to date of office operations.

Visualizing the System with Investment (FR158-DP158): Since the equipment investment decision affects the cell configurations, the future state value stream map should be revised according to the new situation.

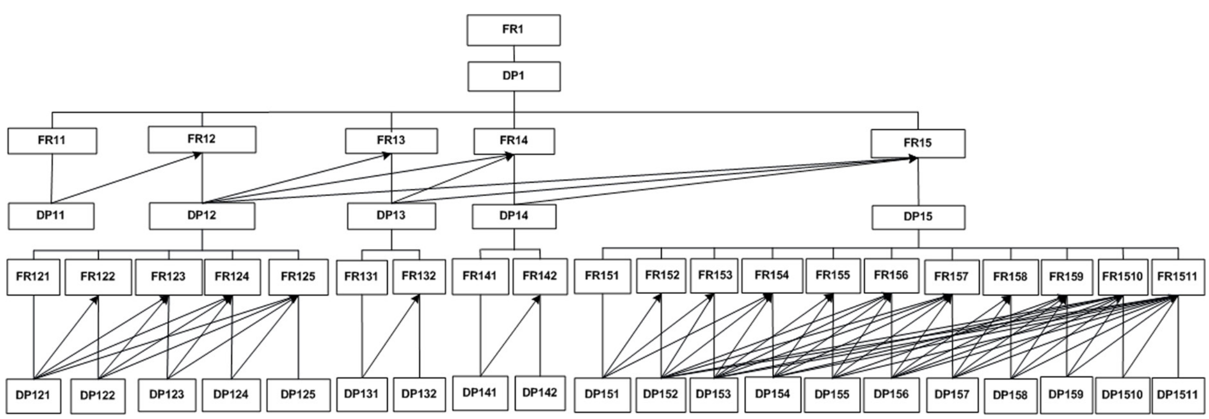
Evaluating the System Performance with Investment (FR159-DP159): Waste elimination in the existing plants and responsibility for new equipment investments are challenging for managers (Sullivan, *et al.*, 2002). Economic analysis based on value stream map should be done in born of the need for equipment investment. Better investment decisions can be made with the use of value stream maps. Cost analysis based on lead time should be made before implementation of future state value stream maps with investment and non-investment decisions. In addition to this, the economic lives of the new equipments affect the investment decision.

Decreasing the Excessive Volume Fluctuations and Variations in Production (FR1510-DP1510): For application of pull production control system according to the lean principles, the production flow must be smoothed primarily. If the flow is leveled according to production-mix throughout the production, the work-in-process inventories and therefore the total lead time will be reduced dramatically. By the accordingly designed Heijunka boxes, the amount of production and how much time it will take to produce this amount can be determined.

Providing Pulling between Inter Cell Flows (FR1511-DP1511): Pull production control system combines the demand and production. Kanban cards are used for the pull production control system. To be successful in Kanban, smoothed production flow is required. Kanban system is a different approach for manufacturing according to the customer demand and communication in the production environment for purchasing the materials needed. Kanban assigned to the cells draws parts from the cells, which produces these parts (Suzaki, 1987).

So far, a road map was presented for lean thinking based investment planning at design stage of cellular/hybrid manufacturing system (see Figure 8). Design matrixes also showed that leaf-level design decisions are consistent.

Figure 8. The decomposition of AD model



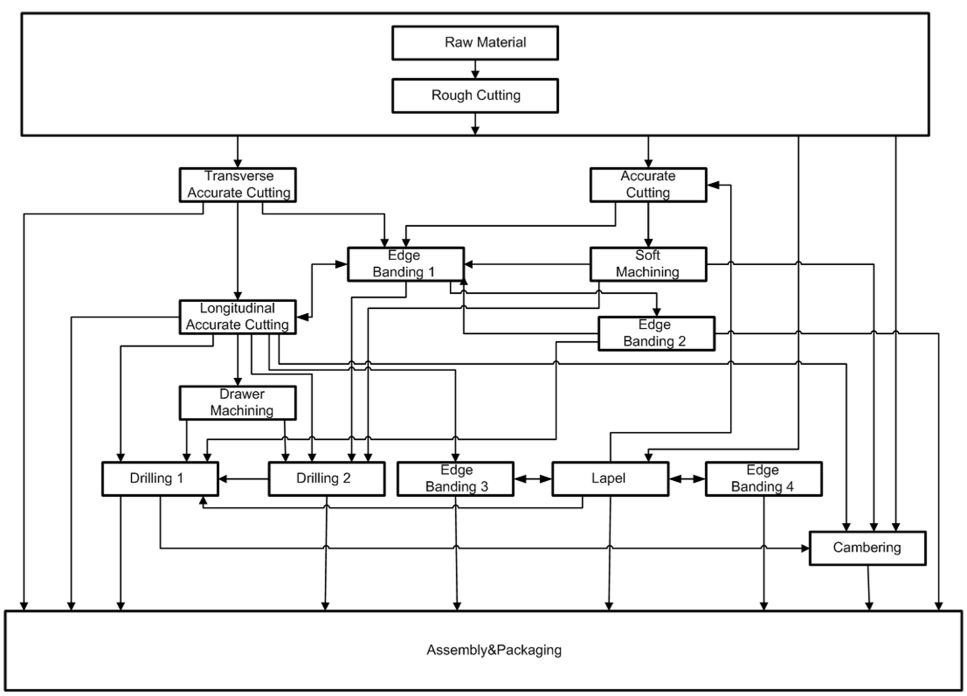
Implementation of the Proposed Methodology

The proposed methodology was tested on a real case application. The proposed methodology was implemented step by step for transforming the existing traditional manufacturing system to cellular/hybrid manufacturing system at a furniture factory. Before implementation, the facility layout of the system was functionally organized (see Figure 9). Plans have been devised for company-wide participation. The first main step (FR11-DP11) was the collection of information about market to define customer requirements. The second main step (FR12-DP12) was making experts and employees conscious on lean thinking by training programs. Around this time, lean manufacturing training programs were prepared and nearly 90% of the employees participated to lectures and workshops about lean tools and techniques.

The third main step (FR13-DP13) was to divide production system into sub-systems for simplification of the system. At this stage, the product families were defined based on manufacturing characteristics. The fourth main step (FR14-DP14) was drawing current state value stream map for the selected product family to visualize wastes and to define which lean tools would be applied to eliminate waste resources. The last main step (FR15-DP15) for the roadmap was applying the proposed plan to eliminate waste in production processes and offices by future state value stream management. The takt time was determined for the selected product family. Determination of parts for that product family and proper allocation of machines for each cell have also been done.

By application of the multi product flow line algorithm developed by Aneke & Carrie (1986), the new layout of the facility was decided based on one piece flow. The new layout consists three newly formed cells and a functional area. Staffing of the cells was finalized regarding of the current cell configurations according to the takt time. Final acquisition in each cell was determined with the

Figure 9. Spaghetti diagram before cell formation



participation of cell teams. Machine locations were defined in the sequence of part movements. After this stage, to increase performance of the systems, supporting manufacturing, lean office studies were planned and started. Before making new investment, the system was tried to improve by kaizen procedures. For maintaining the 5S discipline, 5S evaluation worksheets were designed and routinely implemented. Once the standard works in each cell were defined, proper metrics were developed for continuous improvement monitoring. In order to maintain and improve the performance, equipment effectiveness was calculated and also, total productive maintenance applications and visual management tools were developed. Single minute exchanges of die (SMED) plans were applied to machines to reduce setup times. Beside these, process kaizens were applied continuously for the bottleneck areas.

At this stage, there were still some bottlenecks on the manufacturing system. New machines investment was needed for solving those bottlenecks. Future state value stream map was revised considering new machine investment decision. Finally, four new machines investment is needed to be installed in order to maintain smooth product flow (see Figure 10). Each machine was selected with an AHP based model for the cell and functional area. To evaluate the system performance with investment before purchasing, some economical cost analysis based on lead time was done for the cases of before and after investment. Finally, we decided to make new machine investments by considering the cost analysis results.

At this stage, new machine purchasing procedure was completed, and then, to decrease the excessive volume fluctuations and variations in production, heijunka boxes were planned and to provide continues part flow, a combination of Kanban and push production control system were planned. Based on customer demands and forecasted sales, mixed leveled production plans were established for each cell. Based on these leveled production plans, the convenient batch sizes have been determined for each product family. For Kanban card implementation, new cards were designed. The Kanban cards traffic between the cells and supermarkets were planned. Finally, it has been seen that this methodology is very practical and beneficial for production system perfor-

Figure 10. Spaghetti diagram after cell formation

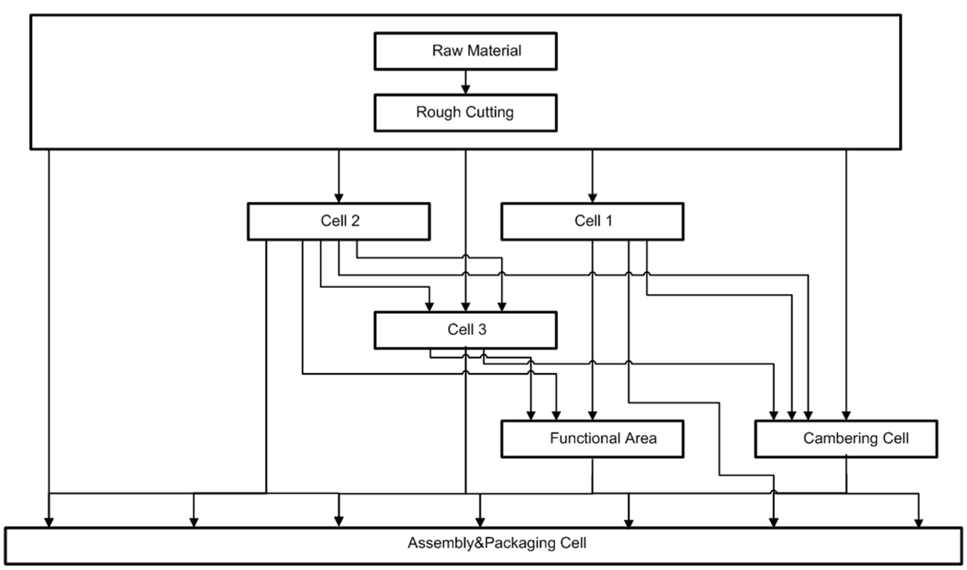


Figure 11. Comparison of business metrics

Performance Criteria	Before Cellular Manufacturing	After Cellular Manufacturing
Lead time (days)	7.5	3.5
Training time (person-hour/year)	7200	16000
Equipment effectiveness (%)	38	85
Number of Poka-Yokes	-	5
Number of Kaizen suggestions (1/year)	4154	4944
Machine breakdown (%)	9.12	5
First time through (%)	50	95
Scrap (%)	3	1
Setup time reduction (%)	0	50

mance improvement and economical investment decisions. The result of this implementation on this real case is listed in Figure 11.

Some of the indicators used in Figure 11 are as explained below:

Manufacturing lead time is called as duration from the moment the chipboards entered to the storage is ready for assembly. It is calculated as following:

$$Lead\,Time = \frac{Work\;In\;\Pr ocess\;Inventory\,(units)}{Demand\;Rate\,(units\;/\;day)} \tag{7}$$

Training time is called as multiplication of the planned duration of training for lean manufacturing applications by the number of participants. Cellular equipment effectiveness (CEE) is the ability to produce high quality and at the right speed at the machineries of cell and to use machines when necessary.

$$Equipment\;Effectiveness = Availability * Performance * Quality \tag{8}$$

$$Availability = \frac{(Total\;Time - Downtime)}{TotalTime} \tag{9}$$

$$Performance\;Efficiency = \frac{Actual\;Run\;Rate}{Ideal\;Run\;Rate} \tag{10}$$

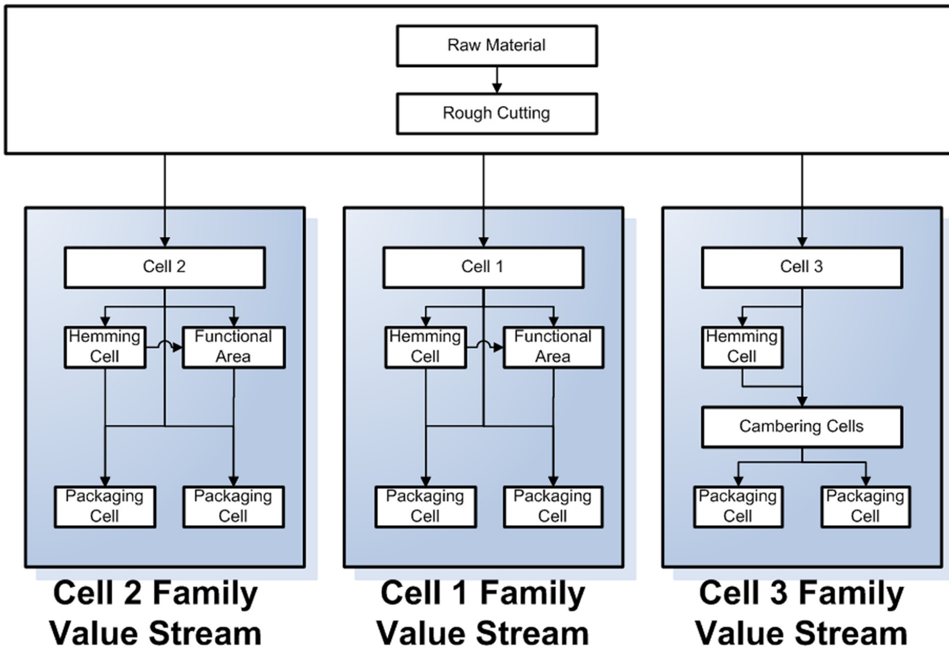
$$Ideal\;Run\;Rate = \frac{1}{Takt\;Time} \tag{11}$$

$$Quality = \frac{Total\,Quantity\,Manufactured - Number\;\;Rejected}{Total\,Quantity\,Manufactured} \tag{12}$$

Number of Poka-Yoke is the number of error preventing applications. Number of Kaizen suggestion is the annual number of suggestions for continuous improvement. First time through is called as the ratio of the number of error-free parts to total quantity manufactured. Scrap rate is the ratio of the number of scrapped parts to total quantity manufactured. Reduction of setup time is the decline in the percentage of duration between the last good part of the previous setup and the first acceptable part in the new setup.

As shown in Figure 11, all the indicators were improved significantly. In order to simplify the work flow further as a continuous improvement effort, a new facility layout has also been planned as shown in Figure 12. This facility layout is expected to decrease the current lead time by 20%. After investigation on the accidents has occurred previously, the number of Poka-Yokes was decided to enhance for the prevention of accidents resulting from misuse of machines. The types of kaizen gifts have been decided to increase. After maturation of lean practices, the number of monthly control tables was planned to increase. For the development related to the considered parameters, it was also decided to form the numerous Kaizen teams.

Figure 12. Spaghetti diagram for future state goal



CONCLUSION

Lean manufacturers must use lean thinking when implementing new purchasing strategies for machines that coincide with the product value stream. Most companies are ignoring the value stream in the decision-making process. In this chapter, we have provided a methodology for transforming a process oriented manufacturing facility into a CMS or HMS with a reasonable investment decision making. The proposed methodology is based on Axiomatic Design principles. Here, a roadmap for how lean thinking based investment planning can be applied at the design stage of cellular/hybrid manufacturing system has been presented. The concept in this chapter can be applied easily to real cases. Value stream mapping is the best tool to visualize wastes and to determine which lean tools can be applied to the system. Visualizing the current state helps to plan the future state by value stream mapping.

In future studies, the proposed methodology for new investment planning can be extended to the process domain which is comprised of the process variables. Decision making when there are multiple axiomatic design alternatives is another research field for the future.

Chapter 25
Internal Supply Chain Integration:
Effective Integration Strategies in the Global Context

Virpi Turkulainen
Aalto University, Finland

ABSTRACT

Supply chain relationships and subsequent supply chain integration have received significant attention among both academics and practitioners over several decades. The majority of the prior research has focused on assessing the relationships between the focal manufacturing firm and its suppliers and/or customers. Recent research, however, suggests that successful management of external relationships requires effective integration of the internal supply chain within the focal firm. In this chapter, we focus on internal supply chain integration. The author starts with the assumption that integration is an investment and that the importance of it is context-dependent. By examining data collected in 210 plants in eight countries, the author exploratively examine internal supply chain integration strategies; using cluster analysis, they classify the plants into four groups based on their use of various individual integration mechanisms. In addition, the author assess the use of the four integration strategies under various task contexts and across countries.

INTRODUCTION

Due to recent developments in globalization, companies can be viewed as complex structural networks, which span across different geographical locations and number of businesses and partners. In order to successfully manage those networks, complex managerial decision making structures are needed; in today's globalized environment, companies compete with their capability to integrate knowledge and information, both internally within the organization and externally with their suppliers, customers, and other stakeholders

DOI: 10.4018/978-1-4666-1945-6.ch025

(Galbraith, 2002). The results of prior research also suggest that problems companies are facing in the global economy are often not due to inappropriate strategic analysis but, in fact, are due to failure in designing the organizational structures and subsequent integration of internal and external parties (Bartlett & Ghoshal, 1989; Galbraith, 2000).

Integration of the supply chain has received significant attention among academic researchers and managers since the 1980s (Miles & Snow, 2007). Especially during the recent years, research addressing the management of supply chain relationships has been numerous (e.g., Bozarth, Warsing, Flynn & Flynn, 2009; Cousins & Menguc, 2006; Das, Narasimhan & Talluri, 2006; Germain, Claycomb & Dröge, 2008; Koufteros, Cheng, & Lai, 2007; Vachon & Klassen, 2008; Van der Vaart & Van Donk, 2007). Supply chain integration can broadly be divided into two parts (e.g., Chen & Paulraj, 2004; Fawcett & Magnan, 2002): management of the relationship between a firm and its suppliers and/or customers (external integration) and management of the cross-functional relationship within the manufacturing firm (internal integration).

In this chapter, we focus on internal supply chain integration in manufacturing organizations. The aim of the chapter is to set the stage for effective and efficient management of global supply chain relationships and integration in the global supply network. Integration is often assumed to provide wide benefits and is considered critical in order to survive in the global, constantly changing environment (e.g., Fine, 1998; Koufteros, Vonderembse & Jayaram, 2005). In this chapter, we present a somewhat contrasting view of integration. We build on the idea that integration can be considered as an investment requiring both financial and managerial resources (Adler, 1995; Lawrence & Lorsch, 1967b; O'Leary-Kelly & Flores, 2002). Hence, it is of fundamental importance to understand when integration is particularly relevant and how it can be effectively managed in different contexts. We are especially interested in configurations of individual integration mechanisms, which we label as integration strategies. In this chapter, we address questions such as: How do companies manage the internal integration challenge? Is it possible to identify different integration strategies? Does the use of different strategies differ, depending on the characteristics of the organizational task? Does the use of integration strategies differ across countries? We approach these questions exploratively and analyze empirical data collected in 210 manufacturing organizations in eight countries across the world (Austria, Finland, Germany, Italy, Japan, Korea, Sweden, US).

LITERATURE REVIEW AND THEORETICAL BACKGROUND

Defining Supply Chain Integration

The idea of supply chain integration is not new; integrated supply chain relationships have long been encouraged among manufacturing firms and their supply chain partners (e.g., Lambert, Robeson, & Stock, 1978) and supply chain integration has received significant attention among academic researchers since the 1980s (Miles & Snow, 2007). Despite the long history of research on supply chain relationships and supply chain integration, the perceptions and definitions of it vary widely among scholars. The predominant approach to supply chain management has been to focus on the relationships between a focal firm and its partners (suppliers and/or customers) (Chen & Paulraj, 2004). Yet, others relate supply chain management to the management of both cross-functional relationships within the firm itself and relationships with external parties (e.g., Ballou, Gilbert, & Mukherjee 2000; Barki & Pinsonneault, 2005; Germain & Iyer, 2006; Pagell, 2004; Rodriques, Stank, & Lynch, 2004).

Building on prior definitions of supply chain management (e.g., Chen & Paulraj, 2004), we define supply chain integration as the degree to which a manufacturer collaborates with its supply chain partners (both upstream and downstream) and collaboratively manages *intra*- and *inter*-organizational processes. We make a clear distinction between two aspects of supply chain integration: (1) internal supply chain integration, which refers to the management of intra-organizational relationships and (2) external supply chain integration, which refers to the management of inter-organizational relationships. The goal of supply chain integration, then, is to achieve efficient and effective flows of for example products, services, and information, as well as to manage organizational decision making (Frohlich & Westbrook, 2001).

Prior Research on Supply Chain Integration

Prior research on supply chain integration has focused primarily on external integration. Most of this research has looked at the relationship between a manufacturing firm and its suppliers, taking the perspective of the buyer (Clark, 1989; Cousins & Menguc, 2006; Fine, 2000; Koufteros et al., 2007; Spina, Verganti & Zotteri, 2002). Some have also taken the supplier perspective and addressed the relationship between a manufacturing firm and its customers (Bagchi & Skjoett-Larsen, 2002; Bajaj, Kekre, & Srinivasan, 2004). Others have combined these two approaches and taken a broader perspective, assessing the relationship of a manufacturer to both its suppliers and customers (Rodriques et al., 2004; Swink, Narasimhan & Wang, 2007; Vickery, Jayaram, Droge & Calantone, 2003). Finally, some have assessed the internal supply chain and intra-organizational relationship within the manufacturing firm (Ellinger, Daugherty & Keller, 2000; Kahn & Mentzer, 1996; Pagell, 2004) or both internal and external supply chain relationships either separately (Ballou et al., 2000; Das et al., 2006; Germain & Iyer, 2006; Gimenez & Ventura, 2005; Narasimhan & Kim, 2002) or as an overall measure of supply chain integration (Rosenzweig, Roth, & Dean 2003; Vickery et al., 2003).

In terms of research approach, prior research on supply chain integration can be characterized as looking at the effects of various integration practices on different dimensions of performance. For example, Swink et al. (2007) studied the effects of both customer and supplier integration, conceptualized as the use of various integration mechanisms, on business performance and manufacturing competitive capabilities, and Vachon and Klassen (2008) studied the effects of supplier and customer collaboration on various operational performance measures. Vickery et al. (2003) assessed the effect of supply chain integration on customer satisfaction and financial performance. Several researchers (e.g., Germain & Iyer, 2006; Gimenez & Ventura, 2005; Rodriques et al., 2004) have also related supply chain integration to logistical performance.

Prior research tends to build on the idea that integration has positive performance effects and more emphasis on integration always leads to higher performance (for an excellent exception, see Germain et al., 2008). In the context of internal supply chain integration, Pagell (2004) suggests that "the importance of integration is not in doubt." Even though it has been suggested that the importance of customer, supplier, and internal integration varies from context to context (Das et al., 2006), less attention has been paid to understanding when and how to integrate the supply chain. The benefits of supply chain integration are widely recognized, and integration has been suggested as a strategy to overcome, for example, different thought worlds by incorporating information and inputs from other parties to internal planning (Frohlich & Westbrook, 2001; Swink et al., 2007). However, prior research on the effects of supply chain integration on performance are still somewhat inconclusive and inconsistent (cf.

Das et al., 2006; Germain & Iyer, 2006; Gimenez & Ventura, 2005). This calls for a more detailed analysis of supply chain integration.

Practical evidence from industry suggests that effective internal integration is the first step towards external integration or facilitates it (Gimenez & Ventura, 2005; Stevens, 1989). Evidence also suggests that managers view internal integration as the crux of supply chain management (Fawcett & Magnan, 2002). Furthermore, partly as a response to the inconclusive results of prior research on the performance effects of supply chain integration, Flynn et al. (In press) suggest that successful management of the relationships with suppliers and customers requires that the manufacturing firm is internally integrated; "internal integration provides a vital link between customer and supplier integration, without which companies are unable to reap the full benefits of their SCI [supply chain integration] efforts". This suggests that, in order to benefit from integration with customers and suppliers, firms need to effectively manage their own strategies, practices, and processes in a collaborative manner. Since the prior research has mainly focused on external supply chain integration, the underlying (implicit) idea has been that, despite the firm's engagement in internal integration, external integration provides performance benefits. As an example, let us consider a situation in which a manufacturer integrates processes with a retailer through information systems, such as checkout counter POS system to reduce supply chain costs and uncertainty. However, if the manufacturer is not internally integrated, the advantages of customer integration would not be realized, as the data could not be used across the functional borders of the manufacturer, such as production and inventory control (Germain & Iyer, 2006).

In this chapter, we build on the idea that effective internal integration is indeed needed in order to engage in successful external integration in the supply chain context. We focus on addressing how manufacturing firms can manage the internal integration challenge. Hence, this chapter serves as a basis for increasing understanding of how to successfully manage integration with customers and suppliers. Instead of focusing on the effects of internal integration on performance, however, we are specifically interested in how firms manage internal integration. We call this integration strategy and define it as a configuration of individual integration practices that the manufacturing firm uses.

Few authors have addressed configurations in the supply chain integration context. Frohlich and Westbrook (2001) developed a taxonomy of supply chain integration, "the arcs of integration", based on supplier and customer integration patterns. The taxonomy they presented includes five different types: inward-, periphery-, supplier-, customer-, and outward-facing integration strategies. The taxonomy was developed based on the quartiles of the extent of integration emphasized towards suppliers or customers, excluding the internal aspect of integration. Flynn et al. (in press), on the other hand, present a configuration of supply chain integration based on the general emphasis the firm has put on the three different dimensions of internal, customer, and supplier integration. In this chapter, we approach configurations from a somewhat different perspective; rather than focusing on the overall emphasis on integration, our aim is to understand what managerial mechanisms are used in combination to manage the integration challenge. As stated before, we focus on the internal integration challenge.

Contingency Theory Perspective to Integration

In this research, we build on the contingency theory of organization design (Lawrence & Lorsch, 1967b; March & Simon, 1958; Thompson, 1967) and information processing perspective (Galbraith, 1973; Tushman & Nadler, 1978). In its very basic form, the task-dependent contingency theory suggests that the characteristics of the task determine the most effective organization design and integration (Burns & Stalker, 1961; Child, 1975; Lawrence & Lorsch, 1967a, 1967b; Van de Ven & Delbecq, 1974). Organizational tasks are seen to vary in terms of uncertainty, which is suggested to create varying needs for information processing.

What are the relevant task characteristics? At the overall level, "task" refers to the goal of the organization (Dill, 1958) and it has been characterized for example by uncertainty, predictability, complexity, routineity, analyzability, controllability, and variety (e.g., Drazin & Van de Ven, 1985; Gerwin, 1981; Lawrence, 1981; Perrow, 1967; Tushman & Nadler, 1978; Van de Ven & Delbecq, 1974; Van de Ven, Delbecq, & Koenig, 1976). Based on a literature review, it is possible to trace the overall concept as being uncertainty, which has two sources: unpredictability and complexity (this also resembles the conceptualization made by Bensaou and Venkatraman (1995) in the supply chain context). ***Unpredictability refers to the*** predictability of the task and it can further be divided into task variability and task difficulty (Drazin & Van de Ven, 1985; Van de Ven & Delbecq, 1974; Van de Ven et al., 1976; Woodward, 1965). Task variability is defined as the number of exceptions, whereas task difficulty is defined as the unanalyzability of the search process. Also complexity can further be divided into two dimensions (Lawrence, 1981; Rivkin, 2001): the number of variables in decision making and their interdependence (in order of increasing complexity: pooled, sequential, reciprocal, and team interdependence (Thompson, 1967; Van de Ven et al., 1976)). Recently, Bozarth et al. (2009) conceptualized complexity in the supply chain context as detail and dynamic complexity. Detail complexity can be considered synonymous to the number of elements, whereas dynamic complexity is more related to unpredictability.

According to the information processing perspective, in effective organizations there is a fit between the information processing requirements created by the task characteristics and the capacity of the organization to process information (Galbraith, 1973). ***In order to facilitate information processing, organizations implement vertical and horizontal integration mechanisms***. Integration mechanisms vary in their capacity to facilitate information processing and the richness of the information they facilitate (Daft & Lengel, 1986; Galbraith, 1973). Furthermore, integration mechanisms also vary in their complexity and costs of implementation and use (Galbraith, 1973, 1994; Lawrence & Lorsch, 1967b; Porter, 1985). Integration mechanisms can be classified into five broad categories (Galbraith, 1973; Martinez & Jarillo, 1989) as presented in Table 1. These are presented in order of increasing capacity to facilitate information processing and increasing cost of implementation and use.

Table 1. Classification of integration mechanisms

Integration mechanisms		References
1	Vertical mechanisms of centralization, standardization and formalization	(Burns & Stalker, 1961; Child, 1972; 1973a; 1973b, 1975; Pierce & Delbecq, 1977; Pugh, Hickson, Hinings, & Turner, 1968; 1969)
2	Information systems	(Galbraith, 1973; 1977; 1994)
3	Informal lateral mechanisms, such as cross-functional job rotation	(Edström & Galbraith, 1977)
4	Formal lateral mechanisms, such as cross-functional teams, committees, and integrator roles	(Adler, 1995; Galbraith, 1973; 1977; 1994; Hage, Aiken, & Marrett, 1971; Lawrence & Lorsch, 1967b; Tushman, 1977)
5	Organization-level incentives and other social mechanisms	(Barnard, 1938; Grandori & Soda, 1995)

Instead of focusing on the use of individual integration mechanisms, we approach contingency theory from a configuration perspective (Ketchen, Thomas & Snow, 1993; Meyer, Tsui, & Hinings, 1993; Snow, Miles, & Miles, 2006). Rather than looking at the use of various individual integration tools to manage the internal supply chain integration challenge, the configuration approach assesses the use of integration mechanisms in combination and simultaneously. Although the configurational approach has received less attention in organization research, it is suggested to overcome the critique of contingency theory being a reductionist theory and is seen as a holistic approach (Meyer et al., 1993).

Building on contingency theory and the information processing perspective, it is expected that the use of integration strategies will vary depending on the task characteristics presented above; strategies relying more heavily on the use of complex mechanisms are more likely found in organizations having more uncertain tasks. Furthermore, in order to develop successful global supply chain integration strategies, it is interesting to also understand whether internal supply chain integration strategies differ across countries. However, as we do not know the different strategies and there are no theoretical arguments on what kind of strategies could be found, we cannot present any precise hypotheses about the effect of task characteristics and country variables on the use of integration strategies, but rather must assess the issues empirically and exploratively.

INTERNAL INTEGRATION STRATEGIES

Data and Measures

In order to identify the internal integration strategies implemented by manufacturing firms, we use data collected in the third round of the High Performance Manufacturing (HPM) research initiative (previously known as the World Class Manufacturing Project (Schroeder & Flynn, 2001)). Data were collected from 236 plants in eight countries (Austria, Finland, Germany, Italy, Japan, Korea, Sweden, and the United States) and three industries (electronics, machinery, and transportation) between the years 2003 and 2006. Due to missing data, 210 plants are analyzed in this research. Because of the focus of the research on *internal* integration within the manufacturing firms, the unit of observation is a manufacturing plant. In order to obtain a similar number of plants for each combination of industry and country, stratified sampling (Forza, 2002) was used. The sample characteristics are presented in Table 2. Throughout it duration, the focus of the HPM project has been on world-class manufacturing practices and, hence, the sampling focused on mid-sized or larger plants with more than 100 employees.

The response rate varied across countries, average being approximately 65%. In order to achieve such a high response rate, plant managers were contacted in advance and asked to participate in the survey. In addition, each plant was promised a profile of responses. In these profiles the focal

Table 2. Stratification of the sample

	Country								
Industry	**AUT**	**FIN**	**GER**	**ITA**	**JPN**	**KOR**	**SWE**	**USA**	**Sum**
Electronics	10	14	8	10	9	8	7	9	75
Machinery	5	6	13	9	8	8	10	7	66
Transportation	4	10	19	7	10	7	5	7	69
Sum	19	30	40	26	27	23	22	23	210

organization was compared to the rest of the sample in terms of for example strategy, manufacturing practices, and performance. Data were collected using written survey questionnaires in the native language in each country. Translation and back-translation were carried out to check for consistency across the countries. The data collection instrument was pilot tested with both academics and managers in different countries. The data were collected using multiple respondents per plant; the questionnaire was differentiated to focus on the specific expertise area of each respondent (i.e. key informant method (Bagozzi, Yi, & Phillips, 1991)). In total, 12 different questionnaires were developed. These were distributed to 12-23 individuals in various organizational units and at different levels in the vertical organization (managers, supervisors, and direct labor).

Measurements

Five integration mechanisms were selected for analysis, in this research: centralization of decision making, information systems, cross-functional job rotation, cross-functional teams, and plant-level incentives. These mechanisms represent the five different categories presented in Table 1 and subsequently differ in their capacity to facilitate information processing, as well as in terms of the costs of implementation and use. In this research, the adoption of a particular integration mechanism is assessed as the intensity of use rather than whether a particular mechanism is adopted or not (e.g., Ettlie, 1995; Ettlie & Reza, 1992), because it is emphasized that the level of adoption of a mechanism, such as information systems, can vary. Previous OM literature on integration has also included items referring to the use of several mechanisms, such as job rotation and cross-functional teams, in the same construct (e.g., Swink, 2000; Swink et al., 2007). In this research, different mechanisms are operationalized as separate constructs because it is perceived that different mechanisms can be utilized to a varying extent, independently of each other. This is also required in order to identify integration strategies based on the use of various individual integration mechanisms, in contrast to an overall emphasis on integration mechanisms.

The five integration mechanisms were operationalized using seven-point Likert scales (anchor points as 1 = Strongly disagree, 7 = Strongly agree), except for one (information systems). The respondents were asked to rate specific statements regarding the use of integration mechanisms. Mainly multi-item scales were used. The operationalizations are presented in Table 4 and Table 5.

This research incorporates five measures of task characteristics, which are directly related to the dimensions presented above: task variability, task difficulty, number of variables in decision making, and reciprocal task interdependence. The operationalization of the task characteristics in the context of this research is based on prior research. Links to previous research is presented in Table 3. Two of the measures are objective (introduction of new products, reciprocal interdependence). Three constructs are measured on a 7-point Likert scale (1 = Strongly disagree,…, 7 = Strongly agree), including both single-item (customization of orders) and multi-item scales (modularity of products, introduction of new technology). In case of a subjective single-item measure, multiple respondents were used to avoid single-informant bias. Operationalization of task characteristics are presented in Table 4 and Table 5.

For multi-item scales, each plant-level item value was first calculated as an arithmetic average of multiple (three) responses. Scales were then developed with confirmatory factor analysis (CFA) using structural equation modeling (SEM). Appropriateness of factor analysis is established by high and statistically significant inter-item correlations ($p < 0.01$), high value of the measure of sampling adequacy (MSA), and statistically significant Bartlett test score ($p < 0.01$). Maximum Likelihood estimation was used for SEM. The standardized factor loadings of CFA are pre-

Table 3. Characteristics of tasks and their application to OM context

Dimension	Application to OM context	Explanation	References
Task variability	Customization of orders	Customization causes exceptions in the manufacturing task because the output changes in an unexpected manner; when the degree of customization is high, the manufacturing task is unpredictable and cannot be preplanned requiring information processing across units.	(Forza & Salvador, 2002; Perrow, 1967; Wheelwright & Clark, 1992; Vickery, Dröge, & Germain, 1999)
Task difficulty	Product modularity	Modularity affects the difficulty in performing work when exceptions (customization) occur; when modularity is high, changes in products can be made quickly requiring less information processing across units for example regarding designs and required manufacturing capabilities.	(Koufteros, Vonderembse, & Doll, 2002; Perrow, 1967; Salvador, 2007; Van de Ven & Delbecq, 1974)
Number of variables in decision making	Introduction of new products	Development of new products increases the need for information processing between units because it makes the manufacturing task less understandable; can new products be produced with the technology.	(Ettlie, Bridges, & O'Keefe, 1984; Fine, 1998; Takeuchi & Nonaka, 1986)
	Introduction of new technology	Development of new technology increases the need for information processing between units because it makes the manufacturing task less understandable; for example can products be produced with the new technology according to required timelines and quality.	(Allen, Tushman, & Lee, 1979; Ettlie et al., 1984; Olson, Walker, Ruekert, & Bonner, 2001)
Reciprocal task interdependence	Reciprocal task interdependence	Interdependence creates information processing needs because the organizational unit is dependent on the actions and outcomes of others. In particular reciprocal interdependence (consequently also team interdependence) creates integration needs.	(Galbraith, 1977; Thompson, 1967; Van de Ven et al., 1976)

sented in Table 4. The factor scores were then calculated with regression method (Bollen, 1989: 305; Hair, Anderson, Tatham, & Black, 1998: 119).

For multi-item scales, CFA was used to examine validity and reliability. Unidimensionality is established by a good fit of a single-factor model using CFA. Convergent validity is established by high and statistically significant factor loadings in the CFA model (average of loadings is 0.72 and all loadings are statistically significant at $p = 0.05$) (Bagozzi & Yi, 1991). Discriminant validity is established by low inter-construct correlations (CFA is conducted simultaneously for integration constructs and for task characteristics and the correlations are at maximum 0.27) (Bagozzi et al., 1991; O'Leary-Kelly & Vokurka, 1998). Finally, reliability is examined by calculating composite reliabilities (Hair et al., 1998). All composite reliabilities well exceed the threshold of 0.70 (see Table 4). Hence, we can conclude that unidimensionality, convergent and discriminant validities as well as reliability are adequate.

Identification of Internal Integration Strategies

In order to identify internal integration strategies, cluster analysis (Hair et al., 1998; Ketchen & Shook, 1996) was used. Using cluster analysis, the manufacturing organizations were classified based on their use of the five integration mechanisms. All variables were standardized (Ketchen & Shook, 1996). A two-step cluster procedure was conducted (for similar approach, see Bozarth et al., 2009; Zhao, Yeung, & Lee, 2004). First, we conducted hierarchical cluster analysis to determine the number of clusters. The hierarchical cluster analysis suggested four clusters. The decision was based on the changes in the agglomeration coefficient (Ketchen & Shook, 1996); the percentage in the change of the agglomeration coefficient

Table 4. Operationalization of multi-item scales

Construct, MSA, CR – Items, respondents		Loading
Centralization of decision making(MSA = 0.78, CR = 0.87) (based on Hage and Aiken (1967))		
	CE1 Even small matters have to be referred to someone higher up for a final answer.	.90
	CE2 This plant is a good place for a person who likes to make his own decisions. (reversed item)	.40
	CE3 Any decision I make has to have my boss's approval.	.85
	CE4 There can be little action taken here until a supervisor approves a decision.	.74
	Respondents: direct labor, HR manager, supervisor	
Cross-functional job rotation (MSA = 0.77, CR = 0.77)		
	JR1 Frequent rotation of managers between functions is normal practice in this plant.	.73
	JR2 Managers permanently specialize in one function at our plant. (reversed item)	.60
	JR3 Most of the managers here have had positions in more than one function.	.80
	JR4 Our managers have not worked outside of their own areas, for the most part. (reversed item)	.77
	Respondents: HR manager, plant manager, plant superintendent	
Plant-level incentives (MSA = 0.85, CR = 0.89)		
	IC1 Our incentive system encourages us to vigorously pursue plant objectives.	0.91
	IC2 The incentive system at this plant is fair at rewarding people who accomplish plant objectives.	0.90
	IC3 Our reward system really recognizes the people who contribute the most to our plant.	0.72
	IC4 The incentive system at this plant encourages us to reach plant goals.	0.93
	IC5 Our incentive system is at odds with our plant goals.	0.58
	Respondents: product development team member, process engineer, plant supervisor	
Product modularity (MSA = 0.77, CR = 0.96)		
	MO1 Our products are modularly designed, so they can be rapidly built by assembling modules.	.66
	MO2 We have defined product platforms as a basis for future product variety and options.	.54
	MO3 Our products are designed to use many common modules.	.89
	MO4 When we make two products that differ by only a specific feature, they generally require only one different subassembly/component.	.36
	MO5 We do not use common assemblies and components in many of our products. (reversed item)	.60
	Respondents: info systems manager, product development team member, process engineer	
Introduction of new manufacturing technology (MSA = 0.78, CR = 0.97)		
	NMT1 We pursue long-range programs, in order to acquire manufacturing capabilities in advance of our needs.	.62
	NMT2 We make an effort to anticipate the potential of new manufacturing practices and technologies.	.80
	NMT3 Our plant stays on the leading edge of new technology in our industry.	.63
	NMT4 We are constantly thinking of the next generation of manufacturing technology.	.85
	Respondents: process engineer, plant manager, plant superintendent	

was highest when the number of clusters changed from four to three, which suggests that a four-cluster solution yields the best result. Second, a non-hierarchical cluster analysis was conducted to generate the cluster results, setting the number of clusters to four. The cluster centroids, representing the mean values for each of the cluster variables, are presented in Table 6. The mean values represent the general characteristics of the clusters. We named the identified four clusters as centralizers (Group 1), information integrators

Table 5. Operationalization of single-item measures

Information systems	
	Are the following application areas supported by software: (i) demand planning, (ii) design (CAD, CAE), (iii) project management, and (iv) groupware tools? *Respondent:* info systems manager *Indicator:* A summated scale of the above items (0 = none of the applications is supported by software,…, 4 = all the four application areas are supported by software), standardized
Cross-unit teams	
	Assess the following statement (Scale: 1 = Strongly disagree,…, 7 = Strongly agree): We work in teams, with members from a variety of areas (marketing, manufacturing, etc.) to introduce new products. *Respondents:* product development team member, process engineer, supervisor
Customization of orders	
	Identify the importance of the goal rapid customization of orders (Scale: 1=Least important, …, 5=Absolutely crucial) *Respondents:* process engineer, plant manager, plant superintendent
Introduction of new products	
	What is the percentage of the plant sales that come from products introduced in the five years prior to the data collection? *Respondent:* process engineer
Reciprocal task interdependence	
	The product development process can be described by the following four stages: (1), Concept development/idea generation, (2) Product planning/technical and market feasibility, (3) Detailed design development and prototypes, (4) Manufacturing process development/pilot production Check the statement below that most closely describes your product development process: (i) The four stages were sequential, (ii) The four stages were sequential with some overlap, (iii) The four stages had significant overlap, (iv) The four stages were carried out simultaneously. *Respondent:* product development team member *Indicator:* Dichotomous (0 = sequential interdependence (categories 1 and 2), 1 = reciprocal interdependence (categories 3 and 4))

(Group 2), informal centralizers (Group 3) and intensive lateral integrators (Group 4).

After the cluster solution was generated, one-way analysis of variance (ANOVA) was conducted to compare the clusters. The results of ANOVA (Table 6) suggests that the use of all five integration mechanisms is different in the four integration strategies (p-value = 0.000). The Scheffe-test shows that 24 pairs, out of the 30 possible combinations of the five integration mechanism constructs, are highly significant (p

Table 6. Cluster centroids for the four-cluster solution

** p < 0.01; * p < 0.05; † p < 0.10

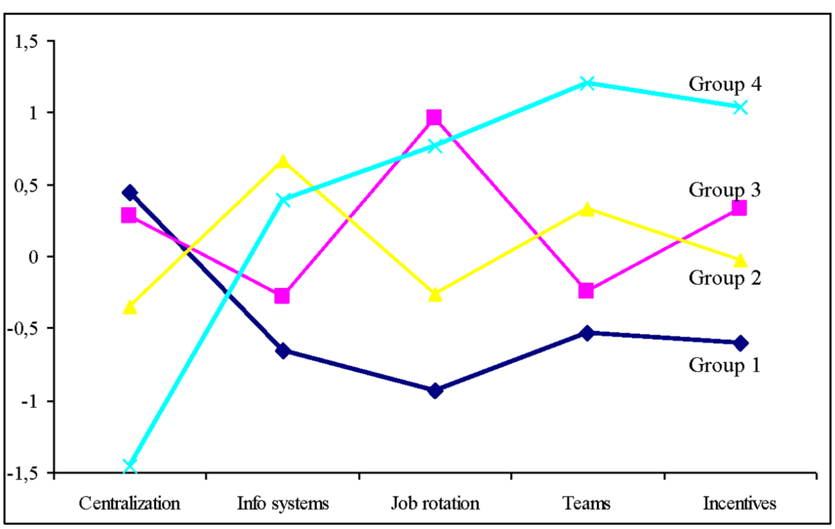
< 0.05) giving further support to the cluster solution.

The four clusters can be characterized as follows.

- Group 1: *Centralizers*. As Table 6 shows, the first group of plants is high on centralization of decision making and simultaneously low on the use of all other integration mechanisms. Hence, activities in these organizations are coordinated in traditional vertical ways by centralizing decision making to higher levels in the organization, and significantly less attention is put on managing coordination in a horizontal manner. Out of the 210 organizations, 62 (26%) organizations belong to this group.
- Group 2: *Information integrators*. The second group of organizations is low on centralization. Integration in this group is managed by heavy reliance on information systems and moderate reliance of cross-functional teams. Hence, rather than coordinating activities vertically, these organizations emphasize information processing across units by implementing information systems to support that and by establishing cross-unit teams. Out of the 210 plants, 55 (23%) belong to this group.
- Group 3: *Informal centralizers*. The third group of organizations is moderately centralized. However, instead of relying purely on centralization (cf. Group 1), this group of organizations has also implemented lateral mechanisms to manage the integration challenge. In particular, heavy emphasis has been put on cross-unit job rotation and moderate emphasis on incentives. This is the largest group, with 71 (30%) organizations out of the 210 belonging to this group.
- Group 4: *Intensive lateral integrators*. The last group of organizations is very low on centralization. In these organizations, activities are coordinated by relying heavily on all lateral mechanisms, including information systems, cross-unit job rotation, cross-unit teams, and incentives. Out of 210 organizations, 22 (9%) belong to this group.

The four-cluster solution is graphically presented in the following Figure 1.

Figure 1. The four-cluster solution



To conclude the cluster analysis, the results suggest that manufacturing organizations differ in terms of the emphasis they put on internal integration; rather than all organizations moving towards lateral integration, a significant amount of organizations also rely on more vertically focused integration strategies. The analysis points out four different integration strategies: centralizers, information integrators, informal centralizers, and intensive lateral integrators. Although the results are exploratory in nature, the findings are important and interesting because prior research has paid less attention to integration strategies. Furthermore, prior research looking at configurations has focused on the extent of integration (Das et al., 2006; Flynn et al., In press; Frohlich & Westbrook, 2001), rather than looking at how firms actually achieve integration with different combinations of managerial tools. This also makes it difficult to compare our findings with the configurations identified in the prior research. To a limited extent, it is possible to compare the configurations identified in this research with the overall organizational level structures proposed by Mintzberg (1980). Although he developed his configurations based on somewhat different variables, our centralizers closely resemble the simple structure proposed by Mintzberg (1980), being high on centralization and low on lateral relations and thus relying on coordination by direct supervision. Our intense lateral integrators, on the other hand, resemble Mintzberg's (1980) adhocracy, being low on centralization and high on reliance on lateral ways for coordinating activities.

Linking Integration Strategies to Task Characteristics

Building on contingency theory and the information processing perspective, the underlying assumption in this research is that the use of the identified integration strategies would differ depending on the characteristics of the organizational task. In the following, we assess whether the identified groups differ in terms of task characteristics. We used Analysis of Variance (ANOVA) to identify the potential differences in the characteristics of the task faced by the focal organization across the four clusters. The results of ANOVA are presented in Table 7.

The results suggest that there are some significant differences in the task characteristics across the clusters. However, the results are not very strong. In particular, significant differences are found in number of variables in cross-functional decision making, operationalized as the focus on introduction of new products and intro-

Table 7. Results of ANOVA assessing the differences in the task characteristics across the four clusters

	Group 1 Centralizers (N = 62)	Group 2 Information integrators (N = 55)	Group 3 Informal centralizers (N = 71)	Group 4 Intensive lateral integrators (N = 22)	F-statistic (Sig.)
Customization	-0.057	0.126	0.041	-0.285	0.990 (0.199)
Modularity	0.094	-0.127	-0.114	0.294	1.414 (0.120)
Introduction of new products	-0.166 (2)	0.345 (1, 3)	-0.110 (2)	0.021	2.375 (0.036)
Introduction of new tech.	-0.551 (2, 3, 4)	0.237 (1)	0.093 (1)	0.550 (1)	11.216 (0.000)
Reciprocal interdependence	0.509	0.320	0.448	0.571	1.827 (0.072)

Numbers in parentheses indicate the cluster(s) from which that particular cluster is significantly different at p<0.10

duction of new technology ($p < 0.05$) and reciprocal task interdependence ($p < 0.10$). Task variability (operationalized as customization of orders) and task difficulty (operationalized as product modularity) did not reveal differences across the clusters. The results suggest that centralizers are significantly lower than information integrators, in terms of introduction of new products and technology. Centralizers are also lower than informal centralizers and intensive lateral integrators, in terms of introduction of new technology. Information integrators, on the other hand, are higher than informal centralizers in terms of introduction of new products.

Building on the contingency theoretical perspective to integration (Galbraith, 1973; Lawrence & Lorsch, 1967b; Thompson, 1967), we suggested that, due to the various costs related to the implementation and use of integration mechanisms, we cannot assume that more emphasis on integration mechanisms would always be beneficial. In line with this, it is not suggested that there would be cumulative performance gains for organizations when moving from one configuration to another more complex one (cf. capability configurations presented by Narasimhan, Swink & Kim, 2005). Rather, we hypothesized that the effective integration could be related to the organization's task characteristics. Taking the classical contingency theory arguments to the configuration perspective, we could assume that there would be at least some difference in the use of the strategies so that, for example, centralizers have lower information processing requirements than intensive lateral integrators. The results suggest some differences in the use of different integration strategies, depending on the task characteristics. However, the results do not really support this, except for the case of introduction of new technology; the stronger the emphasis on introduction of new technology, the less centralizers are found and rather the organizations have implemented intensive lateral integration strategies. Significantly more research is still needed on addressing when different strategies are used and when they are effective.

Cross-Country Analysis of Integration Strategies

Additionally, our aim in this research was to explore how the use of the different integration strategies varies across countries. Understanding potential differences across countries would be especially managerially relevant and helpful in designing effective integration efforts, for example, in different units of a global manufacturing company. We used ANOVA to assess differences in the use of various integration strategies across countries. The results are presented in Table 8. The table includes both the number of plants, as well as the percentage of plants (in parenthesis) representing each strategy within a country.

The Pearson chi-square suggests that there are statistically significant differences in the use of integration strategies across the countries (p-value = 0.000). For example, US plants tend to be either information integrators or informal centralizers. Most of German, Finnish, and Swedish tend to have a somewhat different profile and be either centralizers or informal centralizers. Most of Korean plants are centralizers or information integrators, and Japanese plants tend to be information integrators. When looking at the use of different integration strategies across countries, the results suggest that Finnish, Austrian and German plants follow relatively more often the intensive lateral integration strategy, whereas none of the Japanese or Korean plants in the sample followed that integration strategy.

One explanation for the different use of integration strategies can be found in the differences between the national cultural environments in different countries. In the organization design literature, it has been reported that, due to, for example, the cultural dimensions of individualism–collectivism (Hofstede, 1980), centralization is higher in Asian countries than in Scandinavia.

Table 8. Differences of integration strategies across countries

		Group 1 Centralizers (N = 62)	Group 2 Information integrators (N = 55)	Group 3 Informal centralizers (N = 71)	Group 4 Intensive lateral integrators (N = 22)	Total
Country	Austria	2 (11%)	4 (21%)	9 (47%)	4 (21%)	19
	Finland	8 (27%)	6 (20%)	10 (33%)	6 (20%)	30
	Germany	12 (30%)	2 (5%)	19 (48%)	7 (17%)	40
	Italy	13 (50%)	4 (15%)	9 (35%)	0 (0%)	26
	Japan	5 (18%)	18 (67%)	4 (15%)	0 (0%)	27
	South Korea	9 (39%)	12 (52%)	2 (9%)	0 (0%)	23
	Sweden	9 (41%)	1 (4%)	9 (41%)	3 (14%)	22
	United States	4 (17%)	8 (35%)	9 (39%)	2 (9%)	23
	Total	55	62	71	22	210

This could give an explanation for why Korean and Japanese plants follow a centralization strategy rather than being intensive lateral integrators. More research is clearly needed in this area, both in the context of external and internal integration.

CONCLUSION

This chapter has discussed supply chain integration by focusing on internal integration within a manufacturing unit. Based on an international survey of manufacturing plants, our aim was to identify internal integration strategies. Our empirical analysis revealed the existence of four separate groups of plants, which differ in terms of managerial tools that they have implemented to achieve integration within their organization. These were named centralizers, information centralizers, informal integrators, and intensive lateral integrators. We further suggested, based on contingency theory and the information processing perspective, that none of the integration strategies is superior in overall terms. Rather, effective use of integration strategy depends on the organizational context. This argument builds on the idea that implementation and use of integration mechanisms poses benefits, but also costs, to an organization. We analyzed the use of different integration strategies under varying task characteristics, as well as across countries.

This chapter is highly exploratory in nature. The research presented in this chapter extends prior research on supply chain integration in several different ways. First, this chapter complements prior research on supply chain integration by focusing on internal integration within a manufacturing organization. The majority of the prior work on supply chain integration has focused on discussing external relationships between the focal firm and its suppliers and customers. Second, the chapter also complements prior research by discussing how companies actually achieve integrated behavior in different contexts. The majority of the prior work has focused on looking at the effects of integration on performance, giving less emphasis on how integration is managed. The chapter has, in particular, contributed to the research by assessing different integration strategies of manufacturing firms. Finally, and most importantly, this chapter has emphasized the potential costs of integration efforts. The majority of the prior research builds on the assumption that supply chain integration is highly and equally important to all organizations.

We question this assumption and suggest that integration efforts pose significant and varying costs to the focal organization. Hence, in order to operate effectively and efficiently, organizations need to assess whether integration is needed and how it can be managed in an efficient way.

In addition to the academic implications, the research is also managerially relevant. We identified internal integration strategies can work as a framework for managers when analyzing integration within their organization. The chapter also draws managers' attention to the costs of integration. The analysis of contextual, as well as national, differences in the use of the internal integration strategies can also help managers when designing their manufacturing units in the global economy, for example, which integration strategies could be more applicable in different circumstances and environments.

Limitations

Although contributing to the discussion on supply chain integration, this research is not without limitations. First, this research used five integration mechanisms, in order to identify possible integration strategies. Although these mechanisms represent different categories of integration mechanisms, and subsequently different capacity to facilitate integration and different costs, there are number of other mechanisms which could be included in subsequent analysis. Second, some operationalizations, especially single-item constructs, are problematic. Third, contingency theory has sometimes been criticized for its cross-sectional nature (e.g., Dewar & Hage, 1978), and longitudinal studies have been called for (Aldrich, 2001). Porter (1991), however, argues that cross-sectional studies are logically prior to longitudinal ones, justifying the cross-sectional research approach. Hence, it is important to first build theoretical arguments and conduct empirical analysis with cross-sectional data and only later develop and test those arguments in a dynamic context. Finally, common method bias is a potential limitation (for a detailed discussion, see Podsakoff, MacKenzie, Lee & Podsakoff, 2003). Potential sources of common method bias include for example social desirability, leniency bias, and item ambiguity.

Future Research

Empirical analysis revealed four different integration strategies for internal integration within manufacturing organizations. The analysis was highly exploratory in nature. Although the clusters are interesting and theoretically rational from a contingency perspective, they are still highly preliminary in nature. Also analysis of task characteristics under which different strategies are used yielded only weak results. Hence, future research could engage in more detailed empirical, but especially theoretical, analysis of configurations of integration mechanisms. What kind of strategies could be expected to be found? In which situations are certain strategies more effective and used than others? Which factors determines the viable integration strategy?

This chapter focuses on internal supply chain integration in manufacturing companies. The ideas and discussion presented in the chapter raise ideas for research regarding external integration in the supply network. Future research could address how decision making is managed across firms which have different goals and interests; what different kinds of integration strategies are used to manage the external integration challenge? Are similar types of strategies found in that context? Is there a link between the internal integration strategy and external strategy used?

This research has focused on analyzing integration strategies. In addition, this research has also explored whether the use of strategies differs across different conditions. Hence, the focus has been on understanding the internal design of organizations giving less emphasis to the performance effects of organization design. Future research could address how internal integration strategies are related to performance; how are integration strategies related to performance in different contexts? Which integration strategy provides the most benefits in terms of performance in various contexts? How do internal integration strategy and external integration support each other in improving organizational performance?

KEY TERMS AND DEFINITIONS

Configuration: Any multidimensional constellation of conceptually distinct characteristics that commonly occur together.

External Integration: Integration in the context of management of relationships between formally separated organizations. These organizations can be for example in supplier-customer relationship or in other kinds of partnership.

Integration (Coordination): Both the state of unity in effort in the actions of various subunits, as well as the process of achieving that unity. In this research, the terms coordination and integration are used interchangeably.

Integration Mechanism: Any managerial tool for achieving integration and coordinated activities within an organization, including for example centralization, information systems, and lateral structures.

Integration Strategy: A combination (configuration, pattern) of individual integration mechanisms implemented and used by an organization in order to manage inter-organizational or intra-organizational relationships.

Internal Integration: Integration in the context of management of relationships between organizational units within an organization. These organizational units can be for example functionally related (different functional units), within the same function (for example manufacturing units located in different geographical locations), or in a vertical relationship (for example corporate office and manufacturing unit).

Supply Chain Integration: The degree to which a manufacturing firm collaborates with its supply chain partners and manages intra- and inter-organizational processes in a collaborative way. Managing inter-organizational relationships refers to external integration and intra-organizational relationships to internal integration.

Uncertainty: The difference between the amounts of information required to perform a task and the amount of information already possessed by the organization.

ABSTRACT

The main problem of establishing equipment replacement decisions rules under specific conditions is to find decision variables that minimize total incurred costs over a planning horizon. Basically, the rules differ depending on what type of production type is used. For a batch production organization the suitable criterion is built on the principle of economies of scale. Proposed econometric models in this chapter are focused on a multiple machine replacement problem in flexible manufacturing cells with several machines for parts' processing, and industrial robots for manipulation and transportation of manufactured objects. Firstly, models for a simple case multiple machine replacement problems are presented. Subsequently, the more complicated case is considered where technological improvement is taken into account.

INTRODUCTION

Historically, development of production processes has passed from production structures in automatic rigid flow lines, efficient for mass and wide-range production, to flexible structures, especially efficient in low and medium-range production. Because manufacturing firms has to be flexible towards new market requirements, flexible production forms are increasingly seen as one of the most important manufacturing concepts. Currently, the trend in flexible manufacturing systems is toward small flexible manufacturing structures,

DOI: 10.4018/978-1-4666-1945-6.ch026

called flexible manufacturing cells (FMC). In this sense, two or more CNC machines are considered a flexible cell and two or more cells are considered a flexible manufacturing system (Groover, 2001). Flexible manufacturing cell, in general, allows the processing of pieces which are different in terms of shape and dimensions, in a determined range. This creates prerequisites for the accomplishment of variable products, under high yield conditions. Considerable savings are made because the utilizations increases, the processing time is shortened, the handling distances are reduced, intermediate storage expenses decrease, the area required for production is reduced, the process may be systematized, proper conditions for continuous work are created and direct expenses are reduced. However, the real occurrence of failures during the exploitation stage can markedly modify the FMC performances (Corbaa et al, 1997). For this reason, downtime of FMC has to be analyzed and its influence on the processing cost has to be pondered over. In addition, to ensure that manufacturing process is held to be competitive, upgrading or replacing of equipment due to rapid innovations in technology also has to be considered. In this context often encountered issues in production planning are: Should this equipment be replaced? If not now, then when? Usually, written equipment replacement policy, in which units are scheduled for replacement based on age and expected condition, contains answers on such questions. In this chapter we wish to show several econometric models that could inspire managers to develop their own specific tools in building of an effective equipment replacement policy.

THE PROBLEM STATEMENT

Theoretically, any equipment replacement decision would be made based on thorough modeling equipment deterioration and projected remaining life. Practical approaches to equipment replacement decisions are mostly based on subjective appraisal. But it is generally accepted that tools for equipment replacement decision create important element of repair/replacement policy. Such a policy provides guidance to production and economic manager regarding when to replace existing equipment or its part; how to conduct the acquisition process; and what should be done with the equipment being replaced. Then, the main importance of developing of equipment replacement decision models in production planning consist in establishing rules for the replacement of old equipment or its part(s) by new. The main problem of establishing the rules is to find decision variables that minimize total incurred costs over a planning horizon (Dehayem Nodem et al 2009). Basically, the rules differ depending on what type of production type is used. For batch production organizations suitable criteria are built on the principle of economies of scale, where the large fixed costs of production are depreciation-intensive because of huge capital investments made in high-volume operations and are spread over large production batch sizes in an effort to minimize the total unit costs of owning and operating the manufacturing system (Sullivan, 2002). When solving equipment/parts replacement problem within a flexible manufacturing cell, it is necessary to consider the impacts of the replacement decisions on all of the components of the system. Therefore, possible equipment stoppages due to wrong decision results at least in diminishing capacity or stopping the operations in a manufacturing cell. Accordingly, proposed methods are dedicated for a multiple machine replacement problem that is also characterized as a flexible flow shop problem. A parallel flow shop production concept is consisting of a number of production lines. Jobs in such work shop may be composed of a series of works, each requiring several machines (Jianhua and Fujimoto, 2003).

Firstly we will model a simple case multiple machine replacement problem that is characterized for a parallel flexible flow shop environment, in which no technological improvement in equipment is in concern. Then we will consider the more complicated case where we also take account of technological improvement.

RELATED WORK

Equipment replacement, as a specific field of knowledge and practice, has been extensively studied in the professional literature from the third decade of the 20th century (Castro et al 2009). Operations research approaches utilized in this domain are classified based on methods used to solve replacement problems, such as: integer programming (Hritonenko and Yatsenko, 2007), dynamic programming (Flynn and Chung, 2004), simulation techniques (Freeman, 1996) and Markov decision problems (Love et al, 2000).

Equipment replacement decision approaches related to this work can be divided into two basic types: parallel and series. The difference between these two categories is that in parallel models, the capacity of the system is simply the sum of the capacities of the individual assets and in the series – flow shop models, the minimum capacity assets in the series defines the capacity of the system (Hartman and Ban, 2002). The literature on parallel models is relatively rich. Among the many papers published on this topic, the interested reader may refer to Bean et al. (1994). As regards to series models, there is limited work. For instance, Tanchoco and Leung (1987), Suresh (1991, 1992) and Stinson and Khumawala (1987) present various approaches in which machines operate in series.

Equipment Replacements models can be grouped as: simple and complex ones. By simple models are meant those with a small number of unknown parameters. An instance, where only a small number of observations of time to fail are required to determine a near-optimal value of the critical age for preventive replacement may be an example for age-based replacement models (Baker and Scarf, 1995). The second group of models with a large number of parameters is characterized by high correlations between parameter estimates. This indicates that the available data is insufficient to distinguish between equally plausible parameter combinations (Scarf, 1997).

Recent discussions in econometric models are highlighted the question when to use a capital replacement modeling or an economic life modeling. By comparison of these two approaches, capital replacement modeling methods are evidently more application-oriented than second ones (Christer and Scarf, 1994; Scarf and Bouamra, 1995).

Pioneering approaches of equipment replacement studies are mainly addressed to the replacement of single machines or systems. Developed methods stated to multi-machine systems have mostly assumed linear production flows, with limited operational flexibility. A multi-period replacement model for flexible automated systems was developed by Lotfi and Suresh (1994). Their model was formulated as a nonlinear integer programming problem and was intended to serve as an analytical approximation along with closed queuing networks.

Obviously, it would be possible to mention more similar works from different authors on that topic, but this was comprehensively provided, for instance, by Fine and Freund (1990) or Cheevaprawatdomrong and Smith (2003).

MODELS DEVELOPMENT

The further presented equipment replacement decisions models are econometric-based methods. Econometric methods are in generally concerned with using relevant data for modeling relations between economic and business variables. In these methods one problem is the fact that the selection of variables is somewhat subjective. Their role in decision support for the equipment management and replacement consists of finding the adequate moment to change machine-tool in use or its part(s), based on a specified criterion. In the next subparagraphs several mathematical methods regarding the equipment replacement decision are described.

The OEC and ORC Dependence Based Method

The problem is to choose an optimal replacement policy such that sum of operating equipment cost (OEC) and replacement equipment cost (REC) per unit time is minimized.

In general, the calculation of operating costs (OC) requires the examination of various influencing parameters. Moreover, there is some difference of opinion about whether the wages of equipment operators should be included in the operating equipment cost (Sears et al 2008). In this method the wages are included to this cost. Because we are looking at all costs from cash flow perspective equipment, thus a replacement cost in our approach deals with present value analysis.

The instrumental assumptions of this method imply that at the beginning of every year, data regarding operation and replacement costs of a certain machine are collected. The data usually shows an increase in the operation cost, because of the damages in certain components of the machine. Some of these components may be replaced, thus the equipment operating cost are reduced. The replacement thereof implies costs with the materials and salaries and, hence, such costs have to be compensated through the savings which may be obtained pursuant to the reduction of operating costs. Thus, we want to determine an optimal replacement policy, able to minimize the sum of operating and replacement expenses during the period between two successive data collections.

Let us consider $c(t)$, the operating cost per time unit at the moment t, after replacement and c_r, the cost of a replacement. Then, the relation between the operating cost, replacement cost and time is shown in Figure 1.

The replacement policy is presented in Figure 2, with the following notations: $[0,T]$, the time interval regarding the collection of data on the machine and t_r, intervals when n replacements shall occur.

The assumed goal is the determination of the optimal interval between successive replacements, so that the sum of the operating and replacement cost $C(t_r)$ is minimal.

Then, $C(t_r)$ present the replacement cost during the period $[0,T]$, plus operating cost during the period $[0,T]$.

Figure 1. Relation between operation cost and replacement cost

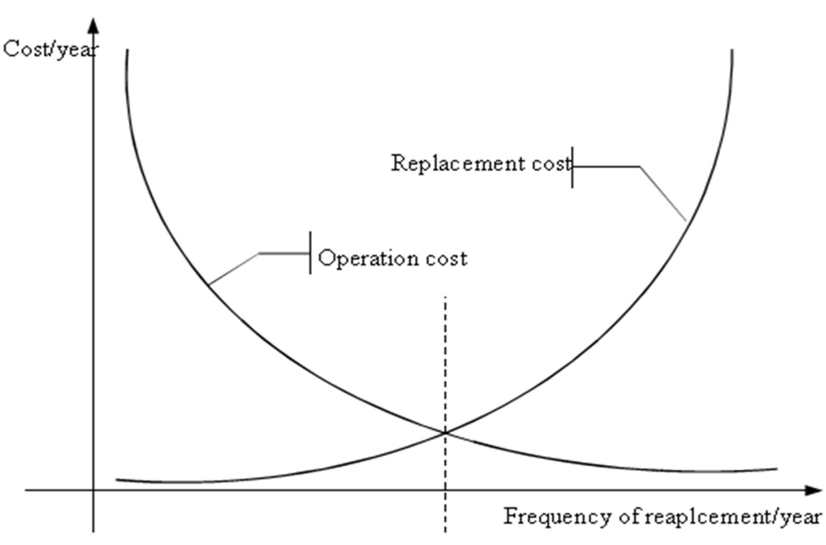

Figure 2. Graphical representation of the replacement policy

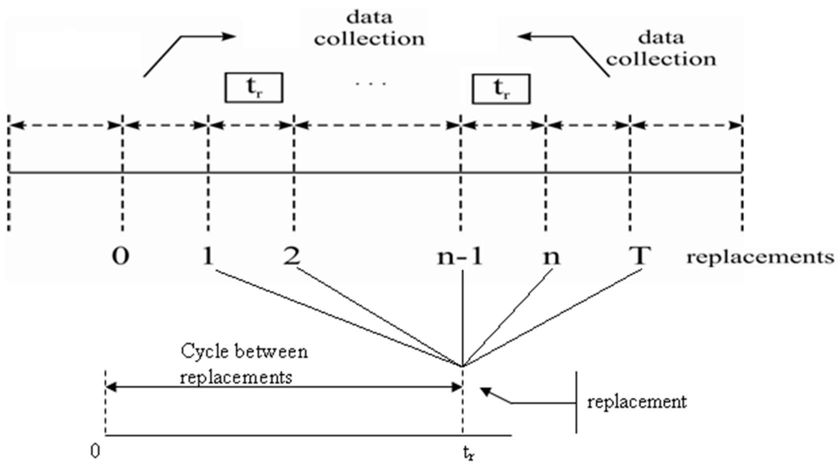


Replacement cost by period $[0,T]$ is calculated by

$$\sum C_r = n \cdot C_r \tag{1}$$

Thus, n are the number of replacements by period $[0,T]$ and C_r, the cost of one replacement.

The total cost per time unit $C(t_r)$, for the replacement performed at the moment t_r is: $C(t_r)$ i.e. total cost in the interval $(0,t_r)$ related to the length of the interval.

The total cost in the interval $(0,t_r)$ is the operating cost plus replacement cost.

$$C\left(t_r\right) = \int_0^{t_r} c\left(t\right) dt + C_r \approx \left[\frac{\int_0^{t_r} c\left(t\right) dt + C_r}{t_r}\right] \tag{2}$$

As we may see, the two different cost calculation procedures are similar, because the minimization of $C(t_r)$ is desired, depending on t_r.

Neither of the two procedures considers the time T_r (see Figure 3) required for performing a replacement.

If the time required for performing a replacement is considered, Equation 2 becomes:

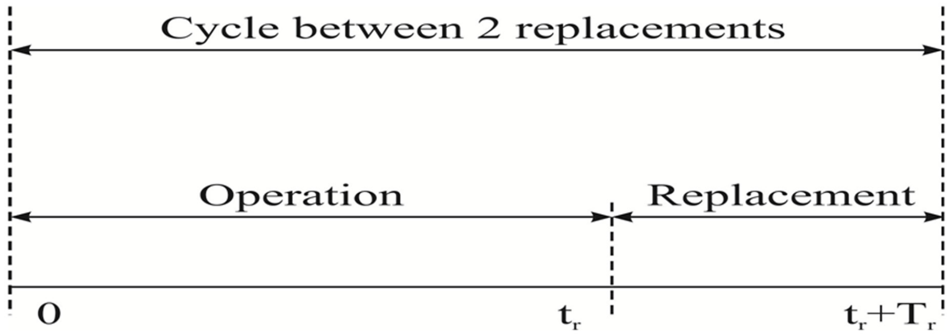
$$C\left(t_r\right) = \frac{\int_0^{t_r} c\left(t\right) dt + C_r}{t_r + T_r} \tag{3}$$

Even though this method is also applicable for job shop problems, the given procedures meet essential requirements of the Total Productive Maintenance concept that have a very important role to effective use the automated production systems like FMC and flexible manufacturing systems.

The Method of Replacing the Equipment at a Certain Age

We consider that the machine shall be used for a certain number of years. Further, we assume that a certain machine fabricates certain products, according to the production plan. In this case the goal, in order to minimize the total operating and replacement cost for a fixed time period, consists in the determination of the replacement policy establishing whether: at a certain age of

Figure 3. Time structure of cycle between two replacements



the machine; the latter should be replaced or left to operate continuously.

Let us use *I* to denote the age of the equipment (from the last replacement, with *n* plan periods of proper operation, until the end of the production plan); *c(a)* to represent the cost of operating the equipment for a plan period, when the equipment has age *a*; *J* to represent the age of the equipment from the moment of the last replacement, having (*n-1*) operating time periods until the end of the production plan; C_r, replacement cost; *C(I,J)*, total cost during the period when the equipment develops from age *I* to age *J*. The proposed goal consists in the determination of a replacement policy, so that the cost of operating and replacing the machine $C_n(i)$, along the following *n* time periods is minimal. When $C_n(i)$ has a minimal value, the smallest cost is defined as $f_n(i)$.

Ten weeks before the end of the production plan, two decisions may be made: continuous use or replacement of the machine. If it is decided that the machine should operate further, the equipment shall have age *4* when a new decision may be made (Figure 4).

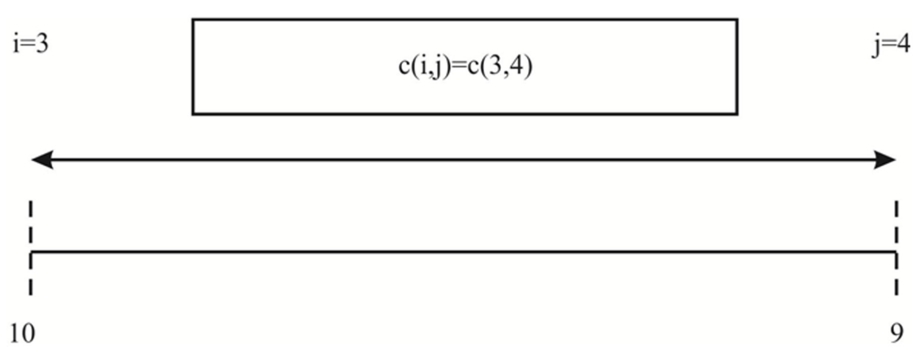
The total operating cost for the period (10, 9) is:

$$C\left(3,4\right)=C\left(3\right) \tag{4}$$

If the decision to replace the machine is made, then the total cost for the period (10, 9) shall be:

$$C\left(3,1\right)=C_r+C\left(0\right) \tag{5}$$

Figure 4. Replacement policy for the machine with age "4"



Thus, C_r is the replacement cost, and *C(0)*, the operating cost for a period, when the machine has age *0*.

The optimal replacement policy is graphically presented in Figure 5.

The mathematical model used for identifying this optimal policy has the following form:

Consider: $f_n(i)$, the minimal cost resulting from taking the best decision at the beginning of the period n plus the cost of the best decision taken on the remaining periods (*n-1*); *C(i,j)* represent the cost resulting from taking the decision at the beginning of the period *n*; $f_{n-1}(j)$, minimal cost by periods (*n-1*) remaining at the moment when the machine has the age *J*.

The cost by the *n* periods is:

$$C\left(i,j\right)+f_{n-1}\left(j\right), \tag{6}$$

so:

$$f_n\left(i\right)=\min\left[C\left(i,j\right)+f_{n-1}\left(j\right)\right] \tag{7}$$

with:

$$f_0\left(i\right)=0$$
$$j=i+1 \quad \text{or } 0$$

The equation (7) that may be solved by means of dynamic programming can be used to determine the replacement policy under a given specifications formulated in a section 'The problem statement'.

The Method of Replacement Based on the Existence of Equipment in Standby

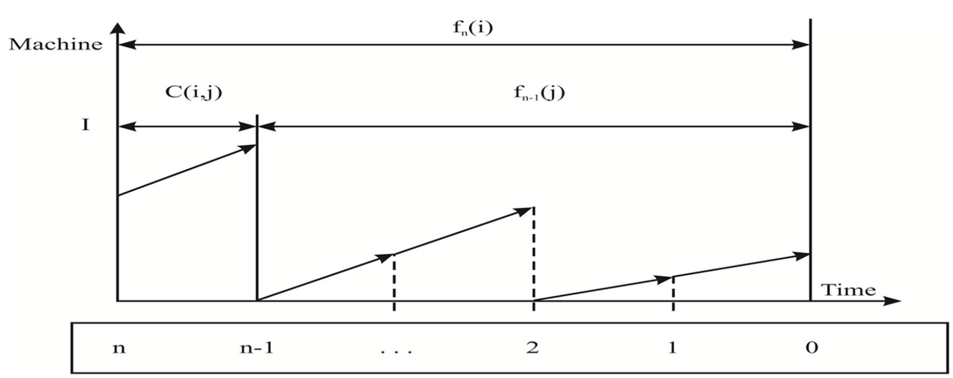
It implies the replacement of assets provided that the manufacturing flow contains a spare asset, and the operating cost increases with the use of the asset existing in production.

In this case, an optimal replacement policy must be determined, combined for the two assets, which shall minimize the total replacement and operating cost for a fixed time period.

The state of the production system at the beginning of a period shall be noted with *I*, where *I* is equivalent to the pair of numbers (*x, y*), where *x* refers to the asset (*A* or *B*) which is generally used, and *y*, to the age of the asset.

Consider: $C_x(y)$, the operating cost for a period; *j*, the state of the production system at the end of a period, where *j* is equivalent to (*x,y*); C_r = replacement cost, considered equal for both assets *C(i,j,)*, total cost of the system between the states of the system *i* and *j*. The time required for the replacement of an asset is a period when the replacement decision is made, and then the *stand by* asset becomes

Figure 5. Optimal replacement policy



operative. The proposed goal is the determination of an optimal combined policy for replacement/operation, so that the operating and replacement cost for the following n time periods is minimal. Figure 6 shows such a policy, where $n=10$, the system is in state $I=(B,2)$. At the beginning of period *10*, a decision is made to go on with asset B.

At the beginning of period *9*, a decision is made to replace asset *B* etc. The total minimal cost for replacement and operation, for the n periods is $f_n(i)$.

The cost of the first decision taken at the beginning of the period n is $C(i,j)$. At the end of this period, the system is in state j, having $(n-1)$ operating periods. Then the minimal cost for the remaining period $f_{n-1}(j)$ is:

$$Total\cos t = C\left(i,j\right) + f_{n-1}\left(j\right) \quad (8)$$

and

$$f_n\left(i\right) = \min\left[C\left(i,j\right) + f_{n-1}\left(j\right)\right] \quad (9)$$

In the next section we will describe the replacing policy model based on considering technological changes.

The Method of Replacing the Equipments Based on Technological Improvement in Finished Time Horizon

Considers that the replacement of an old machine by a new one not always is an exact copy of the old one, but that the latter is better, so that operating and maintenance costs are smaller, efficiency is higher etc. The following model aims at determining the way how the new available machines may be used with a successful purpose, considering that the time period is fixed and finite.

Consider: n, the number of operating periods (periods when the machine must operate); $C_{p,i}$, maintenance cost of the current equipment in the period I ($i = l,2,...n$); $S_{p,i}$, sales value of the current equipment at the end of the time period; A, purchase cost for the new, better equipment; $C_{t,j}$, maintenance cost of the new machine in the dj period after installation ($j=l,2,...n$); $S_{t,j}$, sale value of the new equipment at the end of the operating period j; r – update factor.

The method aims at determining the value T when replacement should be made with the new, better machine (Figure 7), $T = 0, 1,2,....,n$.

Figure 6. Replacement policy given the existence of the standby asset

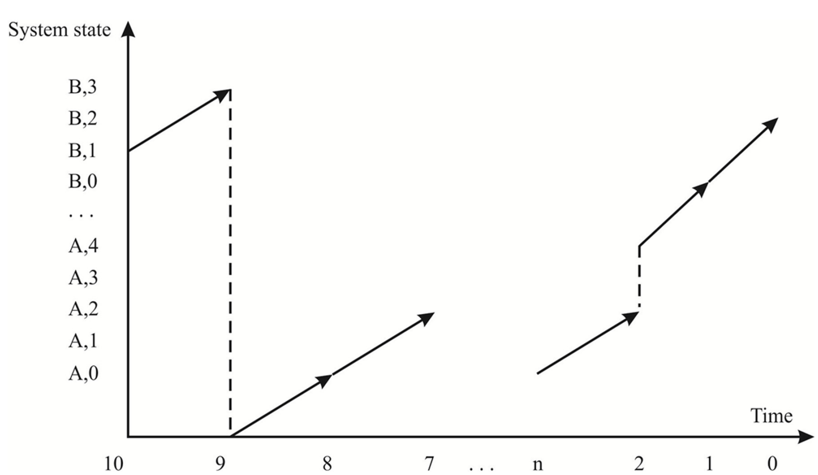


Figure 7. Graphical calculation of T value

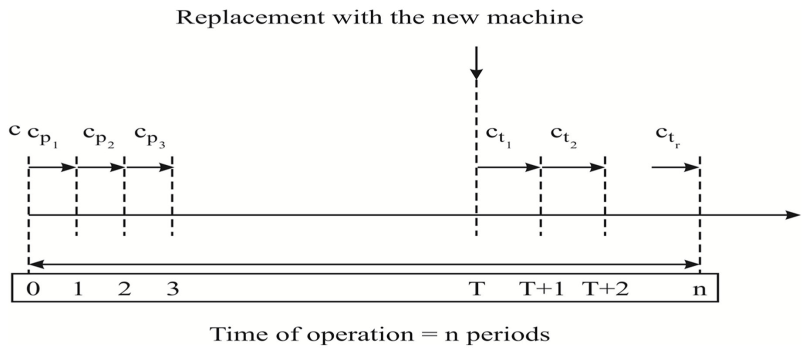

The total updated cost for the *n* periods when replacement occurs at the end of the *T* period is: *C(T)*, updated cost for the maintenance of the current machine in the period *(0,T)*, plus the updated maintenance cost of the new machine in the period *(T,n)*, plus the updated purchase cost of the new machine, minus the updated sale value of the current equipment at the end of the *T* time period, minus the updated sale value of the new equipment at the end of period *n*:

$$C(T) = \left(C_{p,1} \cdot r^1 + C_{p,2} \cdot r^2 + \ldots + C_{p,T} \cdot r^T\right) + \left(C_{t,1} \cdot r^{T+1} + C_{t,2} \cdot r^{T+2} + \ldots + C_{t,n-T} \cdot r^n\right) + A \cdot r^T - \left(S_{p,T} \cdot r^T + C_{t,n-T} \cdot r^n\right) \tag{10}$$

Hence,

$$C\left(T\right) = \sum_{i=1}^{T} C_{p,i} \cdot r^i + \sum_{j=1}^{n-T} C_{t,j} \cdot r^{T+j} + A \cdot r^T - \left(S_{p,T} \cdot r^T + C_{t,n-T} \cdot r^n\right) \tag{11}$$

As the sole unknown variable is *T*, the minimisation of *C(T)* does not raise further related issues.

DISCUSSION AND CONCLUSION

Because of the fact that above presented methods are more or less applicable based on specific theoretical preconditions, it can be handy to view the given problem from a wider user base. Prior to analysing decisions about equipment replacement in flexible manufacturing cells from practical point of view it is useful recognize two different approaches: deterministic or probabilistic. The probabilistic decisions to replace machines referred to as preventive actions are those decisions where the risk is given by the impossibility to exactly determine the moment when such machine falls or the transition moment from proper operating state to non-operating state. Another source of risk is given by the impossibility to determine the state of the equipment when no inspection or other maintenance activity occurs. Let us consider that there are only two states of the equipment that are always known: a proper operating state or a non-operating state. Then, in order to avoid equipment stoppages in flexible manufacturing cells, the positive replacement decision should come during a proper operating state and accordingly should have a preventive character. In such a way understood preventive replacement for fixed assets implies two conditions:

- *the total* replacement *cost shall be higher after the fall itself at the moment when the preventive replacement is made;*
- the replacement of the machine before the fall itself does not affect the chance that the equipment may fall at the following moment.

Therefore, preventive replacement is only justified when the rate of replacement grows. In case the machine is damaged, specialists in the department should increase the preventive replacement activities. This may lead to a mistake, as the preventive replacement of machines or their parts is not always justified.

Another above presented approach to equipment replacement decisions is based on considering technological shifts. Even though it is often assumed that an acceleration in technological improvement should result in a more rapid introduction of new technology, according to Cheevaprawatdomrong and Smith (2003), rapid technological improvement may not and indeed should not necessarily lead to more rapid replacement of old technology. In addition, as regards to methods of replacing the equipments based on technological improvement, it has to be 'calculated' with known difficulties and problems such as:

- workers' resistance, as they are used to the old machine;
- lack of will to change the work style;
- fear of the unknown, i.e. workers are scared that they will lose their jobs pursuant to the introduction of new technologies or that they won't be able to adjust to the new working requirements;
- lack of support regarding specialized documentation;
- difference of opinions regarding the operation of the equipment.

Accordingly, a management attitude toward new manufacturing technology will play a major role in determining whether a firm will acquire such technology (Dorf and Kusiak,1994).

Chapter 27
Enhancing Engineering Education Learning Outcomes Using Project-Based Learning:
A Case Study

Mousumi Debnath
Jaipur Engineering College and Research Centre, India

Mukeshwar Pandey
Jaipur Engineering College and Research Centre, India

ABSTRACT

This paper presents a case study of how project-based learning (PBL) can be seen as a pedagogical innovation for Jaipur Engineering College and Research Centre, Jaipur, India (JECRC) for better recruitment drives for on-campus recruitments. The practical knowledge of engineering, basic knowledge of engineering design, soft skills or personal competences can be correlated with the academic performance and recruitment status. Project based learning (PBL) is a learner-centric pedagogy where the learner is expected to take responsibility for his or her own learning. PBL uses in-depth and rigorous classroom projects to facilitate learning and assess student competence. Students have projects as a compulsory course in their curriculum in the final semester of engineering. The challenge to acquire knowledge and skills during their project gives a student an opportunity to develop their weaker skills and enhance their practical knowledge of engineering. This study has been successful in helping students acquire a high rate of actual skill and technical learning. The learning outcomes of the PBL-course can be correlated with their success in recruitment and academic performances.

DOI: 10.4018/978-1-4666-1945-6.ch027

INTRODUCTION

Today's students need to see and understand the relevance, reality, and authenticity of concepts and apply them to their lives in the real world. One unique teaching method that is proving to be effective in the classroom is project-based learning (PBL). PBL is a hands-on approach to learning. It incorporates a number of need-to-know concepts that they must use technology and inquiry to respond to a complex issue, problem or challenge, understand, and apply in order to complete the project. Project-based education is a learning environment congruent with the principles of student-and competence-centred vision. This has been an ongoing innovation since last 40 years. It can be seen as a pedagogical method which integrates theory and practice by means of problem solving of working life issues (Laynea *et al.,* 2008).

Bransford and Stein (1993) have defined PBL as a comprehensive instructional approach to engage students in sustained, cooperative investigation. The PBL approach is appropriate to acquire generic skills such as problem-solving, communication and teamwork (Wolfs *et al.*, 1997). An important piece of PBL is incorporating technology into projects. The team projects in PBL have a contextual focus enabling students to understand why they are learning the particular content and how it will be applied in the 'real world'.

PBL goes beyond generating student interest. Well-designed projects encourage active inquiry and higher-level thinking (Thomas, 1998). The students' major challenge is to acquire new understanding. PBL helps to enhance creative thinking skills by showing that there are many ways to solve a problem when they are connected to problem-solving activities. The students are helped to understand why, when, and how those facts and skills are relevant (Bransford *et al.,* 2000). Within the project based learning framework students collaborate, work together, and take responsibility for their own learning.

CHALLENGES OF PROJECT BASED LEARNING

Because of an increasing quality concern for higher education, additional attention is being paid to new educational principles with a more student- and competence-centred vision (Van der Bergh *et al.,* 2006). Project-based learning is one of the learning environments congruent with these principles (Van de Bergh *et al*., 2006). Project-based learning offers a wide range of benefits to both students and teachers. Academic research supports the use of project-based learning in college/school to engage students, cut absenteeism, boost cooperative learning skills, and improve academic performance. The major challenges of PBL include enhanced student participation in the learning process (active learning and self-learning), enhanced communication skills, addressing of a wider set of learning styles, and promotion of critical and proactive thinking and finally making them more competent to get jobs in on campus recruitment drives. The real-world problems capture students' interest and provoke serious thinking and motivate them for self-learning process. PBL also facilitates the development of many of the "soft skills" demanded from engineering graduates (Hadim & Esche, 2002). Soft skills and "generic skills" are interchangeable phrases in terms of the categorization of non-technical skills. For students, project-based learning helps to overcome all challenges and convert them into their major success. They include:

- Increased attendance, growth in self-reliance, and improved attitudes toward learning (Thomas, 2000).
- Academic gains equal to or better than those generated by other models, with students involved in projects taking greater responsibility for their own learning than during more traditional classroom activities (Boaler, 1999; SRI International, 2000).

- Opportunities to develop complex skills, such as higher-order thinking, problem-solving, collaborating, and communicating (SRI International, 2000).
- Access to a broader range of learning opportunities in the classroom, providing a strategy for engaging culturally diverse learners (Railsback, 2002).

Program assessment is a vital activity in order to determine the outcomes of student engagement in PBL. These outcomes include programme issues, knowledge, skills, attitudes and identity and post educational professional performance. This is shown in Figure 1. Knowledge and skills are, generally, easy to directly measure by common assessments used in nearly all engineering courses; usually conducted via graded reports, presentation, and other student work. Attitudes are often hard to measure, particularly within the timeframe of a single course where changes often manifest later upon self-reflection. General use of these assessment tools to measure the skills, outcomes and competencies developed from participation in PBL requires further evaluation. The major challenge and the final outcome in the professional programms/course are to obtain jobs (Swan *et al.,* 2009). Recruitment is seen as the final challenge where all the attributes are taken into consideration. PBL plays an important role in making a student technically strong and competent to face interviews.

The research question addressed in this study is the suitability of PBL in achieving the desired learning outcomes like practical knowledge of engineering, basic knowledge on engineering design, soft skills or personal competences and its impact on the student's performance in on-campus recruitment drive. So, a proposed model to correlate PBL with academic proficiency and recruitment would work upon.

Figure 1. Outcomes of project based learning

It was assumed that it depends on two major hypotheses. The first is to believe that the academic performance is not always associated with skill and technical expertise. Thereby, PBL learning delivery requires providers to alter their in-class approach and demands students to be more independent learners. The second concept is the students who are innovative and sincere in their project work have an interdisciplinary learning approach. Thus due to this interdisciplinary approach, these students are well placed in the on-campus recruitment drives. Thus by systematic monitoring and evaluation of the various aspects of the recruitment status of the institute and the performance of the students in PBL, the self-evaluation quality assessment of the institute was performed.

In the first part different kinds of evaluation methods have been compared, whereas the second one refers to specific, self-evaluation quality assessment research which has been done at Lublin University of Technology, Poland (Wac-Włodarczyk & Billewicz, 2008). Its main objective was to conduct precise number of surveys between different groups of people.

CASE STUDY: PROJECT BASED LEARNING (PBL) AT JECRC

For the course of study, the 444 final year students of Jaipur Engineering College and research centre (JECRC) of 2010 enrolled in project based learning course/s were considered and critically assessed. JECRC is one of the leading technical institutions in Northern India. The institute offers a four-year Bachelor of engineering degree in Electronics and Communication Engineering

(ECE), Electrical Engineering (EE), Computer Science and Engineering (CS), Biotechnology Engineering (BT), Information Technology (IT) and Mechanical Engineering (ME). All the courses are approved by All India Council for Technical Education (AICTE) at national level and affiliated to Rajasthan Technical University (RTU), Kota in the state. The enrollments are strictly on the basis of ranking in the various competitive examinations; such as All India Engineering Entrance Examination (AIEEE) and Rajasthan Pre-Engineering Exam (RPET). The institute nurtures the essence of growth in education and its holistic approach focuses on the overall development of its students. As a part of engineering curricula all the students in engineering programs/courses under the RTU syllabus have to pursue a definitive project. The duration of the project-based learning varies from 45 days to six months. The following sections discuss a few examples of the projects undertaken as PBL and then finally analyse the impact of PBL on academics and recruitment.

Challenging Examples of PBL at JECRC

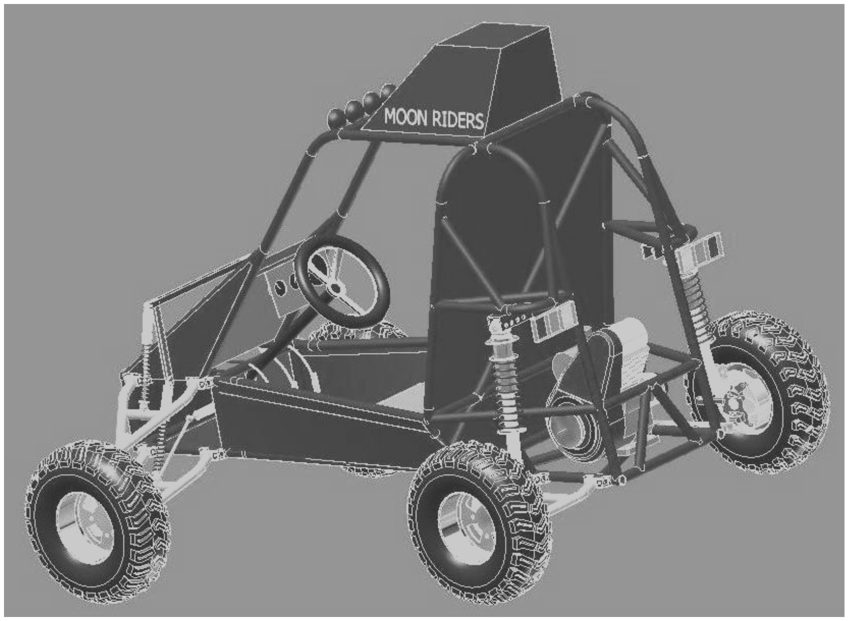
The project-based learning at JECRC depicted various models of instruction such as "active learning", "contextual learning", "design-based modelling", "collaborative learning", "technology-based education" and "design experiments". A number of experimental and theoretical investigations have been done on the application, development, and benefits of project-based learning in education. It was found that the role of the student changes from that of a consumer in a traditional classroom based setup to a more involved role of an active learner in project-based learning (Eugene, 2006).

All the PBL projects at JECRC were asked to be built around thematic units or the intersection of topics from two or more disciplines. For example: a 6 months project on 'Fire vigilance robot" was submitted by students of electronics and IT. In this project an implementation of artificial intelligence and electronic circuitry helped in devising an autonomous machine capable of avoiding obstacles coming in its way. It has a 360 degrees movement, temperature sensing, raising alarms, raising alerts using buzzer alarms. Thus, a multidisciplinary project-based learning helped students to develop competency in engineering, science and technology skills, teamwork and management, and then giving them a competitive advantage in industry.

All these projects involved students in a constructive investigation. The investigations were goal directed process involving inquiry, knowledge building, and solution. All these investigations also involved design, decision-making, problem-finding, problem-solving, discovery and r model-building processes. In this context, a project by the mechanical students on automobile can be taken up as an example. The 19 member team under the leadership of final year mechanical engineering students at JECRC, conducted market surveys and carried out discussions on emerging trends in off road vehicles available across the globe. A reverse engineering paradigm was followed for designing a vehicle "Moon rider" (Figure 2). The final 3-D CAD model was modelled in Autodesk Inventor 2010. A PVC prototype was made of chassis to have an accurate idea about the various constraints and to have a real experience. To save time and cost for physical testing, the finite element analysis (FEA) was carried on ANSYS Workbench 10 and various load analysis was done.

A steel prototype was made after selecting weld type and material for chassis. Fabrication of chassis and the weld strength checks were made to ensure the accuracy of loading conditions. The powering engine of the vehicle and the important aggregates such as suspension and steering were calculated. The steering system was self-customised and customer centred to meet the needs and to add additional value. A customer oriented marketing plan was made in accordance to make a business model to manufacture 4000 vehicles

Figure 2. Moonriders: Innovation of mechanical engineering

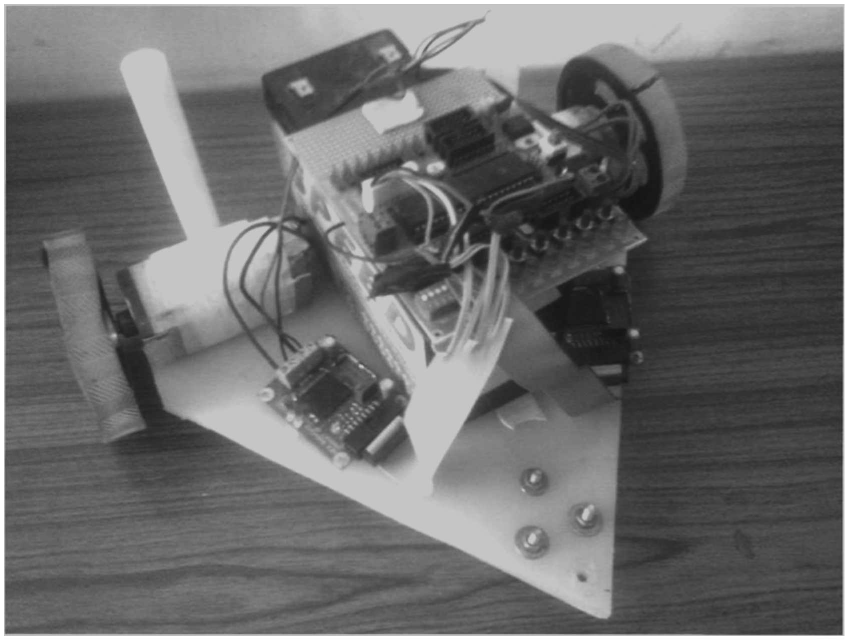


in a year. Proper industrial setup with plant layout was planned and the costing was calculated efficiently so as to minimise the manufacturing cost. After the final testing, the vehicle was transported for final evaluation where various static and dynamic evaluations on the vehicle were done. This project was highly appreciated in different state level and national level competitions and was presented in a national competition for automobile designs, namedBAJA SAEINDIA 2010.

However, in order to be considered a PBL project, the central activities of the project was asked to involve the transformation and construction of knowledge (by definition: new understandings, new skills) on the part of students. The mechanical engineering project could transform their classroom training into their practical innovation and helped them in acquiring the intended learning outcomes within knowledge and skills. This, in turn, also increased the quality of the education imparted by the institute and helped them to stand apart from the rest of the institutes. Another innovative project by student group from the department of computer engineering at JECRC was the **"**Twitli" *Twitter Client for Android* project. The objective of this project was to illustrate the requirements of Twitli, which is a Twitter client for Android phones (social networking website http://www.twitter.com). Twitli will facilitate users to access and use Twitter with all facilities provided by twitter.com. These smart phones use technologies like Android SDK, Android Components (Dalvik VM, Google API etc.) and Java with Android packages, XML etc., Twitter API wwwapiwiki.twitter.com and www.developer.android.com. This project helped the students to create a learning environment towards attaining a competence centred vision.

Projects embody characteristics that give them a feeling of authenticity to students. These characteristics can include the topic, the tasks, the roles that students play, the context within which the work of the project is carried out, the collaborators who work with students on the project, the products that are produced, the audience for the project's products, or the criteria by which the products or performances are evaluated. In this context one the project, named Trinity, by a group of final

Figure 3. Trinity: Innovation of the electronics and communication engineering

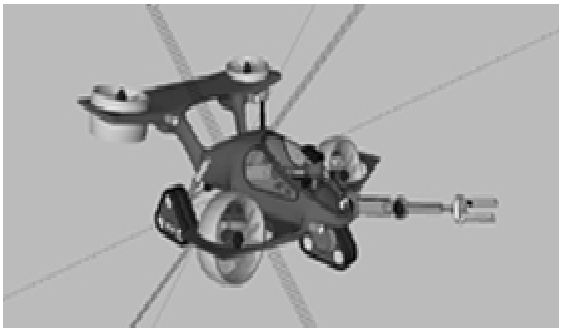


year electronics and communication engineering students can be considered as an example. Trinity project was made to design a control system to interact with a robotic platform wirelessly using voice, remote and visual communication technique was developed (Figure 3). In this robot a voice and remote based control has been completed but visual communication is yet to be implemented. This project also helped students to develop their competence towards learner centred pedagogy where students took full responsibility of making their ideas and innovation into a complete product.

The criteria for selection of a project are centrality, driving question, constructive investigations, autonomy, and realism. Students encounter and learn the central concepts of the discipline via the project. The central teaching strategy behind this PBL follows traditional instruction in such a way that the project serves to provide illustrations, examples, additional practice, or practical applications for material taught initially by other means. However, these "application" projects help students to learn things that are outside the curriculum ("enrichment" projects). In this context, final year students of electrical engineering made a promising project on mission-configurable robot that accommodates a wide range of sensors, including a dexterous manipulator and named it "ABHIMANYU". This robot can performs basic reconnaissance, increase situational awareness in dangerous scenarios for public safety professionals. It is both a terrestrial and an aerial vehicle as shown in Figure 4. This project helped students to make their creativity and constructive ability which gave a new dimension. While working on this project, students could put their ideas into realistic shape.

PBL incorporates real-life challenges where the focus is on authentic (not simulated) problems or questions and where solutions have the potential to be implemented. The Intelligent Notice Board is an initiative to design and implement an interactive notice board for use in college campus. The project is in the initial circuit design stage and is to be implemented using larger LCD screen. Initial control system built using Atmega-16, Max-232 and a 16*2 LCD. This project is a unique example of real life challenges.

Figure 4. Abhimanyu: Innovation of the electrical engineering



But it was finally concluded that the initial step for making a good project and learning from the project depends upon the first step of the project selection. If students can select projects themselves, the outcome is both interesting and exciting (Pucher *et al.*, 2003). Such a project can assure a quality improvement to the academic performance and personality development of the student.

Strategic Analysis of PBL in JECRC

A number of engineering schools have reframed their education around project-based learning (Beddos *et al.,* 2010) or active learning but recruitment is always the major motivator for professional study. In this study, the recruitment data from 2007-2010 was collected from the HR department of JECRC showing the number of students recruited in various engineering courses (Figure 5). On the basis of the recruitment data collected and analysed, it can be concluded that JECRC is blessed with high number of successful on-campus recruitment. This is clearly demonstrated in Figures 5 and 6. However, the question was how to increase the recruitment number in engineering departments other than CSE and ECE. There may also be several other factors apart from PBL that could have influenced the recruitment status of the institute.

There is some indication that PBL programs can help attract a more diverse population of students in engineering. The popularity of these experiences with students is clear, but it is not clear if this leads to any overall benefits to recruiting in engineering. There is virtually no quantitative assessment of the benefits of PBL experiences to professional trajectory. It is not fully clear if companies view this as a way to attract and retain qualified engineers, value the unique skills developed in engineers with these experiences, etc. Therefore, the impacts in this area require further study.

Figure 5. Recruitment statuses in JECRC

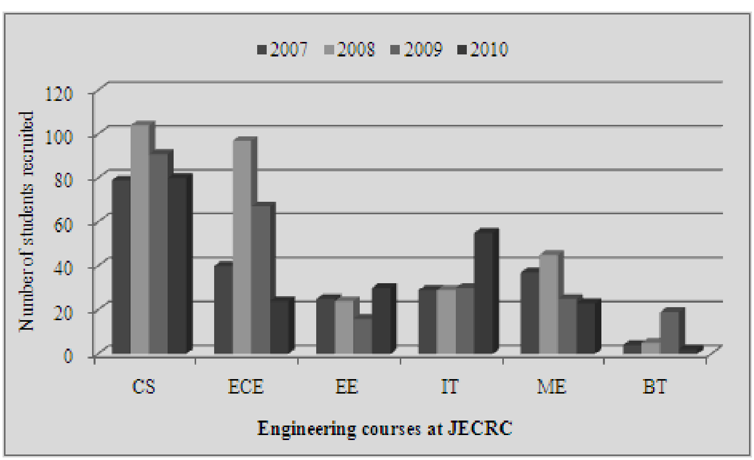


Figure 6. Probability of recruitment in engineering department of JECRC

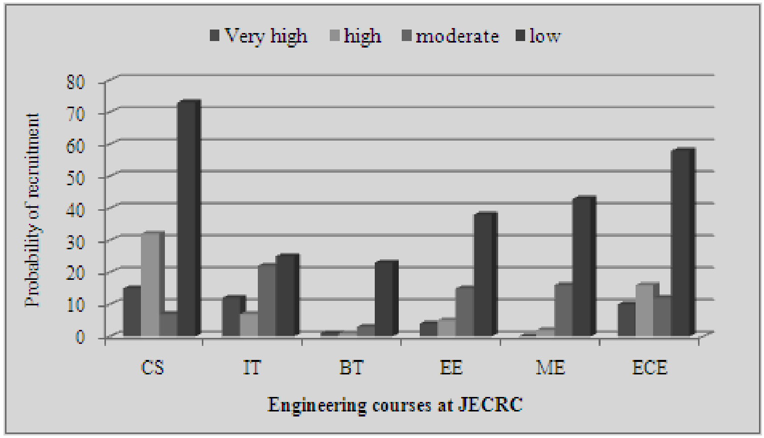

An assessment of project based learning of the final year engineering students of the year 2010 at JECRC was done and correlated to the academic performance and also on campus recruitment of the students. The parameter taken were skills learnt during PBL, hands on training, innovation in the project, and practical application of the project. A grading scale for PBL was taken up from 10, 20, 30 and 40 for below average, average, good and excellent projects. The assessment grades were collected from the respective departments. Further it was found that students worked for these projects in groups as well as individually. The projects were completed in industries and as well as in the JECRC. The academic performance was also correlated taking into consideration their performance in school, high school and engineering studies and given a grading scale (below 60% =5; 60-69%=10; 70-79%=15; 80-89%=20; 90-100%=25). Students of JECRC have shown their abilities/potential to obtain jobs in top companies. They are usually placed in their final year while still studying in the JECRC In year 2010, 21 companies visited the campus for recruitments. To grade the recruitment, a scaling was done on the basis of the status of the company in terms of the salary package (excellent pay =15; moderate =10; average =5) and also the attempt the candidate made in securing the job (first attempt 21; second attempt 20 and so on).

On the basis of the aggregate scoring for academics, PBL and recruitment status of individual candidate, all students were further categorized for their very high (150-200), high (120-149), moderate (80-119) and low (below 80) probability for recruitment in the on campus placement drives as shown in Figure 6.

It was found that CS, IT and ECE had a very high probability of getting placed in good companies followed by ME and EE whereas BT had a low chance of recruitment. This was further investigated considering each variable (Table 1).

A relationship of PBL with recruitment was assessed. When the average of the variables were plotted, in almost all the departments, a direct relationship of an increase in the PBL performance could be seen with that of the recruitment status except for the BT, This is also shown in Figure 7.

It was found that in the year 2010, most of the on-campus recruitments were for IT and software based companies where BT students could not perform better in comparison to the other students. It was obvious that students with high academic performance would be good in PBL and a correlation between the academic performance and PBL was also analysed after plotting the mean of

Table 1. Data analysis of the engineering departments on the basis of academics, PBL and recruitment status in JECRC

Departments	Academics	PBL*	Recruitment status	Probability of on campus Recruitment
CS	51.33	30.00	86.86	Very High
	46.90	29.14	54.68	High
	45.00	25.71	23.71	Moderate
	41.36	28.00	0.00	Low
IT	51.25	25.00	88.16	Very High
	46.42	27.14	62.57	High
	41.36	20.45	29.13	Moderate
	39.20	23.60	0.00	Low
ECE	53.50	29.00	87.80	Very High
	52.18	27.50	55.87	High
	43.88	26.66	33.55	Moderate
	39.83	26.72	0.00	Low
ME	50.00	30.00	46.00	High
	41.94	25.55	19.82	Moderate
	33.47	26.58	0.00	Low
EE	55.00	37.50	85.25	Very High
	46.66	26.66	55.00	High
	40.00	28.23	20.23	Moderate
	32.50	23.68	0.00	Low
BT	50.00	40.00	61.00	Very High
	50.00	30.00	61.00	High
	53.33	40.00	0.00	Moderate
	41.50	21.00	0.00	Low

* Project Based Learning
CS = Computer Science and Engineering
IT = Information Technology
EE = Electrical Engineering
BT = Biotechnology Engineering
ECE = Electronics and Communication Engineering

the probabilities (Figure 8). Except in EE and BT, there was no direct correlation between the variables. It was revealed that only in the BT and EE disciplines, those students who were academically good were research oriented and showed better performance in PBL. Most of the departments except BT, worked on PBL in teams ranging from 2 to 6. The team spirit, networking along with on-site hands-on guidance for building practical skills helped the students to gain all the qualities required to be hired.

CONCLUSION

PBL emphasizes on students' learning in cooperation with others, and on their own participation in the act of learning. From the study, it was concluded that the probability of recruitment increases for those students who are innovative, skilful, disciplined and dedicated to PBL. The fundamental knowledge of engineering, engineering design, soft skills or interpersonal competences can be correlated with the academic performance and recruitment status. These students acquire the skills and competencies during PBL and this experience help them to secure a job in the on-campus recruitment drive. Hence it can be concluded that PBL is one of the major factors related to performance in on-campus recruitment at JECRC.

Thus, such an educational system is allowing students to obtain an acknowledged degree in an academic education, acquire specialised hands-on-training at the same time helping gain confidence for their recruitment programmes for their professional growth. It stresses the social dimension of learning, its negotiated nature, the need for a process in which learning is "anchored" in the real world. From the onset, it was realized that offering a PBL course such as project dissertations/training would require different teaching and learning strategies. Students and teaching faculty also acknowledged the same in the study conclusion.

It's important to note that throughout the project, the students have to employ their innovative skills and improvise the technique. During PBL, the students have to learn to move from commonsense ideas to more substantiated ideas based on practical experience and theoretical reflection, after all, that's what engineering is all about. A number of items need to be evaluated with respect

Figure 7. Relationship of recruitment and PBL in different engineering departments in JECRC

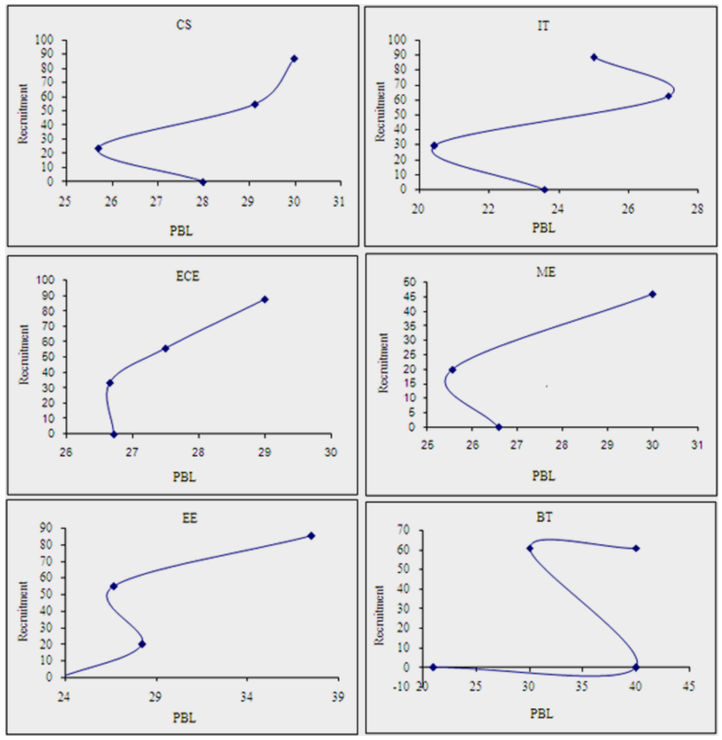

Figure 8. Relationship of academic performance and PBL in different engineering departments in JECRC

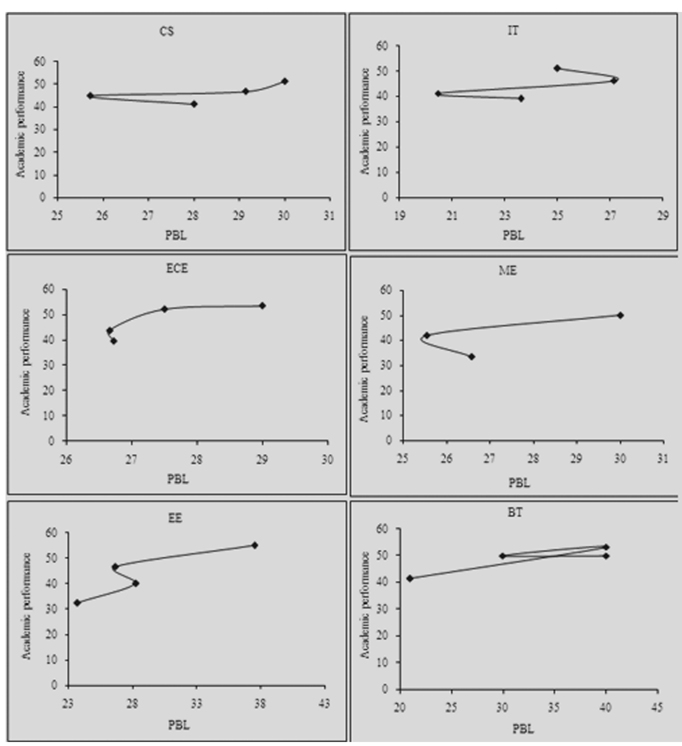

to the skills that the students develop by their involvement in PBL efforts. This study voiced the importance of PBL for learners in a quality higher education, the results of which will be recognized by society. PBL-based learning creates opportunities for groups of students to investigate meaningful questions and think critically. Answers to these questions can provide evidence that PBL is of value for a sustainable engineering education across a career.

Section 3
Tools and Technologies

This section presents an extensive coverage of various tools and technologies available in the field of Industrial Engineering that practitioners and academicians alike can utilize to develop different techniques. These chapters enlighten readers about fundamental research on the many tools facilitating the burgeoning field of Industrial Engineering. It is through these rigorously researched chapters that the reader is provided with countless examples of the up-and-coming tools and technologies emerging from the field of Industrial Engineering. With 14 chapters, this section offers a broad treatment of some of the many tools and technologies within the Industrial Engineering field.

Chapter 28
Semantic Technologies in Motion:
From Factories Control to Customer Relationship Management

Ricardo Colomo-Palacios
Universidad Carlos III de Madrid, Spain

ABSTRACT

Semantic technologies are evolving to reach a mature state. Given the importance of Information Technologies in general and Internet in particular to organizations worldwide, these technologies can provide enhanced functionality to both existing and future solutions. This chapter provides an overview of the use of semantic technologies in several application domains, namely: construction & real estate, customer relationship management, e-government, e-learning, environmental sciences, health domain, human resource management, Information Technology, manufacturing, media and tourism, and cultural heritage. More than a hundred references are provided to support the idea that semantic technologies are applicable to almost all areas of interest.

INTRODUCTION

In recent years, the information technologies (IT) field has expanded beyond traditional stove-pipe organizational systems to infiltrate companies and homes alike (García Crespo et al., 2008). Today, the contribution of IT to economies is unquestioned (Stehr, 2007). IT has been considered fundamental for the development of productivity and knowledge-intensive products and services (Soto-Acosta et al., 2010). Moreover, the Internet-driven networked economy is evolving to the point where businesses are fully aware of the enormous business opportunities of online transactions (García-Crespo et al., 2011a) and such importance in recent years has turned their development into

DOI: 10.4018/978-1-4666-1945-6.ch028

a critical task for corporations (García-Crespo et al., 2009a). Given that organizations must continuously innovate in terms of product, process, market and business model to remain sustainable (O'Sullivan & Dooley, 2010), many organizations rely their innovation process and, in many cases, the whole of their business to IT systems. Advances in technology, emergence of new business practices, and shifting social and geopolitical circumstances have combined to create a "brave new IT world" for organizations (Goles, Hawk & Kaiser, 2008).

In this scenario, organizations use multiple IT/IS solutions to support their activities at all management levels (Trigo, Varajao & Barroso, 2009) and this is so because IT-enabled services makes possible to overcome geographical, temporal and organizational barriers to communication and knowledge transfer (Corso, Giacobbe & Martini, 2009). Moreover, Information technology organisations, who frequently lead the development of change based around ICT, are being asked to develop new products and services that add significant value for customers and to radically change their internal processes so that they are more cost effective (O'Sullivan & Dooley, 2010). One of the main strengths of the Web is that it allows any party of its global community to share information with any other party (Presutti & Gangemi, 2008). In an environment of globalization and competition, institutions have turned to knowledge as a strategic asset that drives sustainable economic advantage (Sharma et al., 2010) in which technology is the means in which enterprises collaborate all over the world. In this environment, the power of knowledge in our contemporary life has produced many new terms and concepts including: "knowledge society"; "knowledge economy", "knowledge management", and "knowledge culture" (Bakry & Alfantookh, 2010).

Since its humble beginnings, the Internet has gained vast importance in today's society, both in terms of consumer reach and the volume of fundamental information it contains for millions of users worldwide. Transforming from a host-to-host network connection in ARPANET (Abbate, 1999) on October 29, 1969, it has advanced to become what Tim Berners-Lee has termed the "Giant Global Graph" (Berners-Lee, 2007). As stated by Bieber et al. (1997), one of the original success factors of the Web is that it provides simple access to the information contained in it. Because of the power of IT, human kind has been turning its concentration on developing web-based services (Sudhahar et al., 2010). Moreover, according to Targowski (2009) Web technology is key solution for the provision of e-Service systems. When we talk about the development of the web and where we stand today, we stumble across two main buzzwords: Web 2.0 and Semantic Web (Lux & Dösinger, 2007).

The evolution of the Web from Web 1.0 to Web 2.0, and to what has recently been termed by some as Web 3.0, has caused a paradigm shift in a user's access to and control of websites. The Web 2.0 phenomenon made the Web social, initiating an explosion in the number of users of the Web, thus empowering them with a huge autonomy in adding content to web pages, labeling the content, creating folksonomies of tags, and finally, leading to millions of users constructing their own web pages (Breslin & Decker, 2007). Logically, the result of this movement was a significant increase in the number of web pages available. Surfing through endless links is no longer an efficient method for finding relevant information. This not only applies to the standard user, all owners of web pages, whether organizations or consumers, lose target audiences as users of the Web are unable to access their pages in an efficient time frame (García-Crespo et al., 2010a). Both the information that is stored on the Web and the number of its human users have been growing exponentially in recent years and, for many people, the Web has started to play a fundamental role as a means of providing and searching for information (Eiter et al., 2008). In this environment, both user computing and IT in organizations can benefit from the application of semantic technologies that enable the access and storage of information in an unified way. Not in vain, this technology promises to solve many challenging and cost-intensive problems of the current generation of Web applications (Nixon et al., 2008).

This chapter presents the implications of Semantic Technologies in several areas of interest, giving a sight of the main efforts devoted to the adaptation of semantic technologies to organizations and human activities in literature.

OUTLINE: SEMANTIC TECHNOLOGIES

Semantic Technologies have been pointed out as the future of Web (Benjamins et al., 2008) and a new way to support knowledge (Vossen et al., 2007; Fensel & Musen, 2001) in a wide range of domains (Lytras & García, 2008). Semantic technologies, based on ontologies (Fensel, 2002), provide a common framework that enables for data integration, sharing and reuse from multiple sources. Durguin and Sherif (2008) portrays the Semantic Web as the future web where computer software agents can carry out sophisticated tasks for users.

This approach facilitates the integration of data coming from a broader non-relational domain of data, which additionally might be distributed and outside enterprise boundaries and control (García, 2010a). Taking this into account, according to Alani et al., (2008), Semantic Web applications are beginning to be pragmatic. Technology Journalist Markoff (2006) begun to call this new web applications as Web 3.0 and this tendency was latter followed by others (e.g. Lassila & Hendler, 2007; Hendler, 2008; Wang, 2008; Hendler, 2009). Web 3.0 can bring a new breed of spectacular applications compared to Web 2.0 with the same magnitude that separates Web 2.0 from Web 1.0 (Cardoso, 2007).

Semantic Technologies have emerged as a new and highly promising context for knowledge and data engineering (Vossen et al., 2007). The term "Semantic Web" was coined by Berners-Lee, Hendler and Lassila (2001), to describe the evolution from a document-based web towards a new paradigm that includes data and information for computers to manipulate. The essential difference between the classic Web and the Semantic Web is that structured data is exposed in a structured way (Gruber, 2008).

The Semantic Web enables automated information access based on machine-processable semantics of data. Being machine-processable means that semantic search services can be made this information available for providing precise and exhaustive information retrieval (Guha, 2003). Ontologies provide information systems with a semantically rich knowledge base for the interpretation of unstructured content (Mikroyannidis & Theodoulidis, 2010).

According to Lytras and García (2008), in recent years, Semantic Web research has resulted in significant outcomes and the adoption of this technology from the market and the industry is becoming closer. Moreover, according to Ding (2010), Semantic Web is fastmoving in a multidisciplinary way. The Semantic Web provides an alternative solution to represent the comprehensive meaning of integrated information and promises to lead to efficient data management by establishing a common understanding by ontologies (Shadbolt et al., 2006). Ontologies (Fensel, 2002) are the technological cornerstones of the Semantic Web, because they provide structured vocabularies that describe a formal specification of a shared conceptualization. Ontologies were developed in the field of Artificial Intelligence to facilitate knowledge sharing and reuse (Fensel et al., 2001). An ontology can be defined as "a formal and explicit specification of a shared conceptualisation" (Studer et al., 1998). Ontologies provide a common vocabulary for a domain and define, with different levels of formality, the meaning of the terms and the relations between them. Knowledge in ontologies is mainly formalized using five kinds of components: classes, relations, functions, axioms and instances (Gruber, 1993). The theory which supports the use of ontologies is a formal theory within which not only definitions but also a supporting framework of axioms is included (Smith, 2003). Besides Semantic Web, ontology defines a set of representational primitives with which a domain of knowledge is modeled. Knowledge in ontologies is mainly formalized using five kinds of components: classes, relations, functions, axioms and instances (Gruber, 1993). Classes in the ontology are usually organized into taxonomies. Sometimes the definition of ontologies has been diluted, in the sense that taxonomies are considered to be full ontologies (Studer et al., 1998). Languages such as RDF and OWL have been developed; these languages allow for the description of web resources, and for the representation of knowledge that will enable applications to use resources more intelligently (Horrocks, 2008). These languages, and the tools developed to support them, have rapidly become de facto standards for ontology development and deployment; they are increasingly used, not only in research labs, but in large scale IT projects (Horrocks, 2008). The Semantic Web consists of several hierarchical layers, where the Ontology layer, in form of the OWL Web Ontology Language (recommended by the W3C), is currently the highest layer of sufficient maturity (Lukasiewicz & Straccia, 2008).

Taking full advantage of ontologies, the Semantic Web provides a complementary vision as a knowledge management environment (Warren, 2006) that, in many cases has expanded and replaced previous knowledge and information management archetypes (Davies, Lytras & Sheth, 2007). Thus, Semantic Web has emerged to be a new and highly promising context for knowledge and data engineering (Vossen, Lytras & Koudas, 2007). The goals of the Semantic Web initiative include the integration of data from different sources in a machine processable format in order to make them accessible to computer programs and facilitating the use of data in ways that have not been thought of when the data was entered or recorded (Battré, 2008). It is agreed that semantic enrichment of resources would lead to better search results (Scheir, Lindstaedt & Ghidini, 2008).

Having outlined the importance of Semantic Technologies, these technologies has recently attracted much attention, both from academia and industry, and is widely regarded as the next step in the evolution of the World Wide Web (Lukasiewicz & Straccia, 2008) and this recent boom in Semantic Web technologies has been occurring in the so-called "Web 3.0" technologies (Hendler & Golbeck, 2008).

SEMANTIC TECHNOLOGIES IN ORGANIZATIONS

In the past years our community has seen continuous, sustained growth in the deployment of Semantic Web inventiveness in large and small organizations of many types (Cardoso, 2007) and as a result of this, various industries have adopted SW technologies (Lytras & García, 2008). According to Breslin et al. (2010), industry has begun to watch developments with interest and a number of large companies have started to experiment with Semantic technologies to ascertain if these new technologies can be leveraged to add more value for their customers or internally within the company, while there are already several offers of vendors of Semantic solutions on the market. These authors stated that Semantic technologies are not only valuable on an open environment like the Web, but also in closed systems such as in industrial settings.

The aim of this section is to illustrate the use of semantic technologies in industries through a state of the art study in which for every area of application several works are outlined in which authors employ semantic technologies. In Table 1, these works are cited ordered by area of application and issue covered.

Table 1. Semantic technologies efforts ordered by area of application

Business Integration	Business integration tools	Arroyo et al. (2007)
Construction & Real Estate	Cadastrial domain application	Hess and de Vries (2006)
	Corporate memory management in building construction	El-Diraby and Zhang (2006)
	Real Estate Product Finder	Langegger and Wöß (2007)
	Communication in construction	Zhang and El-Diraby (2009)
	Domain Ontology for Processes in Infrastructure and Construction	El-Gohary, and El-Diraby (2010)
	Retail Real Estate Agencies Information System	García-Crespo et al (2010e)
Customer Relationship Management	Employee driven CRM ontolgy	Van Damme, Christiaens & Vandijck, (2007)
	Customer complaint management	Jarrar, (2008)
	Knowledge for Customer Relationship Management	Magro and Goy, (2008)
	Emotions analysis	García-Crespo et al (2009d)
	Customer social networks analysis	García-Crespo et al (2010f)
	State of the art	García-Crespo et al (2010g)
eGovernment	Data models and interfaces to eGovernment services:	Álvarez Sabucedo et al. (2009a)
	eGovernment interoperability	Peristeras, Tarabanis and Goudos (2009)
	Multi-agent based framework for e-government	Mellouli and Bouslama (2009)
	Operational procedures facilitation in public administration	Savvas & Bassiliades (2009)
	Provision of Services	Álvarez Sabucedo et al. (2009b)
	Semantic interoperability	Guijarro (2009)
	eGovernment agents	Álvarez Sabucedo et al. (2010)
	Information Processes	Klischewski and Ukena (2010)
eLearning	Dynamic e-Learning	Lytras, Pouloudi and Poulymenakou (2002).
	Knowledge Management Learning Activities	Sicilia et al. (2006)
	IMS Learning design	Naeve, Sicilia and Lytras (2008)
	Learning content usage analysis	Jovanovic et al. (2008)
	Learning in various domains	D'Avanzo, Kuflik and Lytras (2008)
	Ontology to Automate Learning Scenarios	Rius, Sicilia and García-Barriocanal (2008)
	Personalised learning services	Vargas-Vera & Lytras (2008)
	Developing semantic web-based educational systems	Bittencourt et al. (2009)
	Intelligent techniques in eLearning	Gladun et al. (2009)
	Interoperability of Learning Objects Copyright	García and Pariente (2009)
	Ontology-based training	Macris (2009)
	Recommendation methods to efficiently personalise resources	Kerkiri, Manitsaris and Mavridis (2009)
	Semantic web technology based framework for educational-offer selection	Kumar, Kumar and Jain (2009)
	Support Learning Content Development	Pahl & Holohan (2009)

	Hotel recommendation	García-Crespo et al. (2011b)

CONCLUSION AND FUTURE WORK

Semantic technologies are beginning to be good shape. These technologies can be efficiently deployed for domains including Web Services, Enterprise Application Integration, Knowledge Management and E-Commerce, fulfilling existing gaps in current applications (Breslin et al., 2010). In this chapter, author has reviewed the use of Semantic Technologies in diverse industry and services domain. From the technological and research point of view it's clear that semantic technologies are mature, but their use in industrial settings is far from being extensive. Too few vendors bet for these technologies and include them into their products or solutions, while there is a legion of researchers around the world nurturing this phenomenon: producing thousands of papers, assisting to hundreds of conferences and even starting and editing a handful of good journals.

This chapter, as a part of the book devoted to CRM and Semantic Technologies, is aimed to prove that these technologies are applicable is practically every business domain.

KEY TERMS AND DEFINITIONS

Knowledge Management: Discipline in which an organization manages its knowledge in terms of resources, documents, and people skills in order to enable the adoption of insights and experiences.

Ontology: Formal representation of the knowledge in a given domain by a set of concepts and the relationships between those concepts.

OWL: Set of languages designed and established in order to be used in Semantic Web and more in detail for authoring ontologies.

Semantic Web: Evolution of the traditional Web in which contents are described in a unified manner.

Web 2.0: Set of technologies associated with WWW in which contents are usually created by users (prosumers) in contrast to websites where users (consumers) are limited to the passive viewing of content that was created for them.

Chapter 29

Similarity-Based Cluster Analysis for the Cell Formation Problem

Riccardo Manzini

University of Bologna, Italy

ABSTRACT

This chapter illustrates the cell formation problem (CFP) supported by similarity based methods. In particular, problem oriented indices are based on several factors which play an important role in the determination of the value of similarity between two generic machines, e.g. the number of machines visited by each part, the sequence of manufacturing operations, the production quantity for each part, et cetera. A numerical example illustrates the basic steps for the implementation of an effective hierarchical procedure of clustering machines into manufacturing cells and parts/products into families of parts. Literature presents many indices, but a few significant case studies and instances not useful to properly compare them and support the best choice given an operating context, i.e. a specific production problem. As a consequence the authors illustrate an experimental analysis conducted on a literature problem oriented instance to compare the performance of different problem settings and define best practices and guidelines for professional and practitioners.

INTRODUCTION

Group technology (GT) is a manufacturing philosophy for the identification of similar parts and grouping them to take advantages from their similarities in design and manufacturing (Manzini et al. 2010). A special application of GT is *cellular manufacturing* (CM), defined as a hybrid system including the advantages of both flexible and mass production approaches. CM can be defined as an application of GT that involves grouping machines

DOI: 10.4018/978-1-4666-1945-6.ch029

based on the parts manufactured by them. The design of a CM system is called the *cell formation* (CF) problem and includes also the definition of families of "parts", i.e. products and components, assigned to the groups of manufacturing resources, called "machines".

Since 1966 when the first contribution on CM and its topics was published (Yin and Yasuda 2006), the large number of advantages presented by CM compared to batch production (generally implemented in the so-called *functional layouts* or *job shop* systems) have been widely discussed in the literature, e.g. inventory level reduction, production lead time reduction, reduced set-up times, etc. The main difference between a traditional job shop environment and a CM environment is in the grouping and layout of machines: in a job shop system, machines are grouped on the basis of their functional similarities; in a CM environment each cell is dedicated to the manufacture of a specific part family, and the machines in each cell have dissimilar functions (Heragu 1997).

An effective approach to forming manufacturing cells and introducing families of similar parts, consequently increasing production volumes and machine utilization, is the use of similarity coefficients in conjunction with clustering procedures.

Recent studies and applications on cluster analysis (CA) to industrial problems and applications are illustrated by Manzini and Bindi (2009) in transportation issues, Bindi et al. (2009) in warehousing and storage systems, Manzini et al. (2006) and (2001) in GT and CM.

Object of this chapter is the introduction, illustration and application of a cluster based systematic procedure for the design of a CM system by the adoption of *general purpose* and *problem oriented similarity* indices.

A general design of a CM system consists of the following three basic activities (Papaioannou and Wilson, 2010):

1. part families formation usually formed according to their processing requirements;
2. machine groups formation. These groups are usually called "manufacturing cells" and "clusters";
3. part families assignment to cells.

Three different strategies to execute these activities can be applied:

1. *Part family identification (PFI) strategy.* Part families are formed first and then machines grouped into families in accordance to the part families formation;
2. *Machine group identification (MGI) strategy.* Manufacturing cells are first created and then parts are allocated to cells;
3. *Part family/machine grouping (PF/MG) strategy.* Part families and manufacturing cells are formed simultaneously.

This chapter adopts the second strategy. As a consequence, this chapter illustrates a systematic procedure for the cell formation problem, i.e. the allocation of machines to cells. The number of cells to be formed is not known in advance. In a second decision step the assignment of manufacturing parts to the previously defined clusters is executed in accordance with a known processing sequence.

The simultaneous parts and machines clustering processes is usually based on the minimization of intercell movement of parts (Stawowy 2004) which specifically deals with the CF problem and methods. In other words, the object is to minimize the interactions between manufacturing cells, where an interaction occurs if a part requires machines belonging to two or more cells. The degree of interaction between manufacturing cells is measured by the number of the "exceptional elements" as illustrated below in the discussion of the efficiency in the formation process.

The remainder of this chapter is organized as follows: Section 2 presents a literature review on CM and CF problems, Section 3 illustrates the proposed similarity based hierarchical clustering process based on the application of a *threshold* *level of group similarity* as introduced by Manzini et al. (2010). In particular, Section 3 presents both a set of general purpose similarity indices and a set of problem oriented indices. Section 4 reports the most important clustering performance evaluation metrics. Section 5 illustrates a few significant numerical examples, and Section 6 discusses about the results obtained by an experimental analysis conducted on an instance of the literature adopting different settings of the decision problem. Finally Section 7 presents conclusions and further research.

LITERATURE REVIEW

A survey on CF problem methodologies is presented by Papaioannou and Wilson (2010). They distinguish three main categories: informal/visual methods, part coding analysis methods, and production based methods which can be further classified as follows (see Figure 1):

- cluster analysis (CA)
- graph partitioning approach
- mathematical programming method
- heuristic and metaheuristic algorithms
- artificial intelligent methodologies.

In particular, the CA, which is the adopted set of methods for the CF problem and CM in this chapter, groups either objects or entities into clusters such that the generic cluster is made of individual with high degree of homogeneity, i.e. “natural association”, but different clusters have very little association between them.

The proposed CA is supported by the application of “agglomerative methods” where the process of grouping starts with singleton clusters and merges them into larger sets. The systematic approach proposed in this chapter is similarity based, adopts cluster analysis and heuristic agglomerative and hierarchical algorithms.

SIMILARITY BASED HIERARCHICAL CLUSTERING PROCESS

The clustering process of parts and machines for CM presented and applied in this chapter is based on the adoption of similarity indices both “general purpose” and “problem oriented”. The main decisional steps are cited by Manzini et al. (2010) and are discussed in this section in detail. Figure 2 illustrates the proposed systematic procedure for the formation of manufacturing cells and homogeneous part families. This procedure takes inspiration from the *cluster analysis (CA)*,

Figure 1. CF solution methods classification

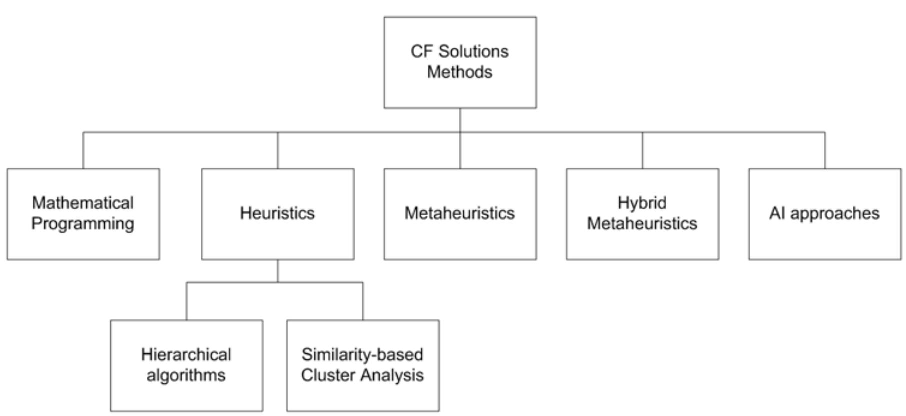

Figure 2. Systematic procedure for the similarity based hierarchical clustering

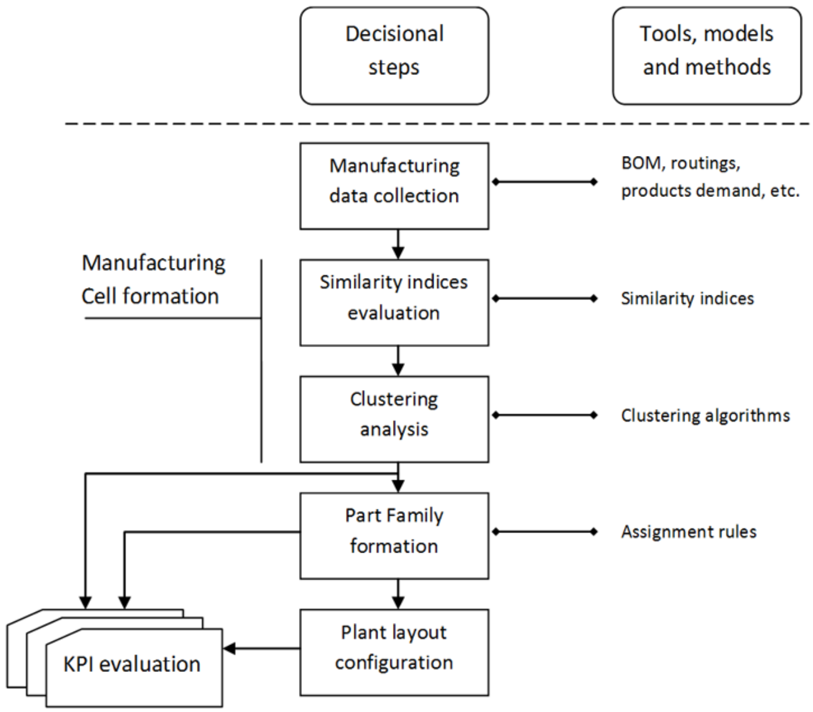

as a set of statistics based techniques and tools designed for grouping items and partitioning a set of elements in different research areas, e.g. economics, medicine, biology, etc., and is made of the following main steps.

Step 1: Manufacturing Data Collection

It deals with the analysis of product mix including all parts and components, both *product structure*, e.g. the bill of materials (BOM), and *production process*, e.g. the manufacturing work cycle, frequently called routing. The level of detail for the collection of data is significantly influenced by the adopted similarity index for the CA. In particular, in presence of a *general purpose index* the necessary data generally refer to the assignment of products and components, the so called "parts", to the manufacturing resources, the so called "machines". The adoption of a *product oriented similarity index* justifies the collection of several product data, e.g. expected production demand, manufacturing process unit time eventually including the set-up time, sequence of visited machines, existence of alternative manufacturing routines, tools assignment and availability, production costs, etc.

The basic and elementary data collection activity is usually supported by the construction of the well known *part-machine incidence matrix* (PMIM) whose generic entry a_{ik} is defined as follows:

$$a_{ik} = \begin{cases} 1 \text{ if part i visits machine k} \\ 0 \text{ otherwise} \end{cases} \tag{1}$$

where

$i=1,..,I$ part index
$k=1,..,K$ machine index.

The transpose of the part-machine matrix is known as the *machine-part incidence matrix* (MPIM).

An example of a MPIM is illustrated in Table 3. Obviously, the collection of data for the evaluation of problem oriented indices is more onerous, but the performance of the clustering process is expected to be higher than in presence of not problem oriented indices.

Step 2: Similarity Index Evaluation

The clustering activity is a process of grouping and set-partitiong items in homogeneous and disjunctive groups, called "clusters". The generic cluster of parts is called "part-family", while the cluster of machines is called "manufacturing cell". A similarity index refers to a generic pair of items of the same typology in the beginning mix of parts and machines to be partitioned. The index measures the degree to which two items, e.g. two different machines, need to belong to the same cluster, i.e. a manufacturing cell of homogeneous machines.

The literature presents a very large number of similarity coefficients. A taxonomy for these indices is presented by Yin and Yasuda (2006). They distinguish the previously cited two distinct main groups of coefficients: *problem-oriented* (*l*1.1 in Figure 3) and *general purpose* (*l*1.2). Problem-oriented measures are specifically designed for application to manufacturing problems in industry, while general purpose are used in many disciplines, e.g. medicine, sociology, biology, economics, decision science, etc.

Table 1 lists a not exhaustive set of general purpose indices S_{ij} as proposed by the literature and based on the following assumptions: given two machines i and j, a is the number of parts visiting both machines, b is the number of parts visiting machine i but not j, c is the number of parts visiting machine j but not i, d is the number of parts visiting neither machine i, j. These coefficients are applied in the numerical example and experimental analysis illustrated in this chapter.

Jaccard - J is the most commonly used general-purpose similarity coefficient in the literature. Jaccard similarity coefficient between machine i and machine j is defined as follows (McAuley, 1972):

$$S_{ij} = \frac{a}{a+b+c}, \quad 0 \leq S_{ij} \leq 1 \qquad (2)$$

Figure 3. Similarity coefficients by Yin and Yasuda (2006)

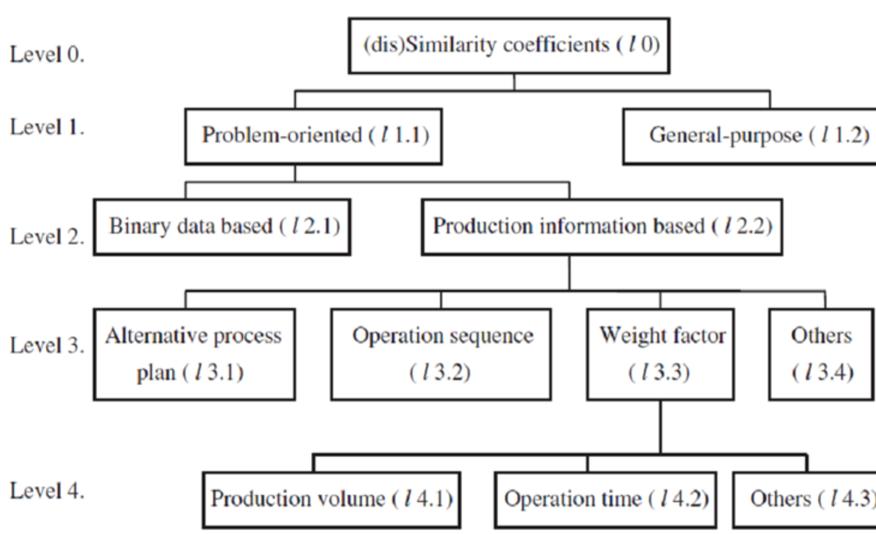

Table 1. General purpose similarity indices

Code	Coefficient	Range	S_{ij}
B	Baroni-Urbani and Buser	0–1	$[a+(ad)^{1/2}]/[a+b+c+(ad)^{1/2}]$
H	Hamann	-1 to 1	[(a+d)-(b+c)]/[(a+d)+(b+c)]
J	Jaccard	0–1	a/(a+b+c)
O	Ochiai	0–1	$a/[(a+b)(a+c)^{1/2}]$
R	Rogers and Tanimoto	0–1	(a+d)/[a+2(b+c)+d]
RM	Sarker and Islam (Relative matching)	-1 to 1	$[a+(ad)^{1/2}]/[a+b+c+d+(ad)^{1/2}]$
SK	Sokal and Sneath	0–1	2(a+d)/[2(a+d)+b+c]
SO	Sorenson	0–1	2a/(2a+b+c)
SI	Sokal and Michener (Simple matching)	0-1	(a+d)/(a+b+c+d)
RR	Russel and Rao	0-1	a/(a+b+c+d)

Problem oriented similarity coefficients can be classified into binary data based (*l*2.1 in Figure 3) and production information based (*l*2.2) similarity coefficients. The similarity coefficients at the level *l*2.1 only consider assignment information (a part need or need not a machine). Yin and Yamada (2006) present a list of binary data problem oriented indices. The level 3 (*l*3), see Figure 3, introduces different manufacturing factors for cell formation, e.g. machine requirement, machine setup, utilization, workload, alternative routings, machine capacities, operation sequences, set-up cost and cell layout. Finally level 4 (*l*4) introduces different weights for the evaluation of weighted similarity coefficients in order to adjust the strength of matches or misses between objects pairs to reflect the resemblance value more realistically (Yin and Yamada, 2006).

A few examples of problem oriented measures are reported below and are based on the following basic assumptions: n is the number of parts, $k=1,\ldots,n$ the generic part, m the number of machines and $i,j = 1,\ldots, m$ the generic machine (Alhourani and Seifoddini 2007). Then:

$$x_{ijk} = \begin{cases} 1 \text{ if part } k \text{ visits both machine } i \text{ and machine } j \\ 0 \end{cases}$$

$$y_{ijk} = \begin{cases} 1 \text{ if part } k \text{ visits either machine } i \text{ or machine } j \\ 0 \end{cases}$$

- S - Seifoddini (1987). He modifies the Jaccard's coefficient incorporating the production volume as follows:

$$S_{ij} = \frac{\sum_{k=1}^{n} x_{ijk} \cdot m_k}{\sum_{k=1}^{n} y_{ijk} \cdot m_k + \sum_{k=1}^{n} x_{ijk} \cdot m_k} \qquad (3)$$

where m_k planned production volume during a predefined period of time for part type *k.*

- GS - Gupta and Seifoddini (1990). They extend the Jaccard's similarity coefficient to incorporate the effect of the operational time, operational sequence and production volume. The proposed index is:

$$S_{ij} = \frac{\sum_{k=1}^{n} (x_{ijk} \cdot T_{ijk} + \sum_{o=1}^{n_k} z_{ko}) \cdot m_k}{\sum_{k=1}^{n} (x_{ijk} \cdot T_{ijk} + \sum_{o=1}^{n_k} z_{ko} + y_{ijk}) \cdot m_k} \qquad (4)$$

where n_k number of times the part type *k* visits both machines in row, i.e. sequentially

$$z_{ko} = \begin{cases} 1 \text{ if part } k \text{ visits both machines } i \text{ and } j \text{ in row} \\ 0 \end{cases}$$

$$T_{ijk} = \frac{\min\left\{T_{ik}, T_{jk}\right\}}{\max\left\{T_{ik}, T_{jk}\right\}} \quad (5)$$

T_{ik} global time spent by part type *k* on machine *i*

T_{jk} global time spent by part type *k* on machine *j*.

- SH - Seifoddini and Hsu (1994). They propose a weighted similarity coefficient with the aim of eliminating *improper machine assignment* by giving a higher weight to components having common operations on both the machines.

$$S_{i,j} = \frac{\sum_{k=1}^{n} f_{bk} \cdot x_{ijk}}{\sum_{k=1}^{n} f_{bk} \cdot x_{ijk} + \sum_{k=1}^{n} f_{ek} \cdot y_{ijk}} \quad (6)$$

where

f_{bk} weighting factor for parts visiting both machines *i* and *j*

f_{ek} weighting factor for parts visiting either machine *i* or *j* but not both.

In the numerical example and experimental analysis illustrated below, the adopted value of f_{bk} and f_{ek} are respectively 0.6 and 0.4.

- N - Nair and Narendran (1998).They propose a similarity measure as the ratio of the sum of the movements common to the machines *i* and *l*, and the sum of the total number of movements to and from machines *i* and *l*.

$$s_{il} = \frac{c_i + c_l}{t_i + t_l} \quad (7)$$

$$t_i = \sum_{j=1}^{n} \sum_{p=1}^{n_{ji}} w_j t_{jip} \quad (8)$$

$$c_{il} = \sum_{j=1}^{n} \sum_{p=1}^{n_{jil}} w_j c_{jilp} \quad (9)$$

where

m number of machines

n number of parts

n_{ji} number of times part *j* visits the *i*th machine

n_{jil} number of times part *j* visits the *i*th and *j*th machine

b_{jip} operation sequence number if the part *j* visits machine *i* for *p*th time ($0 \le p \le n_{ji}$); zero otherwise

b_{jlp} operation sequence number if the part *j* visits machine l for *p*th time ($0 \le p \le n_{ji}$); zero otherwise

r_j maximum number of operations for part *j*

$$t_{jip} = \begin{cases} 0 \ \text{if} \ b_{jip} = 0 \\ 1 \ \text{if} \ b_{jip} = 1 \ \text{or} \ r_j \\ 2 \text{ otherwise} \end{cases}$$
$$c_{jilp} = \begin{cases} 0 \ \text{if} \ b_{jip} = 0 \ \text{or} \ b_{jlp} = 0 \\ 1 \ \text{if} \ b_{jip} = 1 \ \text{or} \ r_j \\ 2 \text{ otherwise} \end{cases} \quad (10)$$

Equation (8) accounts for the total number of movements to and from the machine *i*. Equation (9) quantifies the total number of movements to and from machine *i* made by all parts that visit both machine *i* and machine *l*.

Step 3: Clustering Analysis and Manufacturing Cells Formation

The Clustering step deals with the grouping of machines into different homogeneous clusters so that machines in each cluster have high values of correlation. The clustering analysis is supported by the application of a grouping algorithm, which is a hierarchical heuristic for the partitioning of machines into disjunctive cells. There are usually substantial differences between the machine groups obtained by clustering, but the individuals within an individual machine group are similar because they are similarly visited by different parts/components. The clustering process is generally supported by one of the following well known hierarchical algorithms (Mosier 1989): Complete Linkage Method (CLINK) also known as farthest neighbor (fn) clustering, Single Linkage Method (SLINK) also known as nearest neighbor (*nn*) clustering, Unweighted Pair-Group Method using Arithmetic Average (UPGMA), Weighted Pair-Group Method using Arithmetic Average (Average Linkage), and Unweighted Pair-Group Method using Centroid (UPGMC).

In particular, the authors (of this chapter) choose to illustrate the *fn* clustering and the *nn* clustering algorithm (Aldenderfer and Blashfield, 1984). The generic algorithm is based on a scheme that erases rows and columns in a similarity matrix *S* that collects the values of similarity for each couple of items, as old clusters are merged into new ones by the degradation of the level of similarity within each under construction cluster. The similarity matrix *S* (dimension $N x N$) contains all the correlations among the machines $s(i,j)$, calculated as described in the previous step. To the clusterings are assigned sequence numbers $0, 1, \ldots, (n-1)$, and $L(k)$ is the level of similarity of the *k-th* clustering. A cluster with sequence number *m* is denoted *(m)* and the correlation between clusters *(r)* and *(s)* is denoted $s[(r),(s)]$. In particular, the *nn* algorithm is composed of the following steps:

1. Begin with the disjoint clustering having level $L(0) = 1$ and sequence number $m = 0$.
2. Find the least dissimilar pair of clusters in the current clustering, say pair *(r)* and *(s)*, according to:

$$s\left[\left(r\right),\left(s\right)\right] = \max_{i,j}\left\{s\left[\left(i\right),\left(j\right)\right]\right\} \tag{11}$$

where the maximum is over all pairs of clusters in the current clustering.

3. Increment the sequence number: $m = m + 1$. Merge the groups of items *(r)* and *(s)* into a single cluster to form the next clustering *m*. Set the level of this clustering to:

$$L(m)=s[(r),(s)] \tag{12}$$

4. Update the similarity matrix *S* by deleting the rows and columns corresponding to clusters *(r)* and *(s)* and adding a row and column corresponding to the newly formed cluster. The level of correlation between the new cluster, denoted *(r,s)* and the old generic cluster *(k)* is defined as:

$$s[(k), (r,s)] = \max \{s[(k),(r)], s[(k),(s)]\} \tag{13}$$

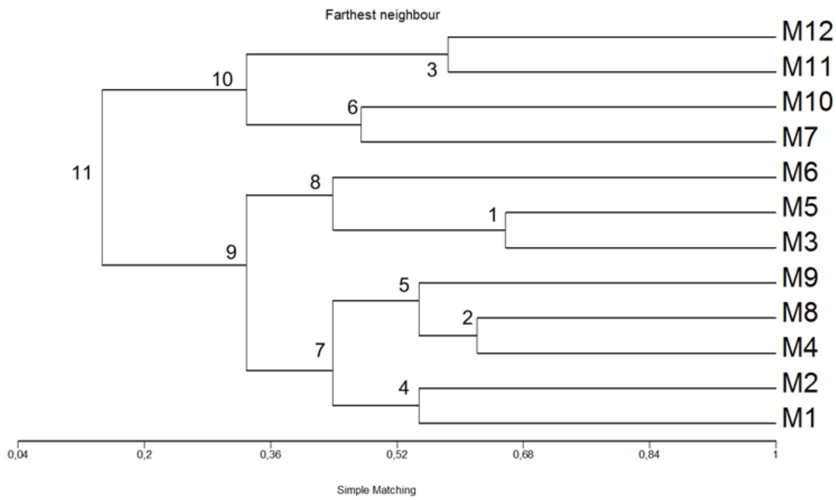
If all the machines are in one cluster, stop. Else, go to point 2.

The *fn* algorithm is based on the same scheme and equation (13) in point 4 is modified as follows:

$$s[(k), (r,s)] = \min \{s[(k),(r)], s[(k),(s)]\} \tag{14}$$

The dendrogram is the graphical representation of the process of degradation of the similarity level as the result of the grouping process executed by the clustering algorithm (Sokal and Sneath 1968, McAuley 1972). Figure 4 exemplifies a dendrogram generated by the execution of the clustering process to an instance of example.

Figure 4. Dendrogram: Simple Matching and farthest neighbour, [1-11] nodes



As a consequence the generic algorithm classifies the machines on the basis of the similarity of the manufacturing characteristics and hierarchically executes aggregations of machines into clusters reducing progressively the level of similarity, i.e. homogeneity, within the under construction heterogeneous clusters.

The result of the clustering process does not only depend on the rule adopting for grouping but also on the threshold level of similarity adopted for grouping, i.e. the minimal admissible value of similarity within the generic cluster as discussed by Manzini et al. (2010). In particular, they demonstrate that a best performing percentile based level of threshold similarity exists to optimize the cell formation process in presence of general purpose similarity metrics. The percentile based threshold value is a range of group similarity measurements which cuts the dendrogram at the percentile number of aggregations identified by the clustering rule, as follows:

$$T\_value_{\%_p} \in \left]simil\left\{\left\lfloor \%_p \times N_{nodes} \right\rfloor\right\}, simil\left\{\left\lceil \%_p \times N_{nodes} \right\rceil\right\}\right[\quad (15)$$

where

$\%_p$ percentile of aggregations, expressed as a percentage

N_{nodes} number of nodes generated by the clustering algorithm

Simil$\{N\}$ similarity value which corresponds to the node *N*.

The basic idea of this criterion is properly illustrated by the example discussed in Section 5. Figure 4 presents a dendrogram generated by the application of clustering analysis. *m1,..,m12* are the identifications of machine items. The number within the diagram (1,..,12) identify the aggregations (called nodes) ordered in agreement with the similarity measurements. In particular, low numbers identify aggregations between under construction clusters characterized by a high level of similarity (very similar clusters). Table 5 reports the list and configuration of nodes as generated by the application of the clustering algorithm in agreement with Figure 4. Assuming the 80° percentile of aggregation (i.e. $\%_p=0.80$) as follows (see Equation (15)):

$$T\_value_{80°} \in \left]simil\left\{\left\lceil 0.80 \times 12 \right\rceil\right\}, simil\left\{\left\lfloor 0.80 \times 12 \right\rfloor\right\}\right[= \\ = \left]simil\left\{10\right\}, simil\left\{9\right\}\right[= \left]0.329,\ 0.329\right[= 0.329$$

Similarly, for a percentile value of 20° (i.e. $\%_p = 0.20$):

$$T\_value_{20°} \in \left]simil\left\{\left\lceil 0.2 \times 12 \right\rceil\right\}, simil\left\{\left\lfloor 0.2 \times 12 \right\rfloor\right\}\right[= \\ = \left]simil\left\{3\right\}, simil\left\{2\right\}\right[= \left]0.585,\ 0.622\right[$$

Step 4: Part Families Formation

Given a generic solution for cells, a part may have to visit more than one group of machines before it is completed. Consequently, the generic part has to be assigned to the manufacturing cell with the minimum number of inter-group journeys. Another way of reducing the number of inter-group journeys is to duplicate machines, but it can be very expensive in terms of space and monetary costs.

Part families can be formed concurrently with the cell/group machine formation (CF steps illustrated above), or otherwise executed after the cells have been defined. In particular, the second of these hypotheses is adopted in this paper, and in particular a hierarchical heuristic rule is applied to assign parts to manufacturing cells. The main steps are:

- Given a configuration of the disjunctive groups of machines (i.e. manufacturing cells) name them as $c=1,..,C$. Then quantify the following measurements for each part *i* and each manufacturing cell *c* in accordance with the working cycle of part *i*:
    - number of intra-cell movements: ICM_{ic};
    - number of tasks executed in the cell: $NTask_{ic}$;
    - processing time of *i* in *c*: $Time_{ic}$.
- Assign part *i* to cell *c** where:

$$ICM_{ic^*} > \max_{\substack{c=1,..,C \\ c \neq c^*}} \left\{ICM_{ic}\right\} \qquad (16)$$

If *c** does not exist than GO to STEP III.

- Assign part *i* to cell *c'* shown in Equation 17 (Box 1). If *c'* does not exist than GO to STEP IV.
- Assign part *i* to cell *c''* shown in Equation 18 (Box 1). If c'' does not exist than assign part *i* randomly to a cell in the last equation shown in Box 1.

Box 1.

$$NTask_{ic'} > \max_{\substack{c=1,..,C \\ c \neq c'}} \left\{ NTask_{ic} : ICM_{ic} = \max_{\substack{c^*=1,..,C \\ c^* \neq c}} \left\{ICM_{ic^*}\right\} \right\} \qquad (17)$$

$$Time_{ic''} > \max_{\substack{c=1,..,C \\ c \neq c''}} \left\{ Time_{ic} : ICM_{ic} = \max_{\substack{c^*=1,..,C \\ c^* \neq c}} \left\{ICM_{ic^*}\right\} \wedge NTask_{ic} = \max_{\substack{c'=1,..,C \\ c' \neq c}} \left\{Ntask_{ic'}\right\} \right\} \qquad (18)$$

$$\left\{ c = 1,\dots,C : ICM_{ic} = \max_{\substack{c^*=1,..,C \\ c^* \neq c}} \left\{ICM_{ic^*}\right\} \wedge NTask_{ic} = \max_{\substack{c'=1,..,C \\ c' \neq c}} \left\{NTask_{ic'}\right\} \wedge Time_{ic} = \max_{\substack{c''=1,..,C \\ c'' \neq c}} \left\{Time_{ic''}\right\} \right\}$$

A result of the assignment of parts to the manufacturing cells is the so-called *block-diagonal incidence matrix* shown in Figure 5 as the result of the application of the proposed procedure to the instance illustrated in Section 5.

Step 5: Plant Layout Configuration

This step deals with the determination of the location of each manufacturing resource (machines and human resources) in the production area. Layout decisions are significantly influenced by the configuration of cells and part families in CM systems, but they are omitted in this chapter. Nevertheless a few significant performance measures on layout results are quantified as clearly explained below.

CLUSTERING PERFORMANCE EVALUATION

Sarker (2001) presents, discusses, and compares the most notable measurements of grouping efficiency in CM. The measurements adopted in the following illustrated experimental analysis are based on the following definitions:

- *lock*. This is a submatrix of the machine-part matrix composed of rows representing a part family and columns representing the related machine cell.
- *Void*. This is a "zero" element appearing in a diagonal block (see Figure 4).
- *Exceptional element*. This is a "one" appearing in off-diagonal blocks (see Figure 4). The exceptional element causes inter-cell movements.

A set of CM measurements of performance quantified in the proposed experimental analysis is now reported and discussed. (high) and (low) labels refer to the expected values for best performing the CF and CM.

Problem Density: PD

$$PD = \frac{\text{number of "ones" in the incidence matrix}}{\text{number of elements in the incidence matrix}} \tag{19}$$

Global Inside cells density: ICD (high)

$$ICD = \frac{\text{number of "ones" in diagonal blocks}}{\text{number of elements in diagonal blocks}} \tag{20}$$

Figure 5. Block-diagonal matrix. Simple matching, farthest neighbour.& 75° percentile.

	p11	p12	p16	p17	p5	p6	p13	p14	p15	p18	p19	p9	p10	p1	p2	p3	p4	p7	p8

m5												1							1
Cell 4																			
m1					1									1	1	1	1		
m2															1	1			1
m9					1	1						1		1		1	1	1	1
m4												1	1	1	1	1	1	1	1
m8						1						1	1	1	1	1		1	1

Exceptional elements: EE (low)

EE = Number of exceptional elements in the off-diagonal blocks (21)

Ratio of non-zero elements in cells: REC

$$REC = \frac{\text{total number of "ones"}}{\text{number of elements in diagonal blocks}} \quad (22)$$

Grouping Efficiency: η (Sarker 2001) (high)

It is a weighted average of two functions and it is defined as:

$$\eta = q\eta_1 + (1-q)\eta_2$$
$$\eta_1 = \frac{e_d}{\sum_{r=1}^{k} M_r N_r} \quad (23)$$
$$\eta_2 = 1 - \frac{e_o}{mn - \sum_{r=1}^{k} M_r N_r}$$

where

e_d number of 1s in the diagonal blocks
e_o number of 1s in the off-diagonal blocks
k number of diagonal blocks
M_r number of machines in the *r*th cell
N_r number of components in the *r*th part-family
q weighting factor (0≤q≤1) that fixes the relative importance between voids and inter-cell movements. If q=0.5 both get the same importance: this is the value adopted in the numerical example and in the experimental analysis illustrated in sections 5 and 6.

Quality Index: QI (Seifoddini and Djassemi 1994, 1996) (high)

It is a measure of independence of machine-component groups. High values of QI are expected in presence of high independency. QI is defined as:

$$QI = 1 - \frac{ICW}{PW} \quad (24)$$

where

ICW total intercellular workload
PW total plant workload.
ICW and PW can be defined as:

$$ICW = \sum_{c=1}^{C}\sum_{i=1}^{m}\left[Y_{ic}\left(\sum_{k=1}^{n}(1-Z_{kc})X_{ik}m_k T_{ik}\right)\right] \quad (25)$$

$$PW = \sum_{i=1}^{m}\sum_{k=1}^{n} X_{ik} m_k T_{ik} \quad (26)$$

where *n* is the number of parts, *k=1,…,n* the generic part, *m* the number of machines and *i,j=1,…,m* the generic machine. This is the notation previously introduced

$$Y_{ic} = \begin{cases} 1 \text{ if machine } i \text{ is assigned to cell } c \\ 0 \text{ otherwiswe} \end{cases}$$
$$Z_{kc} = \begin{cases} 1 \text{ if part } k \text{ is assigned to cell } c \\ 0 \text{ otherwiswe} \end{cases}$$
$$X_{ki} = \begin{cases} 1 \text{ if part } k \text{ has operation on machine } i \\ 0 \text{ otherwiswe} \end{cases}$$

m_k volume of part *k*
T_{ki} processing time of part *k* on machine *i*

QI measures the number of intracellular movements which ask to be maximized minimizing intercellular ones.

Now the authors introduce a new grouping efficiency based on QI as previously defined.

Grouping Efficiency based on QI: ηQI (high)

$$\eta_{QI}=q\eta_1+(1-q)QI \tag{27}$$

The adopted value of weighting factor *q* is:

$$q=\frac{\sum_{r=1}^{k}M_rN_r}{mn} \tag{28}$$

Grouping Efficacy: τ (Kumar and Chandrasekharan 1990) (high)

Group efficacy can be quantified by the application of the following equation:

$$\tau=\frac{e-e_0}{e+e_v} \tag{29}$$

where

e total number of "ones" in the matrix (i.e. the total number of operations)

$e_0=EE$ number of exceptional elements (number of "ones" in the off-diagonal blocks)

e_v number of voids (number of "zeros" in the diagonal blocks).

Grouping measure: ηG (Miltenburg and Zhang 1991) (high)

It gives higher values if both the number of voids and exceptional elements are fewer, and it is defined as:

$$\begin{aligned}\eta_g&=\eta_u-\eta_m\\ \eta_u&=\frac{e_1}{e_1+e_v}\\ \eta_m&=\frac{e_o}{e}\end{aligned} \tag{30}$$

where

η_u ratio of the number of 1s to the number of total elements in the diagonal block (this is the inside cell density - ICD)

η_m ratio of exceptional elements to the total number of 1s in the matrix

e_1 number of 1s in the diagonal block.

Group technology efficiency: GTE (Nair and Narendran 1998) (high)

It is defined as the ratio of the difference between the maximum number of inter-cell travels possible and the number of inter-cell travels actually required to the maximum number of inter-cell possible:

$$\begin{aligned}GTE&=\frac{I-U}{I}\\ I&=\sum_{j=1}^{n}(r_j-1)\\ U&=\sum_{j=1}^{n}\sum_{s=1}^{r_j-1}xl_{js}\end{aligned} \tag{31}$$

where

I maximum number of inter-cell travels

U number of inter-cell movements required by the system

r_j maximum number of operations for component j

$$xl_{js}=\begin{cases}0 \text{ if operations } s,\ s+1 \text{ are performed in the same cell}\\ 1 \text{ otherwise}\end{cases}$$

Bond efficiency: BE (high)

This is an important index because depends on both the within-cell compactness (by the ICD) and the minimization of inter-cell movements by the GTE. It is defined as:

$$BE = q \cdot IDC + (1-q) \cdot GTE \quad (32)$$

The adopted value of weight q in the experimental analysis is 0.5.

NUMERICAL EXAMPLE

This section presents a numerical example which relates to a problem oriented instance presented by De Witte (1980) and made of 19 parts and 12 machines. Manufacturing input data are reported in Table 2.

Table 3 reports the *12x19 machine-part* incidence matrix useful for the evaluation of a general purpose similarity index.

A General Purpose Evaluation

This section presents the results obtained by the application of a general purpose similarity index in cluster analysis for the cell formation problem.

Table 4 reports the result of the evaluation of the general purpose index known as Simple Matching (SI) and defined in Table 1. Figure 4 shows the dendrogram generated by the application of the fn combined with the SI similarity coefficient. In particular a sequence of numbers is explicitly reported in figure for each node of the diagram. The generic node corresponds to a specific aggregation ordered in agreement with the similarity metric and the adopted hierarchical rule. The list of nodes and aggregations, the related values of similarity, and the number of objects per group are also reported in Table 5. The obtained number of nodes is 11.

Now it is possible to define a partitioning of the available set of machines by the identification of a cut value, the so called "cutting threshold similarity value". The adopted level of homogeneity within the generic cluster is the percentile-based threshold measure discussed in Section 3.

Given the dendrogram in Figure 4 and assuming a threshold percentile cut value equal to 20°, the corresponding range of similarity is (0.585, 0.622) as demonstrated in Section 3. The obtained configuration of the manufacturing cells (nine different cells are obtained) is:

Cell 1 (single machine): M12
*Cell 2 (*single *machine): M11*

In case a cut value corresponds to one or more nodes generated by the hierarchical process of aggregation, it is possible to include (exclude) the node in the formation of cells. In particular, assuming a level of threshold similarity equal to 80°, two alternative configurations can be obtained as the result of inclusion/exclusion of one or more nodes of the dendrogram located in correspondence of the cutting level:

Case 1: Including node 10 and node 9

Cell 1 (four machines): M12, M11, M10 and M7
Cell 2 (eight machines): M6, M5, M3, M9, M8, M4, M2, M1.

Case 2: Not including node 10 and node 9
Cell 1 (two machines): M12, M11
Cell 2 (two machines): M10, M7
Cell 3 (3 machines): M6, M5, M3
Cell 4 (5 machines): M9, M8, M4, M2, M1.

The second column in Table 8 reports the obtained values of the performance evaluation for the case study object of this numerical example adopting the Simple Matching similarity index, the fn heuristic, and the cutting threshold percentile value equal to 75°.

A Problem Oriented Evaluation

Table 6 reports the result of the evaluation of the problem oriented similarity coefficient as proposed by Nair and Narendran (1998). Figure 6 shows the dendrogram as the result of the application of the fn clustering rule. The generic node of the dendrogram corresponds to a specific aggregation ordered in agreement with the adopted similarity metric and the adopted hierarchical rule. The list of nodes and aggregations, the related values of similarity, and the number of objects in group are also reported in Table 7 as the result of the application of the fn rule and Nair and Narendran (1998) problem oriented similarity coefficient. The obtained number of nodes is 11.

Figure 6 reports the dendrogram obtained by the application of the fn clustering heuristic rule and the "Nair and Narendran" problem oriented similarity coefficient to the literature instance of interest.

Grouping Efficiency QI [%]	n_{QI}	68.8	72.8
Group Technology Efficiency [%]	GTE	61.9	45.5
Bond Efficiency [%]	BE	66.2	66.1
Group Efficacy [%]	τ	82.9	84.5
Grouping measure	n_G	0.438	0.468

The third column in Table 8 reports the obtained values of the performance evaluation for the case study object of this numerical example adopting the “Nair and Narendran” similarity index, the fn heuristic, and the cutting threshold percentile value equal to 75°.

Which is the best similarity index? It is not correct to try to reply to this question as is, because previous sections demonstrate that there are different factors affecting the performance of the system configuration: the similarity index, the clustering rule, the threshold cutting value of similarity, and the part assignment rule. As a consequence it is useful to measure the simultaneous effects generated by different combinations of these critical factors. Next section presents an experimental analysis conducted on the instance proposed by De Witte (1980) comparing the performance obtained adopting general purpose and problem oriented similarity metrics.

EXPERIMENTAL ANALYSIS

This section presents the results obtained by the application of the proposed systematic procedure to cell formation and parts assignment to cells (*part family formation*), as the result of different settings of the similarity and hierarchical procedure as illustrated in previous sections. This what-if analysis is applied to the problem oriented instance introduced by De Witte (1980) and reported in Table 2. This analysis represents the first step to identify the best combination of

Table 9. What-if analysis, factors and levels

	general purpouse	problem oriented
Similarity Coefficient	J, SI, H, B, SO, R, SK, O, RM, RR	S, GS, SH (f_{bk}=0.6;f_{ek}=0.4), N
Rule	CLINK, ALINK, SLINK

values, called *levels*, for the parameters, called *factors*, of the decision problem.

Table 9 reports the adopted levels for each factor in the experimental analysis.

Figures 8 to 10 present the *main effects plot* (Minitab ® Statistical Software Inc.) for the following performance indices: η_G, called η(G) in figures, τ, BE.

Similarity indices perform in a different way in terms of η_G, τ, BE. In particular problem oriented (PO) perform better than general purpose (GP). Clink rule and percentile threshold value equal to 50° (or 75°) seem to be the best levels to set the clustering algorithm. The best performing indices are Seiffoddini - S (1987) and Nair and Narendran - N (1998).

Figure 8. Main effects plot for grouping measure

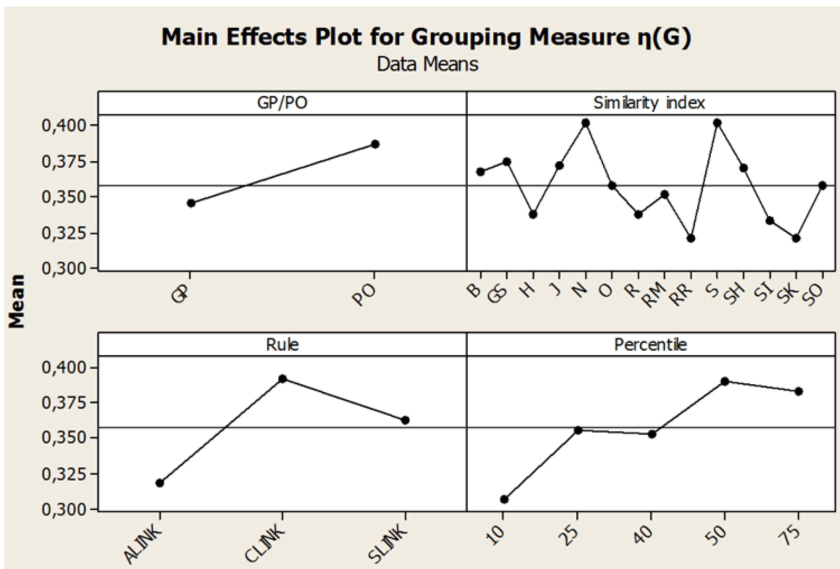

Figure 9. Main effects plot for grouping efficacy

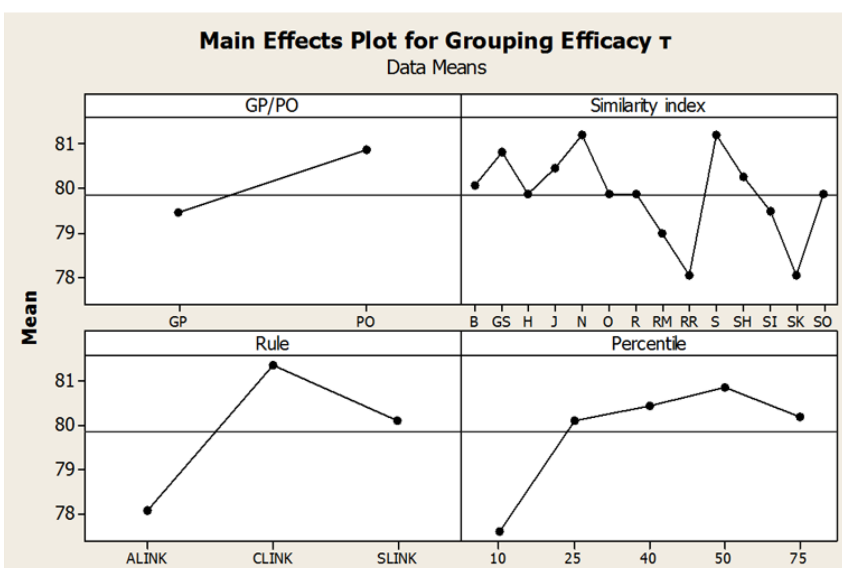

Figure 10. Main effects plot for bond efficiency

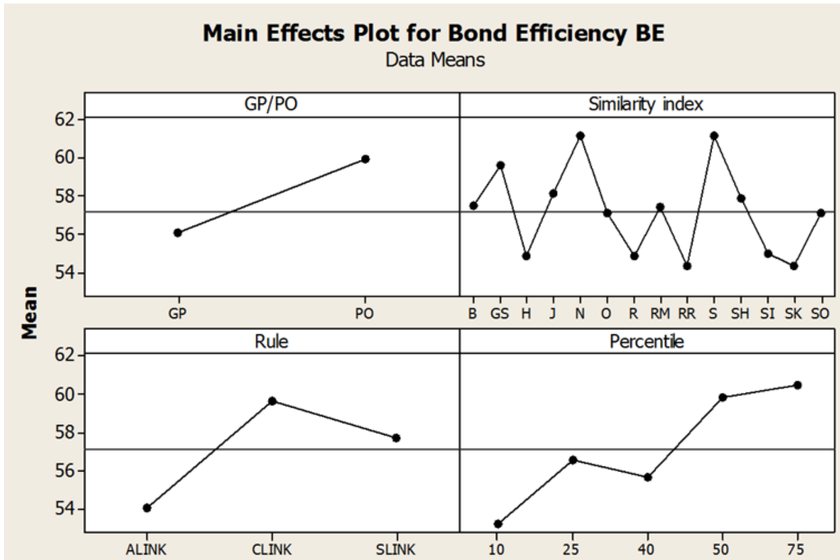

Figure 11 shows that the number of exceptional elements significantly depends on the adopted threshold value of group similarity, but the adopted similarity index is not important.

η_{QI}, called η(QI) in Figure 12, has an anomalous trend if compared with previous graphs.

Figure 13 shows the trend of the EE for different values of couples of factors, and the importance of the percentile threshold value of group similarity.

Similarly, Figure 14 shows the importance of threshold value of similarity and clink rule for grouping items.

Figure 11. Main effects plot for exceptional elements

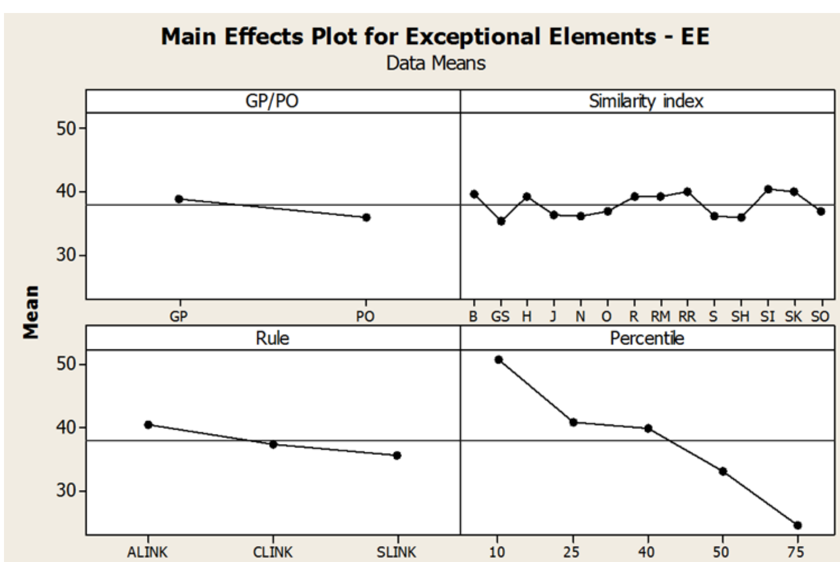

Figure 12. Main effects plot for grouping efficacy based on QI

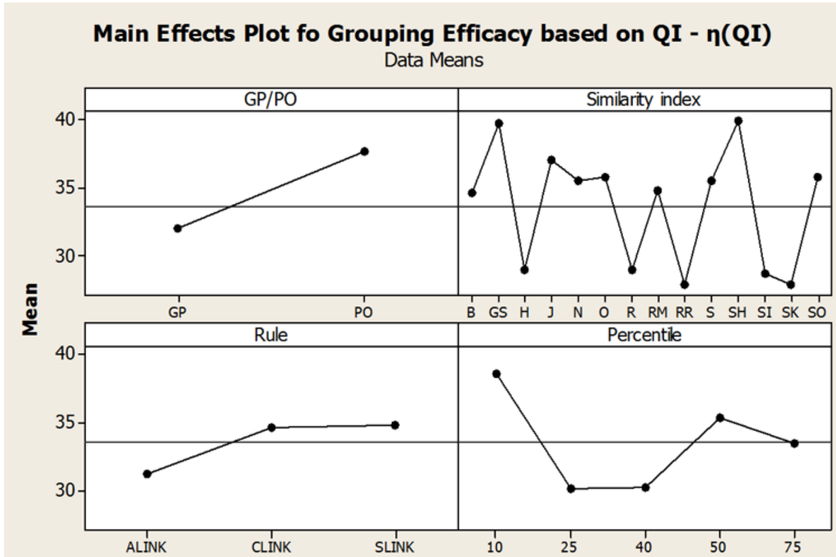

CONCLUSION AND FURTHER RESEARCH

This chapter illustrates the CFP as supported by the similarity based manufacturing clustering, and a hierarchical and systematic procedure for supporting managers in the configuration of cellular manufacturing systems by the application of cluster analysis and similarity indices. In particular, both general purpose and problem oriented indices are illustrated and applied. The experimental analysis conducted on a literature problem oriented case study represents the first basis for the identification of the best setting of the cell formation problem and supporting decision models and tools.

Figure 13. Exceptional elements for couples of factors

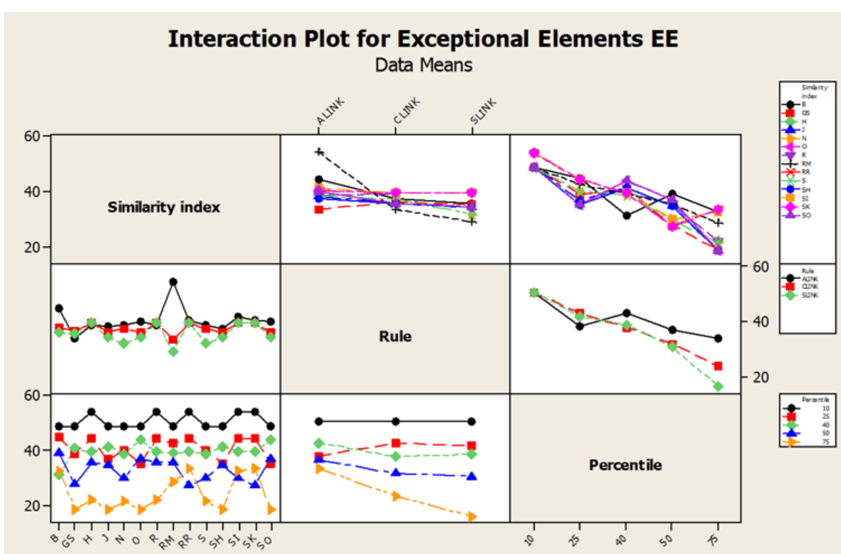

Figure 14. Interaction plot for τ

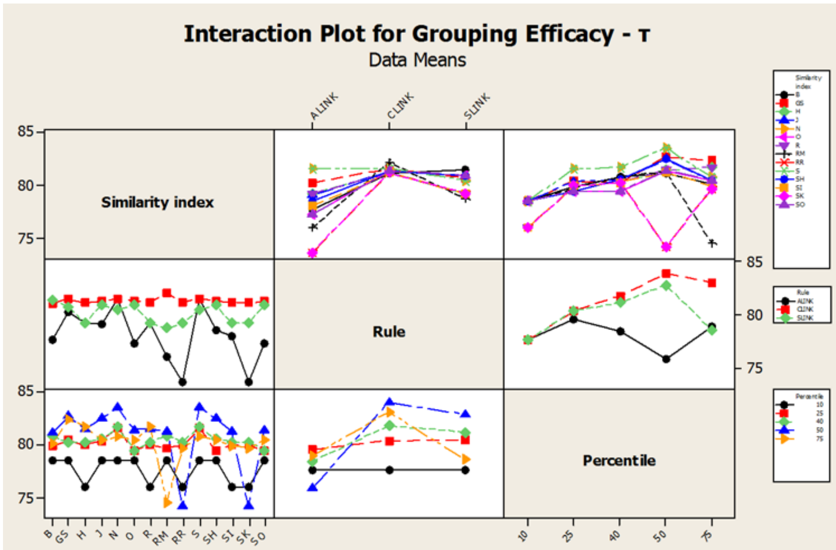

For the first time, this chapter successfully applies the threshold group similarity index to problem oriented similarity environment. The threshold value was introduced by the authors in a previous study on general purpose indices evaluation (Manzini et al. 2010).

This chapter confirms the importance of this threshold cut value for the dendrogram when it is explained in percentile on the number of nodes.

Further research is expected to improve the experimental analysis including more case studies and applications. Finally it is important to improve the critical process of part family formation and the decisions regarding the duplication of machines and resources in different manufacturing cells in order to minimize intercellular flows.

Chapter 30
Performance Comparison of Cellular Manufacturing Configurations in Different Demand Profiles

Paolo Renna
University of Basilicata, Italy

Michele Ambrico
University of Basilicata, Italy

ABSTRACT

Cellular manufacturing systems (CMSs) are an effective response in the economic environment characterized by high variability of market. The aim of this chapter is to compare different configurations of cellular models through the main performance. These configurations are fractal CMS (defined FCMS) and cellular systems with remainder cells (defined RCMS), compared to classical CMS used as a benchmark. FCMSs consist of a cellular system characterized by identical cells each capable of producing all types of parts. RCMSs consist of a classical CMS with an additional cell (remainder cell) that in specific conditions is able to perform all the technological operations. A simulation environment based on Rockwell ARENA® has been developed to compare different configurations assuming a constant mix of demand and different congestion levels. The simulation results show that RCMSs can be a competitive alternative to traditional cells developing opportune methodologies to control the loading of the cells.

INTRODUCTION

Competitiveness in today's market is much more intense compared to the past decades. Considerable resources are invested on facilities planning and re-planning in order to adapt the manufacturing systems to the market changes. A well-established manufacturing philosophy is the group technology concept.

Group technology (GT) can be defined as a manufacturing philosophy identifying similar parts and grouping them together to take advantage

DOI: 10.4018/978-1-4666-1945-6.ch030

of their similarities in manufacturing and design (Selim et al.,1998). It is the basis of so-called cellular manufacturing systems (CMSs). In current production scenario demand for products is characterized by continuous fluctuations in terms of volumes, type of product (part mix), new products introduction and the life cycle of products has significantly reduced. The planning horizon needs to be divided into smaller horizons (time bucket) and the length of each period is related to the characteristics of products. These characteristics need to be considered in design process of a manufacturing system. Introduction of Cellular Manufacturing Systems has already introduced significant improvements. They are conceived with the aim of reducing costs such as setup costs or handling costs and also to reduce lead time and work in process (WIP). They combine advantages of flow shop and job shop, but a further step can be accomplished to be competitive in the market. They allow significant improvements such as: product quality, worker satisfaction, space utilization. Benefits and disadvantages (Irani et al.,1999) are showed in Table 1. They documented that companies implementing cellular manufacturing have a very high probability of obtaining improvements in various areas.

The first column of Table 1 shows the case studies with improvements and the second column reports the percentage of improvement of the measures. Similarly, the third column shows the percentage of cases with worsening and in the fourth column is evidenced the rate of deterioration.

The demand volatility and continuous new product introduction lead to re-configure several times the cellular manufacturing systems in order to keep a high level of performance.

For the above reasons, new configurations have been proposed in literature such as Virtual Cell Manufacturing System (VCMS), Fractal Cell Manufacturing System (FCMS), Dynamic Cell Manufacturing System (DCMS), with the aim of keeping high flexibility of manufacturing systems.

The concept of DCMS was introduced for the first time by Rehault et al. (1995). It provides a physical reconfiguration of the cells. The reconfiguration activity can be periodic or resulting from the variation of performance parameters. Reconfigure can mean duplicating machines,

Table 1. Benefits and disadvantages of CMS

Measure	Percentage cases with improvements	Average percentage improvement	Percentage cases with worsening	Average percentage worsening
Tooling cost	31%	-10%	69%	+17%
Labor cost	91%	-33%	9%	+25%
Setup Time	84%	-53%	16%	+32%

WIP inventory	87%	-58%	13%	+20%
Labor turnover/absenteeism	100%	-50%	0	-
Variable production cost	93%	-18%	7%	+10%

relocating machines between cells, removing machines, or also subcontracting some parts to other companies. These problems must be addressed by the decision maker.

The concept of VCMS requires that the machines are dedicated to a part family but these machines are not necessarily close together in a classical cell. One machine can belong simultaneously to different cells. Hence sharing of machine makes the system more flexible. Moreover the machines are not shifted as dynamic cellular system therefore costs of reallocation are eliminated. On the other hand we must consider the increase in the movements of parts (or batches) across machines. A further problem may be the complication in the measurement of performance of the cells. This is because monitoring stations are usually located out of the cell, but in this case the cell does not exist physically.

The FCMSs are based on the constructions of identical cells and they are not built for different families. The idea comes from Skinner (1974) and that is to build factory within a factory with duplication of processes. Each cell can work all products. Working time will be greater but these configurations are very effective if there are changes in part mix and in cases of machine breakdowns. Even if for example there are flash orders.

A further idea was mentioned by Sripathy Maddisetty (2005). The author referred to so-called remainder cells and we can call them RCMSs. In addition to traditional cells refer to the product families you may create an additional cell that operates when conditions such as machine failures or overloaded machines occur. Focusing on an advanced design the RCMSs could provide interesting results in terms of competitiveness.

Our goal in this chapter is to compare the various approaches to the design of manufacturing systems, making a complete performance comparison. In particular we aimed to compare the following systems: CMSs, FCMSs and RCMSs. A simulation environment has been developed to compare the performance (WIP, Throughput Time, Tardiness, Throughput and Average Utilization) using as a benchmark the classic CMS. The aim is to evaluate the responses of different systems when market fluctuations occur in terms of arrival demand. The chapter is structured as follows. Section 2 provides an overview of the literature of various manufacturing system configurations, while in section 3 the system context is formulated. In section 4 there is a brief description of scheduling approaches. Section 5 presents the simulation environment and the case study while in section 6 are discussed simulation results. In Section 7 conclusions and future developments are discussed.

BACKGROUND

Recently, several authors have investigated the configuration of manufacturing cells in order to keep a high level of performance when the market conditions change.

Hachicha et al. (2007) proposed a simulation based methodology which takes into consideration the stochastic aspect in the CMS. They took into account the existence of exceptional elements between the parts and the effect of the correspondent inter-cell movements. They compared two strategies: permitting intercellular transfer and exceptional machine duplication. They used the simulation (Rockwell Arena) and they analyzed the following performance: mean transfer time, mean machining time, mean wait time, mean flow time. They assumed demand fixed and known for the parts. They did not consider failures of machines and maintenance policies.

A multi-objective dynamic cell formation was presented by Bajestani et al. (2007) where purpose was to minimize simultaneously total cell load variation and sum of miscellaneous costs (machine cost, inter-cell material handling cost, and machine relocation cost). Since the problem is *NP-hard* they used a scatter search approach for finding locally Pareto-optimal frontier.

Safei et al. (2007) proposed to use an approach based on fuzzy logic for the design of CMS under uncertain and dynamic conditions. They began by finding that in most of research related on DCMS input parameters were considered deterministic and certain. Therefore they introduced fuzzy logic as a tool for the expression of the uncertainty in design parameters such as part demand and available machine capacity.

Ahkioon et al. (2007) tried to investigate DCMS focusing on routing flexibility. They studied the creation of alternate contingency process routings in addition to alternate main process routings for all part types. Contingency routings had the function to provide continuity in case of exceptional events such as machine breakdowns but also flash orders. Furthermore their work provided discussions on the trade-off between the additional cost related to the formation of contingency routings and the advantages of increased flexibility. Linearized model proposed by the authors was solved with CPLEX.

Aryanezhad et al. (2008) developed a new model which simultaneously embrace dynamic cell formation and worker assignment problem. They focused on two separate components of cost: the machine based costs such as production costs, inter-cell material handling costs, machine costs and human related costs such as hiring costs, firing costs, training costs and wages. They made the comparison of two models. One considered the machine costs and the other considered both machine costs and human related costs. The model was *NP-hard* even though they did not consider learning curve.

Xiaoqing Wang et al. (2008) proposed a nonlinear multi-objective mathematical model in dynamic cells formation problem by giving weighing to three conflicting objectives: machine relocation costs, utilization rate of machine capacity, and total number of inter-cell moves over the planning horizon. A scatter search approach was developed to solve the nonlinear model. Results were compared with those obtained by CPLEX. They considered certain demand and they did not consider machine breakdowns.

Safei et al. (2009) proposed an integrated mathematical model of the multi-period cell formation and production planning in a dynamic cellular manufacturing system (DCMS). The focus was on the effect of the trade-off between production and outsourcing costs on the reconfiguration of the cells.

Balakrishnan (2005) discussed cellular manufacturing system under conditions of changing product demand. He made a conceptual comparison to virtual cell manufacturing and he discussed a case study.

Kesen et al. (2008) investigated three different types of system (cellular layout, process layout and virtual cells) by using simulation. They paid attention to the following performance: mean flow time and mean tardiness. Based on these simulations they used regression meta-models to estimate the systems behaviours. They only considered one family-based scheduling scheme and they did not consider extraordinary events such as machine failures.

Vakharia et al. (1999) proposed and validated analytical approximations for comparing the performance of virtual cells and multistage flow shops. First they used these approximations and hypothetical data to identify some key factors that influenced the implementation of virtual cells in a multistage flow shop environment. Then they concluded with an application of approximations to industrial data.

Kesen et al. (2009) examined the behaviours of VCMs, process layouts and cellular layouts. They addressed the VCMs by using family-based scheduling rule. The different systems were compared by simulation. Subsequently they developed an ant colony optimization based meta-models to reflect the system's behaviours.

Kesen et al. (2010) presented a genetic algorithm based heuristic approach for job scheduling in virtual manufacturing cells (VMCs). Cell configurations were made to optimize the scheduling objective under changing demand conditions. They considered the case with multiple jobs and different processing routes. It was considered multiple machine types with several identical machines in each type and they were located in different locations in the shop floor. The objective was to minimize the total travelling distance. To evaluate the effectiveness of the genetic algorithm heuristic they compared it with a mixed integer programming solution. Results showed that genetic algorithm was promising in finding good solutions in very shorter.

Uday Venkatadri et al.(1997) proposed a methodology for designing job shops under the fractal layout organization as an alternative to the more traditional function and product organizations. The challenge in assigning flow to workstation replicates was that flow assignment is in itself a layout dependent decision problem. They proposed an iterative algorithm that updated layouts depending on flow assignments, and flow assignments based on layouts. Their work has had the far-reaching consequence of demonstrating the validity of the fractal layout organization in manufacturing systems (FCMSs).

Montreuil (1999) developed a new fractal alternative for manufacturing job shops which allocated the total number of workstations for most processes equally across several fractal cells. He introduced fractal organization and he briefly discussed the process of implementing fractal designs. He illustrated a case example and he showed that system is characterized by great flexibility.

Maddisetty (2005) discussed the design cells in a probabilistic demand environment. He discussed idea of remainder cells (RCMS). A remainder cell is a kind of lung to cope in changes in demand. He examined the following performance: total WIP, average flow time, machine utilization. He proposed a comparison using three different approaches: mathematical, heuristic, and simulation.

Süer et al. (2010) proposed a new layered cellular manufacturing system to form dedicated, shared and remainder cells to deal with the probabilistic demand. Moreover they proposed a comparison of its performance with the classical cellular manufacturing system. Simulation and statistical analysis were performed to help identify the best design within and among both layered cellular design and classical cellular design. They observed that the average flow time and total WIP were not always the lowest when additional machines were used by the system, but the layered cellular system performed better when demand fluctuations was observed.

There are several limitations encountered in existing literature. In previous research the demand of products was usually determined at the beginning of each period and it was known. The change in part mix was rarely assumed. Frequently the bottleneck station in each cell was considered as fixed and independent of the type of the part. Almost never were held in account exceptional events such as machine failures and maintenance. Almost never flash orders was considered and similarly backorders. The concept of learning curve was rarely covered. Furthermore hardly researchers focused on a wide range of performance measures.

In this chapter the objective is to evaluate the reaction of different manufacturing systems configurations (CMSs, FCMSs and RCMSs) when there is a fluctuation in terms of arrival demand. The configurations are investigated considering the same machines for all cases; the machines are set in order to obtain the particular configuration. The analysis conducted allows to highlight the most promising configurations in terms of performance measures. Another objective of the chapter is to develop a simulation environment based on Rockwell Arena® tool in order to analyse the different configurations. The simulation allows build a model with minor simplification compared to mathematical models which require significant simplifications (linearization) in cases of complex systems. Moreover the dynamic model (demand not known a priori, unexpected events like machine breakdowns) cannot be obtained with mathematical models.

MANUFACTURING SYSTEM CONTEXT

The mentioned objective of this chapter is to compare the performance of different manufacturing systems. In particular, the configurations analyzed by using simulation tools based on the software Rockwell ARENA® are: CMS, FCMS and RCMS. Moreover another configuration has been considered changing the layout of machines and obtaining a CMS in line.

The manufacturing system consists of *M* machines general purpose that are used for each configuration. It has been considered three part families. We consider a constant mix of each part family.

We introduce the following assumptions for the model:

- the demand for each part type is unknown at priori end it is extracted randomly from an exponential distribution. Therefore, the parameter to set is the exponential parameter;
- set-up times are not simulated. When, the manufacturing cells are configured the set-up times are very low for the product family assigned to the cell;
- the due date is obtained by processing time multiplied with an index greater than or equal to 1;
- Machine breakdowns and maintenance are not considered;
- intra-cell handling times are negligible;
- it is assumed that parts moved in units;
- each configuration presents the same number of machines in order to make a comparison in the same conditions.

The performance measures used to compare the manufacturing systems are the following:

- Work in Process (WIP);
- Average utilization of the manufacturing system;
- Throughput time;
- Average throughput time;
- Tardiness (total of all the parts);
- Throughput.

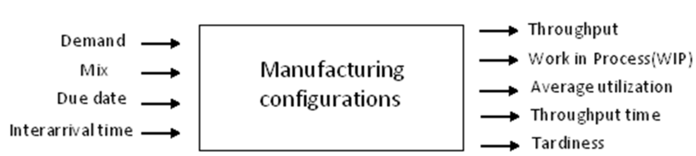
Figure 1 describes the parameters and the performance analyzed in this research.

The first manufacturing system configuration considered is a classical cellular system (CMS). The scheme is showed in Figure 2.

The system manufactures *N* product families with *N* cells. Each cell is specialized to perform the technological operations required by the product family assigned (setup time is not necessary). In this chapter, it has been also considered a CMS with a different routing, as showed in Figure 3.

The second configuration considered is the FCMS. In this case, the allocation of machines to cells is performed in order to obtain N identical cells. Each cell manufactures all product families with higher processing time, because the machines will be able to perform all the technological op-

Figure 1. Manufacturing configurations analysis



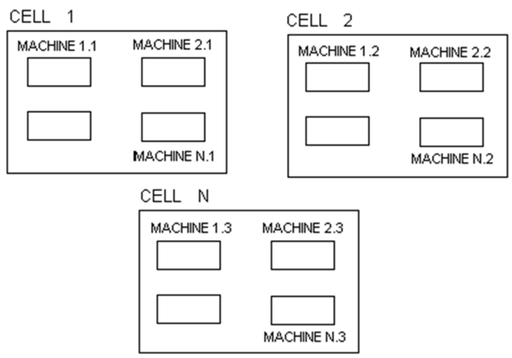


Figure 2. CMS configuration

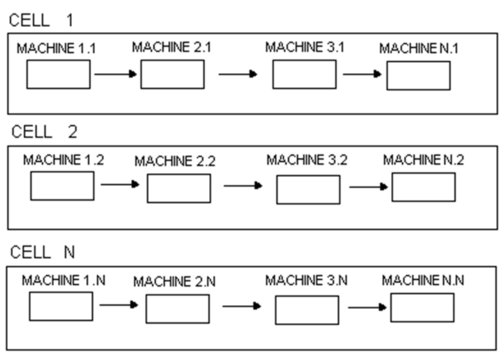

Figure 3. CMS in line configuration

erations required. The scheme of FCMS is showed in Figure 4.

The third configuration considered is the RCMS. In this configuration there are *N* cells respectively for *N* product families. In addition, there is a further cell called remainder cell where all operations can be performed with higher processing times. It may be useful in case of machine failures but also in case of congestion of the system. The scheme of RCMS is showed in Figure 5.

Each configuration includes the same number of machines and the time to manufacture each part is assumed the same, except for fractal cells (belonging to FCMS) and the remainder cell (belonging to RCMS) where machines can produce all kinds of part with a higher processing time (general purpose machine configuration). Therefore the processing time of machine *i-th* in fractal cell (pt_{if}) and processing time of machine *i-th* in remainder cell (pt_{ir}) is major of processing time of the machine *i-th* in the cell *j-th* in CMS (machine configured for the technological operations of a particular family) (pt_{ij}):

$$over = \frac{pt_{if}}{pt_{ij}} = \frac{pt_{ir}}{pt_{ij}}, over > 1 \qquad (1)$$

LOADING POLICY

In the previous section we have discussed the different cell configurations. Each configuration needs a loading approach policy to operate.

For classical CMS parts arrive in the system and each family has its own cell competence. In CMS we have provided two different layouts: one

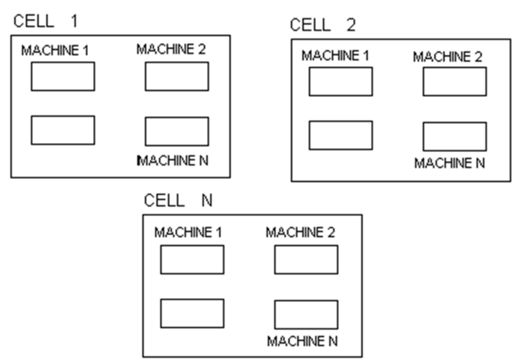

Figure 4. FCMS configuration

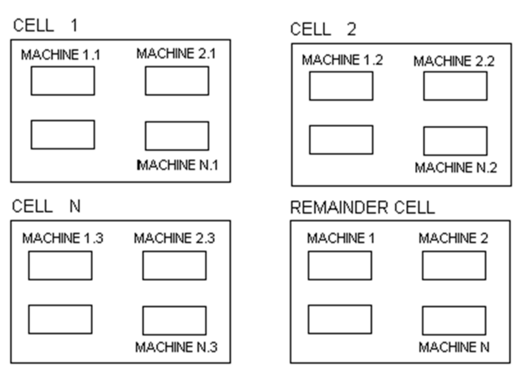

Figure 5. RCMS configuration

with parallel machines and other with machines in line, as described above.

In FCMS configuration parts arrive in the system and they are routed to cells with minor workload.

The RCMS needs a specific loading policy for the use of the remainder cell. Parts arrive in the system and each cell is designed for a part family. In each cell, there is a controller that adopts the following strategy: it measures the number of parts in queue in each machine. If the measured value in cell *j-th* is greater than a maximum threshold of the cell (defined $Smax_j$) then the part is conveyed to the remainder cell. Similarly, when the measured value is minor of a minimum threshold of the cell *j-th* (defined $Smin_j$) then the part is assigned to the cell designed for the part family. The logic of controller above described is showed in the flowchart of Figure 6.

SIMULATION ENVIRONMENT

The manufacturing system consists of *M=10* machines. All different configurations are obtained re-allocating the same number of machines available. It is considered that each machine functions for 24 hours a day. Therefore total numbers of minute that system works is considered to be 43200 minutes per month. This is the simulation horizon considered.

In order to evidence only the difference among the configurations, it is assumed that each part needs 40 minutes to complete processing. This technological time is divided by the number of machines used in the process, depending on manufacturing configuration. As above introduced it is equal for all parts except for those made in fractal cells and remainder cell where machines take more time.

We assume three product families. The product mix is as follow: Product 1 (40%), Product 2 (40%) and Product 3 (20%).

We have analyzed the performance of four different cellular systems changing one parameter: the average inter-arrival time. We have considered five different values of inter-arrival time that leads to different congestion levels of the manufacturing system (see Table 2).

These values were selected to keep the average utilization of machines in a range that goes from 0.56 (low utilization) to 0.99 (high utilization).

The demand for each part type is unknown at priori and it is extracted randomly from an

Figure 6. The logic of RCMS

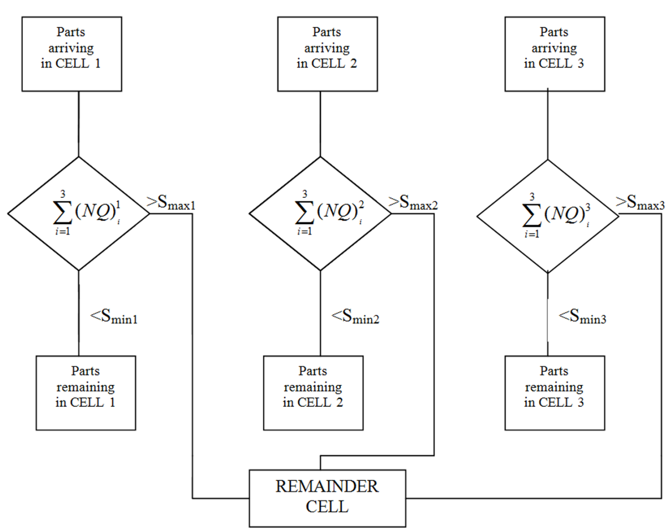

Table 2. Average inter-arrival times

4
4.5
5
6
7

exponential distribution with mean equal to the inter-arrival time reported in Table 2.

The due date is obtained from the sum of the arrival time (*tnow*) and the technological working time (*WT*) multiplied with an index (DdateINDEX), as showed in equation 2.

$$Ddate = tnow + (WT \cdot Ddate_{INDEX}) \qquad (2)$$

The *WT* is obviously equal to 40 minutes. The $Ddate_{index}$ is 1.5 for parts 1 and 2, while it is 1 for part 3. The minor index of part 3 is justified by the lower demand than other part-mix, so there is no shift of the due date. However the due dates are the same for all configurations examined. Therefore not affect the comparison, but they are included in the model for completeness.

Cellular systems analyzed are those already mentioned: CMS, CMS in line, RCMS and FCMS. The benchmark system is the CMS. The simulation environment has been developed by Rockwell Arena® tool.

Arena is characterized by a block diagram that makes it more familiar environment simulation. The arrival stations of the parts and the exit station are showed in the Figure 7.

In the first three boxes are showed the arrival stations where to each part is assigned a delivery time and a destination in the respective cell for processing; then the parts leave the arrival station.

Exit station is equal for all types of configuration: if the delivery time has been observed then the WIP is updated and the part leaves the system. Otherwise the delay is calculated.

Cellular Manufacturing System

In this case we consider three cells of production. The first two cells containing four identical machines working in pairs and in parallel. These cells are respectively for both products type 1 and type 2. The third cell contains 2 machines for products of type 3 (minor product mix). Each machine has a process time equal to 20 minutes. The scheme is showed in Figure 8.

In each rectangle is indicated the working time.

Cellular Manufacturing System in Line

In this case we also consider 3 cells of production. The first two cells containing 4 machines in line. Each machine has a process time equal to 10 minutes. These cells are respectively for type 1 and type 2. The third cell contains 2 machines for product type 3, each machine has a process

Figure 7. Arrival and exit stations

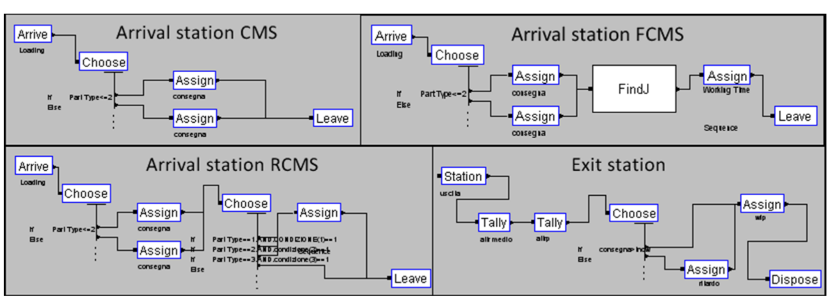

Figure 8. CMS considered in simulation

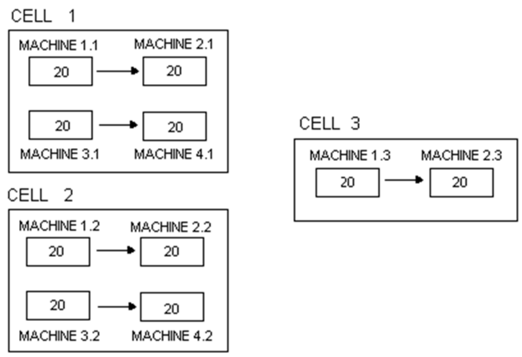

Figure 9. CMS in line considered in simulation

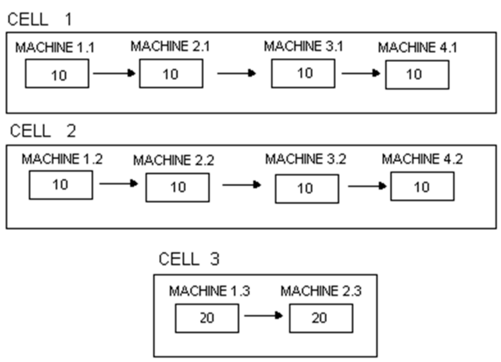

time equal to 20 minutes. The scheme is showed in Figure 9.

Fractal Cellular Manufacturing System

In this case there are 5 identical cells. Each cell contains 2 machines and each cell is able to work on all the product mix. The scheme is showed in Figure 10.

Naturally the machines perform the manufacturing operations with a major process time (see equations 1 and 2) because they are not dedicated to a part family but they are configured for all operations. In fact the process time of each machine is equal to 20 units time increased by 20% (over=1.2).

Remainder Cellular Manufacturing System

In this case there are 3 cells (one for each part type) and there is a remainder cell where is defined a loading policy based on the number of parts in queue in other cells. The scheme is showed in Figure 11.

The three machines operating in cell 1 (product type 1) has a process time equal to 13,33 minutes. The same for the machines operating in cell 2 (product type 2). The two machines operating in cell 3 has a process time equal to 20 minutes. The machines assigned to the remainder cell perform the manufacturing operations with a

Figure 10. FCMS considered in simulation

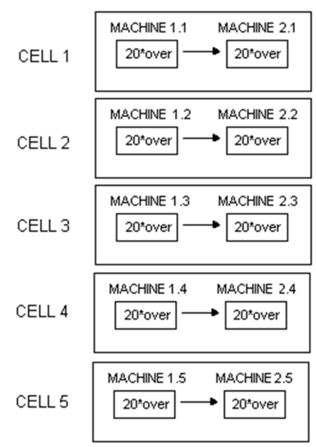

Figure 11. RCMS considered in simulation

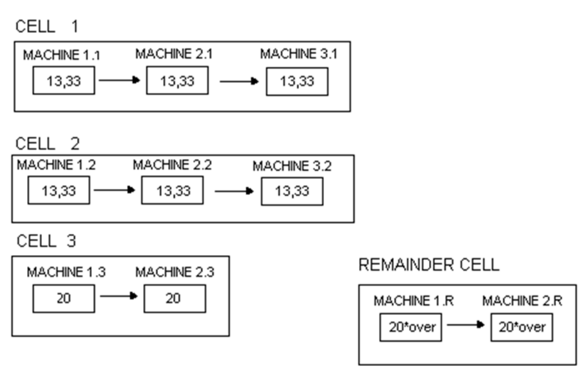


major process time (see equations 1 and 2) because they are configured for all operations; the process time of each machine is equal to 20 units time increased by 20%(over=1.2).

In this work, it has been investigated different instances of the same policy loading about the use of remainder cell. Each cell has a controller that measures the number of parts in queue in each machine. Using thresholds the parts can be conveyed to the remainder cell. In ARENA the controller is showed in Figure 12.

The first *"scan"* controls the maximum threshold ($Smax_j$) and therefore assigns the part to the cell. Similarly, the second "*scan"* checks the minimum thresholds($Smin_j$).

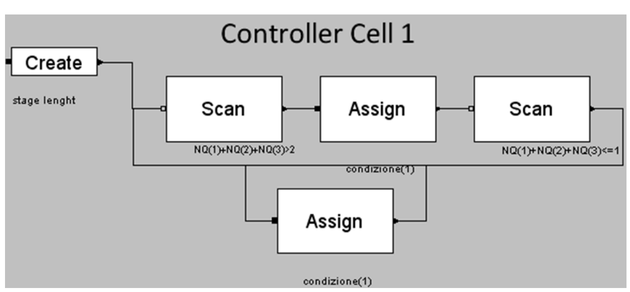
For the values of maximum ($Smax_j$) and minimum ($Smin_j$) thresholds have been considered respectively six cases, equal for all three cells (see Table 3).

SIMULATION RESULTS

The length of each simulation is fixed to 43200 minutes. During this period the average inter-arrival time and part mix are both constant. Table 4 reports the design of simulation experiments conducted for all four configurations of the manufacturing system.

Combining the five inter-arrival times, four system configurations, and for the last configuration (RCMS) six cases regarding the thresholds, it has been obtained 45 experimental classes.

Figure 12. Control blocks cell 1



For each experiment class have been conducted a number of replications able to assure a 5% confidence interval and 95% of confidence level for each performance measure.

As previously described the performance measures investigated are the following:

- Work in Process (WIP);
- Average utilization of the manufacturing system (*av.utilization*);
- Throughput time for each part j(*thr. Time j*);
- Average throughput time (*average thr. Time*);
- Total tardiness time of all the parts (*tardiness*);
- Throughput (*thr.*).

The objective of the analysis of simulation results is the comparison between different manufacturing configurations and classical cellular configuration (CMS, used as base for percentage

computation). The aim is to use the performance parameters to highlight the behaviour of different configurations when changing the volume of demand (the variation of average inter-arrival times).

Table 5 shows the average utilizations of machines in classical CMS at different inter-arrival times.

Therefore the simulations are performed for five congestion levels of the manufacturing system. It is important to emphasize that the results showed do not include machine breakdowns.

Table 6 reports the first three parameters (WIP, Tardiness and Throughput) for the different manufacturing configurations. Table 6 shows the average values over inter-arrival times with the respective standard deviations (St.dev). The standard deviation allows to highlight the variability of the results when the inter-arrival changes. The

Table 5. Average utilizations

Configuration	Inter-arrival time	Av. utilization
CMS	4	0,99
	4,5	0,88
	5	0,80
	6	0,66
	7	0,57

percentages refer to the comparison with the classical CMS. The positive percentages represent an increase of the respective factor while the negative percentages represent a decrease. Table 7 is the same for the throughput time of different parts and for the average throughout time.

Tables 6 and 7 show that CMS with configuration in line has almost the same behaviour of the classical CMS except for the tardiness that increments significantly.

Tables 6 and 7 also show that fractal configuration (FCMS) is the worst configuration. This is because the scheduling policy used is more simply. An opportune policy needs to be implemented for the FCMS. This is a limit of FMCS configuration, because a more complex control system has to be designed. The standard deviation shows the variability of the performance measures related to the inter-arrival changes in fact the FCMS is the configuration with the higher dependence on the inter-arrival changes. As the reader can notice, the RCMS performance depends on the choose of the threshold values.

Table 8 reports the variation of performance observed in correspondence of three values of inter-arrival times (5, 6, and 7). The percentages always refer to the comparison with the classical CMS.

Among the various configurations of RCMS is showed only one (with thresholds 2, 1) with the most interesting results (see Table 8). Except for value of tardiness (when inter-arrival time is

equal to 5) the other performance converge to values close to CMS configuration with differences about 10%. The better performance of RCMS is obtained with inter-arrival time equal to 5 therefore with a medium –high average utilization of the manufacturing system (see Table 5). With high and low congestion levels the other configurations compared to CMS have very low performance level. This is confirmed in Figure 13 that shows the profile of performance at different congestion levels.

Figures 14 and 15 show the comparison of the performance measures. It is clear that FCMS configuration in all cases performs worse especially for average inter-arrival time equal to 5. The design of this configuration needs to be rethought. For higher inter-arrival times the differences tend to decline. The behaviour of RCMS is more interesting and there is more possibility for improvement. In Figure 13 observing the curve of RCMS (2,1), it is interesting to note that the throughput time of product 3 performs better than other configurations. This is probably due to the fact that the cell 3 has lower loads (since part mix 3 is 20%) and it obtains more synergy from the remainder cell. In that configuration queues larger than 2 units (parts) are not tolerated. In this case, the remainder cell is used frequently and this is the key to a better behaviour of system configuration. The results showed indicate that a better balance of utilizations between dedicated cells and remainder cell leads to an improvement in performance.

CONCLUSION AND FUTURE DEVELOPMENT

This chapter investigates several configurations of the cellular manufacturing systems. A simulation environment is used to create equal operating conditions for different cellular systems. Each simulation includes the same number of machines. Thus the comparison between systems is normalized. Volume changes are analysed changing of inter-arrival times. It has been considered interesting to compare the performance because the economic environment is extremely turbulent. In particular our attention has focused on alternative approaches to traditional cells. A solution that looks interesting results is the remainder cellular manufacturing system (RCMS). The results of this research can be summarized as it follows:

- the classical cellular configuration with machines placed in line (CMS in line) is the best solution with static market conditions; the results are very close to the case of machines that are not in line (CMS);
- the fractal cellular configuration(FCMS) gives bad results as it is conceived in a static environment and should think a more complex logic with different loading policies;
- the cellular manufacturing system with remainder cell (RCMS) is already competitive in some cases with larger inter-arrival times; the best configuration is one that requires more stringent threshold values which imply a greater use of the remainder cell.

From this it follows that RCMS could become very competitive when the presence of a turbulent market would involve a greater use of remainder cell, and similarly the presence of noise on the manufacturing system(such as machine breakdowns or maintenance).

In literature, it is known that the FCMS and the RCMS are not very competitive against classical CMS.

But in previous studies remainder cells were often used as support cells with exclusive use in special circumstances. Our proposal is to adopt loading policies designed to achieve a strategic use of the remainder cells. Simple loading policies included in simulation models show how the remainder cell can be used to keep different performance under certain conditions. This work aims to demonstrate under certain dynamic conditions the proposed configurations can be competitive with classical CMS. Furthermore this chapter demonstrates the strong dependence of the results from the design of loading approaches, which deserve special attention.

Future research could focus on defining complex loading policies able to maintain high performance of the manufacturing system in different operating conditions and also taking into account the need for maintenance and possible failures of the machines(also for those belonging to remainder cell). These policies will certainly improve both the RCMS as for FCMS.

Moreover in the RCMS the logic of loading machines have a strong influence on the performance. Under dynamic conditions with market fluctuations these strategies using remainder cells can avoid the reconfigurations of manufacturing systems, avoiding downtimes and reducing costs.

Future works could investigate a variety of systems that integrate the configurations showed in this chapter with decision-making systems with intelligence to interpret the variability of real production scenario, moreover would also be interesting to analyze the economic aspect of different manufacturing solutions and how it may influence the choices.

ABSTRACT

In practice, demands, costs, processing times, set-up times, routings, and other inputs to classical cellular manufacturing systems (CMS) problems may be highly uncertain, which can have a major impact on characteristics of manufacturing system. So, development models for cell formation (CF) problem under uncertainty can be a suitable area for researchers and belongs to a relatively new class of CMS problems that not researched well in the literature. In this way, random parameters can be either continuous or described by discrete scenarios. If probability information is known, uncertainty is described using a (discrete or continuous) probability distribution on the parameters, otherwise, continuous parameters are normally limited to lie in some pre-determined intervals. This chapter introduces basic concepts about uncertainty themes associated with cellular manufacturing systems and briefly reviews literature survey for this type of problem. The chapter also discusses the characteristics of different mathematical models in the context of cellular manufacturing.

INTRODUCTION

During the past few decades, there have been various types of optimization techniques and mathematical programming approaches for cellular manufacturing systems under different random situations. In a cell manufacturing, once work cells and scheduling of parts in each cell are determined, it may be possible that cycle time in a specific cell be more than the other cells which creates a bottleneck in a manufacturing system. In this way, there are two different approaches in order to decrease cycle time in bottleneck cell: duplicating bottleneck machines or outsourcing exceptional parts which are known as group scheduling (GS) in the literature. Selecting each approach to balance cycle times among all cells can lead to variations in machines layout characteristics by changes in type and number of machines. Finally, formations of cells are also changed according to the changes in scheduling decisions. Thus, scheduling problem is one of the operational issues which must be addressed in design stage concurrently in an integrated problem so that the best performance of cells would be achieved. It is noted that scheduling problem includes many tactical parameters with random and uncertain characteristics. In addition, uncertainty or fluctuations in input parameters leads to fluctuations in scheduling decisions which could reduce the effects of cell formation decisions. Figure 1 indicates transmission of uncertainty from tactical parameters to the CMS problem.

Thus, in order to intensify effectiveness of the solution, integrated problem in uncertain conditions must be studied so that final solution will be robust and immune against the fluctuations in input parameters.

In the concerned problem, uncertain parameters can be listed as follows:

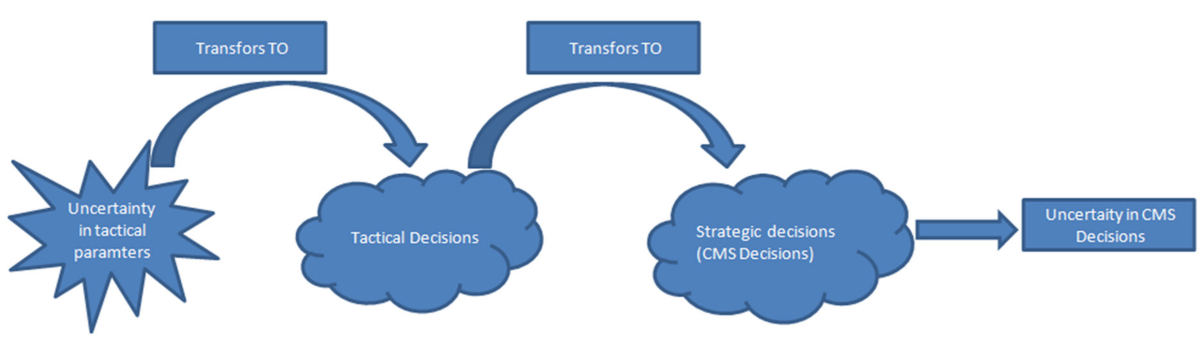
- Demand,
- Processing time,
- Routings or machine-part matrix,
- Machines' availability,
- Failure rate of machines,
- Capacities,
- Lead times,
- Set-up considerations,
- Market aspects,
- …,

where the impact of each factor is discussed in the following sections.

PROBLEM BACKGROUND

Group technology (GT) is a management theory that aims to group products with similar processes or manufacturing characteristics, or both. Cellular manufacturing system (CMS) is a manufacturing

Figure 1. Illustration of uncertainty transmission to the CMS decision



concept to group products into part families based on their similarities is manufacturing processing. Machines are also grouped into machine cells based on the parts which are supposed to be manufactured by these machines. CMS framework is a important application of group technology (GT) philosophy. The basic purpose of CM is to identify machine cells and part families concurrently, and to assign part families to machine cells in order to minimize the intercellular and intracellular costs of parts. Some real-world limitations in CF are:

- Available capacity of machines must not be exceeded,
- Safety and technological necessities must be met,
- The number of machines in a cell and the number of cells have not be exceeded an upper bound,
- Intercellular and intracellular costs of handling material between machines must be minimized,
- Machines must be utilized in effect (Heragu, 1997).

Aggregating traditional considerations with newly ones such as scheduling, stochastic approaches, processing time, variable demand, sequencing, and layout consideration can be more practical. This survey highlights studies that are relevant to the uncertainty planning of CMS problems; however, a survey of certain conditions will also be presented.

Cellular manufacturing decisions are strategic decisions which can be affected by operational decisions such as scheduling, production planning, layout consideration, utilities, productivity and etc. Thus, in order to effecting decision making related to cell formation design, it is necessary to integrate strategic decisions and operational decisions in a single problem. Recently, researchers have had some efforts in order to integrate two types of decisions. But the lack of literature is that most of them are studied in certain situations while in real-world most of the operational parameters are uncertain; and thus, integrated problems must be more studied in uncertain situations.

In the literature correspondence to CMS problems, uncertainty has been considered under different circumstances. We have classified previous researches into different groups which are discussed next.

Group 1: Uncertainty could appear either in demand or in products' mix. In this group, there are two approaches of fuzzy theory and stochastic optimization to handle uncertainty. In some of them stochastic demand is aggregated with tactical aspects such as production planning (Hurley and Whybark 1999), layout problem (Song and Hitomi1996) or dynamic and multi period conditions (Balakrishnan and Cheng 2007). Also, in other studies, uncertainty in products' demand has been resolved by fuzzy approach (Safaei et. al. 2008).

Group 2: Researchers formulated and analyzed CMS problem considering fuzzy coefficients in the objective function and constraints (Papaioannou and Wilson 2009).

Group 3: Processing times of products are assumed to be uncertain where mathematical programming and fuzzy approaches are implemented to obtain the results which are immune against the perturbation on the uncertainty. Also, some studies such as Sun and Yih (1996) and Andres et. al. (2007) attempted to achieve solutions by heuristic procedures. Some studies have formulated the problem as a queue network and then analyzed it by queuing theory (Yang and Deane 1993).

Group 4: Uncertainty normally appears due to fluctuations in design aspects during production process. Since, fluctuations in design aspects are not certain events, so uncertainty can be formulated by a set of future scenarios. In this way, some studies applied interval coefficient to resolve uncertainty (Shanker and Vrat 1998).

Group 5: In some explorations, uncertainty has been considered in the availability of resources for production equipments. In this way, some works have formulated CMS problem applying probability theory (Kuroda and Tomita (2005) and Hosseini 2000). In addition, some of them considered multi processing routes to be substituted once a machine encounters with failure (Siemiatkowski and Przybylski (2007) and Asgharpour and Javadian 2004).

Group 6: Uncertainty has been recognized in similarity coefficients. For example, a new similarity coefficient has been introduced where applied fuzzy theory and then transformed it to a binary matrix (Ravichandran and Chandra Sekhara Rao 2001).

Group 7: Capacity level of machines is considered to be uncertain. Since this critical parameter has an important role to determine bottleneck machine, thus it is vital to make flexible decisions under any realization of this parameter (Szwarc et al 1997).

Group 8: Finally, uncertainty in CMS problem has been detected in products arrival time to cells. Classical models assume that all products are available at the beginning of the production planning while in real application it may be occurred that products arrive to cell with unknown time. In this way, researchers modeled CMS problem as queue network to resolve uncertainty (Yang and Deane 1993).

Literature survey classifications can be described as follows. There exist many researches in certain situations for designing CMS in different areas such as cell formation integrated with scheduling (Solimanpur et al. (2004), Aryanezhad and Aliabadi et al 2011), considering exceptional elements in CF (Tsai et al. (1997), Mahdavi et al. 2007), some works apply meta-heuristics and heuristics methods to solve large scale problems are more practical and appealing real-case problems (Xiaodan Wu et al (2006), Venkataramanaiah 2007).

OPTIMIZATION APPROACHES IN UNCERTAIN SITUATIONS

Rosenhead et al (1972) divided decision environments into three groups of deterministic, risk and uncertain. In deterministic situations, all problem parameters are considered to be given. In risk problems parameters have probability distribution function where it is known for decision maker while in uncertain situations there is no information about probabilities.

The problems which are classified into the risk are named stochastic and the primary objective is to optimize expected value of system outcome. Also, the uncertain problems are known as robust and the primary objective is mainly to optimize performance of the system in the worst case conditions.

The aim of both stochastic and robust optimization methods is to find solution with a suitable performance in realization of any value for uncertain parameter.

Random parameters can be either continues or explained by discrete scenarios. If probability information are known, uncertainty will be explained by continues or discrete distribution functions. But if no information is available, parameters are assumed to be in predefined intervals. Scenario planning is a method in which decision makers achieve uncertainty by indicating a number of possible future states. In such conditions, the goal is to find solutions which perform well under all scenarios. In some cases, scenario planning replaces predicting as a way to assess trends and potential modifications in the industry environment (Mobasheri et al 1989). Decisions makers can thus develop strategic responses to a range of environmental adjustments, more adequately preparing themselves for the uncertain future. Under such conditions, scenarios are qualitative descriptions of possible future states, consequences from the present state with consideration of potential key industry events. In other cases, scenario planning is used as a tool for modeling and solving specific operational problems (Mulvey 1996). While scenarios here also depict a range of future states, they do so through quantitative descriptions of the various values that problem input parameters may resolve. Scenario based planning has two main negative aspects. The first is that identifying scenarios and assigning probabilities to them are a difficult task. The second is that we are unable to increase the number of scenarios since due to limitation on computation time which consequently limits the future correspondence situations for decision making. This approach has the advantageous that provides statistical correlation between parameters (Snyder 2006).

DECISION MAKING APPROACHES IN UNCERTAIN SITUATIONS

There are different approaches which can be applied in modeling process based on the problem characteristics: Stochastic Optimization (SO), Robust Optimization (RO) and Queuing Theory (QT) with defined decision tree as follows.

- Stochastic Optimization
- Discrete Planning - Set of Scenario
- Continues Optimization
- Mean Value model: the most popular objective in any SO problem is to optimize expected value of the system outcome. For example, minimizing expected cost or maximizing expected income.
- Mean – Variance Model: in some studies variance and expected of system performance are considered simultaneously in optimization problem.
- Probability Approaches
- Max Probability Optimization: Maximizing the probability of a random event that solution performs good under each realization of random parameter.
- Chance Constrained Programming: a probability event located in problem constraint sets such as service level constraint.
- Queuing Theory & Markov Chain: It is a well-known approach.
- Robust Optimization

The objective in any stochastic optimization problem mainly focuses on optimizing the expected value of system outcome such as maximizing expected profit or minimizing total expected cost.

In any stochastic programming we must determine which variables are considered in the first stage (design variable) and which are considered in the second stage (control variable). In other words, which variables must be determined first and which of them must be determined after uncertainty is resolved. In modeling process for cellular manufacturing problem, cell formation decisions are the first and operational and tactical decisions are the second variables. If both decisions are made in a single stage, the model is reduced to a certain problem in which uncertainty of parameters are replaced by mean of variables.

Mean-Variance Models

The mean value models discuss only the expected performance of the system without reflecting on the fluctuations in performance and the decision maker's risk aversion limitations. However, a portion of literature incorporates the company's level of risk aversion into the decision-making process, classically by applying a mean–variance objective function.

$$\text{Min} = E(\text{Cost}) + \lambda \text{Var}(\text{Cost})$$

Probabilistic Approaches

The mean-variance models consider only the expected value or variance of the stochastic objective function, there is an extensive portion of literature which considers probabilistic information about the performance of the system; for example, maximizing the probability that the performance is good or minimizing the probability that it is bad, under suitable and predefined explanations of "good" and "bad". We introduce two such approaches: (1) max-probability problems; (2) chance-constrained programming;

Queuing Theory for CMS Problem

Queuing theory can be applied to any manufacturing or service systems (also, in cellular manufacturing systems). For example, in a machine shop, jobs wait to be machined; (Heragu 1997b). In a queuing system, customers arrive by some arrival process and wait in a queue for the next available server. In the manufacturing framework, customers can be assumed as parts and servers may be machines or working cells. The input process shows how parts arrive at a queue in a cell. An arrival process is commonly identified by the probability distribution of the number of arrivals in any time interval. The service process is usually described by a probability distribution. The service rate is the number of parts served per unit time. The arrival rate of a queuing system is usually given as the number of parts arriving per unit time. Thus, measurements of a queue system such as maximization the probability that each server is busy (utilization factor), minimization waiting time in queues (that leads to minimization work in process in cells) and etc can be optimized and cells will be formed optimality.

Robust Optimization

Once there is no probability information about the uncertain parameters, the expected cost and other objectives discussed in previous section are inappropriate. Many measurements of robustness have been introduced for this condition. The two most common are mini-max cost and mini-max regret, which are directly related to one another. Just like the stochastic optimization case, uncertain parameters in robust optimization problems may be considered as being either discrete or continuous. Discrete parameters are formulated applying the scenario based planning. Continuous parameters are normally assumed to lie in some predefined interval, because it is often impossible to consider a "worst case scenario" when parameter values are unbounded. This type of uncertainty is described as "interval uncertainty".

The two most common robustness measurements consider the regret of a solution, which is the difference (absolute or percentage) between the cost of a solution in a given scenario and the cost of the optimal solution for that scenario. Regret is sometimes described as opportunity loss: the difference between the quality of a given strategy and the quality of the strategy that would have been chosen had one known what the future held (Snyder 2006).

As it was already described, the performance of a cellular manufacturing system heavily influenced by tactical and operational decisions such as scheduling, production planning, layout and etc. Notable point is that the tactical decisions and operational parameters are dependent on many uncertainties that affect the system. As a result, the tactical and operational decisions are suffering from uncertainty. This causes to transfer uncertainty into the decisions related cell formation. Therefore, it is essential for researchers to recognize different types of uncertainty in the problem and make decisions regarded to their impact into the problem.

The most important parameters with uncertainty in manufacturing cell formation problem considered as below:

- Demand

- Processing time
- Routings or machine-part matrix
- Machine's failure rate
- Capacities

One of the factors causing uncertainty in the problem associated with product design changes during the course of production. Moreover, changes in product design with many features of the product are altered. Design changes can occur based on a variety of reasons such as changes in customer expectations, short-term life products, and competing products to market entry.

Under such circumstances, many characteristics of products such as demand and time will find a process of change.

Note that the reasons of changes expressed are not certain events in the future and thus they have to be predicated as some discrete scenarios. In such case analytical space problem is discrete and can be optimized by discrete optimization.

As it was discussed earlier, one of the product features which can be changed due to changes in product design is product routings. In this way, sequence of machines in which product has to visit them may be changed and therefore part – machine index may be changed. In such cases, the values within the part – machine matrix unlike classical models that were only zero or one can be a probabilistic value between zero and one. In such problems, discrete optimization can be applied to formulation.

Another factor with uncertainty is the rate of access to machines based on their failure. Since failure and machine downtime are not certain events, the machine accessibility for the decision maker at the time of manufacturing cells with defined uncertainty is also under uncertainty.

Another parameter that is uncertain and can affect formation of work cells is features of capacity. These factors include different items: the capacity of processing machinery on parts as well as physical capacities for manufacturing framework. Such variations must be predicted at the beginning planning horizon.

The summary of above discussions can be found Table 1.

MATHEMATICAL MODELLING

In this section, different mathematical models with different optimization approaches which include two new models and one published model are discussed. The selected approaches are stochastic optimization and queuing theory.

Table 1. Summary uncertainty developments in CMS problem

No.	Uncertain parameter	Optimization Approach	Decision space
1	demand	Stochastic	Continuous & Discrete
2	Processing time	Stochastic	Continuous & Discrete
3	Processing time	Robust	Continuous & Discrete
4	Processing time	Queuing Theory	Continuous
5	Routing	Stochastic	Discrete
6	Routing	Queuing Theory	Discrete
7	Capacity	Stochastic	Discrete
8	Machines' Availability	Queuing Theory	Continuous & Discrete
9	Machines' Availability	Stochastic	Continuous & Discrete
10	Lead times	Stochastic & Robust	Continuous & Discrete

Model 1

In this section, a bi-objective mathematical model to form manufacturing cells is presented where uncertainty is accessed in part – machine matrix. As discussed earlier, due to changes in design characteristics of products, several factors are subject to changes such as the processing routings of parts. Thus, according to the forecasting based on the scenario planning, forecasting different routing processes for a part in uncertain situation is possible. In this condition, each part can have different routing process for each scenario. Therefore, in order to design cellular configuration efficiently, all planning conditions must be considered. In current problem the factor with uncertainty is part – machine matrix. In classical models, only zero-one elements are used in part – machine matrix while in the presented problem each element can be a continuous value between zero and one. Each array denotes the probability that part i visits machine j with regard to all scenarios. For example, if there are two scenarios in which the probability of the first scenario is 0.4 and for the second one is 0.6, we have:

$p_1 = 0.4 \Rightarrow$ Routing in scenario 1 for part 1: Machine 1 → Machine 2 → Machine 3 → Finish

$p_2 = 0.6 \Rightarrow$ Routine in scenario 2 for part 1: Machine 1 → Machine 2 → Machine 3 → Finish

$$a_{[ij]} = \begin{bmatrix} M.1 & M.2 & M.3 & M.4 \\ 1 & 0.4 & 1 & 0.6 \end{bmatrix}$$

Where element [ij] indicates the probability that part i processed on machine j.

Since, in both scenarios, machines 1 and 3 are the same in processing routing, so part 1 has to visit them surely (or with probability 1) to do operation process. But, based on the first scenario this part has to visit machine 2 with probability 0.4 and also machine 4 with probability 0.6. As it can be seen, in introduced part – machine matrix each array can have a value between zero and one based on the probability occurrence for scenarios.

In a mathematical model which is presented in this section, the first objective function minimizes the costs associated with the under utilization in a manufacturing system. Also, the second objective function is optimizing a random event in manufacturing system unlike the classical models which optimized only certain events. As it was discussed in definitions of a cellular manufacturing system, one of the most important objectives is to minimize the number of inter cellular transportation. In this problem, since processing rout for parts is uncertain, therefore the number of inter cellular transportation is uncertain too. A random event which is considered for optimization is to "minimizing the probability that the number of inter cellular transportation exceeds the upper bound limitations". For computing above objective the following notations are defined:

Parameters:

$$a_{ijs} = \begin{cases} 1 \\ 0 \end{cases}$$

1 if part *i* needs to be processed on machine *j* in scenario *s*
0 otherwise

p_s: Probability of occurring scenario s
N: Maximum number of intercellular transportation allowed in each scenario

Decision Variables:

n_s: Number of intercellular transportation in scenario *s*.

$$e_s = \begin{cases} 1 \\ 0 \end{cases}$$

1 if no. of intercellular transportation in scenario *s* configuration exceeded up bound *N*
0 otherwise

or

$$e_s = \begin{cases} 1 \\ 0 \end{cases}$$

1 if $n_s \geq N$
0 if $n_s < N$
z_s: Integer additional variable for each scenario.

$$x_{ik} = \begin{cases} 1 \\ 0 \end{cases}$$

1 if part *i* is assigned to cell *k*
0 otherwise

$$y_{jk} = \begin{cases} 1 \\ 0 \end{cases}$$

1 if machine *j* is assigned to cell *k*
0 otherwise

In order to minimizing under utilization costs in the first objective function, the following function is defined:

$$MinZ_1 = \sum_s \sum_i \sum_j p_s \times (1 - a_{ijs}) \times x_{ik} \times y_{jk} \tag{1}$$

Also, based on the above definitions, an attractive random event for minimizing the second function can be defined as follows:

p (no. of intercellular transportation in each condition $\geq N$)

The above random event must be optimized by minimizing the probability of occurrence that leads to maximum utility for decision maker in final solution. In other words, above probability transforms to the following function:

$$MinZ_2 = \sum_s e_s \times p_s \tag{2}$$

Since there is s scenarios in the proposed problem which are similar to s independent random events, thus probability of total events will be equal to summation of probability of each event. In other words, assuming $s_1, s_2, \ldots, s_n$ as *n* independent random events, we have:

$$P\left(s_1 \cup s_2 \cup \ldots \cup s_n\right) = P\left(s_1\right) + P\left(s_2\right) + \ldots + P\left(s_n\right)$$

As a result, in above function if in scenario s the number of inter cellular transportation exceeds the upper bound limitation then we can assume that inter cellular transportation may be occurred with the probability of p_s. Finally, the summation of the probability of scenarios with unsatisfied inter cellular transportation restriction denotes the final probability of the problem.

In this model, the objective functions and also, the following constraints are effective:

$$MinZ_1 = \sum_s \sum_i \sum_j p_s \times (1 - a_{ijs}) \times x_{ik} \times y_{jk}$$
$$MinZ_2 = \sum_s e_s \times p_s$$

Constraints:

$$\sum_k x_{ik} = 1 \quad \forall i \tag{3}$$

$$\sum_k y_{jk} = 1 \quad \forall j \tag{4}$$

$$n_s - \sum_i \sum_j a_{ijs} \times x_{ik} \times (1 - y_{jk}) = 0 \tag{5}$$

$$z_s - \left[\frac{n_s}{N}\right] = 0 \qquad (6)$$

$$z_s \leq M \times e_s \qquad (7)$$

$$x_{ik}, y_{jk}, e_s \in \{0,1\} \quad z_s \text{ integer} \geq 0 \quad n_s \geq 0$$

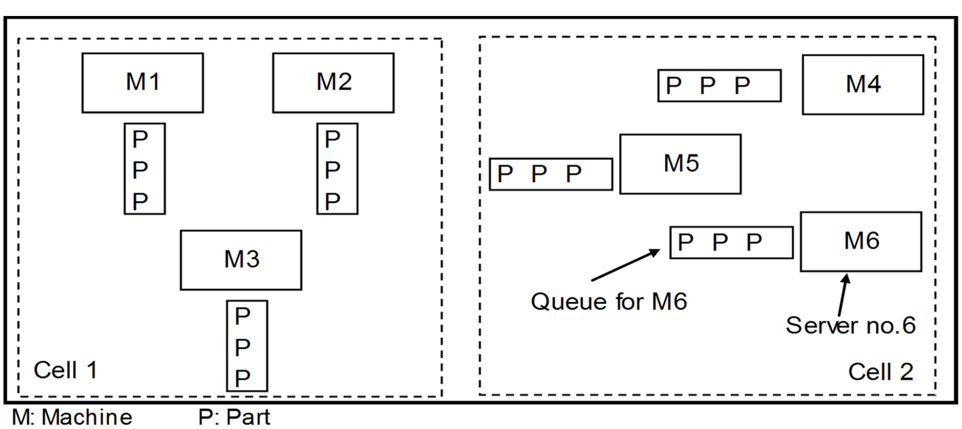
The first objective minimizes total expected cost associated with the utilization computed when a part do not need to be processed on a machine placed together in a same cell. The second objective minimizes the probability that number of inter cellular transportation exceeds the maximum transportation. Set constraint (3) says that each part must be assigned to a single cell. Set constraint (4) states that each machine can be assigned only to one cell. Set constraint (5) computes total number of inter transportation in each scenario. In set constraint (6) additional variable z_s will be zero if the number of inter transportations in scenario s is less than the maximum limit and it is an integer value greater than 1 else. Set constraint (7) guarantees that if $n_s \geq N$ then e_s will be 1. Otherwise, e_s will be 0.

Model 2

Applying Queuing Theory to CMS Problem

In this section, we formulate a CMS problem as a queue system. Also, assume a birth-death process with constant arrival (birth) and service completion (death) rates. The role of the birth-death process in automated manufacturing systems is described in detail in Viswanadham and Narahari (Viswanadham and Narahari 1992). Specifically, let λ and μ be the arrival and service rate of parts, respectively, per unit time. If arrival rate is greater than the service rate, the queue will grow infinitely. The ratio of λ to μ is named utilization factor or the probability that a machine is busy and is defined as $\rho = \lambda \mid \mu$. *T*herefore, for a system in steady state, this ratio must be less than one. In this research, we assume M/M/1 queue system for each machine in CMS where each part arrives to cells with rate *λ*i *an*$_d$ parts served by machines. In this condition, due to operate different parts (or different customers) on each machine and each part has different arrival rate, so for each machine (server) ρ is computed using the following property. Figure 2 illustrates modeling of cellular manufacturing system by queuing theory approach.

Figure 2. A CMS problem and queuing theory framework (Ghezavati and Saidi-Mehrabad 2011)



Pr**operty 1 t**he minimum of independent exponential random variables is also, exponential. Let F1, *F2, ..., Fn* be independent random variables with parameters $\lambda 1$, $\lambda 2, ..., \lambda n$. Let Fmin = min{F1, F2, ..., Fn}. Then for any t ≥ 0,

$$P(F_{\min} > t) = P(F_1 > t) \times P(F_2 > t) \times ... \times P(F_n > t)$$
$$= e^{-\lambda_1 t} e^{-\lambda_2 t} ... e^{-\lambda_n t} = e^{-[\lambda_1 + \lambda_2 + ... + \lambda_n]t}$$

An interesting implication of this property to inter-arrival times is discussed in Hillier and Lieberman (Hillier and Lieberman 1995). Suppose there are n types of customers, with the ith type of customer having an exponential inter-arrival time distribution with parameter λi, arrive at a queue system. Let us assume that an arrival has just taken place. Then from a no-memory property of exponential distribution, it follows that the time remaining until the next arrival is also exponential. Using mentioned property, we can see that the inter-arrival time for entire queue system or efficient arrival rate (which is the minimum among all inter-arrival times) has an exponential distribution with parameter:

$$\lambda_{eff} = \sum_{i=1}^{N} \lambda_i$$

Hence, utilization factor or the probability that each machine (j) is busy is as follow (efficient arrival rate divided by service rate):

$$\rho_j = \frac{\lambda_{eff}}{\mu_j} = \frac{\sum_{i=1}^{N} \lambda_i}{\mu_j} \tag{8}$$

Chance Constrained Programming

Since, both arrival time and service time are uncertain so the amount of time in which each customer spends in server will be uncertain, too. In order to prevent long waiting time for each customer, a chance constraint must be considered in the formulation. Note that distribution function denoting total time for each customer in a M/M/1 system is as follows:

$$P(W_s \geq t) = e^{-\mu(1-\rho)t} \tag{9}$$

Proof: Assume that there are N customers in a system once a new customer is arrived. Thus, based on the conditional probability theory:

$$P(W_s \geq t) = \sum_{n=0}^{\infty} P(W_s \geq t \mid N = n) \times P(N = n) \tag{10}$$

On the other side, total time in which a new customer has to wait is equal to:

$$W_q = F_1 + F_2 + ... + F_n \tag{11}$$

where F_i denotes service time for customer i. So:

$$W_s = W_q + F_{n+1} \tag{12}$$

where F_{n+1} denotes service time for new arrived customer. It is obvious that sum of the n+1 random variables with exponential distribution with rate μ will be an Erlang random variable with parameters n+1 and μ. So:

$$P(W_s \geq t \mid N = n) = P(\sum_{i=1}^{n+1} F_i > t)$$
$$= \int_t^{\infty} \mu \times e^{-\mu \cdot y} \frac{(\mu y)^n}{n!} d_y \tag{13}$$

Note that the probability of being n customers in a M/M/1 model system is:

$$p_n = \rho^n (1-\rho) \quad \text{where} \quad \rho = \frac{\lambda}{\mu} \tag{14}$$

Based on the Equations 13 and 14, Equation 10 will be computed as:

$$P(W_s \geq t) = \sum_{n=0}^{\infty} \rho^n (1-\rho) \int_t^{\infty} \mu \times e^{-\mu \cdot y} \frac{(\mu y)^n}{n!} d_y \tag{15}$$

$$= \mu(1-\rho) \int_t^{\infty} e^{-\mu \cdot y} \sum_{n=0}^{\infty} \frac{\rho^n (\mu y)^n}{n!} d_y \tag{16}$$

Also, based on the exponential series, we have:

$$\sum_{n=0}^{\infty} \frac{\rho^n (\mu y)^n}{n!} = e^{\rho \cdot \mu \cdot y} = e^{\lambda \cdot y} \tag{17}$$

If we replace Equation 17 to the Equation 16, the Equation 9 will be proven. It can be found that W_s has an exponential distribution function with parameter $\mu - \lambda$.

In order to satisfy service level this probability must be at most α. So, the chance constraint will be determined as $P(Ws \geq t) \leq \alpha$. In order to linearize this nonlinear constraint the following procedure is performed:

$$P(W_s \geq t) \leq \alpha \tag{18}$$

$$\Rightarrow e^{-\mu(1-\rho)t} \leq \alpha \tag{19}$$

$$\Rightarrow -\mu(1-\rho)t \leq Ln(\alpha) \tag{20}$$

The achieved constraint indicates that a customer will be in system more than critical time t with probability at most α.

Property 2. If n types of customers have to visit a server to receive service with different arrival rate λi then the probability of a random customer in which visits the server be ith type will be as follows:

$$p_i = \frac{\lambda_i}{\sum_j \lambda_j} \tag{21}$$

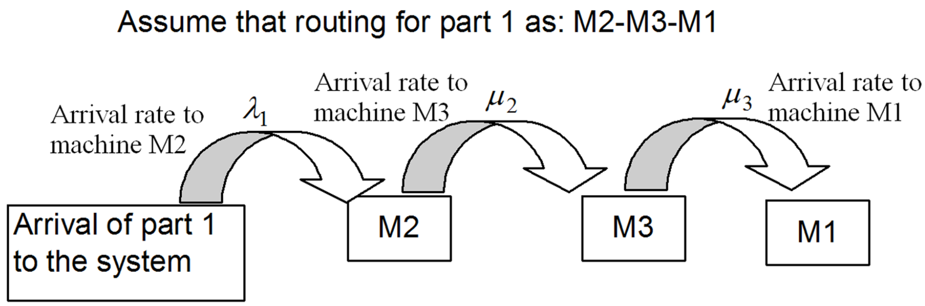
In concerned model, the characteristics of a Jacson service network will be applied. In a Jacson network, it is assumed that each customer has to visit multiple servers in order to complete service stages. For example, each part refers to several machines to complete operation processes. In such network, input rate for machines needed for the first operation will be equal to the arrival rate of the part to the system. But, the ratio for any machines need for the second operation input rate will be equal to the output rate from the previous server (or machine). Similarly, any machine needs for the third operation input rate will be equal to the exit rate of the second machine and this process goes on for the other machines.

In a cellular manufacturing problem formulated as a queue system, each part based on its routing process visits machines or multi cells in order to receive service. Figure 3 illustrates such process.

For each machine, effective input rate is made of two elements. The first fraction is the summation of arrival rate of parts which visit the machine in the first operation. The second fraction is the summation of input rate of parts which visit the machine after the second operation. This rate is equal to the output rate of the previous machine. Figure 3 illustrates difference between arrival rates for machines per a specific part. In this model, such procedure will be applied to compute effective input rate for each machine.

In this section, a part—machine matrix—will be applied where sequence operations of parts are determined. This can help us formulate problem as a Jacson network. Each element of this matrix is defined as follows:

Figure 3. Arrival rate for part 1 into the different machines based on the routing



$$a_{ik} = \begin{cases} j \\ 0 \end{cases}$$

j if kth process of part i is completed by machine j
0 otherwise

$$b_{ij} = \begin{cases} k \\ 0 \end{cases}$$

k if part i refers to machine j to complete kth process
0 otherwise

Other parameters are defined as follows:

$$z_{ij} = \begin{cases} 1 \\ 0 \end{cases}$$

1 if operation on machine j is the first operation of part i
0 otherwise

$$c_{ij} = \begin{cases} 1 \\ 0 \end{cases}$$

1 if part i needs to be processed on machine j
0 otherwise

λI=Arrival rate of part i to manufacturing system.
μj = service rate of machine j (or [$1/\mu j$] denotes average operation time on machine j).
pi_j = The probability that a random part type i leaves machine j.
β = Penalty rate multiplied to arrival process if intercellular movement occurs.

It is assumed that if an operation of a part has to transfer to the other cell (or inter cellular movement) then arrival rate will be multiplied by β in which included transfer time and also waiting time between cells.

λj_e^{ff} = Effective arrival rate for machine j.

Based on the above definitions λj_e^{ff} will be computed by the following equation.

$$\lambda_j^{eff} = \sum_{i=1}^{m}\left(z_{ij} \times \lambda_i\right) + \sum_{i=1}^{m}(1 - z_{ij}) \times c_{ij} \times \lambda^{eff}_{a_{i,b_{ij}-1}} \times p_{i,a_{i,b_{ij}-1}}$$

In above equation, in order to compute effective input rate for each machine two fractions are considered: the first fraction is the summation of the arrival rate for parts which visit machine j in the first operation. The second term is the summation of input rate for parts which visit the machine after the second operation. Number of operation which completed by machine j is b_{ij} based on the defined parameters. Thus, number of previous operation is $b_{ij} - 1$. Finally, according to the definition of a_{ik} (the machine completes kth operation of part i), the machine which completes previous operation of part i will be $a_{i,b\mu-1.}$ Therefore, the second term of above equation effective arrival rate for parts visit machine j after the second operation are computed as follows: effective arrival rate of a machine needs before machine j multiplied by the probability of leaving for part i from previous machine.

For example, assume that customers arrive to a book store with Poisson distribution with rate 10 per hour where 60 percent is man and 40 percent is women. Hence, the number of men arrives to the store will be Poisson with rate 15×0.6 per hour and also, number of women arrives to the store will be Poisson with rate 15×0.4 per hour.

Note that if operation j of part i needs inter cellular transportation, machine j is penalized by increasing arrival rate of part i and the rate is multiplied by β. Finally, the model must determine whether each operation needs inter cellular transportation or not. It must be mentioned that operation j of part i needs inter cellular transportation when machine j and part i are not located in the same cell. Based on the above description λeff^{i}s computed as Equation 22.

Mathematical Model

In this section, a mathematical model optimizes cell formation decisions based on the queuing theory will be proposed. The objective function is to minimize total cost included under utilization cost. Also, a chance constraint will be considered in order to prevent additional waiting time of parts in a queue line in front of each machine. As it was discussed, assuming each machine as a M/M/1 model, the chance constraint (13) satisfies considered objective.

$$MinZ = \sum_{i}\sum_{j}(1 - a_{ij}) \times x_{ik} \times y_{jk} \qquad (23)$$

Constraints:

$$\sum_{k} x_{ik} = 1 \quad \forall i \qquad (24)$$

$$\sum_{k} y_{jk} = 1 \quad \forall j \qquad (25)$$

$$\rho_j - \frac{\lambda_j^{eff}}{\mu_j} = 0 \qquad (27)$$

$$-\mu_j \times (1 - \rho_j)t \leq Ln(\alpha) \quad \forall j \qquad (28)$$

$$\rho_j \leq 1 \quad \forall j \qquad (29)$$

$$p_{ij} - \frac{\lambda_i \times c_{ij}}{\sum_{r=1}\lambda_r \times c_{rj}} = 0 \quad \forall i,j \qquad (30)$$

$$x_{ik}, y_{jk} \in \{0,1\} \quad \rho_j, p_{ij} \geq 0$$

Equation 22.

$$\lambda_j^{eff} = \sum_{i=1}^{m}\left[\left(x_{ik} \times y_{jk}\right) \times \lambda_i + x_{ik} \times \left(1 - y_{jk}\right) \times \lambda_i \times \beta\right] \times z_{ij}$$
$$+ \sum_{i=1}^{m} p_{i,a_{i,b_{ij}-1}} \times \left[\left(x_{ik} \times y_{jk}\right) \times \lambda_{a_{i,b_{ij}-1}}^{eff} + x_{ik} \times \left(1 - y_{jk}\right) \times \lambda_{a_{i,b_{ij}-1}}^{eff} \times \beta\right] \times c_{ij} \times (1 - z_{ij})$$

Equation 26.

$$\lambda_j^{eff} = \sum_{i=1}^{m} \left[\left(x_{ik} \times y_{jk} \right) \times \lambda_i + x_{ik} \times \left(1 - y_{jk} \right) \times \lambda_i \times \beta \right] \times z_{ij} + \sum_{i=1}^{m} p_{i,a_{i,b_{ij}-1}} \times \left[\left(x_{ik} \times y_{jk} \right) \times \lambda^{eff}_{a_{i,b_{ij}-1}} + x_{ik} \times \left(1 - y_{jk} \right) \times \lambda^{eff}_{a_{i,b_{ij}-1}} \times \beta \right] \times c_{ij} \times (1 - z_{ij})$$

Constraints (24) and (25) compute effective arrival rate and utilization factor for each machine, respectively. Set constraint (28) guaranties satisfaction of chance constrained for each machine where the probability that each part has to wait more than critical time *t* is at most a. Set constraint (29) ensures that utilization factor for each machine will be less than one. Set constraint (30) determines the probability that a random part leaves machine *j* be type *i*.

Model 3

Recently, Ghezavati and Saidi-Mehrabad (2010) proposed a stochastic cellular manufacturing problem in where uncertainty is captured by discrete fluctuations in processing times of parts on machines. The aim of their model was to optimize scheduling cost (expected maximum tardiness cost) plus cell formation costs, concurrently. The mathematical model is represented in this part and interested readers are referred to read the paper for more details.

Parameters:

$$a_{ij} = \begin{cases} 1 \\ 0 \end{cases}$$

1 if part *i* required to be process on machine *j*
0 otherwise

c_i: *Penalty* cost of subcontracting for part *i*

$\mu i_{j:}$ Cost part i not utilizing machine j

M_{max}: Maximum number of machines permitted in a cell

$C_{\mu:}$ Maximum number of cells permitted

p_s: Probability of scenario *s* occurs

t_{ijs}: Processing time for part *i* on machine *j* in scenario *s*

DD_i: Due Date of part *i*

pc: Penalty cost for unit time delayed

Decision variables:

$$x_{ik} = \begin{cases} 1 \\ 0 \end{cases}$$

1 if part *i* processed in cell *k*
0 otherwise

$$y_{jk} = \begin{cases} 1 \\ 0 \end{cases}$$

1 if machine *j* assigned to cell *k*
0 otherwise

$$Z_{is[r]} = \begin{cases} 1 \\ 0 \end{cases}$$

1 if part *i* assigned to sequence [*r*] in scenario *s*
0 otherwise

$F_{[r]ks}$: The time in which process of part with sequence $[r]$ ends in cell k and scenario s

$FD_{[r]ks}$: Due date of part with sequence $[r]$ in cell k in scenario s

$L_{[r]ks}$: Tardiness of part with sequence $[r]$ in cell k in scenario s

ML_s: Maximum Tardiness occurred in scenario s

D_{iks}: Total processing times of part i needs to be processed in cell k and scenario s

$T_{[r]ks}$: Total processing times of a part with sequence $[r]$ assigned to cell k in scenario s

CF decisions are scenario – independent: they must be made before occurring scenarios and they are made based on their similarities in processing parts and are independent to quantity of processing time. Scheduling decisions are scenario – dependent, thus Z, D, T, FD, L, ML and F variables are indexed by scenario since they must be made after we realize scenario and where the processing time is occurred.

Mathematical Model (Ghezavati, V.R. and Saidi-Mehranad, M., 2010)

$$\text{Minimize } Z = \sum_s pc \times p_s \times ML_s + \sum_k \sum_j \sum_i c_i a_{ij} x_{ik} (1 - y_{jk}) + \sum_k \sum_j \sum_i u_{ij} (1 - a_{ij}) x_{ik} y_{jk} \quad (31)$$

Subject to:

$$\sum_k x_{ik} = 1 \quad \forall i \quad (32)$$

$$\sum_k y_{jk} = 1 \quad \forall j \quad (33)$$

$$\sum_r Z_{is[r]} = 1 \quad \forall i, s \quad (34)$$

$$\sum_i x_{ik} Z_{is,[r+1]} \le \sum_i X_{ik} Z_{is[r]} \quad \forall k, s, r \quad (35)$$

$$D_{iks} = \sum_j a_{ij} t_{ijs} x_{ik} y_{jk} \quad \forall i, k, s \quad (36)$$

$$\sum_i x_{ik} Z_{is[r]} \le 1 \quad \forall r, s, k \quad (37)$$

$$T_{[r]ks} = \sum_i Z_{is[r]} D_{iks} \quad \forall k, s, r \quad (38)$$

$$F_{[r]ks} = \sum_{r=1} \sum_{\alpha=1}^{r} T_{\alpha ks} \quad \forall k, s, r \quad (39)$$

$$FD_{[r]ks} = \sum_i x_{ik} \times Z_{is[r]} \times DD_i \quad \forall k, s, r \quad (40)$$

$$L_{[r]ks} = \max\left\{0, F_{[r]ks} - FD_{[r]ks}\right\} \quad \forall k, s, r \quad (41)$$

$$ML_s = Max\{L_{[r]ks} : k = 1,...,C \text{ } and \text{ } [r] = 1,...,P\} \quad \forall s \quad (42)$$

$$\sum_j y_{jk} \le M_{\max} \quad \forall k \quad (43)$$

$$x_{ik}, y_{jk}, Z_{isr} \sim (0,1) \quad (44)$$

$$D_{iks}, T_{rks}, F_{rks}, FD_{rks} \ge 0 \quad (45)$$

Set constraints (32), (33) and (43) indicate cell formation constraints and set constraints (34), (35), (36), (37), (38), (39), (40), (41) and (42) perform scheduling computations and rational constraints.

Linearization Approaches

In above formulation, since there are both binary and continuous variables where are multiplied to each other, nonlinear terms are appeared in formulation process. Two common types of nonlinear terms are:

Type 1: Pure 0-1 polynomial problem in which n binary variables are multiplied to each other such as $Z = x_1 \times x_2 \times ... \times x_n$.
Type 2: Mixed 0-1 polynomial problems which n binary variables are multiplied to each other and this term is multiplied to a continuous variable such as $Z = x_1 \times x_2 \times ... \times x_n \times Y$.

For linearization type 1 the following method can be applied by introducing some new auxiliary constraints:

$$Z \leq x_i \qquad i = 1, 2, ..., n$$
$$Z \geq \sum_{i-1}^{n} x_i - (n+1)$$

Also, for linearization type 2 in a minimization problem, the following auxiliary constraints will be applied:

P1: Nonlinear problem

$$MinZ = x_1 \times x_2 \times ... \times x_n \times y$$

St:

$$L(X, Y)$$

P2: Linear form

$$Min \quad Z$$

St:

$$Z \geq y - \left|U\right| \times \left(n - \sum_{i=1}^{n} x_i\right)$$
$$Z \geq 0 \qquad L(X, Y)$$

where U is upper bound for continuous variable y and therefore Z will be a continuous variable (Ghezavati and Saidi-Mehrabad 2011).

CONCLUSION

In summary, in this chapter basic principles of uncertainty in a cellular manufacturing system were established. Since CMS problem is affected by tactical decisions such as scheduling, production planning, layout considerations, utilization aspects and many other factors, thus each CMS problem must be aggregated with tactical decisions in order to achieve maximum efficiency. As it is known, tactical decisions are made of many uncertain parameters. Since strategic decisions are influenced by tactical decisions, therefore CMS decisions will be mixed with uncertainty. There are some popular approaches which can analysis uncertain problems such as: Stochastic Optimization, Discrete Planning - Set of Scenario, Continues Optimization, Mean Value model, Mean – Variance Model, Max Probability Optimization, Chance Constrained Programming, Queuing Theory and Markov Chain, and Robust Optimization. This chapter has proposed two sample mathematical models and also one published model [32]. It was assumed that processing routing, inter arrival and service time and also processing time to be uncertain. Stochastic optimization and queuing theory were to resolve uncertainty in formulation process. A complete survey on meta-heuristic methods to solve CMS problems can be found by Ghosh et al (2011). For future directions, the following suggested developments can be applied for researchers and readers:

- Uncertain Processing time optimized by robust approach in continuous or discrete space
- Uncertain capacities optimized by stochastic or robust approach in discrete space

- Uncertain machines' availability optimized by stochastic or queuing theory approaches in continuous or discrete space.
- Aggregating CMS problem with logistics considerations in uncertain environments.
- Aggregating CMS problem with production planning aspects in uncertain environments.
- Aggregating CMS problem with layout considerations in uncertain environments.
- Aggregating CMS problem with scheduling concerns in uncertain environments.

ABSTRACT

Cellular manufacturing meets the diversified production and quantity requirements flexibly. However, its efficiency mainly depends on the operators' working performance. In order to improve its efficiency, an effective assembly-support system should be developed to assist operators during the assembly process. In this chapter, a multi-modal assembly-support system (MASS) was proposed, which aims to support operators from both information and physical aspects. To protect operators in MASS system, five main safety designs as both hardware and control levels were also discussed. With the information and physical support from the MASS system, the assembly complexity and burden to the assembly operators are reduced. To evaluate the effect of MASS, a group of operators were required to execute a cable harness task. From the experimental results, it can be concluded that by using this system, the operators' assembly performance is improved and their mental work load is reduced. Consequently the efficiency of the cellular manufacturing is improved.

DOI: 10.4018/978-1-4666-1945-6.ch032

INTRODUCTION

Traditionally, when the mass production was major in industry production, various assembly systems had been designed as automated manufacturing lines, which are aimed to produce a single specific product without much flexibility. Nowadays, the tastes of consumers change from time to time; therefore, traditional automated manufacturing lines cannot meet the flexibility and efficiency at the same time. To solve this problem, cellular manufacturing system, also called cell production system, has been introduced. In this system, an operator manually assembles each product from start to finish (Isa & Tsuru, 2002; Wemmerlov & Johnson, 1997). The operator enables a cellular manufacturing system to meet the diversified production and quantity requirements flexibly. However, due to the negative growth of the population in Japan, it will become difficult to maintain the cellular manufacturing system with enough skilled operators in the near future. How to improve the assembly performance of the operators and how to reduce their assembly burden are two important factors, which limit the efficiency of the cellular manufacturing system.

Without an effective supporting system, it is difficult to maintain the cellular manufacturing system in Japan. Taking the advantages of the operators and robots, but avoiding their disadvantages at the same time, a new cellular manufacturing system was proposed, namely, the human-robot collaboration assembly system (Duan, 2008). In this human-robot collaboration assembly system, the operators are only required to execute the complicated and flexible assembly tasks that need human assembly skills; while the robots are employed to execute the monotonous and repeated tasks, such as the repetitions of parts feeding during assembly process (Arai, 2009). To make this system has the applicability to assemble a variety of products in different manufacturing circumstances, the following assembly sequence is assumed: each assembly part is collected from the tray shelf by manipulators; all the parts are automatically fed to the operator on a tray as a kit of parts; an operator grasps the individual part respectively and assembles it to form a final product; the assembled product is transferred out to the next station, and so on.

In the following part, a multi-modal assembly-support system (MASS) is introduced, which aims to support an assembly operator in a cellular manufacturing system from both information side and physical side while satisfying the actual manufacturing requirements. MASS system utilizes robots to support the operator and several information devices to monitor and guide the operator during the assembly process. Since it is a human-robot collaboration assembly system, safety strategy must be designed to protect the operator with a reasonable cost benefit balance in the real production line.

The remainder of the chapter is organized as follows: Firstly, the background information and the related studies are introduced. Then, the entire MASS system and its subsystems are briefly described. After that, a description of two manipulators and a mobile base are introduced in physical support part, which are used to feed assembly parts to the assembly operator. Assembly information support part contains a discussion of a multimedia-based assembly table and corresponding devices. Safety standard and safety design are presented in safety strategy part. Taking a cable harness task as an example, the effect of MASS system was evaluated. Finally, the conclusion and the future work are given.

PREVIOUS RELATED STUDIES

To improve the efficiency of the cellular manufacturing system, various cellular manufacturing systems have been designed to improve the assembly performance of the operators and reduce their assembly burden.

Seki (2003) invented a production cell called "Digital Yatai" which monitors the assembly progress and presents information about the next assembly process. Using a semi-transparent head mount display, Reinhart (2003) developed an augmented reality (AR) system to supply information to the operator. These studies support the operator from information aspect. To reduce the operator's physical burden and improve the assembly precision, Hayakawa (1998) employed a manipulator to grasp the assembly parts during the assembly process. This improved the assembly cell in physical support aspect. Sugi (2005) aimed to support the operators from both information side and physical side, and developed an attentive workbench (AWB) system. In this system, a projector was employed to provide assembly information to the operator; a camera was used to detect the direction of an operator's pointing finger; and several self-moving trays were used to deliver parts to the operator. Although AWB achieved its goal of supporting operators from both information aspect and physical aspect, the direct supporting devices are just a projector and several self-moving trays, which are general purpose instruments that cannot meet the actual manufacturing requirements.

In the coming aging society, it will be impossible to maintain the working efficiency if everything is done manually by the operator in the current cellular manufacturing system. In order to increase working efficiency, many researchers have used robot technologies to provide supports to the operator (Kosuge, 1994; Bauer, 2008; Oborski, 2004). According to these studies, human-robot collaboration has potential advantages to improve the operator's working efficiency. However, before implementing this proposal, the most fundamental issue will be the safety strategy, which allows the operators and the robots to execute the collaboration work in their close proximity.

Human-robot collaboration has been studied in many aspects but has not been utilized in the real manufacturing systems. This is mainly because safety codes on industrial robots (ISO 12100, ISO 10218-1, 2006) prohibit the coexistence of an operator in the same space of a robot. According to the current industrial standards and regulations, in a human-robot collaboration system, a physical barrier must be installed to separate the operator and the assisting robot. Under this condition, the greatest limitation is that the close range assisting collaboration is impossible. Based on the definition of Helms (2002), there are four types of human-robot collaboration: *Independent Operation*, *Synchronized Cooperation*, *Simultaneous Cooperation*, and *Assisted Cooperation*. The assisted cooperation is the closest type of collaboration, which involves the same work piece being processed by the operator and the robot together. In this kind of human-robot collaboration, the operator is working close to the working envelope of the assisting robot without physical separation, so that both of them can work on the same work piece in the same process. The most distinguished concept of this study is that the assisting robot in this work is active and is able to work independently as robot manipulator. The advantage of this collaboration is to provide a human-like assistance to the operator, which is similar with the cooperation between two operators. This kind of assistance can improve the working efficiency by automating portion of the work and enable the operator to focus only on the other portion of work which requires human skill and flexibility. However, since the active robot is involved, this kind of collaboration is extremely dangerous and any mistake can be fatal (Beauchamp & Stobbe, 1995).

The challenge of this research work is to design an effective assembly supporting system, which can support the operator in both physical and information aspects. During the assembly process, employing of the assisting robot is an effective method to reduce the operator's assembly burden while improving the working efficiency. This involves the safety issue in this kind of close range active human-robot collaboration. However, there are no industrial safety standards and regulations. Besides the design of the assembly supporting system, the scope of this work also covers both safety design study and development of prototype production cell in cellular manufacturing.

MULTI-MODAL ASSEMBLY-SUPPORT SYSTEM

Structure of the Entire System

Following the fundamental idea that robots and operators share the assembly tasks can maximize their corresponding advantages, the MASS system was designed and its subsystems are shown in Figure 1 as structure view and in Figure 2 as system configuration.

The entire MASS system is divided into physical support part and assembly information support part, as shown in Figure 1.

1. **Physical Supporting Part**: The physical supporting part is aimed to support operators from physical aspect, and it is composed of two manipulators with six degrees of freedom and a mobile base, which have two functions: one is to deliver assembly parts from a tray shelf to an assembly table; and the other is to grasp the assembly parts and prevent any wobbling during the assembly process.
2. **Information Supporting Part**: The assembly information supporting part is designed to aid operators in assembly information aspect. An LCD TV, a speaker, and a laser pointer are employed to provide assembly information to guide the operator.

Figure 1. Structure of the entire MASS system

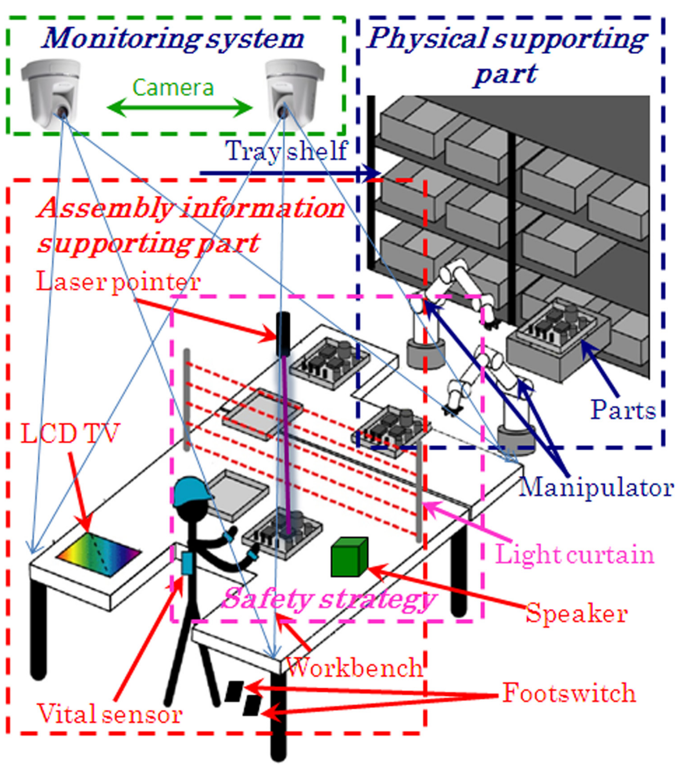

Figure 2. Configuration of MASS system

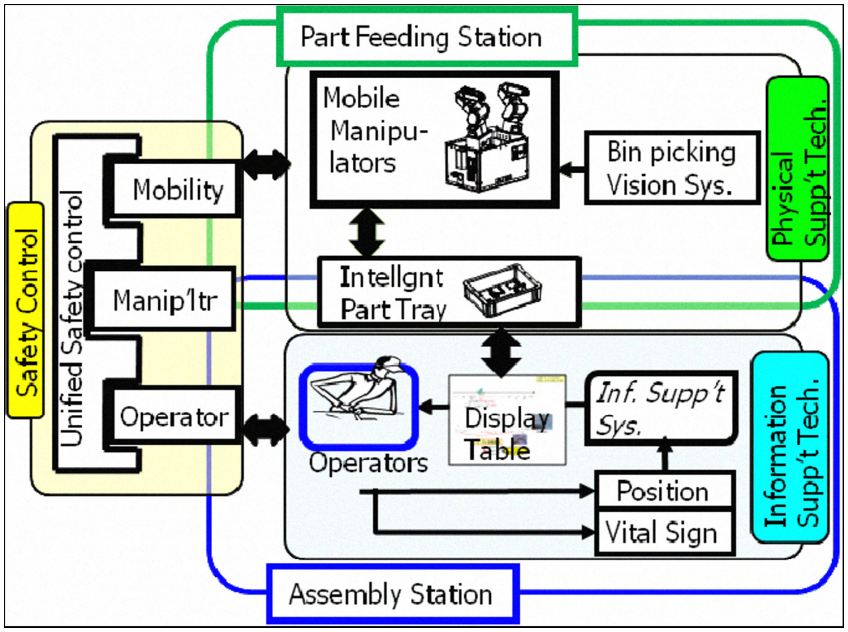


3. **Safety Control Part**: To guarantee the operator's safety during the assembly process, vital sensors are used to monitor the operator's physical conditions during the assembly process, and a serial of safety strategies is used to protect the operator from injury by the manipulators. It controls the collaboration between a robot and an operator (also referred to Figure 2).

In the developed MASS system, there are two stations connected through an intelligent part tray as shown in Figure 2, on which all the necessary parts are fed into the assembly station and the assembled products are transferred out through a shipment from the assembly station.

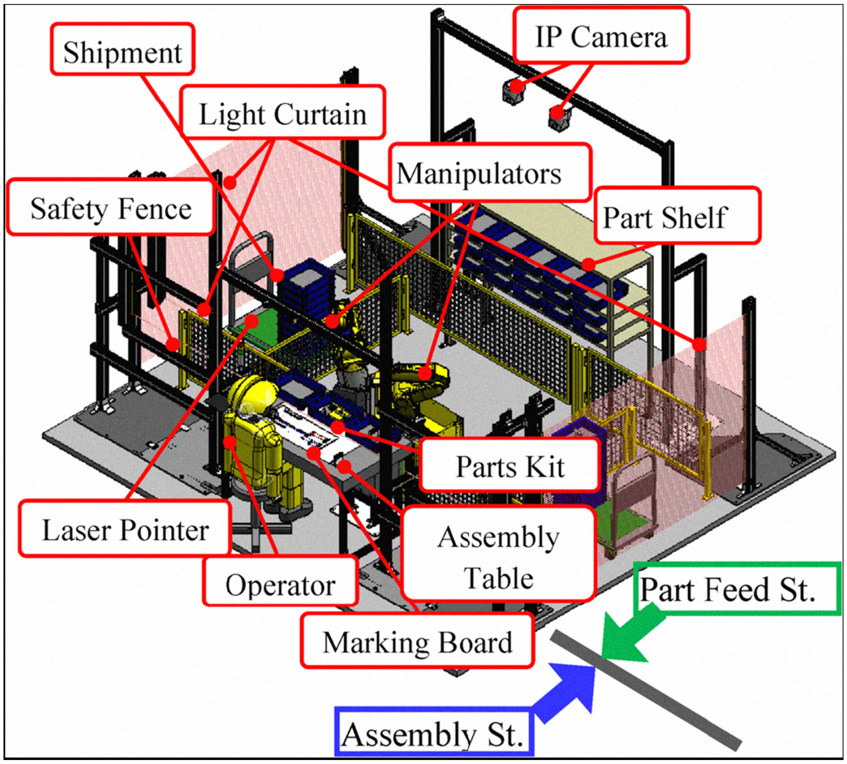
1. **Part Feeding Station**: Only robots work here. It is mainly in charge of part handling, such as bin picking, part feeding, kitting and part transferring.
2. **Assembly Station**: An operator executes the assembly tasks with some aid of the robots. Supporting **information** from the MASS system is implemented to accelerate the operator assembly efficiency.

Figure 1 illustrates the setup of the MASS system, in which an operator assembles a product on the workbench in the area of assembly station. The operator is supported with the assembly information and with physical holding of parts for assembly. In this study, the sample product to assemble is a cable harness with several connectors and faster plates. Even experienced operators maybe spend about 15 minutes finishing this assembly task.

Simulator of the Entire System

To reduce the design period, in this study, a simulator of the entire system was developed based on ROBOGUIDE (FANUC ROBOGUIDE) and OpenGL (Neider, 1993), as shown in Figure 3. This simulator can not only reproduce the actual motion of the manipulators but also predict collisions in the work space.

Figure 3. Simulator of the entire MASS system



Since MASS system is a human-robot cooperation assembly system, considering the operator's safety, the distance between the manipulators and the operator should be optimized to prevent the collisions between them. Furthermore, the moving trajectories of the manipulators should also be optimized to prevent the collisions between themselves. In order to accelerate the development period, all of the optimization assignments are done in this simulator first, and then evaluated in the actual MASS system. With the aid of this simulator, the distance between manipulators and the operator can be adjusted easily, and the moving trajectories of the manipulators' end points can also be reproduced conveniently during the manipulators' moving process. Therefore, based on the simulation results, the actual system could be conveniently constructed.

Physical Support

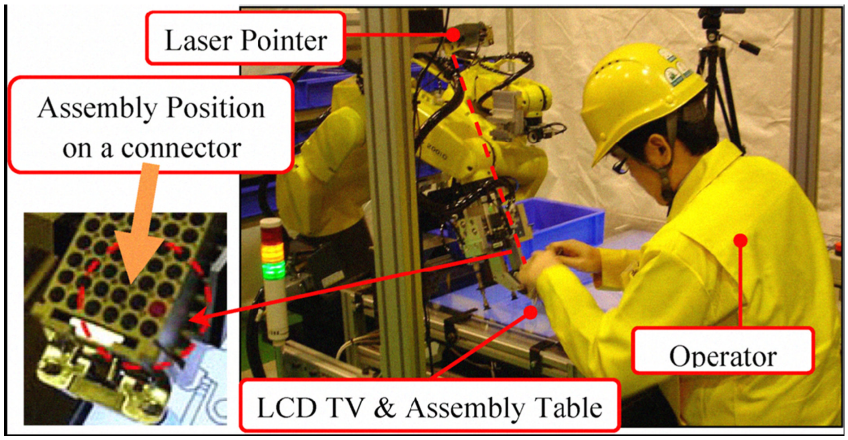
To increase the physical support provided by the MASS system, two manipulators with six degrees of freedom are installed on a mobile base and used to deliver assembly parts to the operator, as shown in Figures 1-4. A CCD camera with an LED light is equipped to each manipulator respectively for recognition of picking target from a part bin in scramble.

The manipulators are utilized in part feeding station to

1. Draw a part bin from part shelves;
2. Pick a part from the bin one by one;
3. Kit parts onto a tray;
4. Check visually the parts in a tray.

The parts are efficiently fed by the manipulators, because one manipulator hangs a bin up and

Figure 4. Assembly operations with the aid of manipulators



the other one grasps a part out like an operator does. Since the bin picking system by manipulators can work 24 hours a day, it enables high productivity. The base carries a few trays and moves to the assembly station, where the base docks in the electric charge connector. In the assembly station, an operator continuously assembles parts one by one, which are transferred by one of the mobile twin manipulators. To increase the precision of assembly and reduce the operator's burden, one manipulator can grasp an assembly part to prevent wobbling during assembly, and the operator executes the assembly task on the basis of the manipulator's assistance, as shown in Figure 4.

Obviously, the assistant manipulators move near to the operator during the assembly process. To achieve this collaboration, the manipulators have to penetrate the operator's area. Since the penetration is prohibited by the regulations of the industrial robots (ISO 12100), a new countermeasure must be developed. After finishing an assembly step, the operator pushes a footswitch to send a control command to the manipulators, and the manipulators provide the next assembly part to the operator and the assembly information of the next assembly step is given. Without this control command, the manipulators cannot move to the next step. Furthermore, the operator can stop the manipulators with an emergency button when an accident occurs. These strategies enable the manipulators to support human operators in physical aspect effectively and safely.

Assembly Information Support

Previous studies, Szeauch as Digital Yatai (Seki, 2003), have already testified that providing assembly information to the operator during his assembly process can not only improve his assembly efficiency, but also reduce his assembly errors. Taking the advantages of the previous studies, and also considering the characteristics of human cognition, an assembly information supporting system is designed to guide operators by means of indicating the next assembly sequence and/or an appropriate way of operation.

The developed system has three major advantages:

1. Each assembly sequence is instructed step by step;
2. Considering the characteristics of human cognition, the assembly information can be provided as easily understandable formats for humans, including text, voice, movie, animation and flashing emphasis marks;

3. The assembly information can be selected and provided to the operator according to his assembly skill level.

The total software system of MASS system in Figure 5 has been developed. It consists of three subsystems as

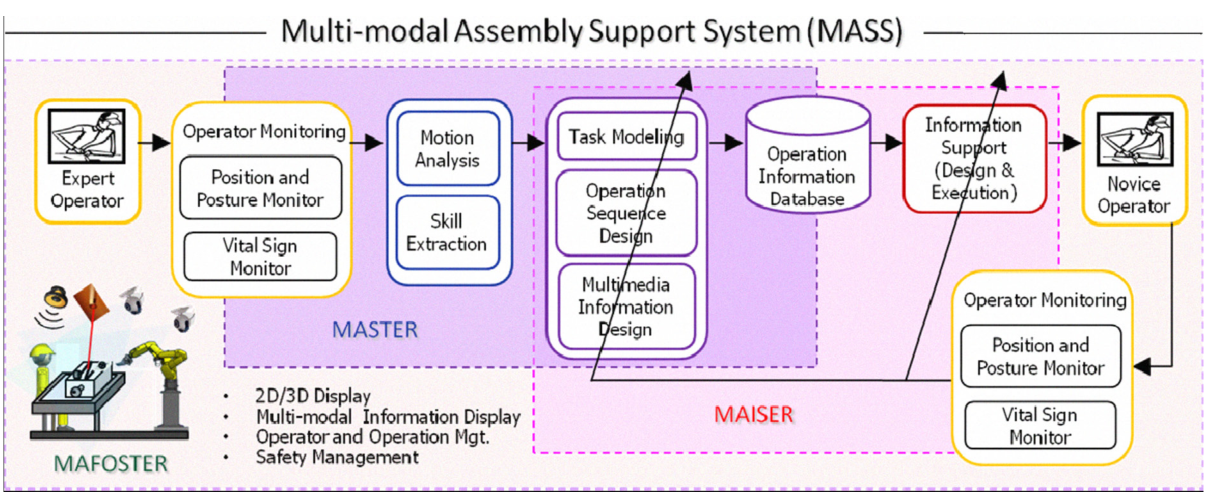
1. Multi-modal Assembly Skill TransfER (MASTER);
2. Multi-modal Assembly Information SupportER (MAISER);
3. Multi-modal Assembly FOSTER (MAFORSTER).

MASS is designed to extract the skill information from skilled operators by MASTER and to transfer it to novice operators by MAISER as illustrated in Figure 5. Here, a human assembly skill model was proposed (Duan, 2009), which extracts and transfers human assembly skills as the cognition skill part and the motor skill part. In the cognition skill part, depending on questionnaire, MASTER obtains the different cognition skills between the skilled operators and the novice operators. In the motor skill part, MASTER mainly utilizes motion capture system to obtain the different motor skills between the skilled operators and the novice operators, especially in the assembly pose aspect and the assembly motion aspect (Duan, Tan, Kato, & Arai, 2009). MAISER provides understandable instructions to novice operators by displaying multi-modal information about assembly operations. MAFOSTER controls interface devices to organize comfortable environment for operators to execute the assembly task like a foster does. MAISER works mainly off-line at a data-preparation phase, and watches on-line the state of an operator to avoid bad motion and dangerous states (Duan, Tan, Kato, & Arai, 2009). MAISER takes the role of an instruction phase.

Interface devices are installed as shown in Figure1 and Figure 4 again:

1. **LCD TV:** The horizontal assembly table with built-in 37 inch LCD TV as shown in Figure 4 may be the first application for assembly. Since it enables operators to read the instructions without moving his/her gaze in different direction, assembly errors can be decreased. The entire assembly scheme is divided into several simple assembly steps, and the corresponding assembly information is written in PowerPoint slides (Zhang, 2008). During the assembly process, these

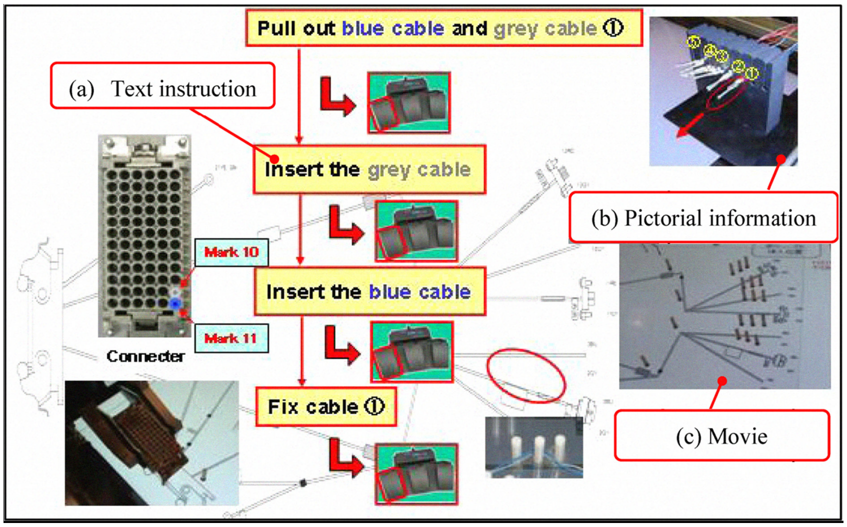
Figure 5. Software system of MASS system



PowerPoint slides are inputted into the LCD TV and switched by footswitch.

2. **Laser Pointer:** Showing the assembly position to the operator is an effective way to reduce assembly mistakes. To this end, a Laser pointer, which is fixed on the environment, is projected onto a task to indicate the accurate position of assembly as shown in the left photo of Figure 4. The position can change by the motion of the manipulator. The operator can insert a wire into the instructed assembly position with the aid of the Laser spot.
3. **Audio Speakers:** To easily permit the operator to understand the assembly information, a speaker and a wireless Bluetooth earphone are used to assist the operator with voice information.
4. **Footswitch:** During the assembly process, it is difficult for the operator to switch the PowerPoint slides with his hands. Therefore, a footswitch is used, as shown in Figure 1. There are two kinds of footswitches: footswitch A has three buttons, and footswitch B has one button. Just stepping the different buttons on footswitch A, the operator can move the PowerPoint slides forward or backward. Stepping the button on footswitch B, the operator controls the manipulators to supply the necessary assembly parts to the operator, or makes manipulators change the position and orientation of the assembly part during the assembly process.
5. **Assembly Information:** The assembly support information is provided to the operators to improve the productivity by means of good understanding in assembly tasks and of skill transfer with audio-visual aids. As the software structure for the assembly task description is not discussed in this study, please refer to our papers (Duan, 2008; Tan, 2008). Applying Hierarchical Task Analysis (HTA) one assembly task is divided into several simpler assembly steps, whose corresponding information is stored in multimedia. Then appropriate level of information is displayed on LCD panel as shown in Figure 6. In each PowerPoint slide, the assembly parts and assembly tools are illustrated with pictures. The assembly positions are noted with color marks. Following the assembly flow chart, videos showing the assembly motions of the experienced operators will appear to guide the novices to execute the assembly tasks. To facilitate the operator's understanding of the assembly process, the colors of the words in the slides are the same as the actual colors used for the assembly parts. For example, there are "blue cable" and "grey cable" in Figure 6. In each slide, several design principals of data presentation are introduced such as multimedia principle, coherence principle and spatial contiguity principle (Mayer, 2001). In Figure 6, three types of information are displayed as (a) text instruction, (b) pictorial information, (c) movie, and the sequence of assembly is also illustrated. During the assembly process, the PowerPoint slides are output to an LCD TV and switched by the operator's foot with footswitch during the assembly process.
6. **Assembly Information Database:** In this multimedia based assembly supporting system, the assembly information is classified into paper, audio, and video files. The assembly guidance is concisely written in paper files. Guidance of each assembly step is recorded in audio files. After the standard motions of the experienced operators are recorded and analyzed into primitive assembly motions, they are saved into video files. Tan (2008) set up an assembly information database to preserve all of these assembly information files and provide them to the operator depending on the situation. This database contains training data and assembly data: training data are designed for novices, and the assembly information files contain

Figure 6. Multimedia based assembly supporting information



assembly details. Assembly data are used to assist experienced operators by indicating the assembly sequence but not assembly details. As a consequence, this system may promote both novice and experienced operators to enter the workforce.

All the operators who used the assembly table with LCD evaluated positively that the instruction on LCD can be read easily and understood smoothly.

Safety Strategy

MASS system is a kind of human-robot cooperation system. Although employing the assistant robots to support the operator can increase the assembly efficiency and reduce the assembly burden, this collaboration can be extremely dangerous because the active robot is involved and any mistake can be fatal. To protect the operator during the assembly process, several safety designs are proposed and developed in this manufacturing system, which cover both hardware and software to achieve good robot-human collaboration. Fundamental concepts are:

1. Risk assessment by ISO regulation;
2. Area division by safety light curtains as illustrated in Figure 7;
3. Speed/Force limiter by serve controller;
4. Collision protector by physical devices;
5. Collision detector by IP cameras;
6. Inherent safety theory.

Risk Assessment by ISO Regulation

Since no direct industrial safety standards and regulations that govern this type of close range active human-robot collaboration, the safety design in this work is formulated by collective reference to related safety standards and regulations to verify component systems' safety first (non-collaboration safety) and then assess system safety as a whole (collaboration safety). Table 1 summarizes the referred industrial safety standards and regulations in mobile robot manipulators system development and total system development.

This chapter mainly focuses on the discussion on human-robot collaboration safety; therefore the non-collaboration safety of component systems is omitted. However, it is important to bear in mind that the following safety designs for collaboration are built in accordance with the referred

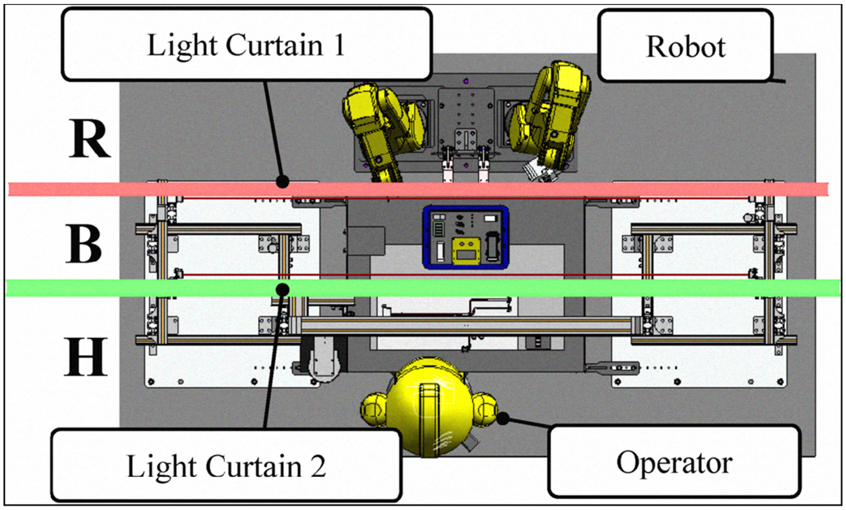
standards and regulations in the component level. EU standard permits the collaboration of robots with the operator when the total output of robots is less than 150 (N) at the tip of the end-effecter. Japanese standard defines that each actuator has the power less than 80 (W). The collaboration safety design is presented in hardware design and control design in the following.

Area Division by Safety Light Curtains

The software systems in robot controller and other computers are prepared as Dual Check Safety (DCS), which checks speed and position data of motors with two independent CPUs in the robot controller. In risk assessment, we listed up to 168 risks and take its countermeasure respectively

Figure 7. Three robot working zones for safety



so as to satisfy the required performance level. Whatsoever definition industrial robots are, it is strongly prohibited that robots exist with the operator in the same space. Thus a cage is required to separate the operator from the robots. For the area division, the whole cell in Figure 7 is divided into human area (**H**), robot area (**R**), and buffer area (**B**) by safety fences, photoelectric sensors and light curtains in order to obtain safe working areas and to monitor border crossing for safety. Robots are allowed to operate in high speed motion in area **R** but low speed movement in area **B**. In area **H**, the strong restrictions are applied to robot motions. When the manipulators move too close to the operators and cross the light curtain 2, the power of the manipulator is cut down by the light curtain. Consequently, the manipulators stop.

Speed/Force Limiter by Serve Controller

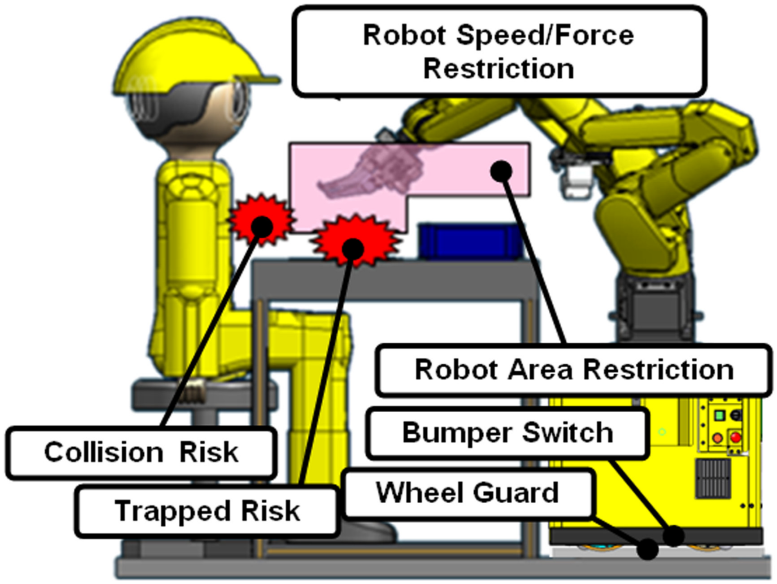
As shown in Figure 8, by the servo controller, the speed of the mobile manipulators is limited, and the force/torque at the end-effecter is also limited by software. The controller also has a function of abnormal force limiter in case of unexpected collision of the manipulator against the environment. Based on the recommendation from safety standards and risk assessment, during collaboration process, the speed of the mobile manipulators is limited to below 150 (mm/s) and the working area of the robot is restricted within the pink region in Figure 8. The minimum distance between the robot gripper and surface of the workbench is 120 (mm) according to ISO 13854.

Collision Protectors by Physical Devices

During the assembly process, several collision protectors by physical devices have been designed for accident avoidance and the protection of the operator.

1. **Mobile Base:** To prevent the operator from being hurt by the manipulators, the localization accuracy of the mobile base should be maintained. With vision system to detect marks on the floor, the system has a localization accuracy of 5 (mm) and 0.1°. The base is equipped with bumper switch for object collision detection and wheel guard to prevent foreign object being tangled with the wheels, as illustrated in Figure 8.

Figure 8. Robot speed, force, and area restrictions



2. **Footswitch:** In the MASS system, the twin mobile manipulators are used to assist the operator to execute the assembly tasks during the assembly process. Without a safety strategy, the operator could be injured by the manipulators. An effective working sequence is one of the effective ways to reduce the probability of collision between an operator and a manipulator. The manipulators are prevented from moving in the direction of the operator as he performs an assembly task. The probability for collisions is reduced with the introduction of the working sequence. To realize the proposed working sequence, a footswitch is used to control the manipulators, as illustrated in Figure 9. When the operator finishes an assembly step, he steps on footswitch, which signals the manipulators to provide the assembly parts to the operator for the next step.
3. **Emergency Button:** When an accident occurs, the operator can just push the emergency button on the right-hand side of the assembly workbench to stop the entire system, as shown in Figure 9. After any problem has been solved, the operator pushes the reset button to restart the assembly process.
4. **Safe Bar:** In addition, steel safe bar is installed in front of the assembly workbench (referred to Figure 9). If other strategies failed to stop the manipulator to collide the operator, this safe bar can protect the operator.

Collision Detector by IP Cameras

The developed system installs a robot with higher ability than both EU and Japan Standard. Even though various countermeasures are introduced, the risk assessment shows residual risks. For the intelligent compensation of safety, two IP cameras are utilized to monitor the operator's safety (referred to Figure 10); that is, the cameras track the color marks on the head and shoulders of the operator to measure the body posture and position to estimate the human operation conditions (Duan, 2009). The vision monitoring system has positioning accuracy of 30 (mm) and process delay of 0.6 (s).

Figure 9. Collision protectors by physical devices

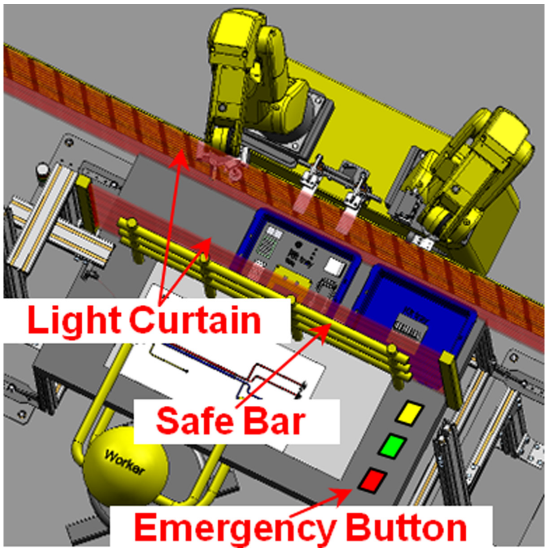


Figure 10. Operator safety monitoring system

Inherent Safety Theory

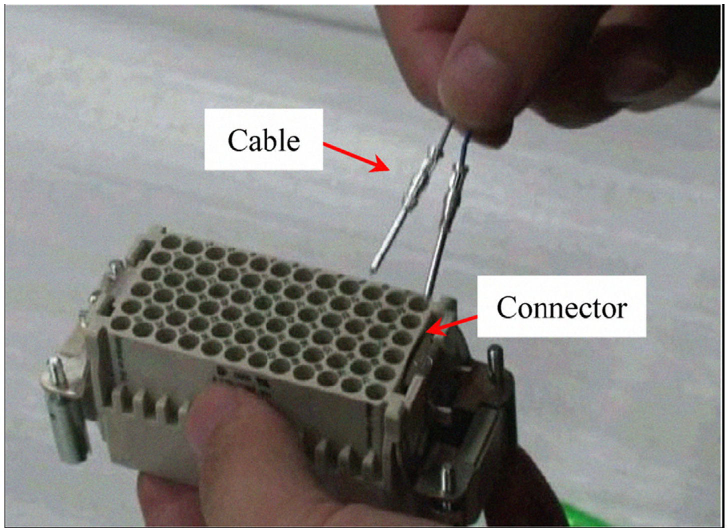
Although several safety strategies are adopted, there is no guarantee that a collision between a manipulator and an operator will never occur. Therefore, the manipulators should be ameliorated according to inherent safety theory (Ikeda & Saito, 2005) to reduce the injury of the operator. The sharp edges of the manipulators are softened into obtuse-angled brims. The force and speed of the manipulators are reduced as much as possible while still meeting the assembly requirement. In addition, the overall mobile robot manipulators system is built with low center of gravity design to prevent tipping.

Evaluation of MASS System

To evaluate the effect of the MASS system, a group of operators were required to execute an assembly task of cable harness, as illustrated in Figure 11. In this task, operators must insert correct cables into corresponding correct holes in the connector. After that, following the cable routes, operators must fix the cables to the jigs on the assembly table. The operators executed the cable harness task in two cases: (1) all of the assembly information, including the cable type, the position of the hole in the connector and the assembly step, was only provided by the assembly manual (Exp I); (2) operators executed the cable harness task under the support of MASS (Exp II). Two parameters were measured in the experiments: assembly time and assembly error. The assembly time is compared between conventional manual assembly setup (Exp I) and the new setup (Exp II). Five novice operators and five expert ones performed three assembly trails respectively for both the setups. From Figure 12, it is proved that the overall performance is better (shorter in assembly time) in the new setup (Exp II). Novices and experts show almost the same assembly time from the first trial in the case of the new setup as the dotted lines.

It means that the assembly can be executed at the minimum time even by the unskilled operators. Comparing to the assembly time of the conventional setup (Exp I), the novice operators need only 50% of the time in the MASS system (Exp II), which indicates double productivity. Note that

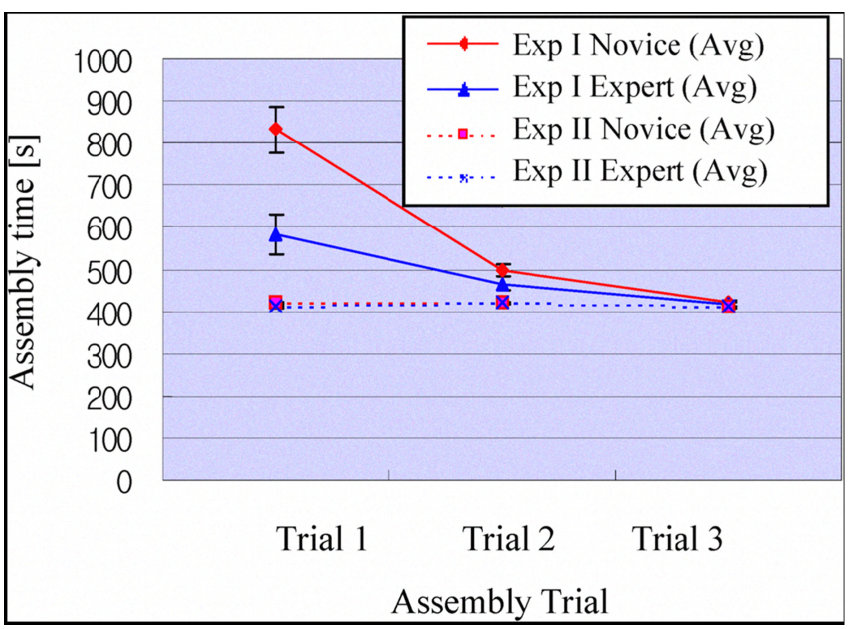
Figure 11. Cable harness task



the assembly time at the third trial converges to the minimum by all the cases. This implies that the assembly operation is easy to achieve and the human ability of learning is high. In other words, this system may be beneficial for very frequent change of products. In terms of assembly quality, 10% to 20% of assembly error (insertion error) is observed in conventional setup (Exp I), while in new cell production setup (Exp II) the error is totally being prevented by the robot assistance, especially by guidance of laser pointer and by the instruction of the assembly sequences.

According to the experimental results, it can be concluded that the developed MASS system

Figure 12. Difference of assembly time by experts and novices



can accelerate the operator's assembly process as well as prevent assembly errors.

According to Zhang (2008), this cable harness task is a kind of cognitive assembly task (Norman, 1993); therefore, the mental work load of the operators cannot be ignored. To evaluate the mental work load of the operators in (Exp I) and (Exp II), NASA-TLX (Task Load Index) method (NASA-TLX for Windows U.S.) was used. After the operators finished the cable harness task, they were required to answer the questionnaires. Based on the NASA-TLX method, the mental work load of the operators can be computed. The mental work load of (Exp I) is 62, which is much higher than that of (Exp II), which is 38. This means that based on the support of MASS, the mental work load of the operators can be reduced significantly.

CONCLUSION

This work aims to realize a new cellular manufacturing system for frequent changes of products. In this chapter, a multi-modal assembly-support system (MASS) was developed for a cellular manufacturing system. In the MASS, two manipulators are used to replace the operators to execute the laborious tasks. Based on the assembly information database and assembly information supporting system, this system is capable of meeting the assembly and training requirements of the experienced and the novice operators. Besides developing the actual system, a simulator for an entire assembly system was created to reduce the time and costs required for development. To protect the operator from harm, several safety strategies and equipments were presented. According to inherent safety theory, two manipulators are ameliorated, which could reduce the injury of the operators even when they were collided by the manipulators.

To evaluate the effect of MASS, a group of experienced operators and novice operators were required to execute a cable harness task. According to the experimental results, basing on the support of MASS, not only the assembly time and the error ratios are reduced, but also the mental work load of the operators is reduced. Therefore, the MASS allows an operator to receive physical and informational support while working in the actual manufacturing assembly process.

Future studies should be directed at identifying and monitoring the conditions that contribute to the operator's fatigue and intention during the assembly process; these efforts will lead to improvements in comfort for the operators and assembly efficiency.

ACKNOWLEDGMENT

This study is supported by NEDO (New Energy and Industrial Technology Development Organization) as one of "Strategic Projects of Element Technology for Advanced Robots". The author Feng DUAN is supported by the Fundamental Research Funds for the Central Universities (No.65010221). We appreciate NEDO and MSTC for accelerating the development of this practical system. In particular, we would like to acknowledge FANUC Company for their excellent cooperation and technical support.

Chapter 33
Modeling and Simulation of Discrete Event Robotic Systems Using Extended Petri Nets

Gen'ichi Yasuda
Nagasaki Institute of Applied Science, Japan

ABSTRACT

This chapter deals with modeling, simulation, and implementation problems encountered in robotic manufacturing control systems. Extended Petri nets are adopted as a prototyping tool for expressing real-time control of robotic systems and a systematic method based on hierarchical Petri nets is described for their direct implementation. A coordination mechanism is introduced to coordinate the event activities of the distributed machine controllers through friability tests of shared global transitions. The proposed prototyping method allows a direct coding of the inter-task cooperation by robots and intelligent machines from the conceptual Petri net specification, so that it increases the traceability and the understanding of the control flow of a parallel application specified by a net model. This approach can be integrated with off-the-shelf real-time executives. Control software using multithreaded programming is demonstrated to show the effectiveness of the proposed method.

1. INTRODUCTION

Complex robotic systems such as flexible manufacturing systems require sophisticated distributed real-time control systems. A major problem concerns the definition of the user tasks and the cooperation between the subsystems, especially since the intelligence is distributed at a low level (machine level). Controlling such systems generally requires a hierarchy of control units corresponding to several abstraction levels. At the bottom of the hierarchy, i.e. machine control level, are the programmable logic controllers (PLC). The next level performs coordination of the PLCs. The third level implements scheduling, that is, the real-time assignments of workpieces

DOI: 10.4018/978-1-4666-1945-6.ch033

and tools to machines. At the machine level, PLCs perform local logical control operations of flexible, modular, high-speed machines through the use of multiple independent drives (Holding, et al. 1992). Implementation languages can be based on ladder diagrams or more recently state machines (Silva, et al. 1982). However, when the local control is of greater complexity, the above kinds of languages may not be well adapted. The development of industrial techniques makes a sequential control system for robotic manufacturing systems larger and more complicated one, in which some subsystems operate concurrently and cooperatively (Neumann, 2007).

In the area of real-time control of discrete event robotic systems the main problems that the system designer has to deal with are concurrency, synchronization, and resource sharing problems. Presently, the implementation of such control systems makes a large use of microcomputers. Real-time executives are available with complete sets of synchronization and communication primitives. However, coding the specifications is a hazardous work and debugging the implementation is particularly difficult when the concurrency is important. It is important to have a formal tool powerful enough and allowing developing validation procedures before implementation. Conventional specification languages do not allow an analytical validation. Consequently, the only way to validate is via simulation and step by step debugging. On the other hand, a specification method based on a mathematical tool may be more restricting, but analytical procedures can strongly reduce the simulation step. Rapid prototyping is an economical and crucial way to experiment, debug, and improve specifications of parallel applications. Increasing complexity of synchronizing mechanisms involved in concurrent system design makes necessary a prototyping step starting from a formal, already verified model. Petri nets allow to validate and to evaluate a model before its implementation. The formalism allowing a validation of the main properties of the Petri net control structure (liveness, boundedness, etc.) guarantees that the control system will not fall immediately in a deadlocked situation. In the field of flexible manufacturing cells, the last aspect is essential because the sequences of control are complex and change very often.

When using Petri nets, events are associated with transitions. Activities are associated to the firing of transitions and to the marking of places which represents the state of the system. The network model can describe the execution order of sequential and parallel tasks directly without ambiguity (Silva, 1990). Pure synchronization between tasks, choices between alternatives and rendezvous can be naturally represented. Moreover at the machine level Petri nets have been successfully used to represent the sequencing of elementary operations (Yasuda, et al. 1992). In addition to its graphic representation differentiating events and states, Petri nets allow the possibility of progressive modeling by using stepwise refinements or modular composition. Libraries of well-tested subnets allow components reusability leading to significant reductions in the modeling effort. The possibility of progressive modeling is absolutely necessary for large and complex systems, because the refinement mechanism allows the building of hierarchically structured net models. Furthermore, a real-time implementation of the Petri net specification by software called a token player can avoid implementation errors. This is because the specification is directly executed by the token player and the implementation of these control sequences preserves the properties of the model. In this approach, the Petri net model is stored in a database and the token player updates the state of the database according to the operation rules of the model. For control purposes, this solution is very well suited to the need of flexibility, because, when the control sequences change, only the database needs to be changed.

Some techniques derived from Petri nets have been successfully introduced as an effective tool for describing control specifications and realizing the control in a uniform manner (Murata, et al. 1986). However, in the field of flexible manufacturing cells, the network model becomes complicated and it lacks the readability and comprehensibility (David, et al. 1992). Therefore, the flexibility and expandability are not satisfactory in order to deal with the specification change of the control system. Despite the advantages offered by Petri nets, the synthesis, correction, updating, etc. of the system model and programming of the controllers are not simple tasks (Zhou, et al. 1993), (Desrochers, et al. 1995), (Lee, et al. 2006). Some Petri net implementation methods have already been proposed for simulation purposes or for application prototyping (Butler, 1991), (Garcia, 1998), (Piedrafita, et al. 2008). However the implementation method for hierarchical and distributed control of complex robotic systems has not been established sufficiently so far (Breant, et al. 1992), (Girault, et al. 2003), (Zhou, et al. 1999). If it can be implemented using Petri nets, the modeling, simulation and control can be realized consistently.

This chapter describes a Petri net based prototyping method for real-time control of complex robotic systems. The presented method, based on the author's previous works (Yasuda, et al. 2010), (Yasuda, 2010), involves three major steps, and progressively gathers all information needed by the control system design and the code generation for simulation experiments. The first step consists in specifying the conceptual net model for overall system control. The second step consists in transforming the net model into the detailed net model. Based on the hierarchical and distributed structure of the system, the specification procedure is a top-down approach from the conceptual level to the detailed level. The third step consists in decomposing the detailed net into local net models for machine control and the coordination model. The coordination algorithms are simplified since the robots and machines in the system are separately controlled using dedicated task execution programs. In order to deal with complex models, a hierarchical approach is adopted for the coordination model design. In this way, the macro representation of the system is broken down to generate the detailed nets at the local machine control level. Finally, the C++ code generation using multithreaded programming is described for the prototype hierarchical and distributed control system.

2. MODELING OF DISCRETE EVENT SYSTEMS USING EXTENDED PETRI NETS

A Petri net is a directed graph whose nodes are places shown by circles and transitions shown by bars. Directed arcs connect places to transitions and transitions to places. Formally, a Petri net is a bipartite graph represented by the 4-tuple $G=\{P,T,I,O\}$ such that:

$P=\{p_1,p_2,\ldots,p_n\}$ is a finite, not empty, set of places;
$T=\{t_1,t_2,\ldots,t_m\}$ is a finite, not empty, set of transitions;
$P\cap T=\phi$, i.e. the sets P and T are disjointed;
I: $T\rightarrow P^\infty$ is an input function, a mapping from transitions to bags of places;
O: $T\rightarrow P^\infty$ is an output function, a mapping from transitions to bags of places.

The input function I maps from a transition t_j to a collection of places $I(t_j)$, known as input places of a transition. The output function O maps from a transition t_j to a collection of places $O(t_j)$, known as input places of a transition. The pre-incidence matrix of a Petri net is $C^- = [c_{ij}^-]$ where $c_{ij}^- = 1$ $(p_i \in I(t_j))$, $c_{ij}^- = 0$ $(p_i \notin I(t_j))$; the post–incidence matrix is $C^+ = [c_{ij}^+]$ where $c_{ij}^+ = 1$ $(p_i \in O(t_j))$, $c_{ij}^+ = 0$ $(p_i \notin O(t_j))$, then the incidence matrix of the Petri net $C = C^+ - C^-$. Each place contains integer (positive or zero) marks or tokens. The number of tokens in each place is defined by the marked vector or marking $M = (m_1, m_2, ..., m_n)^T$. The number of tokens in one place p_i is simply indicated by $M(p_i)$. The firing of a transition will change the token distribution (marking) in the net according to the transition firing rule. In the basic Petri net, a transition t_j is enabled if, $\forall p_i \in I(t_j)$, $M_k(p_i) \geq w(p_i, t_j)$, where the current marking is M_k and $w(p_i,t_j)$ is the weight of the arc from p_i to t_j. A sequence of firings will result in a sequence of markings. A marking M_n is said to be reachable from a marking M_0 if there exists a sequence of firings that transforms M_0 to M_n. The set of all possible markings reachable from M_0 is denoted as $R(M_0)$. A Petri net is said to be k-bounded or simply bounded if the number of tokens in each place does not exceed a finite number for any marking reachable from M_0, i.e., $\forall p_i \in P$, $\forall M \in R(M_0)$, $M(p_i) \leq k$ (Reisig, 1985), (Murata, 1989).

In the basic Petri net, bumping occurs when despite the holding of a condition, the preceding event occurs. This can result in the multiple holding of that condition. From the viewpoint of discrete event process control, bumping phenomena should be excluded. So, the firing rule was modified so that the system is free of this phenomenon. Because the modified Petri net must be 1-bounded, for each place p_i, $m_i = 0$ or 1, and the weight of every arc is 1. A Petri net is said to be ordinary if all of its arc weights are 1's. Thus the axioms of the modified Petri net are as follows.

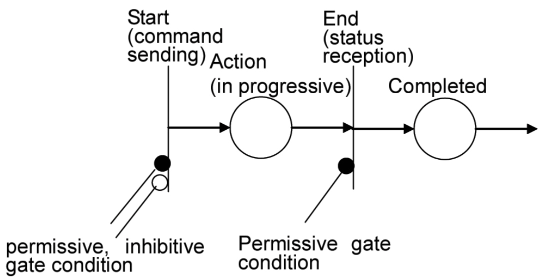
1. A transition t_j is enabled if for each place $p_k \in I(t_j)$, $m_k = 1$ and for each place $p_l \in O(t_j)$, $m_l = 0$.
2. When an enabled transition t_j fires, the marking M is changed to M', where for each place $p_k \in I(t_j)$, $m'_k = 0$ and for each place $p_l \in O(t_j)$, $m'_l = 1$.
3. In any initial marking, there must not exist more than one token in each place.

A transition without any input place is called a source transition, and one without any output place is called a sink transition. A source transition is unconditionally enabled, and the firing of a sink transition consumes a token in each input place, but does not produce any. According to these axioms, the number of tokens in a place never exceeds one, thus the modified Petri net is essentially 1-bounded and said to be a safe graph.

Besides the guarantee of safeness, considering not only the modeling but also the actual system control of robotic systems, the additional capabilities of input and output interfaces which connect the net to its environment are required. The extended Petri net adopts the following two elements: 1) Gate arc, 2) Output signal arc (Hasegawa, et al. 1984). A gate arc connects a transition with a signal source, and depending on the signal, it either permits or inhibits the occurrence of the event which corresponds to the connected transition. Gate arcs are classified as permissive or inhibitive, and internal or external. An output signal arc sends a command request signal from a place to an external machine. The interfaces are a set of transitions which represent the communication activities of the net with its environment. Thus the firing rule of a transition is described as follows: an enabled transition may fire when it does not have any internal permissive arc signaling 0 nor any internal inhibitive arc signaling 1 and it does not have any external permissive arc signaling 0 nor any external inhibitive arc signaling 1.

A robotic action is modeled by two transitions and one condition as shown in Figure 1. At the "Start" transition the command associated with the transition is sent to the corresponding robot or machine. At the "End" transition the status report is received. When a token is present in the "Action" place, the action is in progressive. The "Completed" place can be omitted, and then the "End" transition is fused with the "Start" transi-

Figure 1. Extended Petri net model of robotic action with external permissive and inhibitive gate arcs



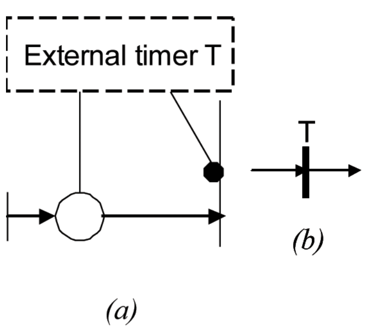
tion of the next action. Activities can be assigned an amount of time units to monitor them in time for real performance evaluation.

The firing of a transition is indivisible; the firing of a transition has duration of zero. Extended Petri nets to consider timing conditions where each activity is assigned an amount of time units can also be used as shown in Figure 2. Through the simulation steps, the transition vector table is efficiently used to extract enabled or fired transitions.

The flow chart of simulation and evaluation procedure is shown in Figure 3. At a step of simulation of robotic task, the configuration of the robots can be seen with graphic simulation. The data structure of the extended Petri net simulator is made up of several tables corresponding to the structural information of the net specifying the robotic task. These tables are the following ones:

1. The table of the labels of the input and output places for each transition,
2. The table of the transitions which are likely to be arbitrated for each conflict place,
3. The table of the gate arcs which are internal or external, permissive or inhibitive, for each transition,
4. The table of marking which indicates the current marking for each place,
5. The table of places to tasks mapping which points out the tasks that have to be put into the ready state when the corresponding place receives a token,
6. The table of the "end of task" transitions, which associates with each of task the set of transitions with external gate arcs switched each time an "end of task" message is received by the simulator. The "end of task" transitions are only fired on the reception of an "end of task" message.

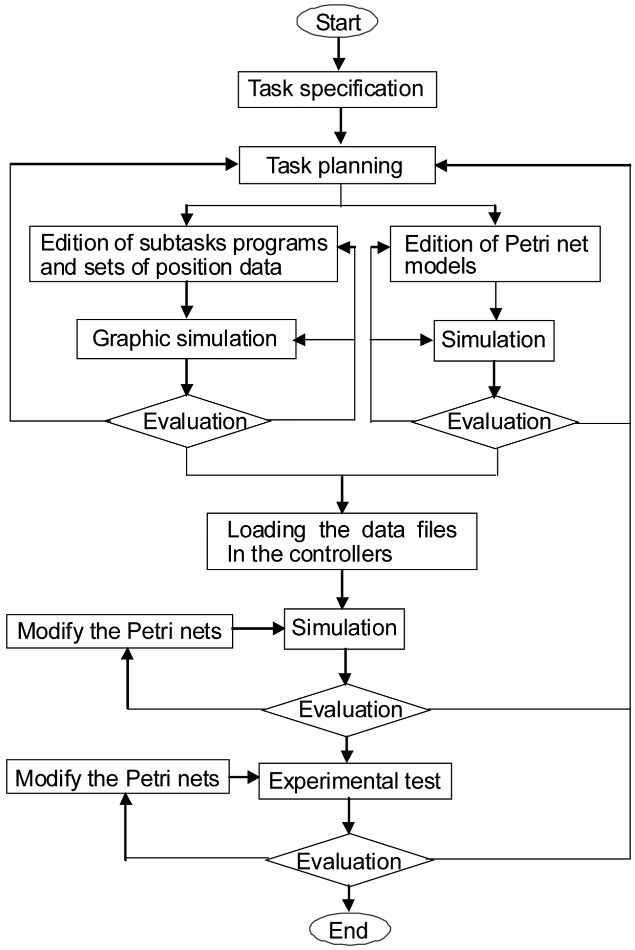
Figure 2. Examples of representation of timing conditions: external timer with output signal arc and external gate arc, (b) timed transition



3. PETRI NET MODELS OF COOPERATIVE CONTROL OF CONCURRENT TASKS

A robotic task consists of several subtasks or operations, and a subtask consists of several actions. Conceptually, robotic processes are represented as sequential constructs or state machines, where each transition has exactly one incoming arc and exactly one outgoing arc. The structure of a place having two or more output transitions is referred to as a conflict, decision, or choice, depending on applications. State machines allow the representation of decisions, but not the synchronization of parallel activities. In a net model of robotic task, the set of places can be classified into three groups: idle, operation, and resource places. A token in an idle place indicates that the robot is ready to work and

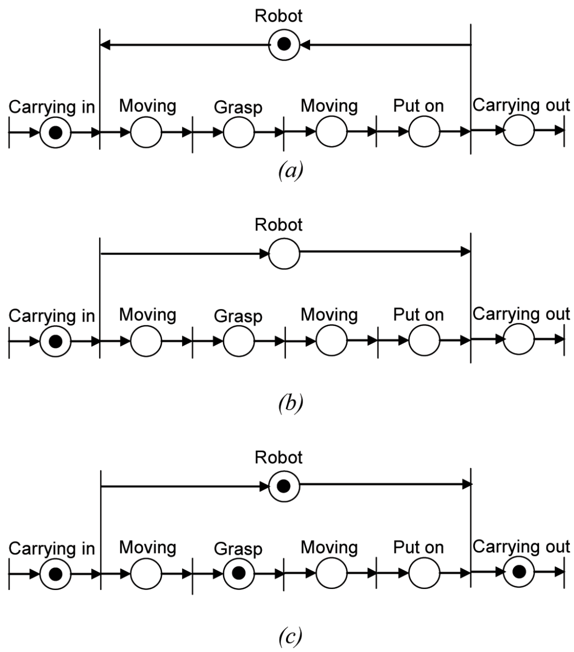
Figure 3. Flow chart of simulation and evaluation procedure



waiting for a specified signal from another robot or its environment. An operation place represents an operation to be processed for a workpiece or part in a manufacturing sequence and initially it has no token. Resource places represent resources (robots and machines) and their initial tokens represent the number of available resource units.

A task executed by a robot or machine can be seen as some connection of more detailed subtasks. For example, transferring an object from a start position to a goal position is a sequence of the following subtasks: moving the hand to the start position, grasping the object, moving to the goal position, and putting it on the specified place. Figure 4 shows the net representation of a robotic task: pick and place operation with the input and output conveyors. While the place "Robot" in Figure 4(a) indicates that the state of the robot is "ready" when the token is in the place, in Figure 4(b) it indicates that the state of the robot is "operating". The place also indicates the macro representation of the pick and place operation. The parallel net in Figure 4(b) is equivalent to the cyclic net in Figure 4(a) with respect to the enabling conditions of all the transitions in the net. The parallel net assures that the robot can load or unload only one workpiece at a time. Figure 4(c) shows the possible evolution of dynamic behavior of the net.

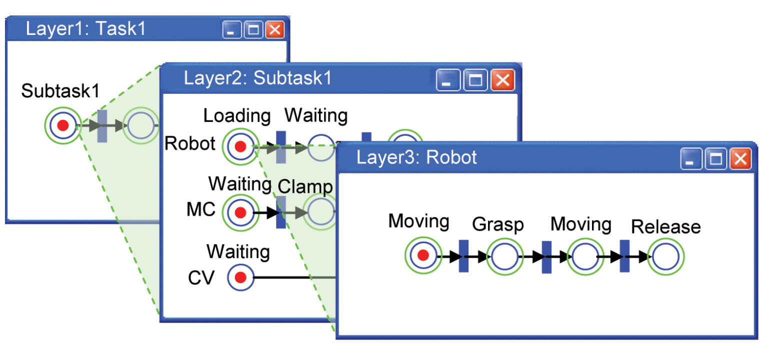
Figure 4. Net representation of robotic task: (a) cyclic net model of robot, (b) equivalent parallel net model, (c) possible state of net model



Furthermore the subtasks are translated into more detailed actions. A hierarchical approach consists in building a model by stepwise refinements. At each step some parts of the model are replaced by a more complex model. A modular approach by model composition affords to build complex validated Petri nets. Figure 5 shows the view of a hierarchical net representation by the graphic net simulator.

A specification procedure for discrete event robotic systems based on Petri nets is as follows. First, the conceptual level activities of the system are defined through a net model considering the task specification corresponding to the aggregate discrete event process. The places which represent the subtasks indicated as the task specification are connected by arcs via transitions in the specified order corresponding to the flow of subtasks and a workpiece. The places representing

Figure 5. Hierarchical net representation of robotic task (loading) on graphic net simulator



robots and machines used for the subtasks are also added to connect transitions which correspond to the beginning and ending of their subtasks. Then, the places describing the subtasks are substituted by a subnet based on activity specification and required control strategies in a manner which maintains the structural properties (Yasuda, et al. 2010).

For concurrent control in the conceptual net model, two implementation methods of synchronous interaction between two tasks which are executed respectively by one robot are shown in Figure 6(a), (b) (Yasuda, 2000), while an implementation with asynchronous communication based on the well-known signal/wait (semaphore) concept is shown in Figure 6(c).

A coordination mechanism is introduced to coordinate concurrent systems with separate robots which require interaction between each other, such as synchronization and resource conflict. Figure 7 shows the net model of a coordination mechanism to conduct synchronous interaction by means of synchronous communication between two robots. This is also the detailed representation of the shared transition. A shared transition for synchronous interaction by separate robots is said to be a global transition, while a transition for independent action by a single robot is said to be a local transition. For synchronous interaction, the coordination algorithm is formally expressed using logical variables such that the global transition is fired if all of associated transitions in the local net models are fired. The firing condition of a global transition G_j in the conceptual net which represents the event of synchronous action by S robots is written as

$$G_j = \bigcap_{sub=1}^{S} t_{jsub} \tag{1}$$

where the corresponding event of action by each robot is represented by t_{jsub} (sub = 1⋯S), and ∩ denotes logical product operation. Figure 8 shows a net model of a coordination mechanism to execute selective control by means of synchronous communication, where the decision place executes any arbitration rule such as order or priority, to select independent action by a robot or cooperative action by two robots.

A hierarchical and distributed control system is composed of one system controller and several machine controllers. The coordination mechanism as well as the conceptual net model of the system is implemented in the system controller and detailed net models are allocated to machine controllers. The coordination program is substantially the firing test program of global transitions using the firing rule and a set of relational data tables of global transitions with their input and output places and associated gate arcs. The coordination procedure through communica-

Figure 6. Net representation of synchronous interaction between two concurrent tasks: (a) synchronous communication with a shared transition, (b) interlock with mutual gate arcs,(c) asynchronous communication (signal/wait)

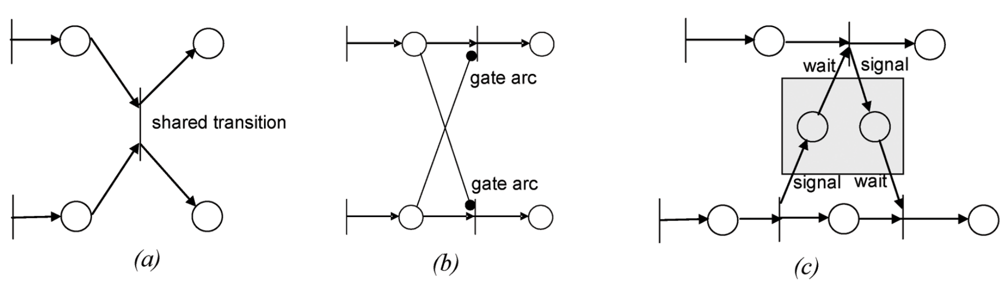


Figure 7. Net model of coordination mechanism for synchronous interaction by means of synchronous communication with a shared transition

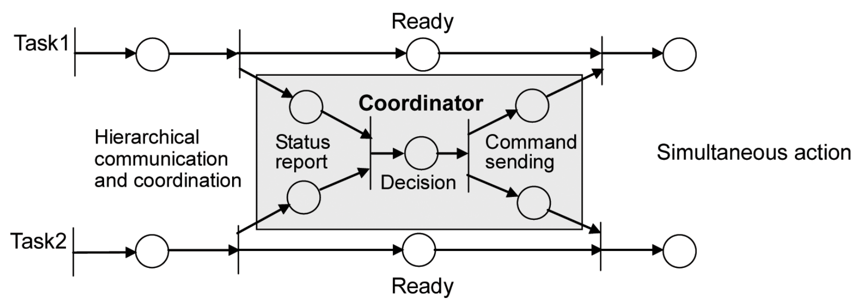

tion between the coordinator and machine controllers is shown as follows:

1. When a machine controller receives a command start signal from the coordinator, it starts the execution of the requested command task.
2. At the end of execution, the machine controller sends a status report as a gate condition to the coordinator.
3. When the coordinator receives the new gate condition, it updates the net model and tests the firing condition associated with the gate condition in the net. If a new transition is fired, then a command associated with the transition is sent to the corresponding machine controller.

For the actual control, the operations of each machine or robot are broken down into a series of unit motions, which is represented by mutual connection between places and transitions. A place means a concrete unit motion of a machine. From these places, output signal arcs are connected to the external machines, and external gate arcs from the machines are connected to the transitions of the net when needed, for example, to synchronize and coordinate operations. When a token enters a place that represents a subtask, the machine defined by the machine code is informed to execute a specified subtask with positional and control data; these code and data are defined as the place parameters. Figure 9 shows the net representation of real-time execution control of a robotic unit action.

Figure 8. Net model of coordination mechanism for selective control

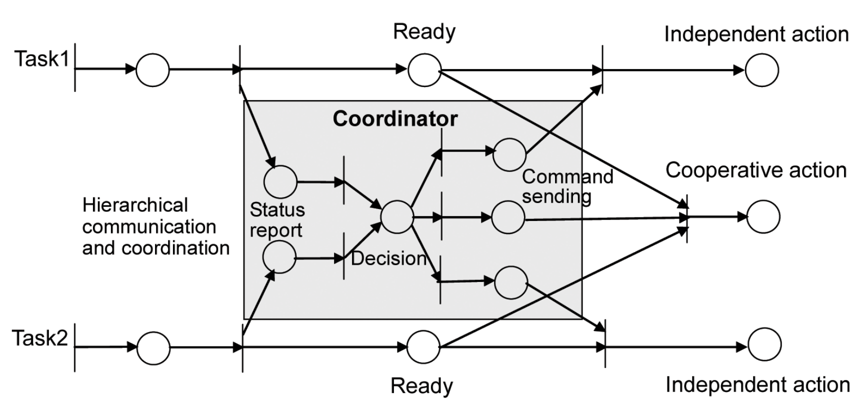

Figure 9. Net representation of execution control of robotic action using output signal arc and external permissive gate arc

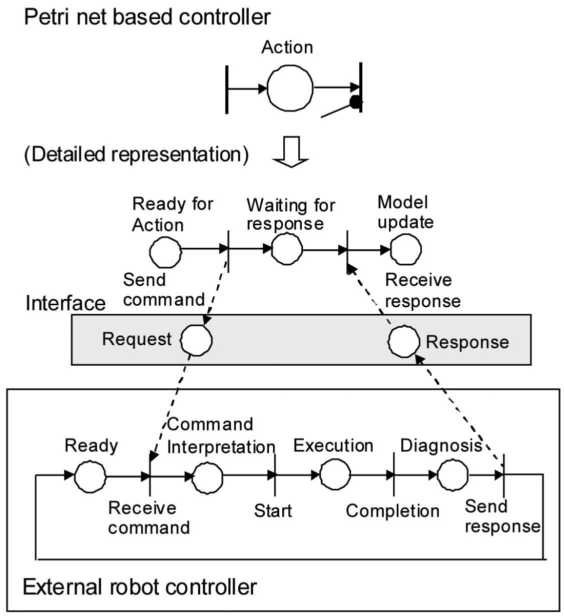


4. IMPLEMENTATION OF DISTRIBUTED CONTROL WITH MULTITHREADS

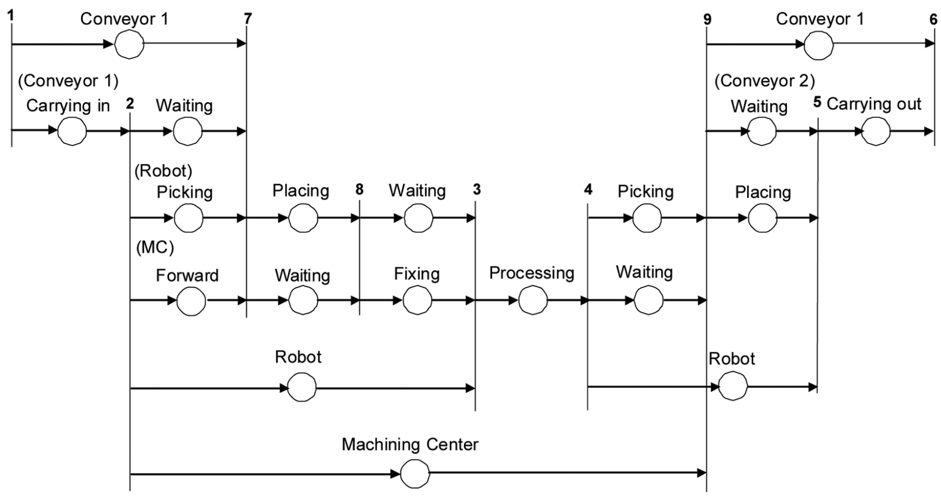
The example robotic system has one robot, one machining center, and two conveyors, where one is for carrying in and the other one is for carrying out. The main execution of the system is indicated as the following task specification:

1. A workpiece is carried in by the input conveyor.
2. The workpiece is loaded to the machining center by the robot.
3. The workpiece is processed by the machining center.
4. The workpiece is unloaded from the machining center by the robot.
5. The workpiece is carried out by the output conveyor.

The robotic system works in the following way: A workpiece comes on the input conveyor up to the take up position. The robot waits in the waiting position in front of the conveyor, and, on stopping, approaches in the take up position, grips the object and returns to the waiting position. Then it turns, goes into the working space of the machine center and there it leaves the workpiece. After automatic gripping of the object the robot draws back and it waits for the machining center to complete object processing. After object processing, the robot goes to the machining center, takes the workpiece from an opened vice and carries it over to a free position on the output conveyor.

The discrete event processes of the robotic system are represented at the conceptual level as shown in Figure 10. All the transitions are used to coordinate the overall system. Shared transitions between the robot and a machine, represent synchronous interaction and are coordinated as global transitions to be fired simultaneously. In this step, if necessary, control conditions such as the capacity of the system between the respective subtasks must be connected to regulate the execution of the manufacturing process. Next, each place

Figure 10. Net representation of robotic task at conceptual level



representing a subtask at the conceptual level is translated into a detailed subnet, which is used for local control of each robot or machine.

The prototyping method was applied to produce semi-automatically C++ program from the net models on a general PC using multithreaded programming (Grehan, et al. 1998). Then, by executing the coordination program and net based controllers algorithms based on loaded information on a network of dedicated microcomputers, experiments on the final test can be performed (Yasuda, 2010). Multithreads control software composed of one modeling thread, one simulation thread and several task execution threads, were designed and written in Microsoft Visual C# under OS Windows XP SP3. The simulation thread executes the coordination program and the conceptual net based controller algorithm, while the task execution threads execute local net based controller algorithms, which control robots and machines through serial interfaces using the command/response concept. An example diagram of two-level net based concurrent real-time control of two external machines using one simulation and two task execution threads is shown in Figure 11.

The modeling thread, which is the main thread, executes the event driven net modeling, drawing and modification based on task specification using windows button clicks and mouse operations, as shown in Figure 12. When the transformation of graphic data of the net model into internal structural data is finished, the simulation thread is activated using window buttons by the user from the modeling thread. The simulation thread executes the enabling and firing test using gate conditions as shown in Figure 13, and when a transition is fired, the simulation thread activates the task execution thread and initiates the execution of a subtask by sending commands attached to the fired transition. When all the subtasks in the system are in progressive, the simulation thread waits for the turning on of any gate condition repeatedly. If a subtask is completed, the gate condition is turned on, then the simulation thread receives the gate signal through the external gate arc and updates the table of gate conditions.

The program structure and the main C# code of the task execution thread are illustrated in Figure 14 and Listing 1. One task execution thread is allocated in each machine. When a task execution thread is activated, it sends the direct commands with specified positional and control data

Figure 11. Two-level net based concurrent real-time control of two external machines

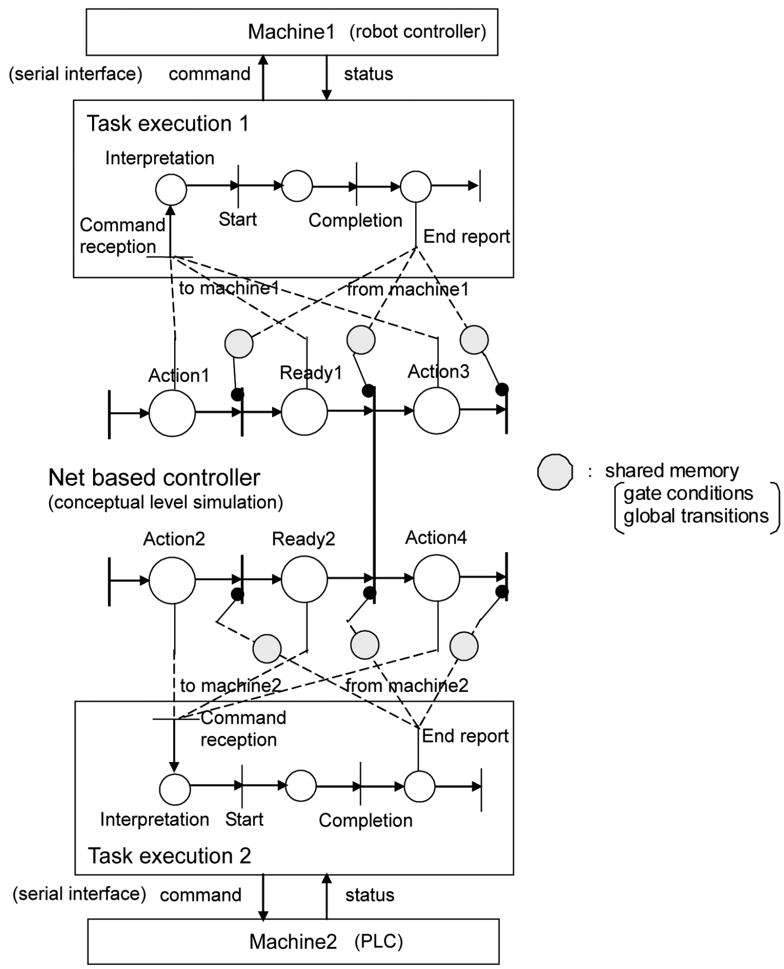


Figure 12. Program structure and main C# code of modeling thread

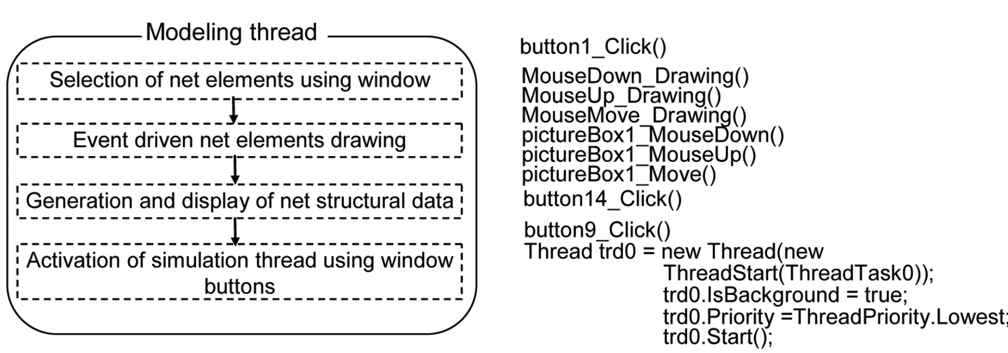

Figure 13. Program structure of simulation thread

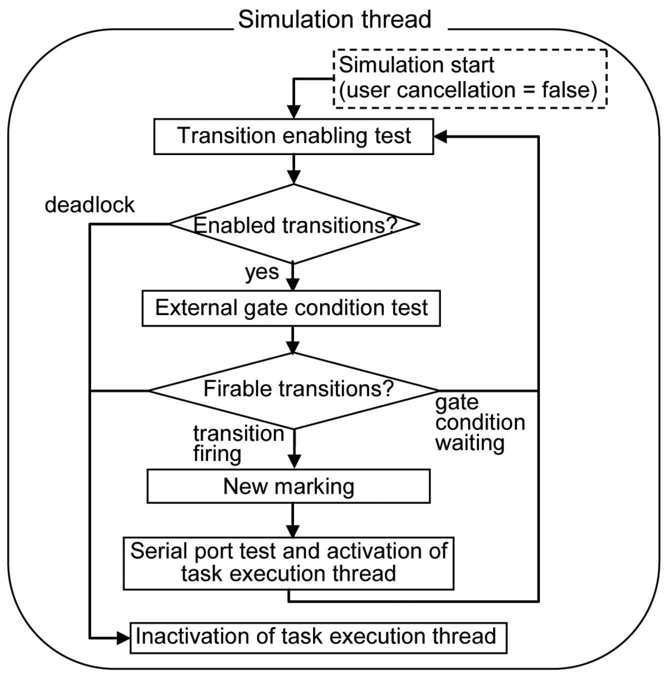

through the serial interface to the dedicated robot or machine. Then the thread searches the target gate condition and waits for any status report through the interface repeatedly. When the subtask ends its activity normally, the thread receives the normal end report. Then, the thread turns the target gate condition on and the current gate condition off, so that the simulation thread can proceed with the next activations through the external gate arc. During simulation and task execution, it is decided by the simulator that whether it is in a deadlocked situation or not, and the user can stop the task execution through the simulator at any time.

In the real-time control both the simulation thread and the task execution threads access to the external gate variables as shared variables; task execution threads write the values of the gate variables after the completion of subtasks and the simulation thread reads them for the friability test considering gate conditions. Mutual exclusive access control and the C# code were implemented as shown in Figure 15 and Listing 2 respectively. The method function uses a "lock" statement of C# for the mutual exclusive access to shared

Figure 14. Program structure of task execution thread

```
private void ThreadTask1()
{
        serialPort1.WriteLine(CC1[TH1 - 1] + "\r\n");        // command of fired transition no.TH1
        for (int j = 0; j < TP_R; j++){
                if (TPC[TH1 - 1, j] > 0){                    // search output place of fired transition
                        PO = TPC[TH1 - 1, j];
                        PH[PO - 1] = 1;  }}                  // output place no.PO
                        for (int i = 0; i < T_No; i++){      // search output transition of place no.PO
                                for (int j = 0; j < TP_R; j++){
                                        if (TPC[i, j] == -(PO + 1)){
                                                for (int m = 0; m < EG_R; m++){
                                                        if (TGE[i, m] > 0)  GC1 = TGE[i, m];     // gate no.GC1
                                                }}}
                                        do{
                                                // method call
                                        }
                                        while (THN == 1);                // gate condition write mode on
                        }
        if (THN == 0) receiveData1 = "EG-WAIT";
}
```

variables so that, while one thread calls the function, the other thread can not call it. Using the method function call, the simulator thread waits for the external gate signal, and after a task execution thread writes the permissive value of the target gate variable, the simulator thread reads it.

Experimental results of multithreads scheduling for one and two task execution threads are shown in Figure 16(a), (b), respectively. In case of two threads, one thread takes charge of a robot controller, and another takes charge of a PLC for sequence control of a conveyor respectively through serial interface. Here, the time slice of the OS is about 15ms, and the timer program is inserted in the reference position of each thread to capture the time the method function is called.

Numerous experiments show that the gate condition is transferred through the shared memory from the task execution thread to the simulation thread as quickly as possible. Experiments using a real robot and conveyors show that the simulation thread and the task execution threads are concurrently executed with even priority, and the values of external gate variables are changed successfully in the conceptual net model. The global transitions fire simultaneously with the transition of the conceptual net of the whole system task. The robot cooperated with the conveyors and the machining center, and the example robotic system performed the task specification successfully.

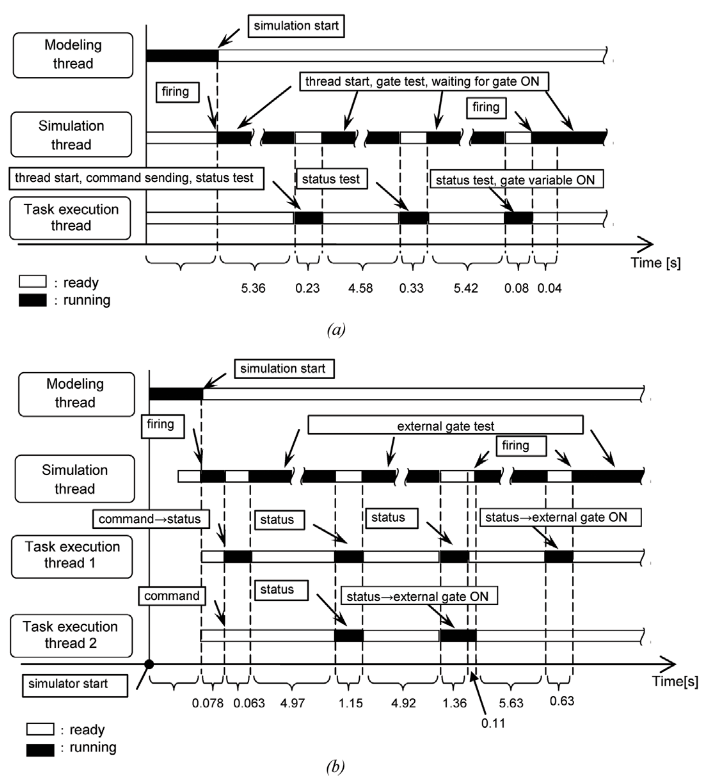
```
private void EG_SET()
{
        lock (this)
        {
        if (EG_f == 1){                              // simulation thread
                for (int i = 0; i < T_No; i++){      // gate condition test
                if (TI[i] == 1){                     // enabled transition
                        for (int j = 0; j < EG_R; j++){
                                GC1 = TGE[i, j];     // gate no.j associated with transition no.i
                                if (GC1 > 0){        // permissive gate
                                        if (EG[(GC1 - 1)] == 0) TI[i] = 0;       // read permissive gate signal off
                                }
                                else if (GC1 < 0) {  // inhibitive gate
                                        if (EG[Math.Abs(GC1 + 1)] == 1) TI[i] = 0;   // read inhibitive gate signal on
                                        }}}}}

        else if (EG_f == 2){                         // task execution thread
                if (recieveData1 == "RDY"){          // received status report 'ready'
                        GC2 = TGE[TH1-1, j];         // write gate no.GC2 off
                        if (GC2 > 0) EG[GC2 - 1] = 0;
                        else if(GC2 < 0) EG[Math.Abs(GC2 + 1)] = 0;
                        EG[GC1 - 1] = 1;             // write gate no.GC1 on
                        TH[TH1 - 1] = 0;             // fired teansition no. initialize
                        PH[k] = 0;                   // working place no. initialize
                        THN = 0;                     // gate condition write mode off
                }
                Application.DoEvents();              // serial communication message buffer initialize
        }}
```

Figure 16. Experimental results of multithreads scheduling: one task execution thread, (b) two task execution threads



In accordance with the implementation using multithreaded programming, hierarchical and distributed implementation under a real-time operating system on a network of microcomputers connected via a shared serial bus is also possible, where each microcomputer is dedicated to the local net model of a subsystem in the overall robotic system. After the arrival of a request, the response carrying the status information crosses the communication network and gets to the input buffer of the network board of the controller and written in the cache memory. The control data issued by the controller is written in the cache memory shared with the network board, sent to its target microcomputer, and there causes the new controlled status. By a shared communication network replacing traditional directly wired systems, a more flexible, reliable and efficient control performance can be surely expected.

5. CONCLUSION

A prototyping methodology to build hierarchical and distributed control systems corresponding to the hardware structure of robotic control systems has been presented. The conceptual net is used to coordinate distributed local machine controllers using the decomposed information of global transitions representing cooperative interaction between machines: the coordination mechanism can be implemented in each layer of the control hierarchy of the system repeatedly.

The overall control structure of the example robotic system was implemented on a general PC with serial interface using multithreaded programming. For the example system, detailed net models can be automatically generated using the database of robotic operations. The hierarchical approach allows us to reuse validated net models, such as loading, unloading, and specific handling operations, already defined for other purposes, that is an efficient way to deal with complex net models. The conceptual and local net models are not so large that all of the net based controllers can be implemented on general microcomputers or PLCs. Thus, modeling, simulation and control of large and complex manufacturing systems can be performed consistently using Petri nets.

Chapter 34
Human-Friendly Robots for Entertainment and Education

Jorge Solis
Waseda University, Japan & Karlstad University, Sweden

Atsuo Takanishi
Waseda University, Japan

ABSTRACT

Even though the market size is still small at this moment, applications of robots are gradually spreading out from the manufacturing industrial environment to face other important challenges, like the support of an aging society and to educate the new generations. The development of human-friendly robots drives research that aims at autonomous or semi-autonomous robots that are natural and intuitive for the average consumer to interact with, communicate with, and work with as partners, besides learning new capabilities. In this chapter, an overview of research done on the mechanism design and intelligent control strategies implementation on different platforms and their application to entertainment and education domains will be stressed. In particular, the development of an anthropomorphic saxophonist robot (designed to mechanically reproduce the organs involved during saxophone playing) and the development of a two-wheeled inverted pendulum (designed to introduce the principles of mechanics, electronics, control, and programming at different education levels) will be presented.

INTRODUCTION

The development of anthropomorphic robots is inspired by the ancient dream of humans replicating themselves. However, human behaviors are difficult to explain and model. The recent technological advances in robot technology, artificial intelligence, power computation, etc. have contributed to enable humanoid robots to roughly emulate the physical dynamics and motor dexterity of humans. Nowadays, humanoid robots are able of displaying motor dexterities for dancing, playing musical instruments, talking, etc. Although the long-term goal of true autonomous humanoid robots has yet to be accomplished, the

DOI: 10.4018/978-1-4666-1945-6.ch034

feasibility of integrating them into people's daily lives is becoming closer.

Towards developing humanoid robots capable of interacting more naturally with human partners, robots are required to process and display human-like emotions. The way a person interacts with a humanoid robot is quite different from interacting with the majority of industrial robots today. Modern robots are generally viewed as tools that human specialists use to perform hazardous tasks in remote environments. In contrast, human-like personal robots are often designed to engage people in order to achieve social or emotional goals. The development of socially intelligent and socially skillful robots drives research to develop autonomous or semi-autonomous robots that are natural and intuitive for the average consumer to interact with, communicate with, work with as partners, and teach new capabilities. In addition, this domain motivates new questions for robotics researchers, such as how to design for a successful long-term relationship where the robot remains appealing and provides consistent benefit to people over weeks, months, and even years. The benefit that social robots provide people extends far beyond the strict task performing utility to include educational, health and therapeutic, domestic, social and emotional goals (e.g., entertainment, companionship, communication, etc.), and more.

However, these mechanical devices are still far from understanding and processing emotional states as humans do. Research on musical performance robots seems like a particularly promising path toward helping to overcome this limitation, because music is a universal communication medium, at least within a giving cultural context. Furthermore, research into robotic musical performance can shed light on aspects of expression that traditionally have been hidden behind the rubric of "musical intuition." The late Prof. Ichiro Kato argued that the artistic activity such as playing a keyboard instrument would require human-like intelligence and dexterity (Kato, et al., 1973). In 1984, at Waseda University, the WABOT-2 was the first attempt of developing an anthropomorphic music robot capable of playing a concert organ (Sugano & Kato, 1987). Then, in 1985, the WASUBOT built also at Waseda, could read a musical score and play a repertoire of 16 tunes on a keyboard instrument. More recently, thanks to the technological advances on power computation, Musical Information Retrieval (MIR) and Robot Technology, several researchers have been focusing on developing anthropomorphic robots and interactive automated instruments capable of interacting with musical partners. As a result, different kinds of wind playing-instrument automated machines and humanoid robots have been developed for playing wind instruments (Doyon & Liaigre, 1966; Klaedefabrik, 2005; Solis, et al., 2008; Takashima & Miyawaki, 2006; Solis, et al., 2009a; Dannenberg, 2005; Toyota Motor Corporation, 2011; Degallier, 2006; etc.). Other researchers have been focusing in analyzing wind instrument playing from a musical engineering approach by performing experiments with simplified mechanisms (Ando, 1970; Guillemain, et al., 2010; etc.) and from a physiological point of view by analyzing medical imaging data of professional players (Mukai, 1992; Fletcher, 2001; etc.). In this research, we particularly deal with the development of an anthropomorphic saxophone-playing robot designed to mechanically emulate the required organs during the saxophone playing. Due to the interdisciplinary nature of this research, our collaboration with musicians, musical engineers, and medical doctors will certainly contributes to better reproduce and understand the human motor control from an engineering point of view.

Certainly, the performance of any musical instrument is not well defined and far from a straightforward challenge due to the many different perspectives and subject areas. An idealized musical robot requires many different complex systems to work together integrating musical representation, techniques, expressions, detailed control and sensitive multimodal interactions within the context of a piece, as well as interactions between performers and the list grows. Due to the inherent interdisciplinary nature of the topic, this research can contribute to the further enhance musical understanding, interpretation, performance, education, and enjoyment.

However, if we consider the use of such a complex mechanisms to introduce undergraduate students the principles of robot technology, there could be difficulties to have experience on-hands with an anthropomorphic robot. On the other hand, the continuous falling of the birthrate in developed countries is resulting in a reduction in the number of students where most of them are going away from scientific fields. This situation may tremendously affect the industry by losing competitive power in the future due to the shortage of talented engineers. Moreover, the curricula of engineering universities is currently lacking in practical, design elements resulting in a shortage of opportunities for promoting the creativity of students. For this purpose, several attempts to built educational robots have been done during the past few decades (Miller, et al., 2008).

DEVELOPMENT OF ANTHROPOMORPHIC MUSICAL ROBOTS

Background

During the golden era of automata, the "Flute Player" developed by Jacques de Vaucanson was designed and constructed as a means to understand the human breathing mechanism (Doyon & Liaigre, 1966). Vaucanson presented "The Flute Player" to the Academy of Science in 1738. For this occasion, he wrote a lengthy report carefully describing how his flutist can play exactly like a human. The design principle was that every single mechanism corresponded to every muscle (Vaucanson, 1979). Thus, Vaucanson had arrived at those sounds by mimicking the very means by which a man would make them. Nine bellows were attached to three separate pipes that led into the chest of the figure. Each set of three bellows was attached to a different weight to give out varying degrees of air, and then all pipes joined into a single one, equivalent to a trachea, continuing up through the throat, and widening to form the cavity of the mouth. The lips, which bore upon the hole of the flute, could open and close; and move backwards or forwards. Inside the mouth was a moveable metal tongue, which governed the airflow and created pauses.

More recently, the "Flute Playing Machine" developed by Martin Riches was designed to play a specially made flute somewhat in the manner of a pianola, except that all the working parts are clearly visible (Klaedefabrik, 2005). The Flute Playing Machine is composed of an alto flute, blower, electro-magnets, and electronics. The design principle is basically transparent in a double sense. The visual scores can be easily followed so that the visual and acoustic information is synchronized. The pieces it plays are drawn with a felt tip pen on long transparent music rolls, which are then optically scanned by the photo cells of a reading device. The machine has a row of 15 photocells, which read felt-tip pen markings on a transparent roll. Their amplified signals operate the 12 keys of the flute and the valve, which controls the flow of air into the embouchure. The two remaining tracks may be used for regulating the dynamics or sending timing signals to a live performer when performing a duet.

Since 1990, the authors have been focusing on development of the anthropomorphic flutist robot designed to mechanically emulate the anatomy and physiology of the organs involved during flute playing. In 2007, the Waseda Flutist Robot No. 4 Refined IV (WF-4RIV) was developed. The WF-4RIV has a total of 41-DOFs and it is composed of the following simulated organs (Solis, et al., 2008): lungs, lips, tongue, vocal cord, fingers, and other simulated organs to hold the flute (i.e. neck and arms). The lips mechanism is composed by 3-DOFs to realize an accurate control of the motion of the superior lip (control of airstream's thickness), inferior lip (control of airstream's angle) and sideway lips (control of airstream's length). The artificial lip is made of a thermoplastic rubber named "Septon" (Kuraray Co. Ltd., Japan). The lung system is composed of two acrylic cases, which are sealed. Each of the cases contains a bellow, which is connected to an independent crank mechanism. The crank mechanism is controlled by using an AC motor so that the robot can breathe air into the acrylic cases and breathe air out from them by controlling the speed of motion of the bellow. Finally, the vocal cord is composed by 1-DOF and the artificial glottis is also made of Septon. In order to add vibration to the incoming air stream, a DC motor linked to a couple of gears is used

One of the first attempts to develop a saxophone-playing robot was done by Takashima at Hosei University (Takashima & Miyawaki, 2006). Such a robot, named APR-SX2, is composed of three main components: mouth mechanism (as a pressure controlled oscillating valve), the air supply mechanism (as a source of energy), and fingers (to make the column of air in the instrument shorter or longer). The artificial mouth consisted of flexible artificial lips and a reed pressing mechanism. The artificial lips were made of a rubber balloon filled with silicon oil with the proper viscosity. The air supplying system (lungs) consists of an air pump and a diffuser tank with a pressure control system (the supplied air pressure is regulated from 0.0 MPa to 0.02 MPa). The APR-SX2 was designed under the principle that the instrument played by the robot should not be changed. A finger mechanism was designed to play the saxophone's keys (actuated by solenoids), and a modified mouth mechanism was designed to attach it to the mouthpiece, no tonguing mechanism was implemented (normally reproduced by the tongue motion). The control system implemented for the APR-SX2 is composed by one computer dedicated to the control of the key fingering, air pressure and flow, pitch of the tones, tonguing, and pitch bending. In order to synchronize all the performance, the musical data was sent to the control computer through MIDI in real-time. In particular, the SMF format was selected to determine the status of the tongue mechanism (on or off), the vibrato mechanism (pitch or volume), and pitch bend (applied force on the reed).

Hosei University has developed the APR-SX2; its design is based on the concept of reproducing melodies on a tenor saxophone. Therefore, the saxophone playing robot has been developed under the condition that the musical instrument played by robots should not be changed or remodeled at all. However, a total of twenty-three fingers have been used to play the saxophone's keys (actuated by solenoids), a modified mouth mechanism has been designed (composed by a flexible artificial lip and a reed pressing force control mechanism were developed) to attach it with the mouthpiece, and no tonguing mechanism has been implemented (normally reproduced by the tongue motion).

In contrast, authors proposed in Solis et al. (2009b) the development of an anthropomorphic saxophonist robot as an approach to enable the interaction with musical partners. Therefore, as a long-term goal, we expect that the proposed saxophonist robot is able not only of performing a melody, but also to dynamically interact with the musical partner (i.e. walking while playing the instrument, etc.). As a first result of our research, we have presented the Waseda Saxophonist Robot No. 1 (WAS-1), which it was composed by 15 Degrees of Freedom (DOF) required to play an alto saxophone (Solis, et al., 2009a). In particular, lower lip (1-DOF), tongue (1-DOF), oral cavity, artificial lungs (air pump: 1-DOF and air flow valve: 1-DOF), and fingers (11-DOFs) were developed. Both lips and oral cavity were made of a thermoplastic rubber (named Septon and produced by Kuraray Co.). An improved version, the Waseda Saxophonist Robot No. 2 (WAS-2) was presented, where the design of the artificial lips was improved and a human-like hand was designed (Solis, et al., 2010a). Furthermore, an

Overblowing Correction Controller was implemented in order to assure the steady tone during the performance by using the pitch feedback signal to detect the overblowing condition and by defining a recovery position to correct it (Solis, et al., 2010b). However, the range of sound pressure was still too limited to reproduce the dynamic effects of the sound (i.e. decrescendo) and deviations on the pitch were detected. Therefore, the design of the oral cavity shape has been improved to expand the range of sound pressure and potentiometers were attached to each finger for implementing a dead-time compensation controller. From the control system point of view, a Pressure-Pitch Controller has been proposed to ensure the accurate control of the pitch during the steady phase of the sound produced by the saxophone. Thus, in the following sub-section, we describe the mechanical improvements on the oral cavity and finger mechanisms. In addition, the implementation of a finger dead-time compensation controller and Multiple-Input Multiple-Output controller to assure the accurate control of both air pressure and sound pitch.

Anthropomorphic Saxophonist Robot: Mechanism Design and Control Implementation

In 2010, we have developed the Waseda Saxophonist Robot No. 2 Refined (WAS-2R), which has improved the shape of the oral cavity for increasing the sound range volume and added sensors to each finger for reducing the response delay. In particular, the WAS-2R is composed by 22-DOFs that reproduce the physiology and anatomy of the organs involved during the saxophone playing as follows (Figure 1): 3-DOFs to control the shape of the artificial lips, 16-DOFs for the human-like hand, 1-DOF for the tonguing mechanism, and 2-DOFs for the lung system. In addition, to improve the stability of the pitch of the sound produced, a pressure-pitch controller system has been implemented.

In the previous mechanism, it was possible to confirm the enhancement of the sound range produced by WAS-2 (Solis, et al., 2010a). However, we detected that the note C3 was not possible to be produced. Therefore, we considered to analyze in more detail the oral cavity (in particular, the gap between the palate and the tongue) of professional saxophonist while playing the instrument. For this purpose, we have used an ultrasonic sound probe (ALOKA ProSound II, SSD-6500SV) to obtain images of the oral cavity from professional players while producing the sound of the note C4. By analyzing the obtained images, when a higher volume sound is produced, a large gap between the palate and the tongue is observed. In contrast, while producing lower volume sounds, the gab is considerably narrowed. As a result from these measurements, a new oral cavity for the WAS-2R has been designed (Figure 2). Basically, based on the measurements obtained from images obtained from the professional player, the sectional area has been designed with 156 mm^2 (previous one was 523 mm^2).

Figure 1. The Waseda saxophonist robot no. 2 refined (WAS-2R)

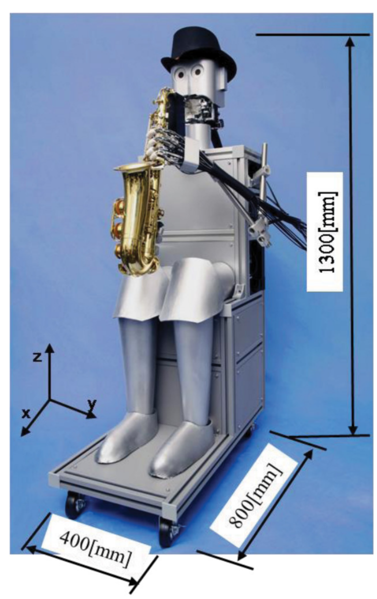

Figure 2. Detail of the oral cavity of WAS-2R

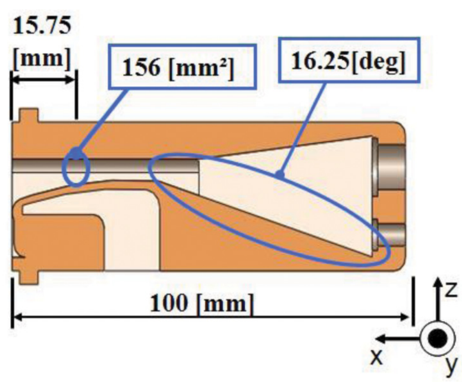

In the previous mechanism, a human-like hand (actuated by a wire-driven mechanism) had been designed to enable the WAS-2 to push all the keys of the alto saxophone (Solis, et al., 2010a). However, due to the use of the wire-driven mechanism, a dynamic response delay (approximately 110ms) has been observed. Therefore, in order to reduce such a delay time, we proposed to embed sensors for measuring the rotational angle of each finger (Figure 3). For this purpose, a rotary sensor (RDC506002A from Alps Co.) has been embedded into the each finger mechanism. In particular, each sensor was placed on a fixing mount device produced by a rapid prototyping device (CONNEX 500). As a result, we were able of attaching the sensing system without increasing the size of the whole mechanism. RC servo motors have been used to control the wire-driven mechanism designed for each finger. As end-effector, an artificial finger made of silicon has been designed. In order to control the sixteen RC motors, the RS-485 serial communication protocol has been used.

On the other hand, the previous mouth mechanism was designed with 1-DOF in order to control the vertical motion of the lower lip. Based on the up/down motion of the lower lip, it became possible to control the pitch of the saxophone sound. However, it is difficult to control the sound pressure by means of 1-DOF. Therefore, the mouth mechanism of the WAS-2 consists of 2-DOFs designed to control the up/down motion of both lower and upper lips (Figure 4a). In addition, a passive 1-DOF has been implemented to modify the shape of the sideway lips. The artificial lips were also made of Septon. In particular, the arrangement configuration of the lip mechanism is as follows: upper lip (rotation of the motor axis is converted into vertical motion by means of a timing belt and ball screw to avoid the leak of air flow), lower lip (a timing belt and ball screw so that the rotational movement of the motor axis is converted into vertical motion to change the amount of pressure on the reed), and sideway lip.

In order to select the motor for the mouth mechanism, the required force for pressing the reed and the maximum stroke of the pins embedded in lip were considered. The target time for

Figure 3. Details of the finger mechanism of WAS-2R

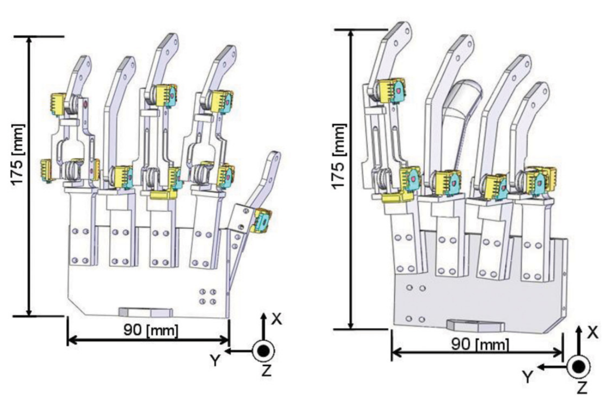

Figure 4. Mechanism details of the WAS-2R: a) mouth mechanism; b) tonguing mechanism; c) lung mechanism

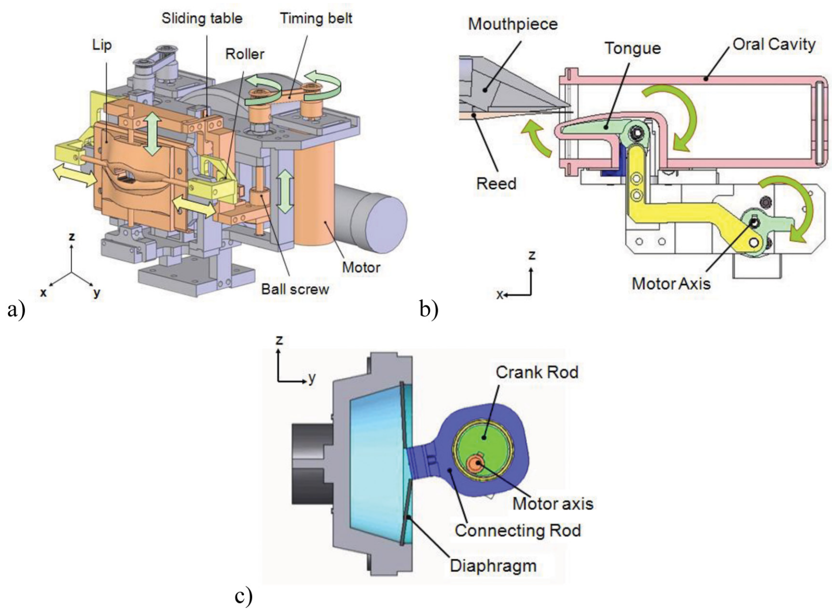


the positioning was set to 100 ms. In order to assure a compact design for the mechanism, a ball screw and timing belt were used. Due to the space constrains, the ball screw SG0602-45R88C3C2Y (KSS Co.) was used. The shaft diameter is 6 mm, and the lead is 2 mm. From those, the axial direction allowable load and allowable revolution were calculated. The requirement of the system is to move 10 mm in 100 ms. Therefore, the average speed v and acceleration a are 0.1 m/s and 4 m/s^2 respectively.

In order to move the pin attached to both sides of lip, the total mass of moving part is 0.05 kg. The axial direction load generated when pin is pulled is given by (1), and this value is the maximum axial direction load applied to the ball screw. The core diameter of the ball screw is 5.1 mm; therefore, the screw shaft minimum moment of inertia of area is given by (2).

$$\begin{aligned} Fa &= 8 + ma \\ &= 8 + 0.05 \times 4 \\ &= 8.2 \quad [N] \end{aligned} \qquad (1)$$

$$I = \frac{\pi}{64} d_1^4 = \frac{\pi \times 5.1^4}{64} = 33.2 \quad [mm^4] \qquad (2)$$

The buckling load is computed by (3), where l_a is the distance between two mounting surfaces (40 mm), E the Young's modulus (2.1×10^5 N/mm^2) and η_1 the factor according to the mounting method (2.0). As a result of the above calculations, we confirmed that the selected ball screw is safe in use.

$$P_1 = \frac{\eta_1 \cdot \pi^2 \cdot E \cdot I}{l_a^2} \times 0.5 = 12485.6 \quad [N] \qquad (3)$$

Then, we have verified the critical speed. Due to the reduction ratio is 1, the required motor revolution is given by (4); the sectional area S of the screw axis is computed by (5).

$$Nm = \frac{V_{\max} \cdot 1000 \cdot 60}{l} \times \frac{1}{A} = \frac{0.20 \times 1000 \times 60}{2} \times \frac{1}{1} = 6000 \quad [rpm] \tag{4}$$

$$S = \frac{\pi}{4} \times 5.1^2 = 20.4 \quad [mm^2] \tag{5}$$

Finally, the allowable revolution of threaded shaft can be computed as (6), where S is the section area (20.4 mm^2), γ the density (7.85×10^{-6} kg/mm^3) and λ_1 is the factor according to the mounting method (3.927). From the above calculations, we could confirm the required revolution is allowable. Thus, we decided to use this ball screw.

$$N_1 = \frac{60 \cdot \lambda_1^2}{2\pi \cdot l_a^2} \times \sqrt{\frac{E \times I \times g}{\gamma \cdot S}} \times 0.8 = \frac{60 \times 3.927^2}{2\pi \times 40^2} \times \sqrt{\frac{2.1 \times 10^5 \times 6.21 \times 9.8 \times 10^3}{7.85 \times 10^{-6} \times 20.4}} \times 0.8 = 1520061 \quad [rpm] \tag{6}$$

After confirming the ball screw specifications, the selection of the motor was verified. For the mouth mechanism, the motor RE-25 (Maxon Co.) was used. In order to calculate the rotary torque required to translate rotary motion into linear motion, the required rotary torque T_1 for an external load is defined as (7), where η is the efficiency of ball screw (0.9).

$$T_1 = \frac{Fa \cdot l}{2\pi \cdot \eta} \cdot A = \frac{10.2 \times 2}{2\pi \times 0.9} \times 1 = 2.90 [N \cdot mm] \tag{7}$$

Because the preload torque T_d of the selected ball screw is 3.0-7.0 Nmm, the preload torque generated T_2 is defined as (8).

$$T_2 = T_d \cdot A = 7.0 \times 1 = 7.0 \; [N \cdot mm] \tag{8}$$

Considering inertia moment of screw shaft and the pulley on the side of motor, the inertia moment J is computed as (9); where J_S is the Inertia moment of screw shaft (2.5×10^{-8} kg*m^2) and J_B is the Inertia moment of pulley on the side of motor (9.11×10^{-7} kg*m^2).

$$J = m\left(\frac{l}{2\pi}\right)^2 \times 10^{-6} + J_S + J_B = 0.05 \times \left(\frac{2}{2\pi}\right)^2 \times 10^{-6} + 2.50 \times 10^{-8} + 9.11 \times 10^{-7} = 9.41 \times 10^{-7} \; [kg \cdot m^2] \tag{9}$$

Because the acceleration time is 0.05 sec, the angular acceleration is computed as (10). Therefore, the required acceleration torque T_3 is given by (11).

$$\dot{\omega} = \frac{2\pi \cdot N_m}{60t} = \frac{2\pi \times 6000}{60 \times 0.050} = 12566.3 \; [rad / \sec^2] \tag{10}$$

$$T_3 = J \times \dot{\omega} \times 10^3 = 9.41 \times 10^{-7} \times 12566.3 \times 10^3 = 11.83 \; [N \cdot mm] \tag{11}$$

From the torques calculated above, the total required acceleration torque T_k is given by (12). The effective value of torque required to the motor is then computed as (13). As a result from the calculations below, it is verified that the RE-25 motor covers the required specifications.

$$T_K = T_1 + T_2 + T_3 = 2.90 + 7.0 + 11.83 = 21.73 \; [N \cdot mm] \tag{12}$$

$$T_{rms} = \sqrt{\frac{T_1^2 \times t_1 + T_2^2 \times t_2 + T_3^2 \times t_3}{t}} = \sqrt{\frac{2.90^2 \times 0.10 + 7.0^2 \times 0.10 + 21.73^2 \times 0.05}{0.10 + 0.10 + 0.05}} = 5.033\ [N \cdot mm] \quad (13)$$

On the other hand, the tonguing mechanism is shown in Figure 4b. The motion of the tongue tip is controlled by a DC motor which is connected to a link attached to the motor axis. In such a way, the airflow can be blocked by controlling the motion of the tongue tip. Thanks to this tonguing mechanism of the WAS-2, the attack and release of the note can be reproduced. In order to select the motor for tongue mechanism, we assumed a response time of 20 ms. As the motor of the tongue mechanism should rotate 20deg in 20ms, the average angular speed is 17.45 rad/s. On the other hand, to approximate the real lingual motion speed, the maximum angular speed is 34.9 rad/s. Therefore, acceleration of it is 3490.7 rad/s^2. The required torque to rotate the tongue mechanism covered with SEPTON is 5.5×10^{-2} Nm and the inertia moment of the center of rotation generated to a part rotate with tongue is 1.19×10^{-5} kg*m^2. Therefore, the required total torque T_{total} for driving the tongue mechanism is computed by (14).

$$T_{total} = T + I\ddot{\theta} = 0.09654[N \cdot m] = 96.54[N \cdot mm] \quad (14)$$

As a result of calculations above, and because of motor size, the motor RE-30 (Maxon Co.) is selected for tongue mechanism.

Regarding the WAS-2R's air source, a DC servo motor has been used to control the motion of the air pump diaphragm, which is connected to an eccentric crank mechanism (Figure 4c). This mechanism has been designed to provide a minimum 20 L/min airflow and a minimum pressure of 30kPa. In addition, a DC servo motor has been designed to control the motion of an air valve so that the delivered air by the air pump is effectively rectified. In order to select the motor for the lung mechanism, the requirement specification was based on the maximum oral cavity pressure (8 kPa) and the calculations of the external force F computed by (15), where F_a is the inertia, F_k is the spring and F_p is the pressure. The force applied to motor arm F_l is then computed by (16), where θ is the angle of rotation and ϕ is the angle of arm. Finally, based on the motor load torque T given by (17), where r is the arm length, the motor RE-30 (Maxon Co.) has been selected.

$$F = Fa + Fk + Fp \quad (15)$$

$$F_l = \frac{F}{\cos\phi} \cdot \sin(\phi + \theta) \quad (16)$$

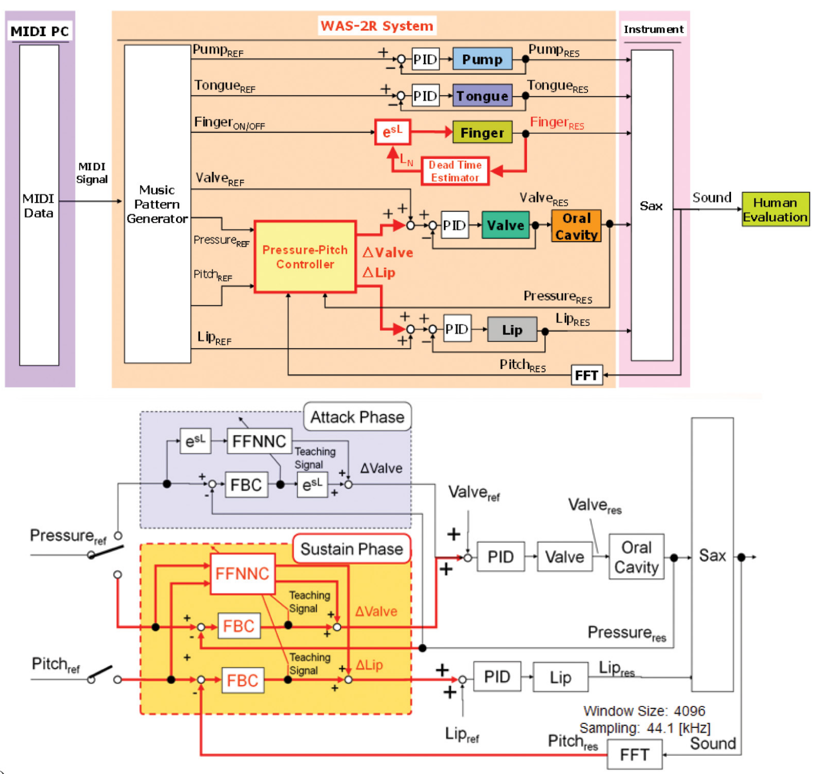
$$T = F_l \cdot r \quad (17)$$

Regarding the control system in our previous research, a feed-forward air pressure controller with dead-time compensation has been implemented to ensure the accurate control of the air pressure during the attack time (Solis, et al., 2010b). Moreover, for the control of the finger mechanism, a simple ON/OFF controller has been implemented. In particular, the feedback error learning during the attack phase of the sound has been used to create the inverse dynamics model of the Multiple-Input Single-Output (MISO) controlled system based on Artificial Neural Networks (ANN). In addition, an Overblowing Correction Controller (OCC) has been proposed and implemented in order to ensure the steady tone during the performance by using the pitch feedback signal to detect the overblowing condition and by defining a recovery position (off-line) to correct it (Solis, et al., 2010b). However, we still detect deviations on the pitch while playing the saxophone.

Therefore, we proposed the implementation of the control system shown in Figure 5a. In particular, the improved control system includes a dead-time compensation controller for the finger mechanism (to reduce the effect of response delay due to the wire-driven mechanism) and a Pressure-Pitch Controller (PPC) for the control of the valve and lip mechanism (to assure the accurate control of the pitch). Regarding the implementation of the dead-time compensation control; for each finger of WAS-2R, the pressing time of the saxophone's key is measured by means of the embedded potentiometer sensor (defined as L_N; where N represents the total number of DOFs designed for the finger mechanism). By including the dead-time factor (referred as e^{sL}), it is possible to compensate the finger's response delay during the saxophone playing (Kim, et al., 2003).

As for the implementation of the control system, a pressure-pitch controller during the sustain phase of the sound has been proposed not only to ensure the accurate control of the air pressure during the attack phase of the sound, but also to ensure the accurate control of both air pressure and sound pitch during the sustain phase of the sound. For this purpose, we implemented a feed-forward error learning method (Kawato & Gomi, 1992) to create the inverse model of the proposed Multiple-Input-Multiple-Output (MIMO) system which is computed by means of an ANN. During the training process, the inputs of the ANN are defined as follows (Figure 5b): pressure reference ($Pressure_{REF}$), pitch reference ($Pitch_{REF}$). In this

Figure 5. Detail of the control system implemented for the WAS-2R: a) block diagram of the improved control system; b) detail of the ANN during the learning phase based on the feedback error learning method



a)

b)

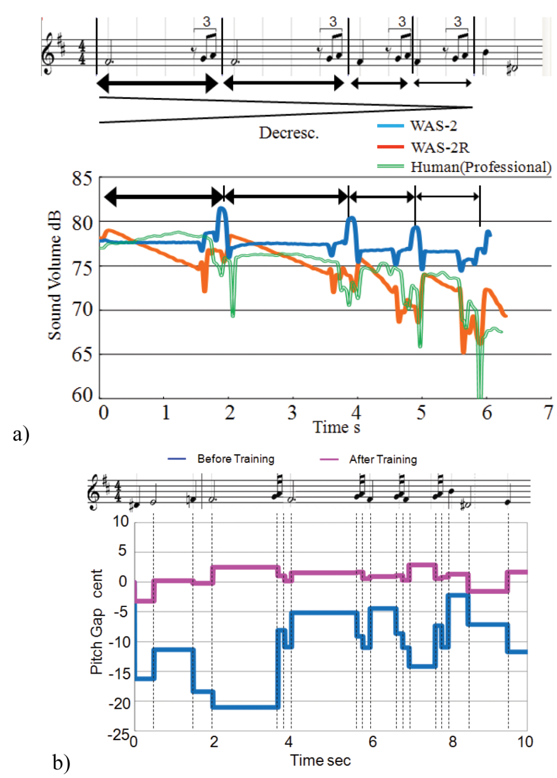
case, a total of six hidden units were used (experimentally determined while varying the number of hidden units). As an output, the position of the air valve (*ΔValve*) and lower lip (*ΔLip*) are controller to ensure the accurate control of the required air pressure and pitch to produce the saxophone sound. Moreover, during the training phase, the air pressure ($Pressure_{RES}$) and sound pitch ($Pitch_{RES}$) are used as feedback signals and both outputs from the feedback controller are used as teaching signals for the effectively training the ANN. As a result from the training phase, during a saxophone playing performance, the created inverse model is used.

Musical Performance

In order to verify if the re-designed shape of the oral cavity contributes to extend the range of sound pressure, we have compared the previous mechanism with the new one while playing the notes from C3 to C5. The average sound pressure ranges for WAS-2R and WAS-2 are 17.7 dB and 9.69 dB, respectively. Moreover, an intermediate player and professional are 13.2 and 22.6 respectively. From this result, we confirmed an increment of 83% thanks to the new shape of the oral cavity. Therefore, we could conclude that the shape of the gap between the palate and tongue has a big influence on the sound pressure range. Thanks to this considerable improvement on the range of sound pressure, we proposed to compare the reproduction of the decrescendo, which is a dynamic sound effect that gradually reduces the loudness of the sound. For this purpose, we programmed the WAS-2 and WAS-2R to play the principal theme of the "Moonlight Serenade" composed by Glenn Miller. The experimental results are shown in shown in Figure 6a. As we may observe, the WAS-2R was able of reproducing nearly similar to the performance of the professional one.

On the other hand, in order to determine the effectiveness of the proposed pressure-pitch controller to reduce the pitch deviations while playing the saxophone, we programmed the WAS-2R to play the main theme of the "Moonlight Serenade" composed by Glenn Miller before and after training the inverse model. In particular, as for the neural network parameters, a total of 6 hidden units were used. For the training process, a total of 144 steps were done. The experimental results are shown in Figure 6b; where 1[cent] is defined as (equi-tempered semitone/100). As we could observe, the deviations of the pitch after the training (Standard Error is 41.7) are considerable less than before training (Standard Error is 2372.8).

Figure 6. Experimental results: a) reproduction of decrescendo effect; b) comparing the deviations of the pitch before and after training the inverse model of the proposed MIMO system with the WAS-2R.



DEVELOPMENT OF EDUCATIONAL ROBOTS

Background

Even though several universities and companies have been building robotic platforms for educational purposes, we may observe that there is still no platform designed to intuitively introduce the principles of RT from the fundamentals to their application to solve real world problems. In fact, most of the current educational platforms focus on providing the basic components to enable students building their own designed system. However; such kind of platforms are used to merely introduce basic control methods (i.e. Sequential Control), basic programming (i.e. Flow Chart Design, C language), and basic mechanism design.

As an approach to cover different aspects of the Robot Technology, in this project we focused in developing an education tool designed to introduce at different educational levels the principle of developing mechatronic systems. In particular, the development of an inverted pendulum mobile robot has been proposed. In fact, the inverted pendulum has been the subject of numerous studies in automatic control (Grasser, et al., 2002; Salerno & Angeles, 2007; Koyanagi, et al., 1992; Kim, et al., 2003; Pathak, et al., 2005; etc.), introduction to Mechatronics (Solis & Takanishi, 2009; etc.), etc.

Up to now, several attempts to build educational robots have been made during the past few decades (Miller, et al., 2008). In fact, the development of educational robots started in the early 1980s with the introduction of the Heathkit *Hero − 1* (Heath Co.). Such kind of robot was designed to encourage students to learn how robots are built. However, no information on the theory or principles behind the assembly is given. More recently, several other companies in cooperation with universities and research centers have been trying to introduce educational robots to the market. Some examples are as follows: K-Team (K-TEAM Ltd.) introduces the *Hemisson*, which is a low-cost educational robot designed to provide an introduction to robot programming by using reduced computational power and few sensors. Another example is the *LEGO ® Mindstorms RCX,* which is a good tool for early and fast robot design by using the LEGO blocks (LEGO Ltd.). In Japan, we can also find some examples such as: the *RoboDesigner* kit designed to provide a general platform to enable students to build their own robots (Japan Robotech Ltd.), *ROBOVIE − MS* from ATRRobotics designed as an education tool to introduce principles of mechanical manufacturing, assembly, and operational programming of small-sized humanoid robot, etc.

From the perspective of introducing RT technology to undergraduate students, it is a good example to provide experience to them on control designing, signal processing, distributed control systems and the consideration of real-time constraints for real applications purposes. However, most of the current proposed robots do not consider the educational issues while designing the inverted pendulum (i.e. possibility of changing the center of mass, etc.). In addition, authors consider the importance to consider the introduction of human-robot interaction to motivate their further interest (i.e. the size of the robot should fit the size of a personal mobile computer, etc.).

Therefore, the authors have proposed the development of a two-wheeled inverted pendulum type mobile robot designed to cover the basic principles in electronics, mechanical engineering, programming, as well as, more advanced topics on control engineering, complex programming, and embedded systems. As a result of our research, the Waseda Wheeled Vehicle No.2 Refined (WV-2R) has been introduced (Solis, et al., 2009c). In particular, the WV-2R has been designed to enable students to verify the changes on the response of the robot while varying some physical parameters of the robot. From the experimental results, we confirm some of the educational functions of the proposed robot (i.e. PID tuning, varying the center of mass, etc.). However, a hand-made control board has been used so that several problems of wire connections were detected. Furthermore, the WV-2R didn't include any additional mechanism for proposing different kinds of robot contest. Finally, from our discussions with undergraduate students, the development of a simulator could considerably increase their knowledge.

Two-Inverted Pendulum Robot: Mechanism Design and Control Implementation

In the 2010, the Waseda Wheeled Vehicle Robot No. 2 Refined II (WV-2RII) was developed as an educational robot designed to implement different educational issues to introduce undergraduate students the principles of RT (Figure 7). The specifications are shown in Table 1. The WV-2RII is composed of two-actuated wheels, a general-purpose control board (Figure 8a), an adjustable weighting bar attached to the pendulum, a gyro and accelerometer sensors, a remote controller (Figure 8b), and two optional mechanisms that can be easily attached/detached from the main body of the robot. In particular, the general-purpose control board consists of a 32 bits ARM microcontroller, 10 general I/O ports, 2 motor drives, a LCD display, 8 LEDs, a Zigbee module, and 2 servo connectors.

The WV-2RII is endowed with two active wheels actuated by DC motors. The model description is shown in Figure 9; where the following parameters are defined as follows.

θ: Tilt angle of the chassis
φ: Axial component of the angular velocity of the wheel
m_1: Mass of the chassis
m_2: Wheel mass
J_1: Moment of inertia of the chassis
J_2: Wheel Moment of Inertia
l: Distance between wheel axis and robot mass center
r: Wheel radius

Figure 7. The Waseda wheeled vehicle no. 2 refined II (WV-2RII).

Figure 8. a) general-purpose control board; b) remote controller for the WV-2RII

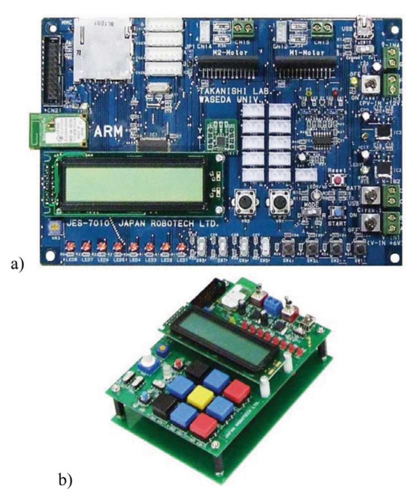

Figure 9. The model of the two-wheeled inverted pendulum robot

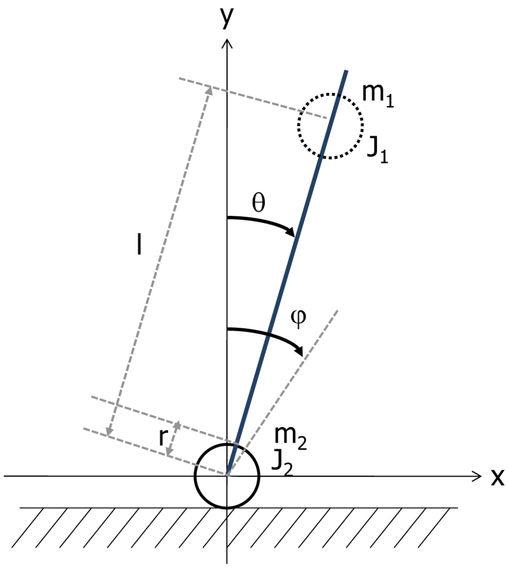


By using the above parameters, and by defining T as torque, n as reduction ratio of the gear and S as the Frictional Force on the wheel along the horizontal ground plane (where f_x and f_y are the components of the force acting between the wheel and pendulum at the center of the wheel), we may define the following Equations (18-23):

$$m_2 x_2'' = S - f_x \tag{18}$$

$$J_2 \varphi'' = nT - rS \tag{19}$$

$$m_1 (x_2'' + (l \sin\theta)'') = f_x \tag{20}$$

$$m_1 (l \cos\theta)'' = -m_1 g + f_y \tag{21}$$

$$J_1 \theta'' = f_y l \sin\theta - f_x l \cos\theta - nT \tag{22}$$

$$x = r\varphi \tag{23}$$

Equations (24) and (25) follow from above equations upon elimination of intermediate variables f_x, f_y, S. From Equation (24), we may notice that when the angular acceleration of the body is less than zero, it is possible to correct the vertical inclination of the body to the standing upright position.

$$\varphi'' = \frac{1}{J_2 + r^2 m_1 + r^2 m_2}\left\{nT - m_1 rl(\theta'' \cos\theta - \theta'^2 \sin\theta)\right\} \tag{25}$$

If we define the maximum tilt angle of the chassis to 50 degrees, and use the respective physical parameters corresponding to the WV-2RII (m_1 = 2.247 kg; m_2 = 0.800 kg; J_1 = 0.015 kgm^2; J_2 = 0.002 kg*m^2; g = 9.81 m/s^2; l = 0.0477 m; r = 0.0725 m) into Eq. (28), we obtain the following relation:

$$\therefore nT \geq 2.2[Nm]$$

Based on the above relation, we have selected the motor RDO-37BE50G9 (stall torque 0.160 Nm and Gear ratio 9:1). If we consider the coef-

Equation 24

$$\theta'' = \frac{1}{J_1 + m_1 l^2 + \dfrac{m_1^2 r l^2 \cos^2\theta}{\dfrac{J_2}{r} + rm_1 + rm_2}}\left[m_1 g l \sin\theta - m_1 l \cos\theta \left\{\frac{nT + m_1 rl\theta'^2 \sin\theta}{\dfrac{J_2}{r} + rm_1 + rm_2}\right\} - nT\right]$$

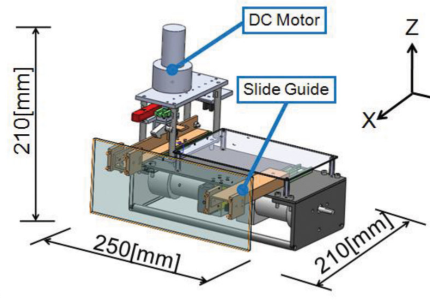
ficient of safety of the power generated by the two motors as 0.8, then nT is 2.3 Nm satisfies the required specification.

On the other hand, as we have previously introduced, we have developed two additional mechanisms that can be easily attached to the main body of the WV-2RII. In particular, a kicking mechanism for soccer (Figure 10a) and an arm mechanism for sumo (Figure 10b) have been designed and constructed. In particular, the soccer-kicking mechanism is composed by a spring, hook, stopper, and a DC motor. In order to kick the ball, a tension spring is used to increase the speed of movement of the kicking mechanism (maximum output load of 22N). Basically, the kicking mechanism is attached to a hook which is moved until a certain point when the hook is automatically released (by a stopper), the reaction force accumulated by the spring is used to kick the ball. On the other hand, the sumo-arm mechanism is composed by sliding-crank mechanism actuated by a DC motor, an arm base actuated by a RC motor to adjust the pitch of the whole arm mechanism and a pushing plate with embedded switches for detecting the contact with the opponent. Basically, in gear wheels of the slider of the crank mechanism, the fixed and movable racks are used. The rotation motion of the crank is transmitted to the gear wheels and the movable rack moves at twice the stroke of the fixed rack. From this, the arm mechanism provides a large stroke (around 88mm) by using a compact mechanism.

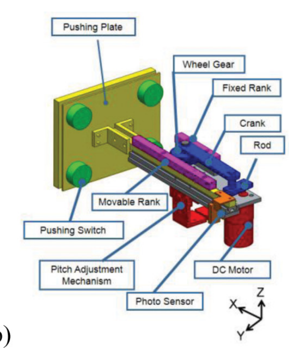
As a further example of application of WV-2RII for showing the potentialities of the proposed system, a female undergraduate student (from mechanical engineering background) during an internship at Waseda University was asked to design an upper body with appearance and gestures that are appealing to children using this new additional robot. For this purpose, we asked the student to design of the upper body mechanism, to develop the required commands for controlling it from a remote controller integrated on the WV-2RII. The detail of the mechanism designed by the internship student is shown in Figure 11a. The proposed upper body uses 4 RC motors to control the motion of head (2-DOFs) and arms/wings (2-DOFs), lending more expression to the robot. Moreover, the possible motions realizable by the upper body are shown in Figure 11b.

In Figure 12, the block diagram of the control system implemented for the WV-2RII is shown. As we may observe, the WV-2RII is controlled by feedback control system. In particular, the rate gyro sensor signal measures the body angular velocity (θ') and the encoder measures the wheel rotational angle (φ). Because the drift on the signal obtained from the gyro is extremely small, the use of a high-pass filer is not required. Therefore, a low-pass filter is only used to compute the

Figure 10. Detail of the additional mechanisms designed for WV-2RII: a) soccer-kicking mechanism; b) sumo-arm mechanism

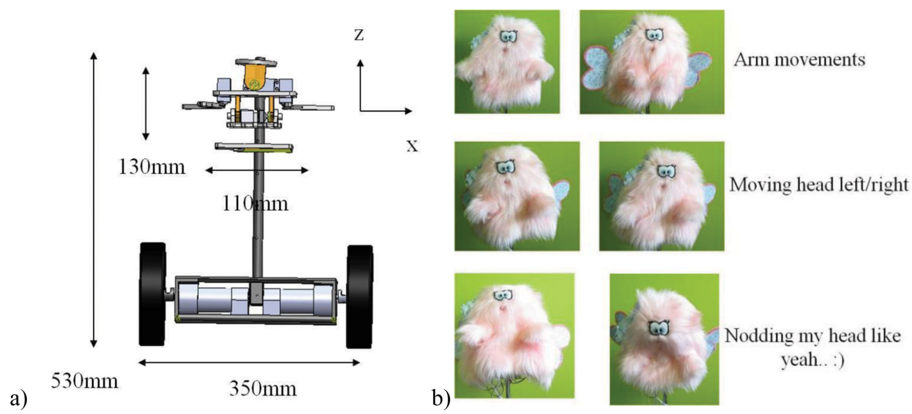


a)



b)

Figure 11. Pictures of the possible motions that the upper body mounted on the WV-2RII

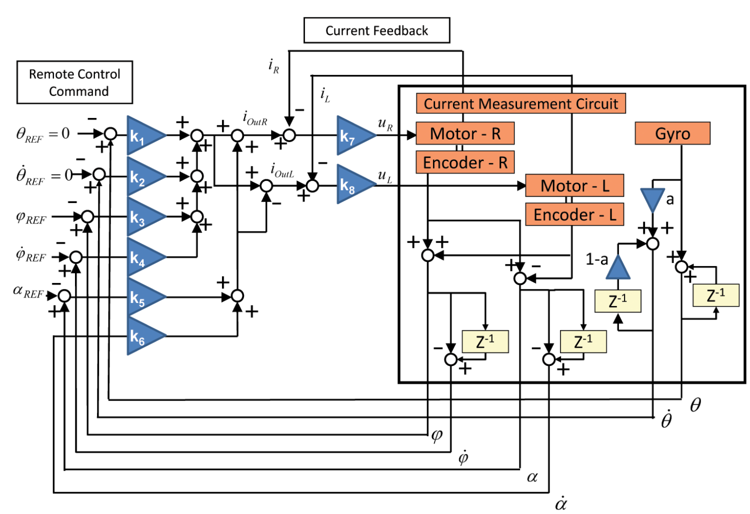


body angular velocity (θ'); where the cut-off frequency is 0.32 Hz. In order to compute the body angle, the body angle and the wheel angular velocity, the body angular velocity and wheel angle are integrated and derivated respectively. In order to control all the parameter, a feedback controller has been implemented by using Equation (26), where k_1~k_6 parameters are the gain coefficients of the controller which are tuned to assure the stabilization of the system. Furthermore, a current feedback controller has been implemented by Equation (27), where the parameter k_7 is tuned for assuring the accurate control of the command current to each motor. As for the command control signal, the θ_{REF}, φ'_{REF}, α'_{REF} are set to zero, while the other commands are sent by a remote controller.

Control Stability

In order to verify the robustness of the proposed controller implemented for the WV-2RII, we have placed the pendulum horizontally on the ground without activating the control. From this starting position, we have activated the control system and given as control goal the vertical position (90

Figure 12. Control block diagram implemented for the WV-2RII



Equations 26 and 27

$$i_{outR} = k_1 \cdot \theta + k_2 \cdot \theta' + k_3 \cdot \left(\phi - \phi_{REF}\right) + k_4 \cdot \left(\phi' - \phi'_{REF}\right) + k_5 \cdot \left(\alpha - \alpha_{REF}\right) + k_6 \cdot \left(\alpha' - \alpha'_{REF}\right)$$
$$u_R = k_7 \cdot \left(i_{outR} - i_R\right)$$

$$i_{outL} = k_1 \cdot \theta + k_2 \cdot \theta' + k_3 \cdot \left(\phi - \phi_{REF}\right) + k_4 \cdot \left(\phi' - \phi'_{RE}\right) - k_5 \cdot \left(\alpha - \alpha_{REF}\right) - k_6 \cdot \left(\alpha' - \alpha'_{REF}\right)$$
$$u_L = k_8 \cdot \left(i_{outL} - i_L\right)$$

degrees). From this experiment, we may observe the dynamic response of WV-2R by analyzing the body angle θ and the motor current measured. The experimental results are shown in Figure 13. As we may observe, the WV-2RII requires around 0.8 sec to reach the target position, where a maximum of 3A is required (the current circuit has been designed to support a peak current up to 7 Amperes).

FUTURE RESEARCH DIRECTIONS

Conventionally, anthropomorphic musical robots are mainly equipped with sensors that allow them to acquire information about its environment. Based on the anthropomorphic design of humanoid robots, it is therefore important to emulate two of the human's most important perceptual organs: the eyes and the ears. For this purpose, the humanoid robot integrates in its head, vision and aural sensors attached to the sides for stereo-acoustic perception. In the case of a musical interaction, a major part of the typical performance (i.e. Jazz) is based on improvisation. In these parts, musicians take turns in playing solos based on the harmonies and rhythmical structure of the piece. Upon finishing his solo section, one musician will give a visual signal, a motion of the body or his instrument, to designate the next soloist. Toward enabling the multimodal interaction between the musician and musical robots, a Musical-based Interaction System (MbIS) will be integrated on the Waseda Saxophonist robot (Figure 14a). The MbIS has been conceived for enabling the interaction between the musical robot and musicians (Petersen, et al.,

Figure 13. Experimental results while programming the WV-2RII to rise from the ground by analyzing the body angle and the applied motor current

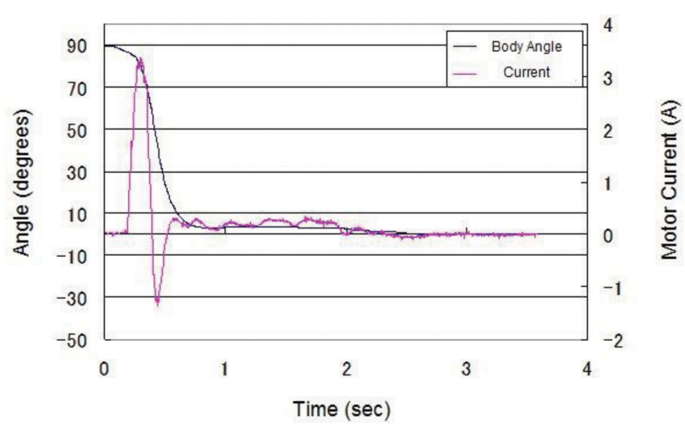


Figure 14. a) proposed musical-based interaction system; b) two-wheeled double inverted pendulum

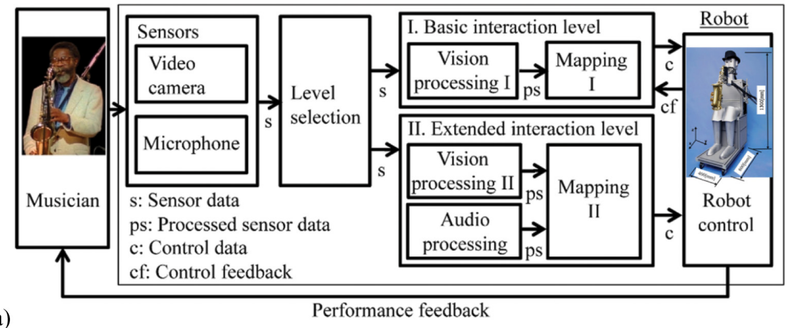
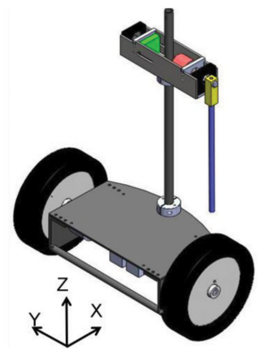


a)



b)

2010). Even though the WAS-2R still requires several improvements from the mechanical and control point of view, we do expect the robot can be used for the entertainment of elderly people, reproduce the performance of famous saxophonist players passed away and for education of young players as practical applications.

On the other hand, in order to introduce interactive educational robotic systems, the educational platform (both for university students and engineering at the industry) must be designed to cover the basic principles in electronics, mechanics, programming as well as more advanced topics on control, advanced programming and human-robot interaction. Moreover, to enhance the entertainment issue, the educational platform could also include some aspects of art (i.e. music, etc.) to learn other basic aspects such as signal processing (i.e. musical retrieval information, etc), recognition systems (i.e. Hidden Markov Model, etc.), game design (i.e. audio/motion design), etc. Further challenges on dynamic control of a two-wheeled double inverted pendulum robot can be also conceived (Figure 14b). Based in this approach, it is possible to be used in classes beyond the classical Electrical, Mechanics, and Mechatronics Engineering curriculum, including Music Engineering (Martin, et al., 2009; Yanco, et al., 2007), etc. The WV-2RII is now being commercialized as "MiniWay" by Japan Robotech Ltd. Even though this robot has been designed as an educational robot, it is possible to conceive (with some mechanical and control design modifications) different kinds of practical applications such as baggage transportation within an airport, guidance for visitors or entertainment of children at museums, etc.

CONCLUSION

In this chapter, the mechanism design and control implementation proposed for two different human-friendly robotic platforms have been introduced.

In particular, the developments of an anthropomorphic saxophonist robot and a two-wheeled inverted pendulum robot have been detailed. The saxophonist robot has been designed to reproduce the organs involved during the saxophone playing and a feed-forward controller has been implemented in order to accurately control both the air pressure and the sound pitch during a musical performance. On the other hand, the two-wheeled inverted pendulum has been designed to introduce the principles of robot technology at different educational levels and a feedback controller has been implemented in order to assure the stability of the inverted pendulum.

ACKNOWLEDGMENT

Part of the research on the Waseda Saxophonist Robot and Waseda Vehicle Robot Part was done at the Humanoid Robotics Institute (HRI), Waseda University and at the Center for Advanced Biomedical Sciences (TWINs). This research is supported (in part) by a Gifu-in-Aid for the WABOT-HOUSE Project by Gifu Prefecture. This work is also supported (in part) by Global COE Program "Global Robot Academia" from the Ministry of Education, Culture, Sports, Science, and Technology of Japan. Finally, the study on the Waseda Saxophonist Robot is supported (in part) by a Grant-in-Aid for Young Scientists (B) provided by the Japanese Ministry of Education, Culture, Sports, Science, and Technology, No. 23700238 (J. Solis, PI).

KEY TERMS AND DEFINITIONS

Anthropomorphic: Musical Robots: A robot designed to reproduce the organs involved during the musical instrument playing able of displaying both motor dexterity and intelligence.

Bio-Inspired Robotics: A robot that mechanically emulates or simulates living biological organisms.

Education Robots: A robot used by students composed by low-cost components commonly found on any robotic platform.

Feed-Forward Error Learning: A computational theory of supervised motor learning that can be used as a training method to compute the inverse dynamics model of the controller system.

Human-Friendly Robotics: Research field focus on the development of new methodologies for the design, control and safety operation of robots designed to naturally and intuitively interact, communicate and work with humans as partners.

Humanoid Robots: A robot designed to reproduce the human body in order to interact naturally with human partners within the human environment.

Inverted Pendulum Robot: A robot composed by an inverted pendulum attached to a mobile base equipped with motors that dive it along a horizontal plane.

Chapter 35
Dual-SIM Phones:
A Disruptive Technology?

ABSTRACT

Dual-SIM mobile phones utilize technology that permits the use of two SIMs at a time. The technology permits simultaneous access to the mobile network services. Its disruptive nature is with reference to the mobile phone market in Nigeria and other parts of the world. Earlier market trend was inclination to "newer" and "better" phones, in favour of established single-SIM mobile phone manufacturers like Nokia and Samsung. Introduction of dual-SIM phones mainly manufactured by Chinese mobile phone manufacturing firms propelled user preference for phones acquisition which permits dual and simultaneous access to mobile network. This technology has compelled its adoption by established manufacturing names in order that they may remain competitive. It is a clear case of a disruptive technology, and this chapter focuses on it need, effects, and disruptive nature.

1.0 INTRODUCTION

Christensen (1997) used the term "*disruptive technology*" in his book *The Innovator's Dilemma*. Such technologies surprise the market by generating a considerable improvement over existing technology, and this can be attained in a number of ways. This technology may not be as expensive as an existing technology or more complicated in nature but does attract more potential users (www.wisegeek.com). At times it may be expensive and complicated, requiring highly skilled personnel and infrastructure to implement. Two types of technology change have shown different effects on the industry leaders. *Sustained technology* sustains the rate of improvement in a

DOI: 10.4018/978-1-4666-1945-6.ch035

product's performance in the industry. Dominant industry firms are always at the fore developing and adopting such technologies. *Disruptive technology* changes or disrupts the performance path and continually results in the failure of the industry leading firms. Few technologies are basically or essentially disruptive or sustaining in nature. It's the impact created by the strategy or business model that the technology enables that is disruptive (Christensen & Raynor 2003). The advent of Global System for Mobile communication (GSM) resulted in a major communication leap worldwide. Mobile phones actually became an indispensible electronic gadget defining the modern world (Sally, Sebire, Riddington, 2010). Mobile phone manufacturers continue to include different features on their mobile phone products in addition to basic functions of communication. This is with a purpose of sustaining the market for the products. The mobile phone has become a gadget with full range of services. Ranging from basic telephony to business and leisure or entertainment features. However, performance issues with mobile network services furnished further basis for multiple SIM (Subscriber Identity Module) acquisition by users, for improved access. The problems that led to this were initially poor network coverage and poor performance problems of mobile network service providers in the country and later lower call tariff. Mobile phone users acquired phones depending on the number of networks to which they were subscribed and the trend still exists today. An opportunity was created for a product that would satisfy user needs with regard to multiple SIM capabilities.

1.1 History of Mobile Phone

The history of mobile phone began in the 1920s. The very first usage of it was in taxis/cars where it was used as a two-way radio for communication. Cell phones evolved over time like any other electronic equipment, and each stage or era was most certainly interesting. From its first official use by the Swedish police in 1946 to connecting a hand-held phone to the central telephone network, modern cell phones evolved tremendously. Ring (1947) created a communication architecture of hexagonal cells for cell phones. Later an engineer discovered that cell towers can both transmit and receive signal in three different directions led to further advancement. Early cell phone users were limited to certain blocks of area often referring to base stations covering a small land area. It was not possible to remain in reach beyond such defined boundaries until Joel's development of handoff system. By this, users were enabled to roam freely across cell areas without interruption to their calls. Cell phone had analog services between 1982 and 1990. In 1990, Advanced Mobile Phone Services (AMPS) turned the analog services to digital and went online ("History of Cell Phone" 2010).

1.1.1 First Generation (1G) Mobile Phones

The USA Federal Communication Commission (FCC) approved for public use the first cell phone called Motorola DynaTAC 8000X from Motorola but was made available to the public market after 15 years and was developed by Dr. Martin Cooper. It was considered to be a lightweight cell phone of about 28 ounces. Its dimensions were 13 x 1.75 x 3.5 inches. First generation mobile phones worked with the Frequency Division Multiple Access (FDMA) technology. The first generation mobiles are large in size and heavy to carry. First generation mobile phones were used only for the voice communication purpose("History of Cell Phone" 2010).

1.1.2 Second Generation (2G) Mobile Phones

The second generation mobile phones were introduced in the 1990s. Second generation (2G) mobile phones worked with both GSM and CDMA (Code Division Multiple Access) technologies.

2G network signals are digital while 1G network signals are analog. 2G cell phones were smaller, weighing between 100 to 200 grams; these were hand-held and were portable. Later improvements on these cell phones included faster internet access with GPRS (General Packet Radio Service) and subsequently, EGDE (Enhanced Data rates for Global Evolution) technology. And sharing of files with other mobile devices using infra red or Bluetooth technology. There were other improvements like Short Message Service (SMS) smaller batteries and longer battery life, etc. Due to all these improvements, the mobile phone customer base expanded rapidly worldwide.

1.1.3 Third Generation (3G) Mobile Phones

Most present day mobile phones are the third generation phones. The standards used on 3G phones differ from one model of the mobile phone to the other which essentially depends on the network providers. These phones were capable of streaming live videos, stream radio, making video calls, send emails, have mobile TV, have high internet access speed due to HSDPA (High Speed Data Packet Access) and WCDMA (Wideband Code Division Multiple Access) technology. They also use Wi-Fi and touch screen technology apart from performing all the functions of the 2G mobile phones ("History of Cell Phone" 2010).

1.2 Dual SIM Mobile Phones

A *dual-SIM mobile phon*e has the capacity to hold two SIM cards. The earliest model of this technology made use of dual-SIM adapters on *single SIM phones* which of course had only one transceiver. The use of this adapter rendered a slim phone bulky. Sometime the SIM card needed to be trimmed to fit into the adapter and the phone. The *dual-SIM adapter* could hold two SIMs at a time and was small enough to fit behind the battery of a regular mobile phone. However both SIMs could not be activated at the same time on the mobile phone. Switching from one SIM to the other was done by restarting the mobile phone; this combination is called a *standby dual-SIM phone*. Recent dual-SIM phones have both SIMs activated simultaneously such that there is no need to restart the phone, these are referred to as *active dual-SIM phones*. Most of these phones have two transceivers in built of which one of the transceivers may support both 2G and 3G while the other transceiver only supports 2G. Another type of dual-SIM mobile phone exists which supports both GSM and CDMA network. A new generation of dual SIM mobile phones makes use of only one transceiver yet provide 2 active SIMs simultaneously e.g. the LG GX200. Some dual-SIM phone use calls management software and can divert calls from one SIM to the other SIM's voicemail when a call is in progress or simply indicate that the line is busy. Both SIM share the phone's memory such that they share the same contact list and SMS and MMS message library (li, R. 2010). A recent introduction is mobile phones capable of holding three SIM cards; an example is the Akai Trio ("Dual SIM" 2011).

1.3 Telephony in Nigeria

Up until 2001 Nigeria experienced problems with the services provided by its then main communications service provider the Nigerian Telecommunication Plc (NITEL) including inefficient services, lack of access, limitation of services to places of institution since only landlines were majorly deployed.In 1992, the telecommunications industry in Nigeria was deregulated. First was the commercialization or corporatization of Nigerian Telecommunications Plc (NITEL) while the second was the establishment of the Nigerian Communications Commission (NCC), the telecommunications industry regulator (Alabi 1996). The deregulation led to the introduction of Global System for Mobile communication (GSM) network providers operating on the 900/1800

MHz Spectrum were MTN Nigeria, Econet (now Airtel), Globacom and Mtel in 2001. As a result the use of mobile phones soared, and has replaced the unreliable services of the Nigerian Telecommunications Limited (NITEL). With an estimated 45.5 million mobile phones in use as at August 2007, and most people having more than one cell phone, Nigeria has witnessed a phenomenal growth in this sector ("Telecommunications in Nigeria," 2011).

2.0 THE NEED FOR DUAL SIM MOBILE PHONE

The GSM service in Nigeria came with its own problems as subscribers were not getting value for their money. Tariffs were high and the GSM service providers were plagued with numerous problems such as instability in power supply, insecurity of infrastructure, call drops, difficulty in network accessibility. Due to the peculiar nature of power supply in Nigeria, GSM service providers had difficulty in powering their cell sites. Electric power generators installed at base stations to supplement or provide power meant additional deployment and operational cost. This in advertently led to increase in call tariffs.

GSM service providers also incurred additional cost with regard to securing installed facilities. GSM Service providers have high numbers of security personnel on their payroll, because these guards are needed to guard their installations against theft and vandals. As of October 2007, Airtel (formerly Zain) had 2500 base stations, MTN-2900, and Globacom-3000 in Nigeria (Adegoke, Babalola, et al 2008). With two security personnel per cell site, one can relate the cost. These costs go into the total cost of operation thereby leading to increases in call tariffs. The presence of security personnel doesn't however guarantee the safety of these facilities since there are reported cases of stolen generators and siphoned fuel from reservoirs (Njoku, 2007).

Major complaints from network subscribers were the inability to access the network to initiate calls. A subscriber had to dial several times before a call could go through. Sometimes after dialing several times, a subscriber might be connected to the wrong number.

Often established calls are abruptly terminated in the middle of conversions. This can happen for several reasons. There may be loss of signal between the network and the mobile phone, when the mobile phone (subscriber) is outside the network coverage area, or the call is dropped upon handoff between cells on the same provider's network. Other causes include cell sites running at full capacity no room for additional traffic, poor network configuration such that a cell is not aware of incoming traffic from a mobile device; the call is lost when the mobile phone cannot find an alternative cell to handoff.

2.1 The GSM Service

Network accessibility, dropped calls and high tariff appear to be must worrisome to the average GSM subscriber. A common maxim then was "of what use is a mobile phone when it cannot be used at will?" Disturbingly, GSM service network problems often persist for days and on rare occasions, for weeks. These problems are peculiar to all the service networks. When one network is down, often service may be available on other networks. The logical option to subscribers was subscription to multiple networks; this of course meant acquisition of multiple GSM phones, with the attendant inconvenience associated with having to keep more than one handset. Many subscribers using multiple handsets experienced loss or theft of some of these phones.

Most Nigerians therefore desired and looked for a means of having two SIMs on a phone to overcome the problem of carrying more than one phone. Major mobile phone manufacturers however concentrated on producing sophisticated phones with mind blowing features like camera, FM radio, memory card, WAP, GPRS and EGDE capabilities at the time. These companies excelled in *product performance* using current technology to produce better and more durable phones with each new release. They sustained *product performance* with their new innovations and high tech phones.

3.0 THE DISRUPTIVE IMPACT OF DUAL-SIM TECHNOLOGY

Mobile phones of all brands, shapes and sizes, were introduced into the phone market at the onset just as GSM service providers were expanding network coverage. Common household names included Nokia, Samsung, Sagem, Sony Erickson and LG. There were a few other brands albeit insignificant compared to these six. The trend was slick, high-tech mobile phones with improved performance and durability. However, Chinese phone manufacturing companies introduced a disruption in this market trend and became a major player on the *Nigerian mobile phone market* via the introduction of dual-SIM capable phones popularly called "China Phones". Although these products did not equal the existing brands in performance, look and durability, they provided an innovational intervention for the target market in providing access to multiple service networks on a single phone. As such, with the additional vantage of being cheap and easily affordable, the Nigerian market embraced the product. Most of the features on existing sophisticated phones are also available on the *dual-SIM phones*. According to a market research company GFK Retail and Technology, 30 per cent of mobile phones in Nigeria are dual-SIM (Rattue, 2011). This development which is directly related to the phenomenal growth of multi-SIM devices globally is not only in Nigeria. In Indonesia, Vietnam, Ghana and India, the market has grown from one in ten in 2009 to one in four by the quarter of 2010. According to the report, in Middle East and Africa, one in every 10 mobile phones sold uses dual SIM. In Asia, 16 per cent of all mobile phones sold have dual SIM capabilities, which represents an increase from 13 per cent at the beginning of 2010 (Rattue, 2011). There were however warranty issues with the first adapter type *dual-SIM phones*; these adapters could be used with normal *single SIM phones*. The use of the *dual-SIM adapte*r voided warranty for such phones. Also "*China Phones*" that are *active dual-SIM phones* are bought from the dealers without warranty. When asked "why?" they reply that they equally bought them wholesale without warranty. Another issue is that of durability; "*China Phones*" broke down unpredictably. In event of fault, local repair shops find it difficult to get replacement parts as there are no service centers or parts shop for such products. The lack of International Mobile Equipment Identity (IMEI) numbers in the unbranded made in China handsets makes them non-traceable and creates security concerns. In spite of these shortcomings the demand for them is ever increasing, as low income earners can easily afford them. Most local mobile phone outlets sell mostly these "*China Phone*". Established firm and global mobile phone manufacturers are facing stiff competition from Chinese brands and "fakes" in the Nigeria mobile phone market. This they have done by enticing consumers with attractive combination of features at affordable prices. Chief among these features is the dual-SIM capabilities of these mobile phones which established manufacturers are slowly introducing (Rattue, 2011). Samsung's D880 Duos was not so successful when it was introduced since calls were only possible with its primary SIM, unlike the Chinese brands which offered dual call capabilities. To initiate call from the secondary SIM of a Samsung D880, it must be made the primary. This difficulty in addition to its high cost were factors that made it unsuccessful. Subsequent Samsung *active dual-SIM phone* models had better performance but their costs were still high. Nokia only introduced their cheap dual-SIM phone, Nokia C Series in Nigeria in 2010. There is general acceptance in the country that Nokia phones are more durable than others. However, the Nokia C1-00 is a *standby dual-SIM phone* as only one of the SIM is active at a time.

Initially most Nigerians embraced the *dual SIM phones* due to inconvenience associated with carrying two mobile phones at the time. Presently, there is improvement in the power sector in the country. There have also been reductions in inaccessibility to GSM networks and the rate of dropped calls. And insecurity still remains an issue at each cell sites. The inclination to ownership of multiple mobile phones is currently not only driven by these factors but by new factors including lower call tariff, promo by various GSM service providers to entice customer and privacy/ personal security issues.

3.1 The Way Forward

Some of the problems facing the dual-SIM "China Phones" and possible steps to address them.

- No warranty Issues
- Poor durability
- No service centres
- Difficulty in Getting Replacement Parts
- Security Issues (No IMEI number)

The cases of void warranties as a result of using *dual-SIM adapter* on normal single SIM mobile has drastically reduced if not eliminated by recent *active dual-SIM mobile phones*. The lack of warranty for a product often creates doubt in the mind of the customers as to durability or authenticity of the product. Wholesale dealers who get these "*China Phones*" should be made to demand that the manufacturers of such phones issue warranties for them. This will encourage more patronage.

The issue of durability can be a result of poor design or the use of substandard materials to implement the *dual-SIM technology*. Since most of these phones are cheap as compared with other *dual-SIM mobile phones* manufactured by big and popular mobile phone manufacturers like Nokia, Samsung etc. There is the likelihood that the use of substandard materials is the cause of poor durability. Better materials will lead to increase in cost of production and product cost. I believe they can strike a balance and still produce phones that are reasonably priced. Initially, the "*China Phones*" had short battery life, but the phones now come with extra battery.

Chinese phone manufacturing companies need to establish service centres in the country or train and certify a hand full of owners of local mobile phone repair shop who will in turn pass on the skills acquired to others such that there will be enough skilled technicians who will be able to repair these phones in the event of faults. Replacement parts for "*China Phones*" should be made available to the trained technicians through the service centres.

There is need for regulation to stop the use of *dual-SIM mobile phones* without IMEI number. International Mobile Equipment Identity (IMEI) number is unique to every GSM and WCDMA mobile phone and found printed inside the battery compartment of the phone. It can be displayed on the screen of the phone by entering*#06# on the keypad.

In India when a large percentage of people used such phones, mobile operators implanted IMEIs onto such phones rather than bar services. But the Indian government placed a ban on the usage of phones without IMEI which took effect from December 1, 2009.

4.0 CONCLUSION

The need for communication in spite of poor network coverage and quality of service by the Mobile (GSM) service providers, informed ownership of multiple number of *single SIM mobile phones* to guarantee access to available network services by mobile phone users in Nigeria, with associated multi-phone ownership problems. Major mobile phone manufacturers who prefer a *sustained technology* model responded to the increase of market with improved and more sophisticated products. Disruptive market innovation by way of *dual-SIM mobile phones* products met market anticipation. These dual-SIM " made in China" phones were not as attractive or as durable as the existing sophisticated brands but had most features on these phones and were cheap and affordable. The dual-SIM phones performance were also affected by short battery life, plus absence of warranties, technical support/services outlets and replacement parts. Additional security issues are associated with the phones' lack of IMEI numbers. However, the *dual-SIM innovation* met a market need and is widely used in Nigeria. Whereas electricity supply, insecurity and other problems which informed telecoms service quality which informed multiple phone ownership are declining, personal security issues and preference of lower tariff offerings continue to inform multiple network access. As such, dual SIM phones remain a popular market choice. Associated problems with this dual SIM products must however be addressed by the China based manufacturers and other market players.

KEY TERMS AND DEFINITIONS

Active Dual-SIM Phone: A dual-SIM that has both SIM activated, calls can be made or received simultaneously and there is no need to restart or switch between SIMs.

Cell Phone: America's name for mobile phone

China Phone: substandard and sometimes unbranded dual-SIM mobile phone manufactured in China

Dual-SIM Phone: Mobile phone capable of holding two SIM cards that may or may not have both SIM cards activated to make or receive calls simultaneously.

Standby Dual-SIM Phone: A dual-SIM mobile that has one SIM activated at a time and needs to be restarted to activate the other SIM or switch between SIMs.

Chapter 36
Data Envelopment Analysis in Environmental Technologies

Peep Miidla
University of Tartu, Estonia

ABSTRACT

Contemporary scientific and economic developments in environmental technology suggest that it is of great importance to introduce new approaches that would enable the comparison of different scenarios for their effectiveness, their distributive effects, their enforceability, their costs and many other dimensions. Data Envelopment Analysis (DEA) is one of such methods. The DEA is receiving an increasing importance as a tool for evaluating and improving the performance of manufacturing and service operations. It has been extensively applied in performance evaluation and benchmarking of several types of organizations, so-called Decision Making Units (DMU) with similar goals and objectives. Among these are schools, hospitals, libraries, bank branches, production plants, but also climate policies, urban public transport systems, renewable energy plants, pollutant emission systems, environmental economics, etc. The purpose of this chapter is to present the basic principles of the DEA and give an overview of its application possibilities for the problems of environmental technology.

INTRODUCTION

The Earth is the common home for all of us and because of this the great attention paid to environmental problems is more than natural and urgent. The lack of economic value of environmental goods often leads to over-exploitation and degradation of these resources. It is extremely important to monitor and control interactions between production technologies and the environment. To keep and conserve the natural environment, environmental technology is developed. Independently of application areas of environment sciences, new approaches and methods, particularly of mathematical modeling, are extremely needed and welcome in this area. It is well-known that mathematical modelling is the most efficient method for investigating different processes, their simulation and prediction.

DOI: 10.4018/978-1-4666-1945-6.ch036

Data Envelopment Analysis (DEA) is a relatively new data oriented mathematical method for evaluating the performance of a set of peer entities traditionally called Decision Making Units (DMU) which convert multiple inputs into multiple outputs. Since DEA was first introduced, in its present form, in 1978 (Charnes et al., 1978), we have seen a great variety of applications of DEA being used in evaluating the performances of many different kinds of entities engaged in many different activities in many different contexts in many different countries. These DEA applications have used DMUs of various forms, such as hospitals, schools, universities, cities, courts, business firms, and others, including the performance of countries, regions, etc. The DEA is frequently applied in many areas of applied economic sciences, including agricultural economics, development economics, financial economics, public economics, macroeconomic policy, etc.; and among others, in addition to its traditional confinements in productivity and efficiency analysis; it has also diffused into the field of environmental economics and environmental technology. As it requires very few theoretical assumptions, DEA has opened up possibilities for its use in cases which have been resistant to other approaches because of the complex (often unknown) nature of the relations between the multiple inputs and multiple outputs involved in DMU.

There are several examples of areas of environmental science, where DEA is used and where remarkable theoretical and practical results have been achieved. In the framework of problems raised by climate change, one of the major threats to the Earth's sustainability, we see that DEA is applied for assessing the relative performance of different climate policy scenarios as DMUs, through accounting their long-term economic, social and environmental impacts as input and output parameters. (Bosetti & Buchner, 2008) Quantitative techniques are crucial here in order to make adequate decisions quickly. In the sense of climate change measuring the carbon emission performance is also important. (Zhou et al., 2008) In another context, the paper by (Piot-Lepetit, 1997) considers the usefulness of DEA for estimating potential input reductions and assessing potential reductions of environmental impact on agricultural inputs. We can see the same in the paper (Madlener et al., 2006), where the assessment of the performance of biogas plants is realized. In the study (Rodrigues Diaz et al., 2004) DEA was used to select the most representative irrigation districts in Andalusia. One can find the use of DEA to assess corporate enactment of Environmentally Benign Manufacturing as work parts move from place to place in a company (Wu et al., 2006); this work touches green manufacturing problems. The DEA is used even in political decision making (Taniguchi et al., 2000), and to discuss a methodology to assess the performances of tourism management of local governments when economic and environmental aspects are considered as equally relevant. (Bosetti et al., 2004)

The structure of the present chapter is the following. First an overview of DEA method is given. Today the DEA itself has developed and has several forms, versions and modifications, each of which has specific application features. Below we formulate only the basic version of it because there is a lot of literature available in libraries and on the internet. The main part of the paper deals with the case studies, the results of which have been achieved by using the DEA. There is a rising trend to apply DEA and naturally some selection of them is included. Finally the reader finds the conclusions and references. One important objective of this chapter is to emphasize that environmental technologies are very open to innovation, and using new methods of mathematical modeling is a part of this.

OVERVIEW OF THE DATA ENVELOPMENT ANALYSIS

In this paragraph we give a short description of Data Envelopment Analysis (DEA). More profound treatments of the topic can be found in many books, (e.g. Cooper et al., 2004; Cooper et al., 2007; Thanassoulis 2003) and there are also books (edited by Charnes et al., 1994) and papers dealing with the applications of DEA. Comprehensive information about DEA can be found on the web-page of Ali Emrouznejad (Emrouznejad 1995-2001) or in the paper (Emrouznejad et al., 2008). Also, it is important to mention that all the papers referred to in the next section "Case Studies" contain a sufficient overview of DEA versions or modifications used in particular cases under consideration.

DEA and Benchmarking

Data Envelopment Analysis belongs to the wider class of efficiency measuring methods, to the so-called frontier methods, and is a data oriented approach for evaluating the performance of a set of peer entities called Decision Making Units (DMUs). DEA is a multi-factor productivity analysis model for measuring the relative efficiencies of DMUs and is receiving increasing importance as a tool for evaluating and improving the performance of manufacturing and service operations. DEA is a powerful methodology for identifying best practice frontier and has been extensively applied in performance evaluation and benchmarking of schools, hospitals, bank branches, production plants, public-sector agencies, etc. Technically DEA represents the collection of non-parametric, linear programming techniques developed to estimate the relative efficiency of DMUs. Largely the result of multi-disciplinary research in economics, engineering and management, DEA is a theoretically sound framework that offers many advantages over traditional efficiency measures such as performance ratios and regression.

The most important feature of DEA is its ability to handle effectively the multidimensional nature of inputs and outputs in the production and management process. Efficiency as an economic category is in use widely in profit – targeted organizations and enterprises. The simple idea that greater input into system brings us greater output and increases the profit lies in the base of the general meaning of efficiency. Theoretically and practically several types of efficiency are in use and every one of them gives a different possibility for interpretation and for making new decisions. The same is also seen in DEA concepts. Here for each DMU the efficiency score in the presence of multiple input and output factors is defined as: weighted sum of outputs divided to weighted sum of inputs. All scores are between zero and one; DMU's whose efficiency is equal to one, are certified as fully efficient or simply efficient. For every inefficient DMU, i.e. for these which efficiency score is less then one, the DEA identifies a set of corresponding efficient units, so called reference group, that can be utilized as benchmarks for the improvement of activities. The estimation of the efficiency of a single DMU, on the base of other organizations acting in the same economic environment, is the main advantage of the DEA approach. Reference group means: the set of real DMUs whose outputs and inputs belong to the outputs and inputs of composite virtual DMU with nonzero weights. The fact that efficiencies of reference DMUs are taken equal to 1 (or 100%) does not mean that the quality of work of those base organizations could not improved. The results of the application of the DEA fix only the situation in the moment when the data for input and output parameters is collected.

Geometrically for every DMU evaluated the reference set determines a frontier in the input – output parameters space. This is called best practice production frontier and the points which correspond to efficient DMUs are situated on this. If in the group of DMUs under consideration are **n** members for all the values of demanded input-output parameters, then in the parameters space we have also **n** data points. The best practice frontier is constructed then as piecewise linear surface in this space which envelopes set of data points and separates it from the beginning of coordinates. Fully efficient DMUs are vertices of this. Efficiency means geometrically a radial measure which quantitatively equals to the rate of distances from the beginning of coordinates of the composite virtual DMU and DMU being evaluated. Evaluation process of every single nonefficient DMU gives in general different efficiency coefficients and individual reference set because the data points are different. Exceptions are efficient DMUs: as mentioned, the efficiency of a DMU which belongs to reference set is established equal to one but over that there may be other DMUs which efficiency is also equal to one but which do not belong to any reference set. In all textbooks one can find the exact explanations also about geometrical issues. (See e.g. Cooper, et al., 2004).

Data for DEA is a set of parameters, evaluated for each DMU. The parameters are divided into input and output parameters which represent different activities of DMUs under consideration. For example, if we consider DMUs as public libraries, the input parameters could be fixed as yearly expenditures on acquisition of new books, yearly expenditures on salaries, the size of collections and the area of the library rooms. As for output parameters one may consider the number of readers and the number of loans. It is interesting to mention some important conclusions of this work although research considered libraries. In the years 2002 by 2005 eight central libraries, i.e. 40% from the whole selection, used their resources effectively. The score of relative efficiency of the rest of libraries varied from 0,740 to 0,979.The data of four years show that the trend of the score of efficiency of central public libraries of Estonia was falling, i.e. the average score decreases. In 2005 there were six central libraries from 20 which were scale efficient, i.e. of optimal size. (Miidla & Kikas, 2009). The list of parameters and division into inputs and outputs can be chosen and fixed differently, depending on the particular goals of research and, naturally, on application area. One can say that DMUs convert multiple inputs into multiple outputs. It is just interesting that the inputs and outputs do not need to have a common measure; they can be quantities of completely different units – meters, dollars, number of persons, number of lakes in regions, etc. It is important that in the whole selection the inputs and outputs of all DMUs have a value; although in the case of absent data there are also approaches which allow the use of DEA (Kao & S-Tai Liu, 2000). Further with regards to the words ‘selection’ or ‘selection group’ we refer to the whole set of DMUs under consideration.

The DEA approach uses a linear programming model for measuring the relative efficiencies of those DMUs on the basis of the given data. First, a DMU is fixed and a hypothetical composite operating unit, a hypothetical DMU, based on all units in the selection group, is constructed. The input and output of this composite virtual DMU are determined by computing the weighted average of the inputs and outputs of all real DMUs in the selection group, and the efficiency score of the initially fixed DMU is defined as the rate output and input of this constructed composite DMU. This procedure is repeated for each single DMU, and as the output for the DEA application itself one gets an array of these relative efficiencies, which lay between zero and one. Thus the DEA approach is a kind of peer comparison method. Constraints in the linear programming model require all outputs of the composite virtual DMU to be greater than or equal to the outputs of the DMU being evaluated. So, if in the selection group there are **n** members then for evaluating all of the members, from the point of view of relative efficiency, we need to establish and solve **n** problems of linear programming. It should be mentioned that often more than one problem of linear programming is needed to solve each DMU. In the advance use of DEA, it is necessary to use more than one problem of linear programming when a more detailed analysis is needed. (Thanassoulis, 2003)

If the inputs for the virtual composite unit can be shown to be less than the inputs for the DMU being evaluated, the composite DMU will be shown to have the same, or more output for less input. In this case, the model will show that the composite virtual DMU is more efficient than the DMU being evaluated. In other words, the DMU under evaluation is less efficient than the virtual DMU. Since the composite DMU is based on all DMUs in the selection group, the DMU being evaluated can be judged relatively inefficiently when compared to the other units in the selection. The estimation of the efficiency of a single DMU on the basis of others acting in the same environment, the so-called reference group, is the main advantage of the DEA approach. The reference group means the set of real DMUs whose outputs and inputs belong to the outputs and inputs of composite virtual DMU with nonzero weights. This approach makes the DEA very attractive because in the case of environmental entities it is difficult to speak about efficiency for all these in one sense, as it is possible, for example, for profit organizations. The efficiency of reference DMUs is taken equal to 1 (or 100%). The results of the application of the DEA can only fix the situation when applying the results to the time frame in which the data for input and output parameters was collected. The environment may have already changed; applying these results to the following year can render inaccurate data.

Geometrically for every DMU evaluated the reference set determines the frontier in the input – output parameters space. This is called the best practice production frontier, although in the case of environmental technologies it is difficult to speak so, and the points which correspond to effective DMUs are situated on this. As mentioned before, the frontier itself is a piecewise linear surface in the input - output parameters space as an envelope to a production possibility set. Points corresponding to the reference or fully efficient DMUs are vertices of this frontier. Efficiency is geometrically a radial measure quantitatively equal to the rate of distances from the beginning of coordinates of the composite virtual DMU and of DMU being evaluated. This rate is just referred to as the relative efficiency. Evaluation of every single DMU gives in principle a different frontier and an individual reference set. The efficiency of DMUs in the reference set is established equal to one and there may be also other DMUs which efficiency is equal to 1 which do not belong to any reference set, they belong to the composite virtual DMU with zero weight. The best practice frontier relies only on the initial data, i.e. on inputs and outputs of all DMUs in the selection. The algorithm of efficiency estimation does not require the construction of the best practice frontier; the numerical method gives the answer without geometrical interpretation.

Considering the DEA methodology one has to assume scaling properties of input parameters, returns to scale. This means the influence of inputs variation to outputs changes. Let us assume that the input parameters are changed, all in the same proportionality. If the outputs change in the same proportion we can speak about constant returns to scale. Otherwise, when outputs do not change in the same rate we can speak about variable returns to scale; more precisely, increasing or decreasing returns to scale if outputs change in a greater or smaller proportion. The scale issue associated with DEA might be under attention when different DEA models are in use and the scaling property leads us to the meaning of optimal size of DMU. Namely, the DMU is shown to be of optimal size when it is efficient both in the sense of constant returns to scale and variable returns to scale. If the DMU is less than optimal, it usually works in the conditions of increasing returns to scale. Conversely, oversized, if compared to the optimal size DMUs, works in the conditions of decreasing returns to scale. This might also be important in some aspects of application in environmental technology.

The DEA approach can be input-oriented or output-oriented. In the first case the main question is: how much is it possible to decrease the input parameters for inefficient DMUs in order to keep the present output. In the case of output-oriented method the main question is: how much is it possible to increase the outputs while keeping the present input. Choosing between these two possibilities depends again on the context of application, both of the cases lead to different modifications of the DEA method.

Mathematical Formulation

In their initial study, Charnes, Cooper, and Rhodes (Charnes et al., 1978) described DEA as a 'mathematical programming model applied to observational data that provides a new way of obtaining empirical estimates of relations, such as the production functions and/or efficient production possibility surfaces, that are cornerstones of modern economics.' In this article they proposed following the fractional program model, known as the CCR DEA model.

Assume that there are **n** DMUs to be evaluated. Each DMU consumes varying amounts of **k** different inputs to produce **m** different outputs. Specifically, DMU **j** consumes amount $\mathbf{x_{ji}}$ of input **i** and produces amount $\mathbf{y_{jr}}$ of output **r**. We assume that $\mathbf{x_{ji} \geq 0}$ and $\mathbf{y_{jr} \geq 0}$ and also assume without loss of generality that each DMU has at least one positive input and one positive output value. The first approach gives us the fractional program problem for evaluating the efficiency score of the DMU number **s**. In this form, as introduced by Charnes, Cooper, and Rhodes, the ratio of outputs to inputs is used to measure the relative efficiency of the DMU to be evaluated relative to the ratios of all of the **n** DMUs. We can interpret the CCR construction as the reduction of the multiple-output/multiple-input situation for each DMU to that of a single virtual output and virtual input. For a particular DMU the ratio of this single virtual output to single virtual input provides a measure of efficiency that is a function of the multipliers $\mathbf{v_1},\ldots,\mathbf{v_m}$, $\mathbf{u_1},\ldots,\mathbf{u_k}$. In mathematical programming parlance, this ratio, which is to be maximized, forms the objective function for the particular DMU being evaluated. Symbolically the problem is the following:

Find

$$\mathbf{max}\ \{(\mathbf{v_1\, y_{1s}} + \ldots + \mathbf{v_m\, y_{ms}})/(\mathbf{u_1\, x_{1s}} + \ldots + \mathbf{u_k\, x_{ks}})\},$$

maximization over

$$\mathbf{v_1},\ldots,\mathbf{v_m},\ \mathbf{u_1},\ldots,\ \mathbf{u_k}$$

subject to:

$$\{(\mathbf{v_1\, y_{1i}} + \ldots + \mathbf{v_m\, y_{mi}})/(\mathbf{u_1\, x_{1i}} + \ldots + \mathbf{u_k\, x_{ki}})\} \leq 1,\quad \mathbf{i} = 1,\ldots,\mathbf{n}$$

$$\mathbf{v_1},\ldots,\mathbf{v_m},\ \mathbf{u_1},\ldots,\ \mathbf{u_k} \geq 0$$

where $\mathbf{v_1},\ldots,\mathbf{v_m}$, $\mathbf{u_1},\ldots,\mathbf{u_k}$ are weights given to real observed output values $\mathbf{y_{1s}}, \ldots, \mathbf{y_{ms}}$ and input values $\mathbf{x_{1i}}, \ldots, \mathbf{x_{ki}}$, correspondingly.

In this first approach, the fractional program problem has an infinite number of solutions:

if

$$(\mathbf{v_1}^*,\ldots,\mathbf{v_m}^*,\ \mathbf{u_1}^*,\ldots,\ \mathbf{u_k}^*)$$

is a solution of this, i.e. optimal, then also

$$(\boldsymbol{\alpha}\,\mathbf{v_1}^*,\ldots,\ \boldsymbol{\alpha}\,\mathbf{v_m}^*,\ \boldsymbol{\alpha}\,\mathbf{u_1}^*,\ldots,\ \boldsymbol{\alpha}\,\mathbf{u_k}^*)$$

has the same property for every $\boldsymbol{\alpha} > 0$. The additional condition

$$\mathbf{u_1\, x_{1s}} + \ldots + \mathbf{u_k\, x_{ks}} = 1$$

makes it possible to convert this fractional problem to following linear programming problem for the estimation of the efficiency of DMU number **s**.

Find

$$\mathbf{z^*} = \max (\boldsymbol{\mu}_1 \mathbf{y}_{1s} + \ldots + \boldsymbol{\mu}_m \mathbf{y}_{ms}),$$

maximization over

$$\boldsymbol{\mu}_1, \ldots, \boldsymbol{\mu}_m$$

subject to:

$$(\boldsymbol{\mu}_1 \mathbf{y}_{1i} + \ldots + \boldsymbol{\mu}_m \mathbf{y}_{mi}) - (\boldsymbol{\gamma}_1 \mathbf{x}_{1i} + \ldots + \boldsymbol{\gamma}_k \mathbf{x}_{ki}) \le 0, \quad \mathbf{i} = 1,\ldots,\mathbf{n}$$

$$\boldsymbol{\gamma}_1 \mathbf{x}_{1s} + \ldots + \boldsymbol{\gamma}_k \mathbf{x}_{ks} = 1$$

$$\boldsymbol{\mu}_1, \ldots, \boldsymbol{\mu}_m, \boldsymbol{\gamma}_1, \ldots, \boldsymbol{\gamma}_k \ge 0.$$

This is a basic linear programming problem for obtaining the efficiency score **z*** of the DMU number **s.** The above problem needs to run **n** times in identifying the relative efficiency scores of all the DMUs. Each DMU selects input and output weights that maximize its efficiency score. As mentioned, a DMU is considered to be efficient if it obtains a score of 1; a score of less than 1 implies that it is inefficient. When working with literature, a reader can find several versions of DEA computational schemes and should clearly understand what version is in use in every particular case, particularly understand the assumptions, etc. In this paper one does not find any exhaustive discussion but simply an example of DEA method formulation. Below we bring the dual problem of linear program.

Find

$$\boldsymbol{\Theta^*} = \mathbf{min}\ \boldsymbol{\Theta},$$

minimization over weights

$$\lambda_1, \ldots, \lambda_n$$

subject to:

$$\boldsymbol{\lambda}_1 + \ldots + \boldsymbol{\lambda}_n = 1$$

$$\boldsymbol{\lambda}_1 \mathbf{x}_{1,i} + \ldots + \boldsymbol{\lambda}_n \mathbf{x}_{n,i} \le \boldsymbol{\Theta} \mathbf{x}_{s,i}\ , \ \mathbf{i} = 1,\ldots,\mathbf{k}$$

$$\boldsymbol{\lambda}_1 \mathbf{y}_{1,j} + \ldots + \boldsymbol{\lambda}_n \mathbf{y}_{n,j} \ge \mathbf{y}_{s,j}\ , \ \mathbf{j} = 1,\ldots, \mathbf{m}$$

$$\boldsymbol{\lambda}_1 \ge 0,\ldots, \boldsymbol{\lambda}_n \ge 0.$$

As in the case of the main problem, for a complete realization of the DEA it is necessary to solve the linear programming problem for every single DMU in the selection. This gives us the array of relative efficiencies, solutions **Θ*** for every single DMU and only then it is possible to start with the interpretation process. Given dual problem is important because the units involved in the construction of the composite DMU, i.e. for which corresponding weight $\boldsymbol{\lambda}_i > \mathbf{0}$, can be used as benchmarks for improving the inefficiency of tested DMU's. DEA allows for computing the necessary improvements required in the inefficient DMU's inputs and outputs in order to make it efficient. If a DMU is inefficient, the corresponding solution **Θ*** is less than one; the solution also gives us the parameters of the corresponding composite virtual DMU which is efficient, of course, i.e. the weights for its input and output. This virtual DMU also presents us the corresponding point on the production efficiency frontier; 'dragging' the inefficient DMU point to the frontier means a decrease in the inputs of this DMU.

Sometimes it so happens that the composite DMU is located on the part of the production efficiency frontier which is parallel to some coordinate plane. In this case it is possible to realize an additional shift of the virtual data point of composite DMU down along of this parallel part towards the beginning of coordinates without decreasing outputs and increasing other inputs. This surplus is called a slack and it gives additional information about the inefficiency of the DMU under consideration. Slacks show the real possibilities to decrease the corresponding input parameter on the existing real example of other DMU working in such conditions. The interpretation of inefficiency in the case of input-oriented DEA, represented by dual linear programming problem, is easy. Namely, if we have **k** input parameters under consideration and if the relative efficiency Θ^* of a DMU is less than one, $\Theta^* < 1$, then to reach the full relative efficiency $(\Theta^* = 1)$ we must decrease inputs $(x_1,\ldots,x_k)$ of this DMU Θ^* times, i.e. to the values $(\Theta^* x_1,\ldots, \Theta^* x_k)$.

Any further discussion of these questions does not fall under the goal of the present paper. It is interesting to mention that in numerous applications of environmental technology, the versions and possibilities of Data Envelopment Analysis have been used in a great variety. The trend is increasing; the full DEA bibliography contains more than 4000 journal articles (Emrouznejad, 1995-2001) comprising many scientific fields.

CASE STUDIES

Next we explore the possibilities of DEA application in different areas of environmental technology. The use of DEA as a quantitative non-parametric performance measurement technique, based on linear programming, for assessing the relative efficiency of homogeneous peer entities called Decision Making Units (DMUs), is successfully implemented into environmental research projects. DEA makes it possible to compare the efficiency of each DMU to that of an ideal operating unit, rather than to the average performance. This ideal unit is constructed only on the base of the data for the whole set of DMUs and because of this several DMUs always become fully efficient. The definition of a DMU is generic and flexible and this enforces the dissemination of DEA into new areas. We explain the use of DEA on the base of some examples and most certainly not all application areas are covered. So, the overview given in this paper is in no way exhaustive of the developments in the field of DEA possibilities. The goal is to show some approach details, possible choices of DMUs, the corresponding input and output parameters, and the conclusions made on the basis of DEA. The interpretations of environmental efficiency in different cases are of interest. The order of examples is of no importance, as it is impossible to line up urgent environmental protection problems.

Climate Policy Scenarios

DEA is extended from its traditional application in (Bosetti & Buchner, 2008) as a quantitative method to assess the relative performance of different climate policy scenarios when accounting for their long-term economic, social and environmental impacts. Indeed, contemporary developments in the political, scientific and economic debate on climate change suggest that it is of critical importance to develop new approaches, particularly quantitative, to compare policy scenarios for their environmental effectiveness, their distributive effects, their enforceability, their costs and many other dimensions. As for input parameters for DEA application economic, environmental and social costs for every possible policy, also indicators of instant climate situation are considered here. Instead, among the outputs, there are indicators for which lower values are preferred and indicators of benefits and welfare. The authors discuss eleven simulated climate policy scenarios, computed three indicators for each of them (cumulated discounted GDP over the century, temperature increase by 2100, and the Gini equity indicator by 2100), add the application of DEA and make interesting conclusions. Two alternative DEA approaches to compare the sustainability of different policy scenarios are used. One of them is based on the efficiency score defined as a relative ratio and the other is based on Competitive Advantage measured in terms of absolute prices. The first case fits the traditional DEA application described above. Relative efficiency estimates are computed for each policy, where efficiency is measured as the ratio of the weighted sum of outputs to the weighted sum of inputs, and are obtained through solving a series of linear programming problems. Both, constant returns to scale and variable returns to scale assumptions are used. The interpretation of relative efficiency, computed using the DEA method, is interesting: the policy is 100% efficient if and only if 1) none of its outputs can be increased without either increasing one or more of its inputs, or decreasing some of its other outputs; 2) none of its inputs can be decreased without either decreasing some of its outputs or increasing some of its other inputs. In the second approach DEA is applied in order to get weights while for each scenario the net economic impact, expressed in monetary value, is aggregated through weights to the social and environmental impacts as DMUs and their efficiencies are expressed in their own unitary measures, on the base of the data from real activity.

Three major findings are pointed out: 1) stringent climate policies can outperform less ambitious proposals if all sustainability dimensions are taken into account; 2) a carefully chosen burden-sharing rule is able to bring together climate stabilization and equity considerations; 3) the most inefficient strategy results from the failure to negotiate a global post-2012 climate agreement. In conclusions the simulated scenarios, also the interpretational role of the DEA, are discussed in details. It is remarkable that it is possible to support the political, scientific and economic debate on climate change using the DEA method.

Measuring Environmental Performance Index

The Environmental Performance Index (EPI) is a method of quantifying and numerically benchmarking the environmental performance of a country's policies and has been in recent years universally adopted and quoted by corresponding policy analysts and decision makers. The construction of an aggregated EPI, which offers condensed information on environmental performance, has evolved as an important focus in systems analysis. Among the existing approaches to developing EPIs, some are data-driven while others are theory-driven. In the article of Zhou et al., (2008) we see an example of direct approach, where an aggregated EPI is directly obtained from the observed quantities of the inputs and outputs of the environmental system studied using Data Envelopment Analysis.

This work is an example of application of environmental DEA technology, in which outputs are assumed to be weakly disposable (Färe et al., 2004) and which have been widely used to measure industrial productivity when undesirable outputs exist. In recent years this approach has gained popularity in environmental performance measurement due to its empirical applicability. The common procedures for applying DEA to measure environmental performance are to first incorporate undesirable outputs in the traditional DEA framework, and then calculate the undesirable outputs orientation (environmental) efficiencies. In fact, many studies have been devoted to modeling undesirable factors in DEA, e.g. the data translation approach (Seiford & Zhu, 2005) and the utilization of environmental DEA technology.

In the article (Zhou et al., 2008) different DEA methods for environmental performance measurement are described (constant returns to scale and variable returns to scale, non-increasing returns to scale) and a study on measuring the carbon emission performance of eight world regions is presented. The centre of attention is on the growing concern on global climate change due to carbon dioxide (CO_2) emissions worldwide. The single input, desirable output and undesirable output are: total energy consumption (Mtoe, megatonne of oil equivalent), GDP (gross domestic product, billion 1995 US$) and CO_2 emissions (Mt), respectively.

Eight regions under consideration (i.e. DMUs for DEA application) are: OECD, Middle East, Former USSR, Non-OECD Europe, China, Asia (excludes China), Latin America and Africa.

In this study all the proposed models are radial DEA-based models where efficiency scores are computed as rate of distances from origin of coordinates, DEA frontier and data point of corresponding DMU. However, in some circumstances it may be difficult to compare some DMUs only by the proposed environmental performance indexes because of the weaker discriminating power of radial DEA efficiency measures compared to with non-radial DEA models. Authors propose to incorporate different environmental DEA technologies with the non-radial DEA efficiency scores and to combine different environmental DEA technologies with slacks-based efficiency measures. The results of the study are interesting. For instance, if the pure EPI is chosen and the reference technology exhibits variable returns to scale, OECD has a better carbon emission performance than Africa eventhough it has a larger carbon intensity and carbon factor.

Greenhouse Gas Technologies

In the paper (Lee et al., 2008), the authors use the Analytic Hierarchy Process (AHP) and Data Envelopment Analysis (DEA) hybrid model to weigh the relative preferences of greenhouse gas technologies in Korea. The Analytic Hierarchy Process is a subjective method used to analyze qualitative criteria in order to generate a weighting of the operating units and is known as a decision-making method which could be used to solve unstructured problems. In general, decision making involves tasks such as planning, the generation of a set of alternatives, the setting of priorities, the selection of the best policy once a set of alternatives has been established, allocation of resources, determination of requirements, prediction of outcomes, designing of systems, measurement of performance, ensuring of system stability, and the optimization and resolution of conflicts. Authors of the paper employed a long-term perspective when establishing the criteria to evaluate energy technology priorities for the greenhouse gas plan. They used the AHP to generate the relative weights of the criteria and alternatives in the greenhouse gas plan. Thereafter, the relative weights were applied to the data used to measure the efficiency of the DEA method. This study represents an example in which the AHP/DEA hybrid model has been used to determine the energy technology priorities for the greenhouse gas plan. The results obtained using this hybrid model provide the government with an effective decision-making tool and also represent a consensus of experts in the greenhouse gas planning sector.

Nine greenhouse gas technologies were considered as DMUs for DEA application: CO_2 capture storage and conversion technology, non-CO_2 gas technology, advanced combustion technology, next-generation clean coal technology, clean petroleum and conversion technology, DME (di-methyl ether) technology, GTL (gas to liquid) technology, gas hydrate technology and greenhouse gas mitigation policy. The parameters of DEA consist of a single input factor and multiple output factors. The input factor consists of the investment cost associated with the development of greenhouse gas technologies; the unit of investment cost was million US dollars in 2006. There are five output factors, namely possibility of developing technology, potential quantity of energy savings, market size, investment benefit, and ease of technology spread. All outputs are multiplied by the relative weights calculated using the AHP approach (these concern United Nations Framework Convention on Climate Change, UNFCCC, economic spin-off, technical spin-off, urgency of technology development, and quantity of energy use) and are thus applied in conjunction with the output factors employed as part of the DEA approach. As a result of the application of the AHP/DEA approach, one greenhouse gas technology, namely non-CO_2 gas technology with efficiency score 1, was found to be more efficient than the other eight greenhouse gas technologies. In conclusion, this hybrid model can be used to efficiently compute the relative efficiency scores of greenhouse gas technologies. This paper also shows decision makers and policy makers in the energy sector that multi-criteria decision making problems can be solved using scientific procedures.

Tourism Management

DEA is also effectively used for assessing the performances of tourism management of local governments when economic and environmental aspects are considered as equally relevant. In (Bosetti et al., 2004) the focus is on the comparison of Italian municipalities located in coastal areas. In order to assess the efficiency status of the considered management units, DEA is applied. In this analysis, the DMU represents a municipality producing the tourism good for which two different inputs are given. The first is the cost of managing the tourism infrastructure. More exactly, the cost of the production of tourism services is fixed on the total number of beds, which is considered as an approximation for management expenses, and it is computed by adding up the number of all beds in hotels, camping, registered holiday houses and other receptive structures. The second input is the environmental cost deriving from the increased number of people depending on the same environmental endowment; this parameter is presented as the amount of solid waste in tons per year. As output parameter, an indicator measuring the rate of use of existing beds has been used as a general approximation for profit deriving from the tourist industry, is considered.

The authors confirm that in the present study output-oriented models have been preferred to input-oriented ones, as they suit more issues considered as relevant for management purposes and they better help in addressing the germane questions. These applications also give the sense to the input and output indicators because in order to augment the efficiency of an inefficient municipality, the most direct policy means is to introduce constraints on the uncontrolled deployment of environmental resources, rather than restricting the dimension of the tourism business. Also, variable return to scale models has mainly been considered, although an analysis using a constant return to scale DEA model has also been conducted on the same data set.

The main result of this DEA performed over the data set is a ranking of the considered municipalities. The analysis for each municipality specifies not only the relative efficiency scores, but also the potential improvements in the case of scores lower than one.

Consumer Durables

A wide program 'Measurement of Eco-efficiency using Data Envelopment Analysis' has been introduced in Finland by the Ministry of the Environment. Economic activity consumes natural resources as its input, and produces undesirable emissions and waste as its output. The empirical approach with the starting point in classical economic theory, which takes into account the substitution possibilities by estimating the so-called efficient production frontiers, takes to natural understanding that a production enterprise is called efficient if the consumption of any input cannot be decreased without the corresponding decrease of at least one output or increase of undesirable outputs. The objective of this project is to investigate the applicability of the DEA-method to the measurement of eco-efficiency, and develop the method further on towards a more comprehensive framework supporting the management and incentive mechanisms. The paper by (Kuosmanen & Kortelainen, 2004) is a very good introduction for how to use DEA in environmental evaluation and for comparative assessment of firm performance in this context.

In (Kortelainen & Kuosmanen, 2005) a method for eco-efficiency analysis of consumer durables by utilizing the DEA was developed. The novel innovation of the paper is to measure the efficiency in terms of absolute shadow prices that are optimized endogenously within the model to maximize the efficiency of the product and producer. The approach is illustrated by an application to eco-efficiency evaluation of a sort of consumer durables, Sport Utility Vehicles. To assess eco-efficiency of a product, one needs to account for both private net economic benefits and external social costs that arise during the use phase of the product's life-cycle. The authors mention that DEA seeks endogenously determined optimal, the so-called shadow prices that present every consumer durable in the most favorable light when compared to other products, and that the method does not require any prior arbitrary assumption as on how to set the prices of environmental pressures.

The key idea of the approach is to test whether there are any nonnegative efficiency prices at which a consumer durable is efficient. The definition of socially efficient is that a product needs to fulfill the conditions of inactivity and optimality. Firstly, it means that the value added for the consumer durable has to be nonnegative at optimal prices and the rationale behind the condition is that the consumers can be inactive, and not purchase any of the goods if the costs outweigh the benefits. The optimality condition demands that the consumer durable must be the optimal choice at some efficiency prices. The goods are eco-efficient if the shadow price of at least one environmental pressure must be positive. Using the efficiency measures and the shadow prices, all goods are classified into the following categories: efficient goods; eco-efficient goods; weakly efficient, economical goods; inefficient goods; inefficient, but environmentally friendly goods; inefficient, environmentally harmful goods.

The authors calculated efficiency scores for 88 different models of Sport Utility Vehicles by using the absolute shadow price approach. For the comparison, the efficiency scores with the environmental efficiency DEA approach were estimated where environmental pressures were modeled as negative outputs. The fuel costs and all environmental pressures were measured per 1 kilometer, which was simultaneously the value of (desirable) output, so the DEA model was invariant to the returns to scale (RTS) specification; all alternative RTS specifications yielded exactly the same results.

Irrigation Districts Management

Application of the DEA is proposed as a methodology to assign the correct weightings for the calculation of indexes and to overcome the subjectivity of the interpretations of the results in management of Andalusian irrigation districts (Spain). The case was presented and discussed by (Rodríguez Díaz et al., 2004). This study was used to select the most representative irrigation districts in Andalusia which were then studied in greater depth. Andalusia is a region of southern Spain, a typical Mediterranean region where irrigation and wealth have been closely linked over time and where 815,000 hectares of irrigated area is divided into 156 irrigation districts. In addition to allowing the production of winter crops, irrigation makes it possible to produce a larger number of crops during the extremely dry summers that are characteristic of this Mediterranean climate, something that would otherwise not be possible under dry-land agriculture. The input-oriented DEA model was used and applied for all the irrigation districts, and separately for interior districts. The authors show that two types of clearly differentiated agricultural districts coexist in Andalusia: interior and littoral districts.

In this research input parameters for DEA application were: irrigated surface area in hectares, labor in annual working units and the total volume of water applied to an irrigation district. The total value of agricultural production in Euros was considered as the output parameter. Following the DEA, none of the districts in the interior achieved high efficiencies in numerical experiments where all districts were considered. This leads to the conclusion that the littoral districts would serve as the reference region for districts in the interior. For this reason, the DEA model was applied separately to the interior districts only, and then it was possible to point out important conclusions. Particularly, the DEA study allowed the five most representative irrigation districts of Andalusia to be selected for a more detailed benchmarking study and the DEA turned out to be a useful tool for detecting local inefficiencies and determining the possible improvements for irrigation.

Biogas Plants

Today it is widely recognized that the largest source of atmospheric pollution is fossil fuel combustion, which current energy production and use patterns rely heavily on, and therefore, the most crucial environmental problems derive from the energy demand to sustain human needs and economic growth. In the paper (Madlener et al., 2006) we find an interesting study of assessing the efficiency of 41 agricultural biogas plants in Austria. The two input parameters were: the amount of organic dry substrate used and the labor time spent for plant operation. Among the three outputs two were desirable: the net electricity produced and external heat which correspondingly refer to the amount of electricity and heat delivered by the biogas plant for external consumption (i.e. net of what the biogas plant consumes itself), including farm operations not directly related to the biogas plant. The third output parameter, methane emissions to the atmosphere, was an undesirable output that contributes to the greenhouse gas problem. In the paper one can find a detailed discussion of DEA efficiency interpretation for biogas plants under consideration.

National Park Management

Wilderness protection is another growing necessity for modern societies, particularly for areas where population density is extremely high and where during the twentieth century the erosion of territory, hence of ecosystems, due to human activities, was dramatically increasing, as for example in Europe. Conservation, however, implies very high opportunity costs and thus it is crucial to create incentives for efficient management practices, to promote benchmarking and to improve conservation management. A methodology based on DEA for assessing the relative efficiency of the management units of the protected area and to indicate how it could be improved, is proposed in (Bosetti & Locatelli, 2005). In it 17 Italian National Parks (National Park Management offices) are considered as DMUs.

Three different models have been used to perform DEA. They differ by the choice of input and output indicators. The set of input parameters contains economic costs, computed aggregating management costs and variable costs and extraordinary expenses. The area extension was considered as a proxy of fixed costs, which were assumed to be proportional to the area covered by the park. The output parameters are: the number of visitors to the park as an indicator of its attractiveness, providing potential indirect benefit to the local economy; the number of the parks' employees, as an indicator of the social and economic indirect and direct benefits; the number of economic businesses which are directly linked, empowered or created thanks to the presence of the park, e.g. the farmers producing within the protected area; the number of protected species, as a good proxy of the environmental quality and biodiversity of the park; and the number of students who visit the park for environmental education trips, as a proxy of social and educational benefits deriving from the park. In some models the inverse of the mentioned biodiversity indicator was included as an input.

There are several different definitions of ecological efficiency known. In the case of protected areas, the problem of efficiency becomes even more complicated, because management and financial features have to be considered as well. In this research this definition appears in the DEA application results: when a DMU is scoring maximum efficiency according to all three models, one can say that the management has attained the sustainable development goal in a very broad sense. In cases where DMUs are partially inefficient the authors use the DEA to obtain information concerning potential improvements in the management. In the final conclusions it is pointed out that the DEA is a good benchmarking technique to monitor multi-objectives efficiency. The DEA also provides the possibility for a detailed analysis of potential improvements in the management of National Parks.

Measuring Residential Energy Efficiency

In the paper (Grösche, 2009) the energy efficiency improvements of US single-family homes between 1997 and 2001, using a two-stage procedure, is estimated. In the first stage, an indicator of energy efficiency is derived by means of Data Envelopment Analysis, and the analogy between the DEA estimator and traditional measures of energy efficiency is demonstrated. The second stage employs a bootstrapped truncated regression technique to decompose the variation in the obtained efficiency estimates into a climatic component and factors attributed to efficiency improvements. The author claims that the improvement of residential energy efficiency is one major goal of energy policy makers.

Put simply, DEA can be considered as a generalization of the energy efficiency defined as the ratio between the amount of a particular produced service **s** and the amount of energy **e** consumed for the production (**s**/**e**). The households' total energy consumption serves as the only input for DEA, measured in kWh. Considering the outputs (the 'produced' energy services), the author approximates the demand for space heating and cooling, and lightning with the size of living space. The number of household members serves as a proxy for the amount of hot water preparation and cooked meals. To account for energy consumption due to the use of electric appliances, the joint number of TV-sets, videos, DVDs, and computers is incorporated. The overall number of refrigerators and freezers in the household is likewise included in the estimation.

The results of the study are mixed: a substantial part of the variation in efficiency scores is due to climatic influences, but households have nevertheless improved their energy efficiency. In particular, households heating mainly with fuel oil or natural gas show significant improvements. A key advantage of the applied procedure is its ease in measuring residential energy efficiency improvements.

Pig Fattening Farms

In the paper (Lauwers & van Huylenbroeck, 2003) a method for analyzing environmental efficiency of Belgian pig fattening farms, based on the farm materials balance and worked out, the DEA technique is proposed. In its most fundamental sense, materials balance means the mass flow equation of raw materials used in the economic system, and of the residuals disposed of in the natural environment. The environmental efficiency of the farm is defined similarly to the economic allocative efficiency of farms as DMUs in the DEA approach. Nutrient surplus in pig fattening, as a typical balance indicator, is used to illustrate the concept in a two input – one output case. The input parameters are feed (nutrients) and the piglets or rotation. Because of juridical constraints on farm dimension, the farmers profit maximization objective turns into a maximization of gross margin per pig place, thus the pig fattening process is simplified to one output, the marketable meat production. Several versions of DEA are applied and discussed: input-oriented and output-oriented. The main conclusion is that, ignoring the balance feature of environmental issues, such as nutrient surplus, might be the main reason why traditional integral analyses of economic and environmental efficiency yield contradictory conclusions.

Environmentally Friendly Manufacturing

The essence of environmentally friendly manufacturing is to define sustainable development in terms of manufacturing; conserving nature's services (resource supplier, water, energy) with the development being centered on economics and trade with a timeline of 20-100 years. Today the corporate environment is an evolving strategy, and it is not surprising that manufacturing operations are required to consider environmental impacts and sustainable development more and more. In Wu et al. (2006) the application of DEA is discussed to measure the efficiency, through material loss and environmental impact of a closed-loop manufacturing process, of a process in the computer industry. The multi-stage DEA is being utilized to measure each manufacturing phase, to compare the starting materials and environmental status to the materials available once the product has been recycled, and the environmental damage (or substances added to the environment) once a product lifecycle has been completed. The multi-stage DEA becomes important for multiple processes, for instance, the closed-loop manufacturing process, and in this case, the outputs from one process can be the inputs for the next. Inputs and outputs varied, the whole set of parameters consisted of expenditure on research and development, years of experience, expenditures on raw materials, number of product parts, use of harmful materials, energy consumption, product recyclability in percents of product/components reusable, emission of pollutants, modification flexibility, amount of products returned, product recyclability and material recovered. The values for the various inputs/outputs were obtained from the literature. This work is a good example of measuring a company's environmental conduct in manufacturing by applying the DEA. The conclusion is that if one organization has multiple locations or is responsible for multiple products, the multi-stage DEA is a promising approach. In addition, on the base of the model it is possible to analyze a company's environmental impact and motivate the company to improve their corresponding indicator numbers.

Grain Farms

The aim of the study (Vasiliev et al., 2008) was to analyze the efficiency of Estonian grain farms after Estonia's transition to market economy and during the accession period to the European Union in 2000–2004. Here DEA is used with the following input parameters: changing expenditures, total investment capital, the surface of land used and the yearly working units. The output was fixed as total production volume in monetary value. The results obtained were: the mean total technical efficiency varied from 0.70 to 0.78, and 62% of the grain farms are operating under the increasing returns to scale. The most pure technically efficient farms were the smallest and the largest, but the productivity of small farms was low when compared to larger farms because of their small scale. Although, solely based on the DEA model, it is not possible to determine the optimum farm scale and the range of Estonian farm sizes operating efficiently.

Final Remarks

Environmental Technologies mean cleaner and resource efficient technologies which can decrease material inputs, reduce energy consumption and emissions, discover valuable by-products and minimize waste disposal problems or some combination of these. Data Envelopment Analysis is widely used in many areas for estimating the peer-based efficiency of Decision Making Units which are defined in each single case. Although not the only method of quantitative analysis and efficiency modeling, the DEA is highly recommended as an approach with interpretable output, and which has improved its effectiveness as a productivity analysis tool. The primary advantages of this technique are that it considers multiple input and output factors of DMUs and does not require parametric assumptions of traditional multivariate methods. In general, inputs can include any resources utilized by a DMU, and the outputs can range from actual products produced to a range of performance and activity measures. The DEA has several versions and modifications, and each of these models and methods can be useful in a variety of manufacturing and service areas.

KEY TERMS AND DEFINITIONS

Constant Returns to Scale: The outputs of a DMU change in the same proportion as inputs; the producers are able to linearly scale the inputs and outputs without increasing or decreasing efficiency.

Decision Making Unit: Decision making units form a homogenous set of peer entities which convert multiple inputs into multiple outputs and efficiency of which is under consideration in DEA.

Efficiency (Computed in Data Envelopment Analysis): Weighted sum of outputs divided by the weighted sum of inputs.

Environmental Technologies: Cleaner and resource efficient technologies which can decrease material inputs, reduce energy consumption and emissions, discover valuable by-products, and minimize waste disposal problems or some combination of these.

Relative Efficiency: A decision making unit is to be rated as fully efficient on the basis of available evidence if and only if the performances of other decision making units do not show that some of its inputs or outputs can be improved without worsening some of its other inputs or outputs.

Variable Returns to Scale: The outputs of a decision making unit change in other proportion as inputs, increasingly or decreasingly.

Chapter 37
Constrained Optimization of JIT Manufacturing Systems with Hybrid Genetic Algorithm

Alexandros Xanthopoulos

Dimitrios E. Koulouriotis
Democritus University of Thrace, Greece

ABSTRACT

This research explores the use of a hybrid genetic algorithm in a constrained optimization problem with stochastic objective function. The underlying problem is the optimization of a class of JIT manufacturing systems. The approach investigated here is to interface a simulation model of the system with a hybrid optimization technique which combines a genetic algorithm with a local search procedure. As a constraint handling technique we use penalty functions, namely a "death penalty" function and an exponential penalty function. The performance of the proposed optimization scheme is illustrated via a simulation scenario involving a stochastic demand process satisfied by a five–stage production/inventory system with unreliable workstations and stochastic service times. The chapter concludes with a discussion on the sensitivity of the objective function in respect of the arrival rate, the service rates and the decision variable vector.

INTRODUCTION

This chapter addresses the problem of production coordination in serial manufacturing lines which consist of a number of unreliable machines linked with intermediate buffers. Production coordination in systems of this type is essentially the control of the material flow that takes place within the system in order to resolve the trade-off between minimizing the holding costs and maintaining a high service rate. A time-honored approach to modeling serial manufacturing lines is to treat them as Markov Processes (Gershwin, 1994, Veatch and Wein, 1992) and then solve the related Markov Decision Problem (MDP), by using standard iterative algorithms such as

DOI: 10.4018/978-1-4666-1945-6.ch037

policy iteration, (Howard, 1960), value iteration, (Bellman, 1957) etc. However the classic dynamic programming (DP), approach entails two major drawbacks: Bellman's curse of dimensionality, i.e. the computational explosion that takes place with the increase of the system state space, and the need for a complete mathematical model of the underlying problem. The limitations of the DP approach gave rise to the development of sub-optimal yet efficient production control mechanisms.

A class of production control mechanisms that implement the JIT (Just In Time) manufacturing philosophy known as *pull type* control policies/mechanisms has come to be widely recognized as capable of achieving quite satisfactory results in serial manufacturing line management. Pull type control policies coordinate the production activities in a serial line based only on actual occurrences of demand rather than demand forecasts and production plans as is the case in MRP-based systems. In this chapter, six important pull control policies are examined, namely Kanban and Base Stock (Buzacott and Shanthikumar, 1993), Generalised Kanban (see Buzacott and Shanthikumar (1992), for example), Extended Kanban (Dallery and Liberopoulos, 2000), CONWIP (Spearman *et al*., 1990) and CONWIP/Kanban Hybrid (Paternina-Arboleda and Das, 2001). Pull production control policies are heuristics characterised by a small number of control parameters that assume integer values. Parameter selection significantly affects the performance of a system operating under a certain pull control policy and is therefore a fundamental issue in the design of a pull-type manufacturing system. In this chapter the performance of JIT manufacturing systems is evaluated by means of discrete-event simulation (Law and Kelton, 1991). In order to optimize the control parameters of the system the simulation model is interfaced with a hybrid optimization technique which combines a genetic algorithm with a local search procedure.

The application of simulation together with optimization meta-heuristics for the modeling and design of manufacturing systems is an approach that has attracted considerable attention over the past years. In Dengiz and Alabas (2000) simulation is used in conjunction with tabu search in order to determine the optimum parameters of a manufacturing system while Bowden *et al*. (1996) utilize evolutionary programming techniques for the same task. Alabas *et al.* (2002) develop the simulation model of a Kanban system and explore the use of genetic algorithm, simulated annealing and tabu search to determine the number of kanbans. Simulated annealing for optimizing the simulation model of a manufacturing system controlled with kanbans is applied in Shahabudeen *et al.* (2002), whereas Hurrion (1997) constructs a neural network meta-model of a Kanban system using data provided by simulation. Koulouriotis *et al.* (2008) apply Reinforcement Learning methods to derive near-optimal production control policies in a serial manufacturing system and compare the proposed approach to existing pull type policies. Some indicative applications of genetic algorithms (GAs) in manufacturing problems can be found in Yang *et al.* (2007), Yamamoto *et al* (2008), Smith and Smith (2002), Shahabudeen and Krishnaiah (1999) and Koulouriotis *et al.* (2010). Panayiotou and Cassandrass (1999) develop a simulation-based algorithm for optimizing the number of kanbans and carry out a sensitivity investigation by using finite perturbation analysis. It has been suggested in the literature that the results of a genetic algorithm can be enhanced by conducting a local search around the best solutions found by the GA, (for related work see Yuan, He and Leng, 2008 and Vivo-Truyols, Torres-Lapasio and Garcıa-Alvarez-Coque, 2001). On that basis, this hybrid optimization scheme has been adopted in the present study.

The main contributions of this work are the following. The performance of six important pull production control policies in a hypothetical scenario is investigated using discrete event simulation. In order to determine the control parameters of each policy the proposed hybrid

GA is employed. The objective function to be optimized is a weighted sum of the mean Work In Process, (WIP), inventories subject to the constraint of maintaining the service level, (*SL*), above a specified target. Due to the fact that the objective function is stochastic we use resampling, i.e., performing multiple evaluations of the same parameter vector and using the mean of these evaluations as the fitness measurement of this individual, a practice discussed by Fitzpatrick and Grefenstette, (1988) and Hammel and Bäck, (1994). As a constraint handling technique two types of penalty functions are explored; a "death penalty" function and an exponential penalty function. The exponential penalty function is designed according to an empirical method which is based on locating points which lie on the boundaries between feasible and infeasible region from the output of the genetic algorithm with the "death penalty" function. Our numerical results support the intuitive perception that the "death penalty" approach most of the times will yield worse results than the exponential penalty function which penalizes solutions according to the level of the constraint violation. The chapter concludes with a discussion on how the objective function behaves for different levels of arrival rate and service rates as well as on its sensitivity to the decision variable vector.

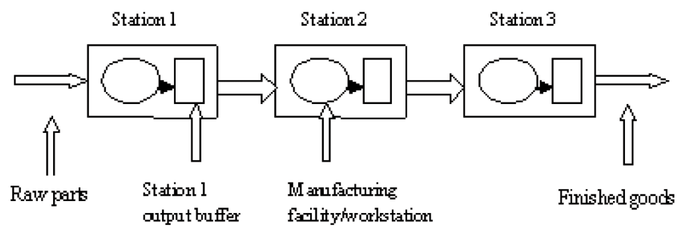
The remaining material of this chapter is structured as follows. Sections "Base Stock Control Policy" to "CONWIP/Kanban Hybrid Control Policy" give a brief description of six important pull production control policies for serial manufacturing lines. In sections "Optimization Problem: Objective Function" and "Hybrid Genetic Algorithm" we discuss the main aspects of the simulation optimization methodology that we followed and namely, the formal definition of the parameter optimization problem and issues concerning the genetic algorithm and local search procedure that was used. We report our findings from the simulation experiments that we conducted for one serial line starting from section "Experimental Results: Simulation Case" and thereafter. Finally, in the last section we state our concluding remarks and point to possible directions for future research.

SYSTEM DESCRIPTION: JIT PRODUCTION CONTROL POLICIES

We examined manufacturing serial lines that produce a single product type and consist of a number of workstations/machines with intermediate buffers. We assume that the first machine is never starved. Customer demands arrive at random time intervals and request the release of one finished part from the finished goods buffer. Demands are satisfied immediately from the finished parts inventory while in the case where there are no parts available in the last buffer the demand is backordered. We do not consider customer impatience in our model, so no demand is ultimately lost to the system. Manufacturing facilities have the ability to work on only one part at a time during a manufacturing cycle. All machines have random production time, time between failures and repair time. As soon as a stage *i* part is manufactured, it is placed in the output buffer of that station. A control policy coordinates the release of parts from the output buffer of that station to the next machine. The unreliability of the manufacturing operations along with the stochastic demand for final products dictates the use of safety buffers of intermediate and finished parts in order to attain the target service rate. However the use of safety stocks incurs significant holding costs that could bring the manufacturer to a position of competitive disadvantage, and therefore, it is essential to balance the trade-off between minimizing WIP inventories and maintaining a high service level. Figure 1 shows a manufacturing system with three stations in tandem.

The following sections briefly explain the way that the Kanban, Base Stock, CONWIP, CONWIP/Kanban Hybrid, Extended Kanban and Generalized Kanban control policies for serial lines operate.

Figure 1. A three station manufacturing line



BASE STOCK CONTROL POLICY

A Base Stock, (see Buzacott and Shanthikumar, 1993), manufacturing line is completely described by *N* parameters, the base stock levels S_i of each production station, $i = 1, 2, \ldots, N$ where *N* is the number of the system's workstations. The S_i parameters correspond to the number of parts that exist in the system's buffers at the time the system is in its initial state that is before any demands have arrived to the system. This control policy operates as follows. When a demand arrives to the system it is immediately transmitted to every manufacturing station, authorizing it to start working on a new station *i* part. Base Stock has the advantage of reacting rapidly to incoming demand, with the drawback of providing no control at all on the system's inventories.

KANBAN CONTROL POLICY

The Kanban control policy that was originally developed by the Toyota Motor industry and became the topic of considerable research thereafter, (Sugimori et al, 1977, Buzacott and Shanthikumar, 1993, Berkley, 1992, Karaesmen and Dallery, 2000). A Kanban manufacturing line's control parameters are the production authorizations K_i of each station, $i = 1, 2, \ldots, N$. The K_i parameter corresponds to the maximum number of parts that are allowed in station *i* (manufacturing facility – output buffer). Workstation *i* is authorized to start working on a new part as soon as a finished station *i* part is released from its output buffer. The information of a demand arrival is transmitted from the last manufacturing station to the first one station – by – station. If there is a buffer with no parts in it then this transmission is interrupted. The Kanban policy offers very tight synchronization between the various production stations of the system at the expense of the relatively slow response to demand fluctuations.

CONWIP CONTROL POLICY

CONWIP is an abbreviation for CONstand Work In Process (Spearman et al, 1990). According to this policy the total number of parts that exist in the system, (Work In Process), can never exceed a certain level, which is the *C* control parameter of the policy. Parameter *C* is equal to the sum of the system's base stocks S_i, $i = 1, 2, \ldots, N$. All machines in a CONWIP line are authorized to produce whenever they have this ability, (they are operational and have a raw part to work on), except the first one. The first machine of the system is authorized to start working on a new part as soon as a unit from the finished parts buffer is released to a customer.

GENERALIZED KANBAN AND EXTENDED KANBAN CONTROL POLICIES

These two control policies combine the merits of Base Stock and Kanban as they react rapidly to the arrival of demands and effectively control the WIP at the same time. They are described by two parameters per station, the base stocks S_i and the production authorizations K_i,($K_i \geq S_i$), which are borrowed from the Base Stock and Kanban policies respectively. The finite number of production authorizations guarantees that the system's inventories will not exceed the pre – defined levels, but the station coordination here is not as tight as in Kanban. A station can be granted a production authorization even if a part is not released from its output buffer. For a detailed description of the way Generalized Kanban and Extended Kanban operate the reader is referred to Liberopoulos and Dallery (2000) and Buzacott and Shanthikumar (1992).

CONWIP/KANBAN HYBRID CONTROL POLICY

A CONWIP/Kanban Hybrid system (see Paternina – Arboleda and Das (2001) for example), as implied, operates under a combination of the CONWIP and Kanban control policies. Departure of a finished part from the system authorizes the first station to allow a new raw part to enter the system. All workstations except the last one have a finite number of production authorizations K_i, $i = 1, 2, \ldots, N-1$. Station production authorizations K_i, the base stock S_N of the last workstation and the total WIP, (parameter C), that is allowed in the system are CONWIP/Kanban Hybrid's control parameters.

OPTIMIZATION PROBLEM: OBJECTIVE FUNCTION

The mathematical formulation of the parameter optimization problem for serial lines controlled by pull production control policies is given below. Let $\mathbf{x} = [x_1\ x_2 \ldots x_n]$, $x_i \in \mathbf{Z}$, be the control parameter vector of some pull production control policy, i.e. the station i production authorizations (kanbans) in a Kanban system, or the initial buffer levels in a Base Stock system etc. The objective is to find the control parameter values $\mathbf{x}$ that maximize the expected value of the stochastic objective function $f(\mathbf{x}, \omega)$, subject to the constraint of maintaining the service level (*SL*) equal to or above a specified target t.

maximize:

$$E\left[f\left(\mathbf{x}, \omega\right)\right],\ x_i \in \mathbf{Z},\ i = 1, 2, \ldots., n \tag{1}$$

subject to:

$$E\left[SL\left(\mathbf{x}, \omega\right)\right] \geq t \tag{2}$$

ω is used to denote the stochastic nature of f, and *SL*. *SL* is an unknown function of $\mathbf{x}$ and $t \in \Re^{+}$. The evaluation of functions f and *SL* is the result of a simulation experiment. The value of *SL* is the number of demands satisfied by on-hand inventory divided by the number of total demands which arrived to the system. The value of f is a weighted sum of the mean WorkInProcess inventories and is calculated according to 3.

$$f = -\sum_{i=1}^{N} h_i \bar{H}_i \tag{3}$$

where h_i stands for the cost of storing one item in output buffer i per time unit, and $\overline{H}_i$ is the average inventory level in buffer i We know that the optimal solution in this type of problems is located very close to the boundaries between feasible and infeasible region. Additional difficulty in obtaining the optimal solution emanates from the fact that fitness measurements contain random "noise" caused by the simulation model.

HYBRID GENETIC ALGORITHM

In order to solve the optimization problem stated in the previous section we propose a hybrid optimization technique which combines a genetic algorithm with a local search procedure. The genetic algorithm evolves a population of candidate solutions (individuals), where each solution is evaluated with the use of a simulation model, and the individual with the highest fitness value found by the GA is used to initialize the local search procedure. The fitness $v\left(\mathbf{x}\right)$ of each individual is represented by Equation (4).

$$v\left(\mathbf{x}\right) = \frac{1}{m}\sum_{i=1}^{m}\left[f(\mathbf{x},\omega) + p\left(SL(\mathbf{x},\omega)\right)\right] \quad (4)$$

where $f(\mathbf{x},\omega)$ is calculated according to (3), $p\left(\mathbf{x}\right)$ is a properly defined penalty function of the service level, and *m* is a positive integer (sample size). The parameters of the GA are the chromosome length *l*, the population size *s*, the sample size m, a positive integer *e* called elite count, the crossover probability P_{cross}, the mutation probability P_{mut} and the max number of generations *g*. The individuals which constitute the genetic algorithm population are encoded as binary bit-strings, therefore parameter *l* controls the size of the search space. Parameter *e* determines the number of individuals that pass deterministically to the next generation. The local search procedure is characterized by a single parameter $\delta \in \Re^{+}$. Let $\mathbf{x}_{cur}$ be the current solution of the local search algorithm, v_{cur} its fitness value and v_{best} the best fitness value found so far. If we denote the search space by S and a distance function, (e.g. Euclidean distance), by *dist()*, then the neighborhood of $\mathbf{x}_{cur}$ is written as $N\left(\mathbf{x}_{cur}\right) = \left\{\mathbf{y} \in S : dist(\mathbf{x},\mathbf{y}) \le \delta\right\}$. The pseudocode of the hybrid genetic algorithm is presented below.

1. Input GA parameters: chromosome length *l*, population size *s*, sample size m, elite count *e*, crossover probability P_{cross}, mutation probability P_{mut}, max number of generations *g*
2. Initialize population randomly, set *generation_counter*←0
3. WHILE(*generation_counter* $< g$)
   a. evaluate population. set

$$generation\_counter \leftarrow generation\_counter + 1$$

   b. scale fitness values proportionally to raw fitness measurements
   c. apply selection operator
      - select *e* individuals with highest fitness values
      - select the remaining $s - e$ individuals using stochastic uniform selection
   d. apply crossover operator
   e. apply mutation operator
4. return individual $\mathbf{x}_{best}$ with highest fitness
5. Initialize local search algorithm: $\mathbf{x}_{cur} \leftarrow \mathbf{x}_{best}$, define neighborhood parameter δ
6. evaluate $\mathbf{x}_{cur}$. Set $v_{best} \leftarrow v_{cur}$, $flag \leftarrow TRUE$
7. WHILE $(flag = TRUE)$
   a. evaluate all points in $N(\mathbf{x}_{cur})$
   b. select $\mathbf{x}_{new} \in N(\mathbf{x}_{cur})$ with best fitness value v_{new}
   c. IF $(v_{new} > v_{best})$ THEN set $v_{best} \leftarrow v_{new}$, $\mathbf{x}_{cur} \leftarrow \mathbf{x}_{new}$ ELSE THEN $flag \leftarrow FALSE$
8. return $\mathbf{x}_{cur}$. Terminate

The selection operator (Step 3.c) determines which individuals will be chosen to create the next generation. The first e individuals in terms of fitness value pass to the next generation by default. The remaining s - e individuals are selected with the use of a stochastic uniform selection routine. This technique can be visualized as a line in which each individual corresponds to a section of the line of length proportional to its scaled fitness value. The algorithm moves along the line in equal-sized steps. At each step, the algorithm selects an individual from the corresponding section it finds itself on. In the crossover stage (Step 3.d), pairs of individuals are selected at random with probability $P_{cross} \in (0,1)$ in order to be recombined. In the implementations of the GA for the one-parameter-per-workstation manufacturing systems we used the single-point crossover method. For the remaining systems, (Extended and Generalized Kanban) uniform crossover was used. According to this technique, two individuals exchange bits on the basis of a randomly generated binary vector of equal length called crossover mask. The mutation operator (Step 3.e) modifies the value of a bit in the population with probability $P_{mut} \in (0,1)$. The genetic algorithm terminates when it completes a predefined number of iterations g and returns the individual with the highest fitness value which is used to initialize the local search algorithm. The complexity of the hill-climbing procedure is $O\left(t \times k\right)$, where *t* is the number of iterations and *k* the neighborhood size. The complexity of the genetic algorithm depends on the number of generations, the size of the population and the genetic operators/parameters used.

EXPERIMENTAL RESULTS: SIMULATION CASE

We examined a five-machine manufacturing line with equal operation times. The base simulation scenario consists of the following parameters: Machines operate with service rates which are normally distributed random variables with mean 1.1 parts/time unit and st.d. 0.01. Repair to failure times are exponentially distributed with mean 1000 time units. Failures are operation dependent. Repair times are also assumed exponential with a MeanTimeToRepair of 10 time units. Times between two successive customer arrivals are exponential random variables with mean 1.11 time units, i.e. the arrival rate is $R_a = 0.9$. Since the service rates are all equal to 1.1 parts/ time unit and the machines are failure-prone, the maximum attainable throughput rate under any control policy will be $T_{\max} < 1.1$. Consequently, the arrival rate set to 0.9 parts/time unit corresponds to a heavy loading conditions simulation case. The inventory costs for storing one part per time unit in buffer *i* are $\mathbf{h} = [h_1 \ h_2 \ldots h_5]$ = [1.0 1.2 1.44 1.73 2.07]. Note that the holding costs increase at a rate of 20% when moving downstream from buffer to buffer. This increase is due to the value which is added to a part as it is progressively converted into a final product. The system operates under a complete backordering policy, which means that no customer demand is ultimately lost to the system. The justification for selecting the aforementioned probability distributions in order to model the arrival process, the service rates etc. can be found in queueing theory and in manufacturing systems literature. Some indicative references, among others, are the influential works of Law and Kelton (2000) and Bhat (2008). The input parameters of the simulation model were selected in a manner to mimic a situation where the system is under heavy loading conditions. This is a case of primary interest since the differences in performance between the various pull type control policies are most clearly illustrated when the manufacturing line is pushed towards its maximum throughput rate. In order to investigate the sensitivity of the production/inventory system under examination for different levels of arrival rates and service rates as well as the robustness of the solutions obtained by the proposed optimization methodology, four variants of the base simulation scenario are also considered. In the first two variants, all inputs to the simulation model are kept constant except for the arrival rates which are set to $R_a = 1.0$ and $R_a = 0.8$

Table 1. Simulation scenarios parameters

	Ra	*Rp*	*st.d.*	*MTBF*	*MTTR*	*inventory costs*
base case	0.9	1.1	0.01	1000	10	**h**
variant 1	1.0	1.1	0.01	1000	10	**h**
variant 2	0.8	1.1	0.01	1000	10	**h**
variant 3	0.9	1.1	0.1	1000	10	**h**
variant 4	0.9	1.1	0.001	1000	10	**h**

respectively, i.e. we examine the system's behaviour for increased/decreased demand for final products. In the remaining two variants of the base simulation case we vary the standard deviation of the service rates. In one case the system's performance is evaluated for service rates that vary significantly around the mean (st.d. = 0.1) and in the other case we examine what would happen if the "randomness" of the service rates decreased (st.d. = 0.001). The system configuration for the five simulation cases is presented in Table 1.

The goal is to maximize the expected value of the weighted sum of the mean WorkInProcess inventories $f = -\sum_{i=1}^{N} h_i \bar{H}_i,\ i = 1,2,..,5$, subject to the constraint of $E\left[SL(\mathbf{x})\right] \geq 90.0\%$.

HYBRID GENETIC ALGORITHM PARAMETERS

The dimensions of the related optimization problem for the Kanban, Base Stock, CONWIP and Kanban/CONWIP Hybrid systems are *dim* = 5. For the Extended and Generalized Kanban systems the dimensionality of the problem rises to *dim'* = 10. The authors conducted a series of pilot experiments in order to come up with the most suitable hybrid genetic algorithm parameters for this particular problem. An important issue was to resolve the trade-off between quality of final solution and computational cost as the evaluation of the fitness value of the candidate solutions is computationally expensive. We experimented with population sizes in the range [20,50], crossover probabilities in the range [0.3, 0.8] and mutation probabilities in the range [0.001, 0.1]. For the one-parameter-per stage policies the single-point crossover operator was implemented whereas for the two-parameter-per-stage policies we applied uniform crossover. The reason for making this distinction is that offspring produced with the latter crossover technique are generally more diverse compared to their parents than offspring generated by single-point crossover. This is a desirable property due to the fact that the search space for the two-parameter-per-stage policies is by orders of magnitude larger that the search space for the one-parameter-per-stage policies and therefore an intense exploration strategy is required. The neighborhood of the local search algorithm was set to include all data points around the current point **x** with Euclidean distance equal to or less than 1: $N\left(\mathbf{x}\right) = \left\{\mathbf{y} \in S : \sqrt{\sum_{i=1}^{n}\left(x_i - y_i\right)^2} \leq 1\right\}$. Given that the decision variables are integers this is obviously the minimum neighborhood size one could select but since the major part of the search is carried out by the genetic algorithm and the local search procedure is used merely to fine-tune the already obtained solutions, it is acceptable to use a small neighborhood. Admittedly, the parameters of the optimization algorithm were initialized heuristically and one cannot discard the possibility that different values for the parameters could yield better results but a full factorial experiment for the design of the optimization scheme would fall beyond the scope of this chapter. The genetic algorithm's parameters that were ultimately selected are: population size = 30, crossover and mutation probabilities, $P_{cross} = 0.5$ and $P_{mut} = 0.05$ respectively. The individual which scored the highest fitness value passes to the next generation with probability 1, i.e. the elite count parameter was set to 1. Each individual was evaluated 50 times, *m* = 50, where each replicate was executed for 80,000 time units. The GA produced 100 generations for the problems with dimensionality *dim* = 5, (optimizing Kanban, Base Stock, CONWIP, CONWIP/Kanban Hybrid systems). For the problems with dimensionality *dim'* = 10, (optimization of Extended Kanban and Generalized Kanban systems) the GA produced 240 generations of individuals.

COMPUTATIONAL COST

The simulators for the six pull type manufacturing systems as well as the proposed optimization algorithm were coded in C++ and the experiments were conducted on a PC with AMD Athlon processor at 1.8 GHz and 512 MB RAM. The factor that primarily affects the execution time of the hybrid GA is the control parameter evaluation, i.e. the computational cost of the simulation model. Every solution evaluation, that is 50 independently seeded executions of the simulation model, lasts approximately 5 seconds and therefore the evaluation of a generation of candidate solutions (30 individuals) takes about 2.5 minutes to complete. The execution of the hybrid GA for a one-parameter-per-stage policy (100 generations) lasts approximately 4.7 hours, of which 4.2 hours are consumed by the simulation model. On the other hand, the execution of the hybrid GA for a two-parameter-per-stage policy (240 generations) lasts approximately 11 hours, where 10 hours are devoted to the solution evaluation phase.

DEATH PENALTY RESULTS

For the implementation of the hybrid genetic algorithm with "death" penalty we used the following penalty function.

$$p\left(\mathbf{x}\right) = \begin{cases} 0.0, & if \quad E\left[SL(\mathbf{x})\right] \geq 90.0\% \\ -1000.0, & if \quad E\left[SL(\mathbf{x})\right] < 90.0\% \end{cases} \tag{5}$$

We reiterate that the expected value $E\left[SL(\mathbf{x})\right]$ is the arithmetic mean of *m* measurements of *SL*. This is a very straight-forward implementation. Every individual that does not satisfy the service level constraint is penalized heavily and will be probably discarded in the next iteration of the algorithm. The results from the hybrid genetic algorithm runs for each control policy are displayed in Table 2. The rows containing the results of the standard genetic algorithm, (without the local search component), are labeled with the initials GA followed by the control policy's name, while the results of the hybrid algorithm are labeled with the initials GAL and the control policy's name. We made this distinction in order to clarify whether the local search offers some significant improvement or not. The last column of Table 2 contains the fitness values calculated according to Equation (4) of the corresponding parameter sets.

The CONWIP system scored the highest fitness value $v_b = -25.29$ followed by the Generalized Kanban, the Extended Kanban, the Hybrid CONWIP/Kanban, the Kanban and the Base Stock systems in decreasing fitness value order. With the exception of the CONWIP system, the local search algorithm enhanced the best fitness values found by the standard genetic algorithm in a range from 1.35% to 9.34%. It is important to stress here that this improvement refers to the fitness values and not the actual objective function values of the optimization problem. In the case of the Generalized Kanban system the local search al-

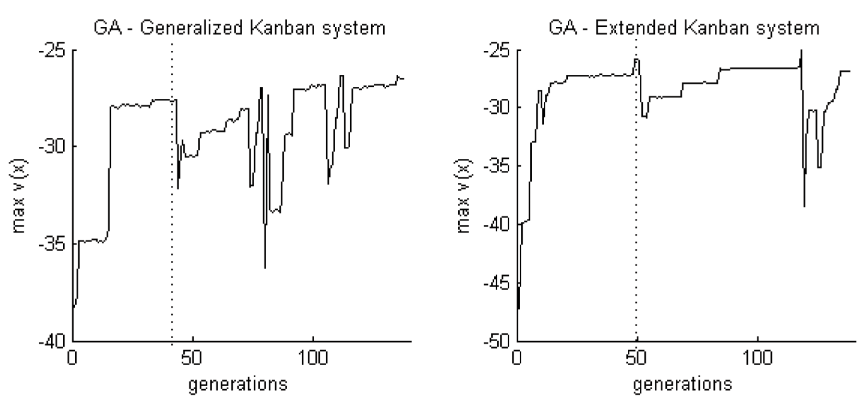
longer simulation than that used to evaluate the fitness of the individuals in the genetic algorithm. By using exhaustively long simulation times we can compute far more accurate estimators, (indicated by the superscript *), which can be considered to approximate the true expected values of these performance measures. This way, relatively safe conclusions can be drawn regarding both the quality of the solutions found by the hybrid genetic algorithms and the performance of each of the competing pull type control policies. Of course, by increasing the simulation time and/or the resampling, the optimization algorithm is less likely to be mislead by "lucky" candidate solutions which score well once by chance but the consequent computational cost is prohibitive of doing so. Apart from that, we are interested in establishing whether the algorithm is capable of locating good and hopefully optimal solutions in the presence of a relatively low signal-to-"noise" ratio. By observing the data in Table 3 we see that the local search algorithm produced actual improvements in the objective function values while preserving the feasibility of the solutions in all cases except the CONWIP and Generalized Kanban systems. The results regarding the Generalized Kanban system are somehow contradicting. In Table 2 the local search algorithm appears to have repaired the infeasible solution, while in Table 3 the original solution is now found to be actually feasible and the local search solution is the one which violates the constraint. Actually, these results merely demonstrate an inherent weakness of search algorithms that generate a single point per iteration when compared to genetic algorithms in "noisy" environments. A hill-climbing method, like the one used here, compares candidate solutions in each iteration only with best solution found so far, and therefore, it is easy to be mislead by a "lucky" solution. In genetic algorithms, on the contrary, for a solution to be maintained it must outweigh an entire collection of solutions and not just a previously best one. As an overall assessment, we could argue that the results presented in this section support the conclusion that even with this simple static penalty function a genetic algorithm can produce quite good solutions. Two typical plots of the best solution found by the genetic algorithm with the "death" penalty function versus the number of generations can be found in Figure 2.

These two plots exhibit a somehow similar pattern. For illustration purposes we use a time window of 140 generations and divide the plot areas in two regions with a perpendicular dotted line. Notice that in the left side of the plots, if we disregard random fluctuations caused by the simulation model, the two curves are increasing

Figure 2. Typical plots of best fitness value found by GA with "death" penalty function versus number of iterations (140 iterations window)



almost monotonically. In this area, the best solution found by the algorithm is not lying somewhere near the boundaries between feasible and infeasible region. In the intersection point of the curve with the dotted perpendicular line the curve suddenly "dives". This is indicative that the currently best individual is marginally feasible, (or infeasible), and that it failed to satisfy the constraint in this evaluation. As a consequence, it was penalized heavily and substituted by another individual which happened to have a lower fitness value. From this point on, the curve displays similar abrupt fluctuations, indicating that the population evolves towards the boundaries between feasible and infeasible region and the optimal solution.

DESIGNING EXPONENTIAL PENALTY FUNCTION

Intuitively, the "death" penalty approach, as attractive as it can be due to its simplicity, does not seem to be the best approach to handle constraints. Even the slightest violation of the imposed constraints results in penalizing heavily a good solution. This way an individual which scores excellently for a series of consecutive generations may be discarded by the algorithm. This is an undesired property in the kind of optimization problem that we are dealing with, where fitness measurements are distorted by random fluctuations caused by the stochasticity of the simulation model. Another weakness of this approach is that it damages the diversity of the population, as the majority of the individuals are crowded in the feasible region. Given that the optimal solution lies on the feasibility boundaries, the search would probably be more efficient if the population evolved towards the boundaries from both feasible and infeasible regions. For example, it is unclear why a slightly infeasible individual which is located very close to the optimal solution should be assigned a worse fitness value than a feasible individual that scores poorly. For all of the above mentioned reasons, the idea of penalizing infeasible solutions according to the level of the constraint violation seems more appealing, (see Venkatraman and Yen (2005) for guidelines on designing penalty functions). The problem that needs to be addressed now is how to design such a "soft-limit" penalty function. A reasonable choice is to use an exponential penalty function $p(\mathbf{x}) = c^u$, where $c = const \in \Re$ and $u = t - SL$ is the difference between the target service level and $E\left[SL(\mathbf{x})\right]$ the measured expected service level. The intuitive, *minimal penalty rule*, (Le Riche *et al.* 1995), suggests that the penalty for infeasible individuals should be just above the threshold below which infeasible solutions score better than their feasible, possibly optimal, neighbors. In practice, however, it is quite difficult to achieve this. The procedure we followed in order to implement, at least to some extent, this intuition, is the following. Using the output of the executions of the genetic algorithm with the "death" penalty function we created plots like the ones in Figure 2. By examining these plots it was easy to locate solutions that were very close to the feasibility boundaries, (these points are indicated by the characteristic "dive" of the curve). The next step was to examine the neighborhood of such a point in order to determine how a small change in parameters affected the service level *SL* as well as the objective function $f(\mathbf{x})$. The value of *SL* is affected primarily by the control parameters of the last three machines so we could limit ourselves to a relatively small neighborhood. Having collected this data, we were able to select the parameter c of the penalty function $p(\mathbf{x}) = c^u$, in the spirit of the "minimal penalty rule". This is an empirical technique that may not be easy or even possible to apply to other problems, nevertheless it provides the means to design a penalty function that will work well and outperform most of the times the "death" penalty approach as supported by our experimental results presented in the following section.

EXPONENTIAL PENALTY FUNCTION RESULTS

After following the procedure outlined in the previous section we were able to construct the following penalty function (6).

$$p(\mathbf{x}) = \begin{cases} 0.0, & u \leq 0.0 \\ 9.0^{u}, & 0.0 < u < 3.0 \\ 9.0^{3}, & 3.0 \leq u \end{cases} \quad (6)$$

where $u = t - E\left[SL(\mathbf{x})\right]$ is the difference between the target service level t=90.0% and the measured service level $E\left[SL(\mathbf{x})\right]$. Note that for service levels equal to or lower than 87.0% we ground the penalty to a constant value. The reason we do this is that we want the raw fitness values $v(\mathbf{x})$ to be within a range for the selection operator of the genetic algorithm to work properly. We reiterate that in our implementation the values of the individuals are scaled proportionally to their raw fitness measurements prior to selection.

The results from the hybrid genetic algorithm runs for each control policy are displayed in Table 4. The rows containing the results of the standard genetic algorithm, (without the local search component), are labeled with the initials GA followed by the control policy's name, while the results of the hybrid algorithm are labeled with the initials GAL and the control policy's name. The last column of Table 4 contains the fitness values of the corresponding parameter sets. The CONWIP system scored the highest fitness value $v_b = -25.31$ followed by the Extended Kanban, the Hybrid CONWIP/Kanban, the Generalized Kanban, the Base Stock and the Kanban systems in decreasing fitness value order. The hybrid optimization algorithm outperformed the standard genetic algorithm in the cases of the Base Stock, the Extended Kanban and the Generalized Kanban systems. For the three remaining systems the local search failed to offer an improvement in minimizing $v\left(\mathbf{x}\right)$. Table 5 contains the objective function values $E\left[f(\mathbf{x})\right]^*$ and service levels $E\left[SL(\mathbf{x})\right]^*$ % with 95% confidence bounds of the best parameters found by both

the standard genetic algorithm and the hybrid genetic algorithm with the exponential penalty function. These data were produced by running 50 replicates of each of the six simulation models for $t_{sim} = 1,500,000.0$ time units and then averaging the corresponding variables.

All three solutions found by the local search algorithm when initialized with the solutions of the genetic algorithm were marginally infeasible. The local search algorithm falsely interpreted the effect of random noise as an actual improvement and thus substituted the feasible solutions by infeasible ones. Of course, we cannot rule out that this was caused in part by the penalty function itself. However, we must mention that the amount of the constraint violation was rather trivial. The average percentage of infeasible solutions in the final generations of the genetic algorithm runs with the exponential penalty function was equal to 8.5%.

DISCUSSION ON THE PERFORMANCE OF THE TWO PENALTY FUNCTIONS

By comparing the data in Tables 3 and 5 we notice that the standard genetic algorithm with the exponential penalty function outperforms both the standard genetic algorithm and the hybrid algorithm with the "death penalty" function for all systems except the CONWIP and the Generalized Kanban. In terms of objective function value, the use of the exponential penalty function rather than the "death penalty" improved the solution by 3.84% for the Kanban system, by 7.89% for the Base Stock system and by 3.43% for the CONWIP/Kanban Hybrid system. For the Extended Kanban system we monitored a 1.5% lower value of $E\left[f(\mathbf{x})\right]^*$, while for the CONWIP system the results were practically the same. Only for the Generalized Kanban system the "death" penalty approach succeeded in producing a 4% better solution than the exponential penalty approach. The superiority of the exponential penalty function over the "death" penalty function can be explained qualitatively as follows: Figure 3 shows typical plots of the genetic algorithm's convergence with the "death" penalty and the exponential penalty function. Notice that at some point near the 60th generation both curves have approximately the same height. The best solutions found by the two implementations of the algorithm in these points probably belong to the same level set and are lying somewhere close to the feasibility boundaries. In some subsequent iteration of the algorithm with the "death" penalty, this solution apparently violates the constraint and is therefore discarded. The height of the curve shows that the individual which replaced it has a significantly lower fitness value. This is not the case in the algorithm with the exponential penalty where the properly designed penalty function prevents the good solution to be discarded, at least not from a much worse candidate solution. Concluding the discussion on the performance of the hybrid GA we state summarize our major findings: i) the incorporation of a local search element can enhance the genetic algorithm's performance with the disadvantage of that the local search algorithm is more susceptible to falsely interpreting random noise as actual objective function improvements than the genetic algorithm, ii) the "death penalty" approach most of the times will yield worse results than a function which penalizes solutions according to the level of the constraint violation like the exponential penalty function used here.

COMPARISON OF PULL TYPE PRODUCTION CONTROL POLICIES-SENSITIVITY ANALYSIS

Table 6 presents the objective function values and the corresponding service levels for the six JIT control policies with the best parameters found by the proposed optimization strategy. Note that the Base stock, CONWIP and Extended Kanban solutions attain a service level below 90% but since the constraint is within the 95% confidence halfwidth we consider them to be feasible. The CONWIP policy ranks first followed in close distance by the Extended Kanban, Hybrid and Base Stock policies. The Kanban and Generalized Kanban policies occupy the last two positions of the objective function value ranking. Since in this simulation scenario the demand process pushes the manufacturing system towards its maximum throughput rate, the poor performance of the Kanban mechanism is anticipated since this policy offers tight coordination between the manufacturing stages but does not respond rapidly to incoming orders. On the other hand the performance of the Generalized Kanban system is somewhat unexpected since it is supposed to be an enhancement of the original Kanban policy. However, this is not the case for the control policy that is mostly related to Generalized Kanban, the Extended Kanban mechanism, which ranks second. The main characteristic of the Base Stock policy, that is fast reaction to demand, is supported by the experimental output. Finally, the fact that in a CONWIP or CONWIP/Kanban Hybrid system the WIP tends to accumulate to the last buffer al-

Table 6. Objective function values – service levels of pull control policies with best parameters for base simulation case

	Kanban	Base Stock	CONWIP	CONWIP/Kanban Hybrid	Extended Kanban	Generalized Kanban
$E\left[f(\mathbf{x})\right]^*$	-28.01±0.03	-25.97±0.03	-25.27±0.02	-25.87±0.02	-25.71±0.02	-28.18±0.02
$E\left[SL(\mathbf{x})\right]^*$	90.10 ± 0.08	89.95 ± 0.13	89.94 ± 0.10	90.21 ± 0.09	89.98 ± 0.10	90.23 ± 0.09

lows this two policies to achieve a high service level while operating a lean manufacturing mode.

Table 7 shows the statistics of the system's performance measures for the four variants of the basic simulation case. In the case where the demand rate increases (first column of Table 7) we notice that the service level as well as the average WIP decreases for all policies, but some control mechanisms are more sensitive to this change than others. Specifically, the service rate in the Kanban and Hybrid systems decreases dramatically, whereas the Base Stock and Generalized Kanban policies seem to be more robust regarding the increase of the demand rate. In the second variant (decreased arrival rate) of the basic simulation case one can see that all six control policies practically achieve the same service level. This is an indication that when the demand can be easily satisfied by the manufacturing system the role of the production control policy diminishes. In this case the distribution of the objective function values over the control mechanisms also tends to level out.

The increase of the standard deviation of the processing times (variant 3) has an effect similar to that of the increase of the demand rate. The reasons for that can be attributed to the resulting decreased coordination among the various production stages which increases the frequency with which machine starvation or blockage events occur. Again, the Kanban mechanism is mostly affected by this parameter due to its tight production coordination scheme, while the Generalized Kanban mechanism seems to react rather ro-

Table 7. Objective function values – service levels of pull control policies with best parameters for variants of base simulation case
