ASM HANDBOOK

VOLUME 2

Properties and Selection: Nonferrous Alloys and Special-Purpose Materials

ASM INTERNATIONAL®
The Materials Information Company

Properties and Selection: Nonferrous Alloys and Special-Purpose Materials was published in 1990 as Volume 2 of the 10 Edition Metals Handbook. With the second printing (1992), the series title was changed to ASM Handbook. The Volume was prepared under the direction of the ASM International Handbook Committee.

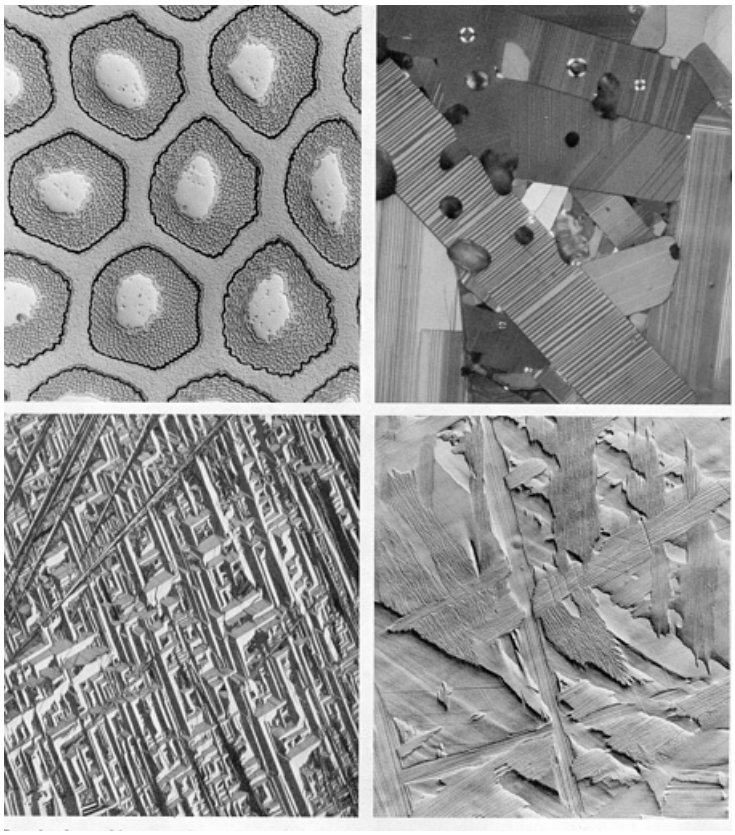

Fig. 1 ***Examples of some of the many nonferrous alloys and special-purpose materials described in this Volume. Shown clockwise from the upper left-hand corner are: (1) a cross-section of a multifilament Nb_3Sn superconducting wire, 1000×; (2) a high-temperature ceramic $YBa_2Cu_3O_{7-x}$ superconductor, 600×; (3) beta martensite in a cast Cu-12Al alloy, 100× and (4) alpha platelet colonies in a Zr-Hf plate, 400×. Courtesy of Paul E. Danielson, Teledyne Wah Chang Albany (micrographs 1 and 4) and George F. Vander Voort, Carpenter Technology Corporation (micrographs 2 and 3).***

Foreword

Throughout the history of *Metals Handbook*, the amount of coverage accorded nonferrous alloys, special-purpose materials, and pure metals has steadily, if not dramatically, increased. That this trend has continued into the current 10th Edition is easily justified when one considers the significant developments that have occurred in the past decade. For example, metal-matrix composites, superconducting materials, and intermetallic alloys--materials described in detail in the present volume--were either laboratory curiosities or, in the case of high-temperature superconductors, not yet discovered when the 9th Edition Volume on this topic was published 10 years ago. Today, such materials are the focus of intensive research efforts and are considered commercially viable for a wide range of applications. In fact, the development of these new materials, combined with refinements and improvements in existing alloy systems, will ensure the competitive status of the metals industry for many years to come.

Publication of this Volume is also significant in that it marks the completion of a two-volume set on properties and selection of metals that serves as the foundation for the remainder of the 10th Edition. Exhaustive in scope, yet practical in approach, these companion volumes provide engineers with a reliable and authoritative reference that should prove a useful resource during critical materials selection decision-making.

On behalf of ASM International, we would like to extend our sincere thanks and appreciation to the authors, reviewers, and other contributors who so generously donated their time and efforts to this Handbook project. Thanks are also due to the ASM Handbook Committee for their guidance and unfailing support and to the Handbook editorial staff for their dedication and professionalism. This unique pool of talent is to be credited with continuing the tradition of quality long associated with *Metals Handbook.*

Klaus M. Zwilsky
President
ASM International

Edward L. Langer
Managing Director
ASM International

Preface

This is the second of two volumes in the *ASM Handbook* that present information on compositions, properties, selection, and applications of metals and alloys. In the first volume, irons, steels, and superalloys were described. In the present volume, nonferrous alloys, superconducting materials, pure metals, and materials developed for use in special applications are reviewed. In addition to being vastly expanded from the coverage offered in the 9th Edition, these companion volumes document some of the more important changes and developments that have taken place in materials

science during the past decade--changes that undoubtedly will continue to impact materials engineering into the 21st century.

During the 1970s and '80s, the metals industry was forced to respond to the challenges brought about by rapid advancements in composite, plastic, and ceramic technology. During this time, the use of metals in a number of key industries declined. For example, Fig. 1 shows materials selection trends in the aircraft industries. As can be seen, the use of aluminum, titanium, and other structural materials is expected to level off during the 1990s, while polymer-matrix composites, carbon-carbon composites, and ceramic-matrix composites probably will continue to see increased application. However, this increasing competition has also spurred new alloy development that will ensure that metals will remain competitive in the aerospace industry. Some of these new or improved materials and methods include:

- Ingot metallurgy aluminum-lithium alloys for airframe components that have densities 7 to 12% lower and stiffnesses 15 to 20% higher than existing high-strength aluminum alloys
- High-strength aluminum P/M alloys made by rapid solidification or mechanical alloying
- Advances in processing of titanium alloys that have resulted in improved elevated-temperature performance
- The continuing development and research of metal-matrix composites and intermetallic alloys such as Ni_3Al, Fe_3Al, and Ti_3Al

These are but four of the many new developments in nonferrous metallurgy that are documented in Volume 2's 1300 pages.

Principal Sections

Volume 2 has been organized into five major sections:

- Specific Metals and Alloys
- Special-Purpose Materials
- Superconducting Materials
- Pure Metals
- Special Engineering Topics

A total of 62 articles are contained in these sections. Of these, 31 are completely new to the *ASM Handbook* series, 8 were completely rewritten, with the remaining revised and/or expanded. A summary of the content of the major sections is given in Table 1 and discussed below. Differences between the present volume and its *Metals Handbook,* 9th Edition predecessor are highlighted.

Table 1 Summary of contents for Volume 2, *ASM Handbook*

Section title	Number of articles	Pages	Figures[(a)]	Tables[(b)]	References
Specific Metals and Alloys	36	757	586	703	646
Special-Purpose Materials	15	265	292	142	694
Superconducting Materials	7	64	101	6	325
Pure Metals	2	111	156	230	622
Special Engineering Topics	2	67	26	21	384
Totals	**62**	**1,264**	**1,161**	**1,102**	**2,671**

(a) Total number of figure captions; some figures may include more than one illustration.

(b) Does not include in-text tables or tables that are part of figures

Specific Metals and Alloys are described in 36 articles. Extensive new data have been added to all major alloys groups. For example, more than 400 pages detail processing, properties, and applications of aluminum-base and copper-base alloys. Included are new articles on "Aluminum-Lithium Alloys," "High-Strength Aluminum P/M Alloys," "Copper P/M Products," and "Beryllium-Copper and Other Beryllium-Containing Alloys." When appropriate, separate articles describing wrought, cast, and P/M product forms for the same alloys system have been provided to assist in materials selection and comparison. Articles have also been added on technologically important, but less commonly used, metals and alloys such as beryllium, gallium and gallium arsenide (used in semiconductor devices), and rare earth metals.

Special-Purpose Materials. The 15 articles in this section, 7 of which are completely new, examine materials used for more demanding or specialized application. Alloys with outstanding magnetic and electrical properties (including rare earth magnets and metallic glasses), heat-resistant alloys, wear-resistant materials (cemented carbides, ceramics, cermets, synthetic diamond, and cubic boron nitride), alloys exhibiting unique physical characteristics (low-expansion alloys and

shape memory alloys), and metal-matrix composites and advanced ordered intermetallics currently in use or under development for critical aerospace components are described.

Superconducting Materials. This is the first time that a significant body of information has been presented on superconducting materials in the *ASM Handbook.* This new section was carefully planned and structured to keep theory to a minimum and emphasize manufacture and applications of the materials used for superconductors. Following brief articles on the historical background and principles associated with superconductivity, the most widely used superconductors--niobium-titanium and A15 compounds (including Nb_3Sn)--are examined in detail. The remaining articles in the section discuss Chevrel-phase superconductors ($PbMo_6S_8$ and $SnMo_6S_8$), thin-film superconductors, and high-temperature oxide superconductors ($YBa_2Cu_3O_7$, $Bi_2Sr_2Ca_2Cu_3O_x$, and $Tl_2Ba_2Ca_2Cu_3O_x$.

Pure Metals are described in an extensive collection of data compilations that describe crystal structures, mass characteristics, as well as thermal, electrical/magnetic optical, nuclear, chemical, and mechanical properties for more than 80 elements. Also included is a review of methods used to prepare and characterize pure metals.

Special Engineering Topics. With environmental issues more important than ever, recycling behavior is becoming a key consideration for materials selection. The articles on recycling in Volume 2 over a wide range of materials and topics--from the recycling of aluminum beverage cans to the reclaiming of precious metals from electronic scrap. Statistical information on scrap consumption and secondary recovery of metals supplements each contribution. A detailed review of the toxic effects of metals is also included in this section.

Acknowledgements

Volume 2 has proved to be one of the largest and most comprehensive volumes ever published in the 67-year history of the *ASM Handbook* (formerly *Metals Handbook*). The extensive data and breadth of information presented in this book were the result of the collective efforts of more than 400 authors, reviewers, and miscellaneous contributors. Their generous gifts of time, effort, and knowledge are greatly appreciated by ASM.

We are also indebted to the ASM Handbook Committee for their very active role in this project. Specifically, we would like to acknowledge the efforts of the following Committee members: Elwin L. Rooy, Aluminum Company of America, who organized and authored material on aluminum and aluminum alloys; William L. Mankins, Inco Alloys International, Inc., who coauthored the article "Nickel and Nickel Alloys"; Susan Housh, Dow Chemical U.S.A., who revised the articles on magnesium and magnesium alloys; Robert Barnhurst, Noranda Technology Centre, who prepared the article "Zinc and Zinc Alloys"; John B. Lambert, Fansteel Inc., who organized the committee that revised the material on refractory metals and alloys; Toni Grobstein, NASA Lewis Research Center, who contributed material on rhenium and metal-matrix composites containing tungsten fibers; and David V. Neff, Metaullic Systems, who organized the committee that prepared the article, "Recycling of Nonferrous Alloys."

Thanks to the spirit of cooperation and work ethic demonstrated by all of these individuals, a book of lasting value to the metals industry has been produced.

General Information

Officers and Trustees of ASM International

- **William E. Quist** Boeing Commercial Airplanes

Previous Chairmen of the ASM Handbook Committee

- **R.S. Archer** (1940-1942) (Member, 1937-1942)
- **L.B. Case** (1931-1933) (Member, 1927-1933)
- **T.D. Cooper** (1984-1986) (Member, 1981-1986)
- **E.O. Dixon** (1952-1954) (Member, 1947-1955)
- **R.L. Dowdell** (1938-1939) (Member, 1935-1939)
- **J.P. Gill** (1937) (Member, 1934-1937)
- **J.D. Graham** (1966-1968) (Member, 1961-1970)
- **J.F. Harper** (1923-1926) (Member, 1923-1926)
- **C.H. Herty, Jr.** (1934-1936) (Member, 1930-1936)
- **J.B. Johnson** (1948-1951) (Member, 1944-1951)
- **L.J. Korb** (1983) (Member, 1978-1983)
- **R.W.E. Leiter** (1962-1963) (Member, 1955-1958, 1960-1964)
- **G.V. Luerssen** (1943-1947) (Member, 1942-1947)
- **G.N. Maniar** (1979-1980) (Member, 1974-1980)
- **J.L. McCall** (1982) (Member, 1977-1982)
- **W.J. Merten** (1927-1930) (Member, 1923-1933)
- **N.E. Promisel** (1955-1961) (Member, 1954-1963)
- **G.J. Shubat** (1973-1975) (Member, 1966-1975)
- **W.A. Stadtler** (1969-1972) (Member, 1962-1972)
- **R. Ward** (1976-1978) (Member, 1972-1978)
- **M.G.H. Wells** (1981) (Member, 1976-1981)

- **D.J. Wright** (1964-1965) (Member, 1959-1967)

Staff

ASM International staff who contributed to the development of the Volume included Robert L. Stedfeld, Director of Reference Publications; Joseph R. Davis, Manager of Handbook Development; Penelope Allen, Manager of Handbook Production; Steven R. Lampman, Technical Editor; Theodore B. Zorc, Technical Editor; Scott D. Henry, Assistant Editor; Janice L. Daquila, Assistant Editor; Alice W. Ronke, Assistant Editor; Janet Jakel, Word Processing Specialist; and Karen Lynn O'Keefe, Word Processing Specialist. Editorial assistance was provided by Lois A. Abel, Robert T. Kiepura, Penelope Thomas, Heather F. Lampman, and Nikki D. Wheaton.

Conversion to Electronic Files

ASM Handbook, Volume 2, Properties and Selection: Nonferrous Alloys and Special-Purpose Materials was converted to electronic files in 1997. The conversion was based on the Fourth Printing (October 1995). No substantive changes were made to the content of the Volume, but some minor corrections and clarifications were made as needed.

ASM International staff who contributed to the conversion of the Volume included Sally Fahrenholz-Mann, Bonnie Sanders, Scott Henry, Grace Davidson, Randall Boring, Robert Braddock, Kathleen Dragolich, and Audra Scott. The electronic version was prepared under the direction of William W. Scott, Jr., Technical Director, and Michael J. DeHaemer, Managing Director.

Copyright Information (for Print Volume)

ASM Handbook is a collective effort involving thousands of technical specialists. It brings together in one book a wealth of information from world-wide sources to help scientists, engineers, and technicians solve current and long-range problems.

Comments, criticisms, and suggestions are invited, and should be forwarded to ASM International.

Introduction to Aluminum and Aluminum Alloys

Elwin L. Rooy, Aluminum Company of America

Introduction

ALUMINUM, the second most plentiful metallic element on earth, became an economic competitor in engineering applications as recently as the end of the 19th century. It was to become a metal for its time. The emergence of three important industrial developments would, by demanding material characteristics consistent with the unique qualities of aluminum and its alloys, greatly benefit growth in the production and use of the new metal.

When the electrolytic reduction of alumina (Al_2O_3) dissolved in molten cryolite was independently developed by Charles Hall in Ohio and Paul Heroult in France in 1886, the first internal-combustion-engine-powered vehicles were appearing, and aluminum would play a role as an automotive material of increasing engineering value. Electrification would require immense quantities of light-weight conductive metal for long-distance transmission and for construction of the towers needed to support the overhead network of cables which deliver electrical energy from sites of power generation. Within a few decades the Wright brothers gave birth to an entirely new industry which grew in partnership with the aluminum industry development of structurally reliable, strong, and fracture-resistant parts for airframes, engines, and ultimately, for missile bodies, fuel cells, and satellite components.

The aluminum industry's growth was not limited to these developments. The first commercial applications of aluminum were novelty items such as mirror frames, house numbers, and serving trays. Cooking utensils, were also a major early market. In time, aluminum grew in diversity of applications to the extent that virtually every aspect of modern life would be directly or indirectly affected by its use.

Properties. Among the most striking characteristics of aluminum is its versatility. The range of physical and mechanical properties that can be developed--from refined high-purity aluminum (see the article "Properties of Pure Metals" in this Volume) to the most complex alloys--is remarkable. More than three hundred alloy compositions are commonly recognized, and many additional variations have been developed internationally and in supplier/consumer relationships. Compositions for both wrought and cast aluminum alloys are provided in the article "Alloy and Temper Designation Systems for Aluminum and Aluminum Alloys" that immediately follows.

The properties of aluminum that make this metal and its alloys the most economical and attractive for a wide variety of uses are appearance, light weight, fabricability, physical properties, mechanical properties, and corrosion resistance.

Aluminum has a density of only 2.7 g/cm^3, approximately one-third as much as steel (7.83 g/cm^3), copper (8.93 g/cm^3), or brass (8.53 g/cm^3). It can display excellent corrosion resistance in most environments, including atmosphere, water (including salt water), petrochemicals, and many chemical systems. The corrosion characteristics of aluminum are examined in detail in *Corrosion,* Volume 13 of *ASM Handbook,* formerly 9th Edition *Metals Handbook.*

Aluminum surfaces can be highly reflective. Radiant energy, visible light, radiant heat, and electromagnetic waves are efficiently reflected, while anodized and dark anodized surfaces can be reflective or absorbent. The reflectance of polished aluminum, over a broad range of wave lengths, leads to its selection for a variety of decorative and functional uses.

Aluminum typically displays excellent electrical and thermal conductivity, but specific alloys have been developed with high degrees of electrical resistivity. These alloys are useful, for example, in high-torque electric motors. Aluminum is often selected for its electrical conductivity, which is nearly twice that of copper on an equivalent weight basis. The requirements of high conductivity and mechanical strength can be met by use of long-line, high-voltage, aluminum steel-cored reinforced transmission cable. The thermal conductivity of aluminum alloys, about 50 to 60% that of copper, is advantageous in heat exchangers, evaporators, electrically heated appliances and utensils, and automotive cylinder heads and radiators.

Aluminum is nonferromagnetic, a property of importance in the electrical and electronics industries. It is nonpyrophoric, which is important in applications involving inflammable or explosive-materials handling or exposure. Aluminum is also nontoxic and is routinely used in containers for foods and beverages. It has an attractive appearance in its natural finish, which can be soft and lustrous or bright and shiny. It can be virtually any color or texture.

Some aluminum alloys exceed structural steel in strength. However, pure aluminum and certain aluminum alloys are noted for extremely low strength and hardness.

Aluminum Production

All aluminum production is based on the Hall-Heroult process. Alumina refined from bauxite is dissolved in a cryolite bath with various fluoride salt additions made to control bath temperature, density, resistivity, and alumina solubility. An electrical current is then passed through the bath to electrolyze the dissolved alumina with oxygen forming at and reacting with the carbon anode, and aluminum collecting as a metal pad at the cathode. The separated metal is periodically removed by siphon or vacuum methods into crucibles, which are then transferred to casting facilities where remelt or fabricating ingots are produced.

The major impurities of smelted aluminum are iron and silicon, but zinc, gallium, titanium, and vanadium are typically present as minor contaminants. Internationally, minimum aluminum purity is the primary criterion for defining composition and value. In the United States, a convention for considering the relative concentrations of iron and silicon as the more important criteria has evolved. Reference to grades of unalloyed metal may therefore be by purity alone, for example, 99.70% aluminum, or by the method sanctioned by the Aluminum Association in which standardized P*xxx* grades have been established. In the latter case, the digits following the letter P refer to the maximum decimal percentages of silicon and iron, respectively. For example, P1020 is unalloyed smelter-produced metal containing no more than 0.10% Si and no more than 0.20% Fe. P0506 is a grade which contains no more than 0.05% Si and no more than 0.06% Fe. Common P grades range from P0202 to P1535, each of which incorporates additional impurity limits for control purposes.

Refining steps are available to attain much higher levels of purity. Purities of 99.99% are achieved through fractional crystallization or Hoopes cell operation. The latter process is a three-layer electrolytic process which employs molten salt of greater density than pure molten aluminum. Combinations of these purification techniques result in 99.999% purity for highly specialized applications.

Production Statistics. World production of primary aluminum totaled 17,304 thousand metric tonnes (17.304×10^6 Mg) in 1988 (Fig. 1). From 1978 to 1988, world production increased 22.5%, an annual growth rate of 1.6%. As shown in Fig. 2, the United States accounted for 22.8% of the world's production in 1988, while Europe accounted for 21.7%. The remaining 55.5% was produced by Asia (5.6%), Canada (8.9%), Latin/South America (8.8%), Oceania (7.8%), Africa (3.1%), and others (21.3%). The total U.S. supply in 1988 was 7,533,749 Mg in 1988, with primary production representing 54% of total supply, imports accounting for 20%, and secondary recovery representing 26% (Fig. 3). The source of secondary production is scrap in all forms, as well as the product of skim and dross processing. Primary and secondary production of aluminum are integrally related and complementary. Many wrought and cast compositions are constructed to reflect the impact of controlled element contamination that may accompany scrap consumption. A recent trend has been increased use of scrap in primary and integrated secondary fabricating facilities for various wrought products, including can sheet.

Aluminum Alloys

It is convenient to divide aluminum alloys into two major categories: casting compositions and wrought compositions. A further differentiation for each category is based on the primary mechanism of property development. Many alloys

respond to thermal treatment based on phase solubilities. These treatments include solution heat treatment, quenching, and precipitation, or age, hardening. For either casting or wrought alloys, such alloys are described as heat treatable. A large number of other wrought compositions rely instead on work hardening through mechanical reduction, usually in combination with various annealing procedures for property development. These alloys are referred to as work hardening. Some casting alloys are essentially not heat treatable and are used only in as-cast or in thermally modified conditions unrelated to solution or precipitation effects.

Cast and wrought alloy nomenclatures have been developed. The Aluminum Association system is most widely recognized in the United States. Their alloy identification system employs different nomenclatures for wrought and cast alloys, but divides alloys into families for simplification (see the article "Alloy and Temper Designation Systems for Aluminum and Aluminum Alloys" in this Volume for details). For wrought alloys a four-digit system is used to produce a list of wrought composition families as follows:

- 1*xxx* Controlled unalloyed (pure) compositions
- 2*xxx* Alloys in which copper is the principal alloying element, though other elements, notably magnesium, may be specified
- 3*xxx* Alloys in which manganese is the principal alloying element
- 4*xxx* Alloys in which silicon is the principal alloying element
- 5*xxx* Alloys in which magnesium is the principal alloying element
- 6*xxx* Alloys in which magnesium and silicon are principal alloying elements
- 7*xxx* Alloys in which zinc is the principal alloying element, but other elements such as copper, magnesium, chromium, and zirconium may be specified
- 8*xxx* Alloys including tin and some lithium compositions characterizing miscellaneous compositions
- 9*xxx* Reserved for future use

Casting compositions are described by a three-digit system followed by a decimal value. The decimal .0 in all cases pertains to casting alloy limits. Decimals .1, and .2 concern ingot compositions, which after melting and processing should result in chemistries conforming to casting specification requirements. Alloy families for casting compositions are:

- 1*xx.x* Controlled unalloyed (pure) compositions, especially for rotor manufacture
- 2*xx.x* Alloys in which copper is the principal alloying element, but other alloying elements may be specified
- 3*xx.x* Alloys in which silicon is the principal alloying element, but other alloying elements such as copper and magnesium are specified
- 4*xx.x* Alloys in which silicon is the principal alloying element
- 5*xx.x* Alloys in which magnesium is the principal alloying element
- 6*xx.x* Unused
- 7*xx.x* Alloys in which zinc is the principal alloying element, but other alloying elements such as copper and magnesium may be specified
- 8*xx.x* Alloys in which tin is the principal alloying element
- 9*xx.x* Unused

Manufactured Forms

Aluminum and its alloys may be cast or formed by virtually all known processes. Manufactured forms of aluminum and aluminum alloys can be broken down into two groups. Standardized products include sheet, plate, foil, rod, bar, wire, tube, pipe, and structural forms. Engineered products are those designed for specific applications and include extruded shapes, forgings, impacts, castings, stampings, powder metallurgy (P/M) parts, machined parts, and metal-matrix composites. A percentage distribution of major aluminum products is presented in Fig. 4. Properties and applications of the various aluminum product forms can be found in the articles "Aluminum Mill and Engineered Wrought Products" and "Aluminum Foundry Products" that follow.

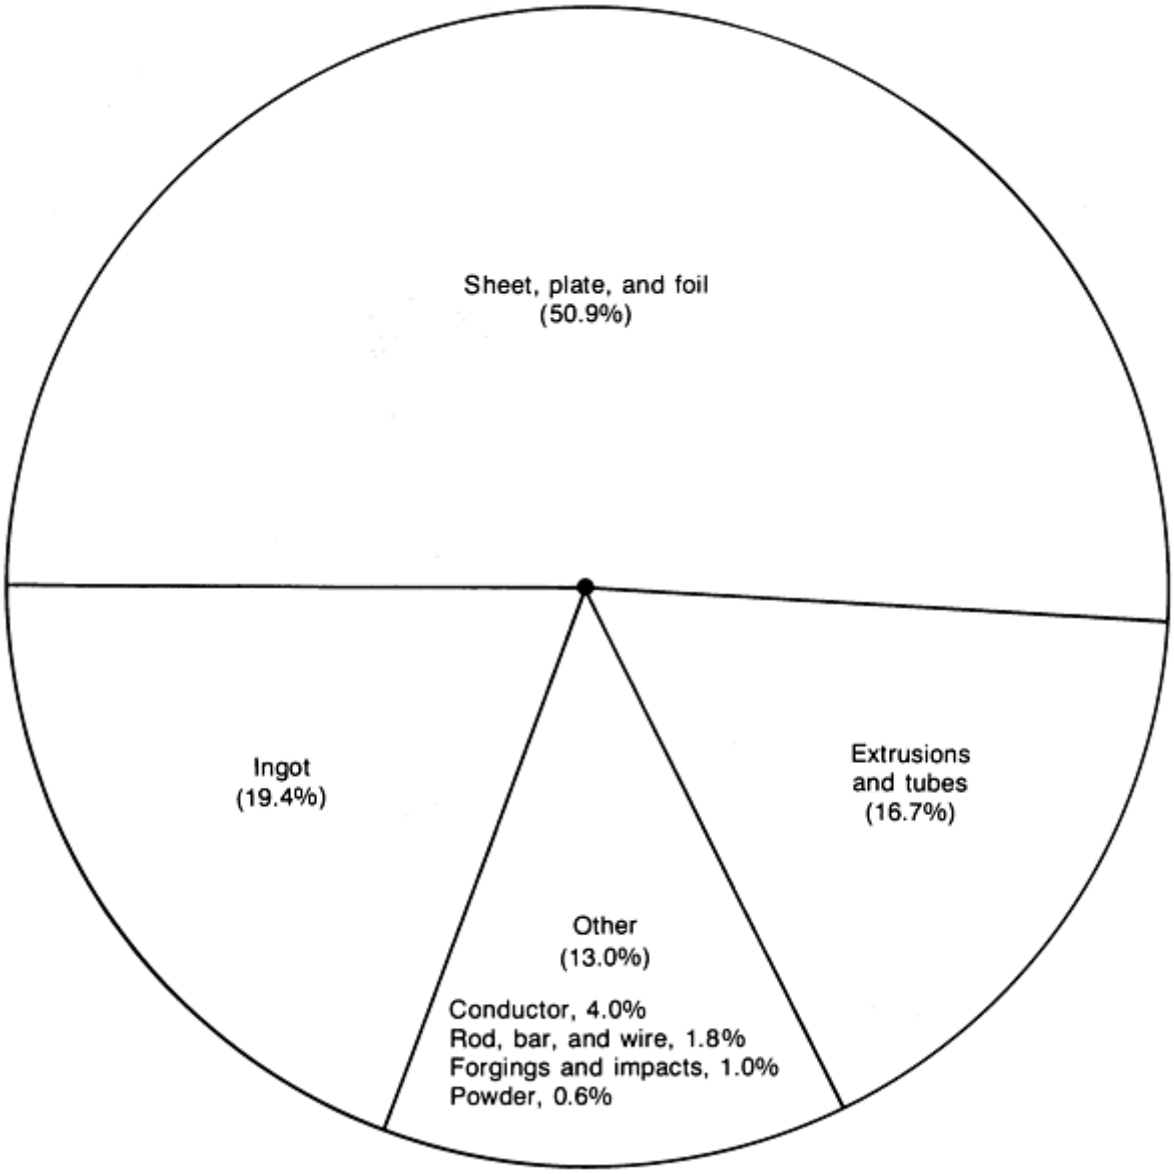

Fig. 4 Percentage distribution of major aluminum products in 1988. Source: Aluminum Association, Inc.

Standardized Products

Flat-rolled products include plate (thickness equal to or greater than 6.25 mm, or 0.25 in.), sheet (thickness 0.15 mm through 6.25 mm, or 0.006 through 0.25 in.), and foil (thickness less than 0.15 mm, or 0.006 in.). These products are semifabricated to rectangular cross section by sequential reductions in the thickness of cast ingot by hot and cold rolling. Properties in work-hardened tempers are controlled by degree of cold reduction, partial or full annealing, and the use of stabilizing treatments. Plate, sheet, and foil produced in heat-treatable compositions may be solution heat treated, quenched, precipitation hardened, and thermally or mechanically stress relieved.

Sheet and foil may be rolled with textured surfaces. Sheet and plate rolled with specially prepared work rolls may be embossed to produce products such as tread plate. By roll forming, sheet in corrugated or other contoured configurations can be produced for such applications as roofing, siding, ducts, and gutters.

While the vast majority of flat-rolled products are produced by conventional rolling mill, continuous processes are now in use to convert molten alloy directly to reroll gages (Fig. 5). Strip casters employ counterrotating water-cooled cylinders or rolls to solidify and partially work coilable gage reroll stock in line. Slab casters of either twin-belt or moving block design cast stock typically 19 mm (0.75 in.) in thickness which is reduced in thickness by in-line hot reduction mill(s) to

produce coilable reroll. Future developments based on technological and operational advances in continuous processes may be expected to globally affect industry expansions in flat-rolled product manufacture.

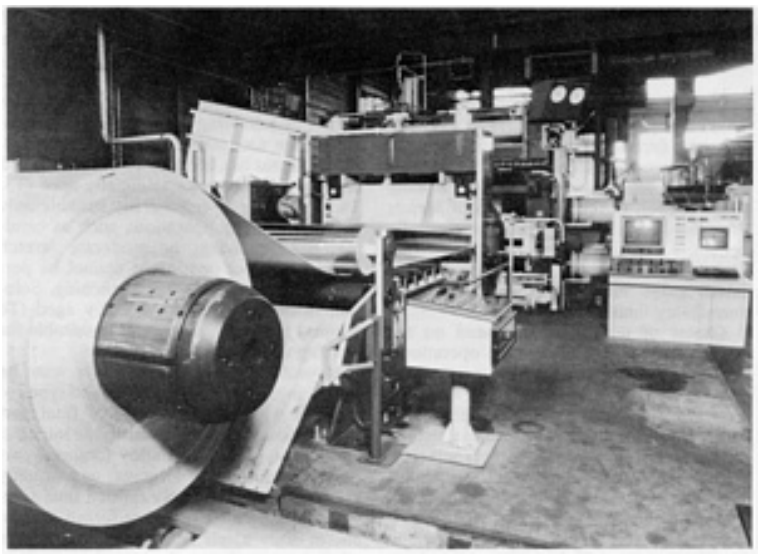

Fig. 5 Facility for producing aluminum sheet reroll directly from molten aluminum

Wire, rod, and bar are produced from cast stock by extrusion, rolling, or combinations of these processes. Wire may be of any cross section in which distance between parallel faces or opposing surfaces is less than 9.4 mm (0.375 in.). Rod exceeds 9.4 mm (0.375 in.) in diameter and bar in square, rectangular, or regular hexagonal or octagonal cross section is greater than 9.4 mm (0.375 in.) between any parallel or opposing faces.

An increasingly large proportion of rod and wire production is derived from continuous processes in which molten alloy is cast in water-cooled wheel/mold-belt units to produce a continuous length of solidified bar which is rolled in line to approximately 9.4 to 12 mm (0.375 to 0.50 in.) diameter.

Engineered Products

Aluminum alloy castings are routinely produced by pressure-die, permanent-mold, green- and dry-sand, investment, and plaster casting. Shipment statistics are provided in Fig. 6. Process variations include vacuum, low-pressure, centrifugal, and pattern-related processes such as lost foam. Castings are produced by filling molds with molten aluminum and are used for products with intricate contours and hollow or cored areas. The choice of castings over other product forms is often based on net shape considerations. Reinforcing ribs, internal passageways, and complex design features, which would be costly to machine in a part made from a wrought product, can often be cast by appropriate pattern and mold or die design. Premium engineered castings display extreme integrity, close dimensional tolerances, and consistently controlled mechanical properties in the upper range of existing high-strength capabilities for selected alloys and tempers.

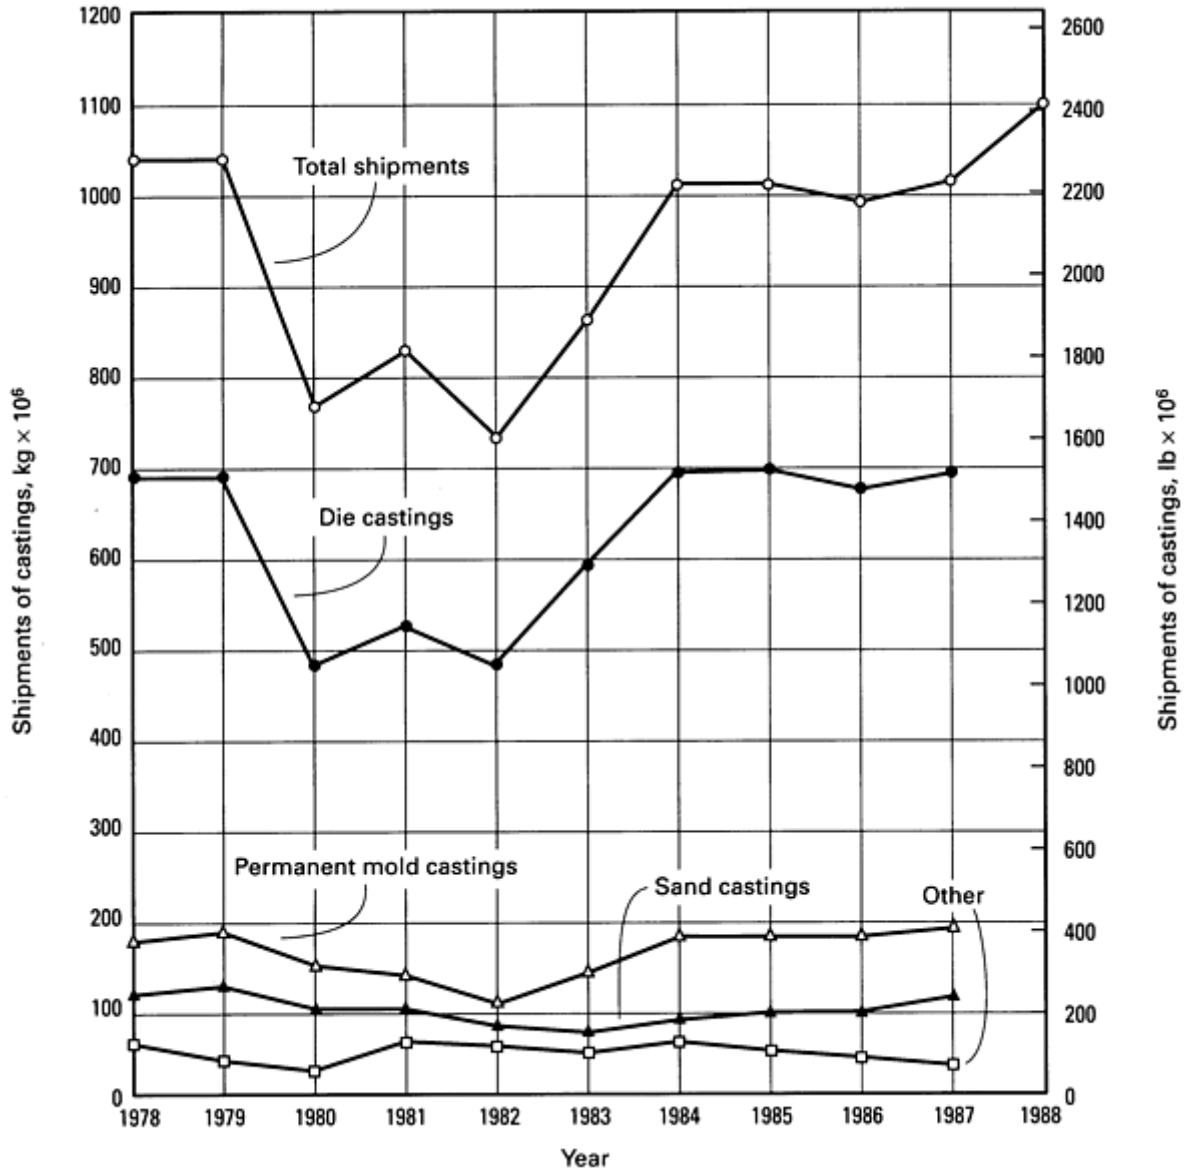

Fig. 6 U.S. casting shipments from 1978 through 1988. Source: Aluminum Association, Inc.

Extrusions are produced by forcing solid metal through aperture dies. Designs that are symmetrical around one axis are especially adaptable to production in extruded form. With current technology, it is also possible to extrude complex, mandrel-cored, and asymmetrical configurations. Precision extrusions display exceptional dimensional control and surface finish. Major dimensions usually require no machining; tolerance of the as-extruded product often permits completion of part manufacture with simple cutoff, drilling, broaching, or other minor machining operations. Extruded and extruded/drawn seamless tube competes with mechanically seamed and welded tube.

Forgings are produced by inducing plastic flow through the application of kinetic, mechanical, or hydraulic forces in either closed or open dies. Hand forgings are simple geometric shapes, formable between flat or modestly contoured open dies such as rectangles, cylinders (multiface rounds), disks (biscuits), or limited variations of these shapes. These forgings fill a frequent need in industry when only a limited number of pieces is required, or when prototype designs are to be proven.

Most aluminum forgings are produced in closed dies to produce parts with good surface finish, dimensional control, and exceptional soundness and properties. Precision forgings emphasize near net shape objectives, which incorporate reduced draft and more precise dimensional accuracy. Forgings are also available as rolled or mandrel-forged rings.

Impacts are formed in a confining die from a lubricated slug, usually cold, by a single-stroke application of force through a metal punch causing the metal to flow around the punch and/or through an opening in the punch or die. The process lends itself to high production rates with a precision part being produced to exacting quality and dimensional standards. Impacts are a combination of both cold extrusion and cold forging and, as such, combine advantages of each process.

There are three basic types of impact forming--reverse impacting, forward impacting, and a combination of the two--each of which may be used in aluminum fabrication. Reverse impacting is used to make shells with a forged base and extruded sidewalls. The slug is placed in a die cavity and struck by a punch, which forces the metal to flow back (upward) around the punch, through the opening between the punch and die, to form a simple shell. Forward impacting somewhat resembles conventional extrusion. Metal is forced through an orifice in the die by the action of a punch, causing the metal to flow in the direction of pressure application. Punch/die clearance limits flash formation. Forward impacting with a flat-face punch is used to form round, contoured, straight, and ribbed rods. With a stop-race punch, thin-walled parallel or tapered sidewall tubes with one or both ends open may be formed. In the combination method, the punch is smaller than an orificed die resulting in both reverse and forward metal flow.

Powder metallurgy (P/M) parts are formed by a variety of processes. For less demanding applications, metal powder is compressed in a shaped die to produce green compacts, and then the compacts are sintered (diffusion bonded) at elevated temperature under protective atmosphere. During sintering, the compacts consolidate and strengthen. The density of sintered compacts may be increased by re-pressing. When re-pressing is performed primarily to improve dimensional accuracy, it is termed "sizing;" when performed to alter configuration, it is termed "coining." Re-pressing may be followed by resintering, which relieves stresses induced by cold work and may further consolidate the structure. By pressing and sintering only, parts having densities of greater than 80% theoretical density can be produced. By re-pressing, with or without resintering, parts of 90% theoretical density or more can be produced. Additional information on conventionally pressed and sintered aluminum P/M products can be found in the Appendix to the article "High-Strength Aluminum P/M Alloys" in this Volume.

For more demanding applications, such as aerospace parts or components requiring enhanced resistance to stress-corrosion cracking, rapidly solidified or mechanically attrited aluminum powders are consolidated by more advanced techniques that result in close to 100% of theoretical density. These consolidation methods include hot isostatic pressing, rapid omnidirectional compaction, ultra-high strain rate (dynamic) compaction, and spray deposition techniques. Using advanced P/M processing methods, alloys that cannot be produced through conventional ingot metallurgy methods are routinely manufactured. The aforementioned article "High-Strength Aluminum Powder Metallurgy Alloys" provides detailed information on advanced P/M processing.

Powder metallurgy parts may be competitive with forgings, castings, stampings, machined components, and fabricated assemblies. Certain metal products can be produced only by powder metallurgy; among these are oxide-dispersioned strengthened alloys and materials whose porosity (number distribution and size of pores) is controlled (filter elements and self-lubricating bearings).

Metal-matrix composites (MMCs) basically consist of a nonmetallic reinforcement incorporated into a metallic matrix. The combination of light weight, corrosion resistance, and useful mechanical properties, which has made aluminum alloys so popular, lends itself well to aluminum MMCs. The melting point of aluminum is high enough to satisfy many application requirements, yet is low enough to render composite processing reasonably convenient. Aluminum can also accommodate a variety of reinforcing agents. Reinforcements, characterized as either continuous or discontinuous fibers, typically constitute 20 vol% or more of the composite. The family of aluminum MMC reinforcements includes continuous boron; aluminum oxide; silicon carbide and graphite fibers; and various particles, short fibers, and whiskers. Figure 7 shows a variety of parts produced from aluminum MMCs. Information on the processing and properties of these materials can be found in the article "Metal-Matrix Composites" in this Volume.

Fabrication Characteristics

This section will briefly review important considerations in the machining, forming, forging, and joining of aluminum alloys. Additional information can be found in the articles "Aluminum Mill and Engineered Wrought Products" and "Aluminum Foundry Products" in this Volume and in articles found in other Handbooks that are referenced below.

Machinability of most aluminum alloys is excellent. Among the various wrought and cast aluminum alloys and among the tempers in which they are produced, there is considerable variation in machining characteristics, which may require special tooling or techniques (see the article "Machining of Aluminum and Aluminum Alloys" in *Machining,* Volume 16 of *ASM Handbook*, formerly 9th Edition *Metals Handbook.*). Hardness and yield strength are variously used as approximations of machinability.

Chemical milling, the removal of metal by chemical attack in an alkaline or acid solution, is routine for specialized reductions in thickness. For complex large surface areas in which uniform metal removal is required, chemical milling is often the most economical method. The process is used extensively to etch preformed aerospace parts to obtain maximum strength-to-weight ratios. Integrally stiffened aluminum wing and fuselage sections are chemically milled to produce an optimum cross section and minimum skin thickness. Spars, stringers, floor beams, and frames are frequent applications as well. See the article "Chemical Milling" in *Machining,* Volume 16 of *ASM Handbook,* formerly 9th Edition *Metals Handbook.* for more information.

Formability is among the more important characteristics of aluminum and many of its alloys. Specific tensile and yield strengths, ductility, and respective rates of work hardening control differences in the amount of permissible deformation.

Ratings of comparable formability of the commercially available alloys in various tempers depend on the forming process, and are described in the article "Forming of Aluminum Alloys" in *Forming and Forging,* Volume 14 of *ASM Handbook,* formerly 9th Edition *Metals Handbook.* Such ratings provide generally reliable comparisons of the working characteristics of metals, but serve as an approximate guide rather than as quantitative formability limits.

Choice of temper may depend on the severity and nature of forming operations. The annealed temper may be required for severe forming operations such as deep drawing, or for roll forming or bending on small radii. Usually, the strongest temper that can be formed consistently is selected. For less severe forming operations, intermediate tempers or even fully hardened conditions may be acceptable.

Heat-treatable alloys can be formed in applications for which a high strength-to-weight ratio is required. The annealed temper of these alloys is the most workable condition, but the effects of dimensional change and distortion caused by subsequent heat treatment for property development, and the straightening or other dimensional control steps that may be required, are important considerations. Alloys that are formed immediately following solution heat treatment and quench (T3, T4, or W temper) are nearly as formable as when annealed, and can be subsequently hardened by natural or artificial aging. Parts can be stored at low temperatures (approximately -30 to -35 °C, or -20 to -30 °F or lower) in the W temper for prolonged periods as a means of inhibiting natural aging and preserving an acceptable level of formability. Material that has been solution heat treated and quenched but not artificially aged (T3, T4, or W temper) is generally suitable only for mild forming operations such as bending, mild drawing, or moderate stretch forming if these operations cannot be performed immediately after quenching. Solution heat-treated and artificially aged (T6 temper) alloys are in general unsuitable for forming operations.

Forgeability. Aluminum alloys can be forged into a variety of shapes and types of forgings with a broad range of final part forging design criteria based on the intended application. Aluminum alloy forgings, particularly closed-die forgings, are usually produced to more highly refined final forging configurations than hot-forged carbon and/or alloy steels. For a given aluminum alloy forging shape, the pressure requirements in forging vary widely, depending primarily on the chemical composition of the alloy being forged, the forging process being employed, the forging strain rate, the type of forging being manufactured, the lubrication conditions, and the forging and die temperatures.

As a class of alloys, aluminum alloys are generally considered to be more difficult to forge than carbon steels and many alloy steels. Compared to the nickel/cobalt-base alloys and titanium alloys, however, aluminum alloys are considerably more forgeable, particularly in conventional forging process technology, in which dies are heated to 540 °C (1000 °F) or less. The factors influencing the forgeability of aluminum alloys as well as applicable forging methods are described in the article "Forging of Aluminum Alloys" in *Forming and Forging,* Volume 14 of *ASM Handbook,* formerly 9th Edition *Metals Handbook.*

Joining. Aluminum can be joined by a wide variety of methods, including fusion and resistance welding, brazing, soldering, adhesive bonding, and mechanical methods such as riveting and bolting. Factors that affect the welding of aluminum include:

- Aluminum oxide coating
- Thermal conductivity
- Thermal expansion coefficient
- Melting characteristics
- Electrical conductivity

Aluminum oxide immediately forms on aluminum surfaces exposed to air. Before aluminum can be welded by fusion methods, the oxide layer must be removed mechanically by machining, filing, wire brushing, scraping, or chemical cleaning. If oxides are not removed, oxide fragments may be entrapped in the weld and will cause a reduction in ductility, a lack of fusion, and possibly weld cracking. During welding, the oxide must be prevented from re-forming by shielding the joint area with a nonoxidizing gas such as argon, helium, or hydrogen, or chemically by use of fluxes.

Thermal conductivity is the physical property that most affects weldability. The thermal conductivity of aluminum alloys is about one-half that of copper and four times that of low-carbon steel. This means that heat must be supplied four times as fast to aluminum alloys as to steel to raise the temperature locally by the same amount. However, the high thermal conductivity of aluminum alloys helps to solidify the molten weld pool of aluminum and, consequently, facilitates out-of-position welding.

The coefficient of linear thermal expansion, which is a measure of the change in length of a material with a change in its temperature, is another physical property of importance when considering weldability. The coefficient of linear thermal expansion for aluminum is twice that for steel. This means that extra care must be taken in welding aluminum to ensure that the joint space remains uniform. This may necessitate preliminary joining of the parts of the assembly by tack welding prior to the main welding operation.

The combination of high coefficient of thermal expansion and high thermal conductivity would cause considerable distortion of aluminum during welding were it not for the high welding speed possible.

Melt Characteristics. The melting ranges for aluminum alloys are considerably lower than those for copper or steel. Melting temperatures and the volumetric specific heats and heats of fusion of aluminum alloys determine that the amount of heat required to enter the welding temperature range is much lower for aluminum alloys.

Electrical conductivity has little influence on fusion welding but is a very important property for materials that are to be resistance welded. In resistance welding, resistance of the metal to the flow of welding current produces heat, which causes the portion of the metal through which the current flows to approach or reach its melting point. Aluminum has higher conductivity than steel, which means that much higher currents are required to produce the same heating effect. Consequently, resistance welding machines for aluminum must have much higher output capabilities than those normally used for steel, for welding comparable sections. More detailed information on welding of aluminum alloys as well as other joining methods can be found in *Welding, Brazing, and Soldering,* Volume 6 of the *ASM Handbook* and in Volume 3, *Adhesives and Sealants,* of the *Engineered Materials Handbook.*

Elwin L. Rooy, Aluminum Company of America

Product Classifications

In the United States the aluminum industry has identified its major markets as building and construction, transportation, consumer durables, electrical, machinery and equipment, containers and packaging, exports, and other end uses. As described below, each of these major markets comprises a wide range of end uses. Figure 8 provides data on annual U.S. shipments of aluminum by major markets. The percentage distribution of these markets is illustrated in Fig. 9.

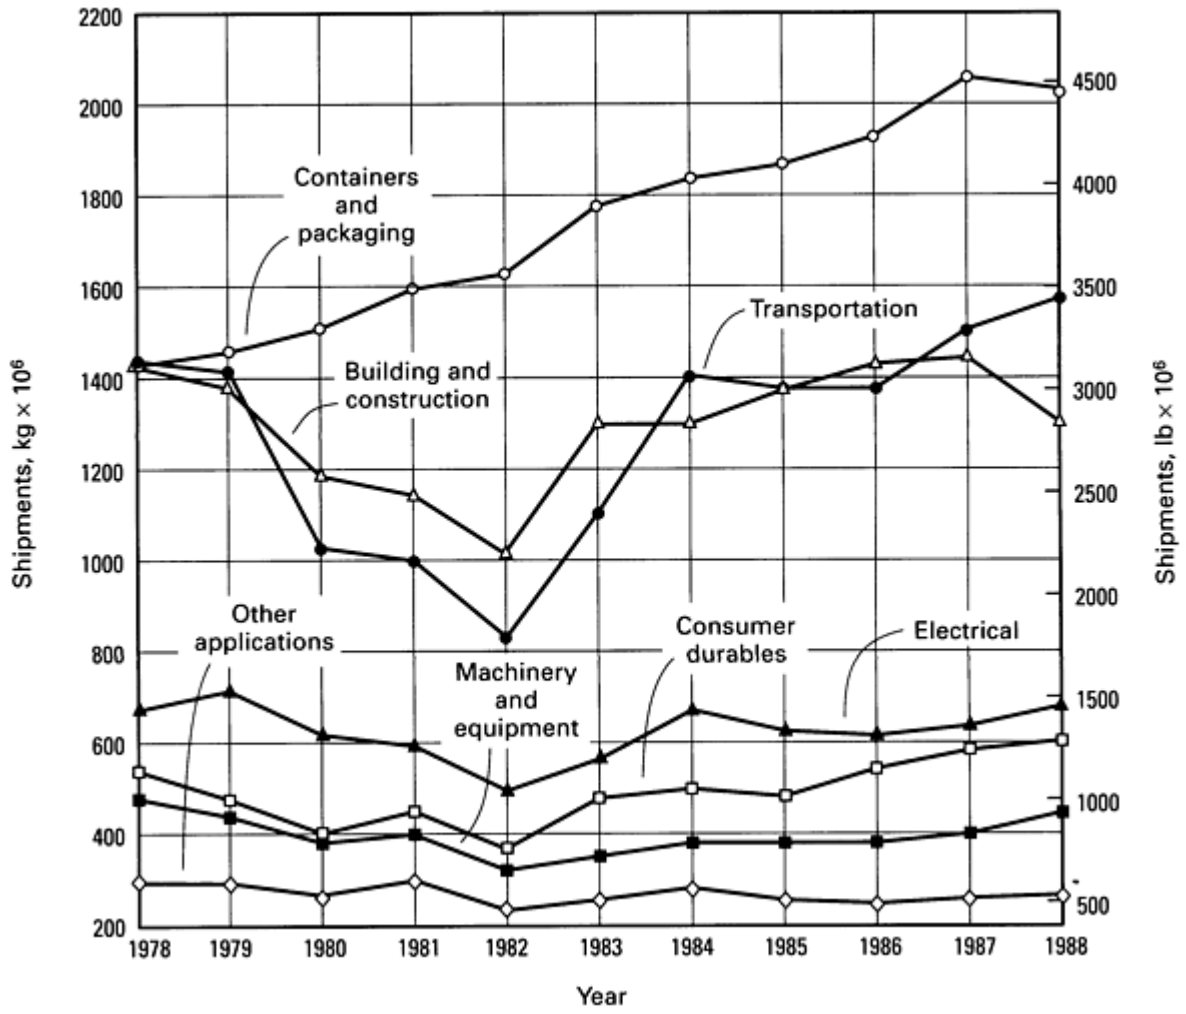

Fig. 8 U.S. net aluminum shipments by major market. Source: Aluminum Association, Inc.

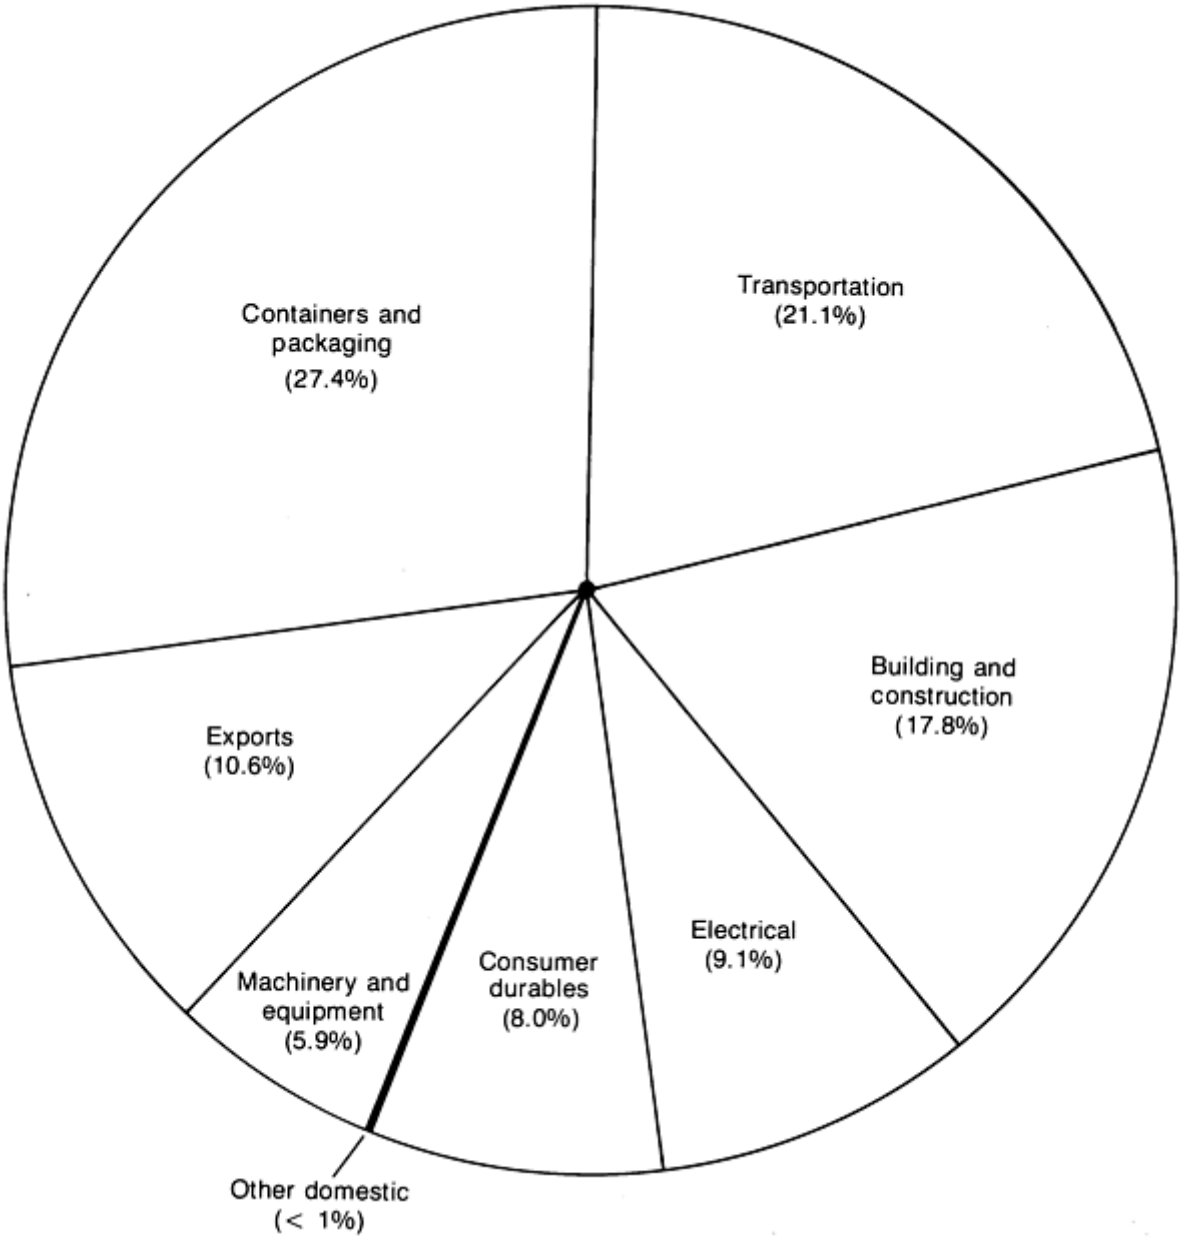

Fig. 9 Percentage distribution of net U.S. aluminum product shipments by major market. Source: Aluminum Association, Inc.

Building and Construction Applications

Aluminum is used extensively in buildings of all kinds, bridges, towers, and storage tanks. Because structural steel shapes and plate are usually lower in initial cost, aluminum is used when engineering advantages, construction features, unique architectural designs, light weight, and/or corrosion resistance are considerations.

Static Structures. Design and fabrication of aluminum static structures differ little from practices used with steel. The modulus of elasticity of aluminum is one-third that of steel and requires special attention to compression members. However, it offers advantages under shock loads and in cases of minor misalignments. When properly designed, aluminum typically saves over 50% of the weight required by low-carbon steel in small structures; similar savings may be possible in long-span or movable bridges. Savings also result from low maintenance costs and in resistance of atmospheric or environmental corrosion.

Forming, shearing, sawing, punching, and drilling are readily accomplished on the same equipment used for fabricating structural steel. Since structural aluminum alloys owe their strength to properly controlled heat treatment, hot forming or

other subsequent thermal operations are to be avoided. Special attention must be given to the strength requirements of welded areas because of the possibility of localized annealing effects.

Buildings. Corrugated or otherwise stiffened sheet products are used in roofing and siding for industrial and agricultural building construction. Ventilators, drainage slats, storage bins, window and door frames, and other components are additional applications for sheet, plate, castings, and extrusions.

Aluminum products such as roofing, flashing, gutters, and downspouts are used in homes, hospitals, schools, and commercial and office buildings. Exterior walls, curtain walls, and interior applications such as wiring, conduit, piping, ductwork, hardware, and railings utilize aluminum in many forms and finishes.

Aluminum is used in bridges and highway accessories such as bridge railings, highway guard rails, lighting standards, traffic control towers, traffic signs, and chain-link fences. Aluminum is also commonly used in bridge structures, especially in long-span or movable bascule and vertical-lift construction. Construction of portable military bridges and superhighway overpass bridges has increasingly relied on aluminum elements.

Scaffolding, ladders, electrical substation structures, and other utility structures utilize aluminum, chiefly in the form of structural and special extruded shapes. Cranes, conveyors, and heavy-duty handling systems incorporate significant amounts of aluminum. Water storage tanks are often constructed of aluminum alloys to improve resistance to corrosion and to provide attractive appearance.

Containers and Packaging

The food and drug industries use aluminum extensively because it is nontoxic, nonadsorptive, and splinter-proof. It also minimizes bacterial growth, forms colorless salts, and can be steam cleaned. Low volumetric specific heat results in economies when containers or conveyors must be moved in and out of heated or refrigerated areas. The nonsparking property of aluminum is valuable in flour mills and other plants subject to fire and explosion hazards. Corrosion resistance is important in shipping fragile merchandise, valuable chemicals, and cosmetics. Sealed aluminum containers designed for air, shipboard, rail, or truck shipments are used for chemicals not suited for bulk shipment.

Packaging has been one of the fastest-growing markets for aluminum. Products include household wrap, flexible packaging and food containers, bottle caps, collapsible tubes, and beverage and food cans. Aluminum foil works well in packaging and for pouches and wraps for foodstuffs and drugs, as well as for household uses.

Beverage cans have been the aluminum industry's greatest success story, and market penetrations by the food can are accelerating. Soft drinks, beer, coffee, snack foods, meat, and even wine are packaged in aluminum cans. Draft beer is shipped in alclad aluminum barrels. Aluminum is used extensively in collapsible tubes for toothpaste, ointments, food, and paints.

Transportation

Automotive. Both wrought and cast aluminum have found wide use in automobile construction (Table 1). Typical aluminum usage per unit of approximately 70 kg (150 lb) is expected to increase dramatically as average fuel economy mandates and emphasis on recycling continue. The most intensive use of aluminum in a passenger car approximates 295 kg (650 lb), defining the present target for further material substitutions. Aluminum sand, die, and permanent mold castings are critically important in engine construction; engine blocks, pistons, cylinder heads, intake manifolds, crankcases, carburetors, transmission housings, and rocker arms are proven components. Brake valves and brake calipers join innumerable other components in car design importance. Cast aluminum wheels continue to grow in popularity. Aluminum sheet is used for hoods, trunk decks, bright finish trim, air intakes, and bumpers. Extrusions and forgings are finding new and extensive uses. Forged aluminum alloy wheels are a premium option.

(a) Extruded rod and bar combined with rolled and continuous cast and rod bar.

(b) Drawn tube combined with extruded pipe and tube.

(c) Shipments to passenger cars cover new domestic automobile production, spare parts, accessories and after-market parts. Shipments for light trucks and vans are included in the trucks and buses classification.

Trucks. Because of weight limitations and a desire to increase effective payloads, manufacturers have intensively employed aluminum in cab, trailer, and truck designs. Sheet alloys are used in truck cab bodies, and dead weight is also reduced using extruded stringers, frame rails, and cross members. Extruded or formed sheet bumpers and forged wheels are usual. Fuel tanks of aluminum offer weight reduction, corrosion resistance, and attractive appearance. Castings and forgings are used extensively in engines and suspension systems.

Truck trailers are designed for maximum payload and operating economy in consideration of legal weight requirements. Aluminum is used in frames, floors, roofs, cross sills, and shelving. Forged aluminum wheels are commonly used. Tanker and dump bodies are made from sheet and/or plate in riveted and welded assemblies.

Mobile homes and travel trailers usually are constructed of aluminum alloy sheet used bare or with mill-applied baked-enamel finish on wood, steel, or extruded aluminum alloy frames.

Bus manufacturers also are concerned with minimizing dead weight. Aluminum sheet, plate, and extrusions are used in body components and bumpers. Forged wheels are common. Engine and structural components in cast, forged, and extruded form are extensively used.

Bearings. Aluminum-tin alloys are used in medium and heavy-duty gasoline and diesel engines for connecting-rod and main bearings. Cast and wrought bearings may be composite with a steel backing and babbited or other plated overlay. Bearing alloys are further discussed in the article "Aluminum Foundry Products" in this Volume.

Railroad Cars. Aluminum is used in the construction of railroad hopper cars, box cars, refrigerator cars, and tank cars (Fig. 10). Aluminum is also used extensively in passenger rail cars, particularly those for mass transit systems.

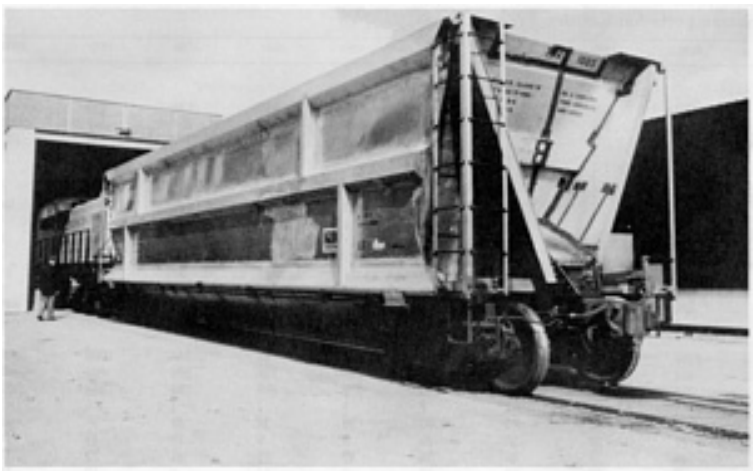

Fig. 10 The intensive use of aluminum in all transportation systems minimizes dead weight and reduces operating and maintenance costs. Courtesy of Alcan International

Marine Applications. Aluminum is commonly used for a large variety of marine applications, including main strength members such as hulls and deckhouses, and other applications such as stack enclosures, hatch covers, windows, air ports, accommodation ladders, gangways, bulkheads, deck plate, ventilation equipment, lifesaving equipment, furniture, hardware, fuel tanks, and bright trim. In addition, ships are making extensive use of welded aluminum alloy plate in the large tanks used for transportation of liquefied gases.

The corrosion-resistant aluminum alloys in current use permit designs that save about 50% of the weight of similar designs in steel. Substantial savings of weight in deckhouses and topside equipment permit lighter supporting structures. The cumulative savings in weight improve the stability of the vessel and allow the beam to be decreased. For comparable speed, the lighter, narrower craft will require a smaller power plant and will burn less fuel. Consequently, 1 kg (2.2 lb) of weight saved by the use of lighter structures or equipment frequently leads to an overall decrease in displaced weight of 3 kg (6.5 lb). Aluminum also reduces maintenance resulting from corrosive or biological attack.

The relatively low modulus of elasticity for aluminum alloys offers advantages in structures erected on a steel hull. Flexure of the steel hull results in low stresses in an aluminum superstructure, as compared with the stresses induced in a similar steel superstructure. Consequently, continuous aluminum deckhouses may be built without expansion joints.

Casting alloys are used in outboard motor structural parts and housings subject to continuous or intermittent immersion, motor hoods, shrouds, and miscellaneous parts, including fittings and hardware. Additional marine applications are in sonobuoys, navigation markers, rowboats, canoes, oars, and paddles.

Aerospace. Aluminum is used in virtually all segments of the aircraft, missile, and spacecraft industry (Fig. 11)--in airframes, engines, accessories, and tankage for liquid fuel and oxidizers. Aluminum is widely used because of its high strength-to density ratio, corrosion resistance, and weight efficiency, especially in compressive designs.

Fig. 11 Aluminum is used extensively in aircraft/aerospace vehicles such as the space shuttle shown in this figure.

Increased resistance to corrosion in salt water and other atmospheres is secured through the use of alclad alloys or anodic coatings. The exterior of aircraft exposed to salt water environment is usually fabricated from clad alloys. Anodized bare stock successfully resists corrosion when only occasional exposure to salt water is encountered. Corrosion resistance may be further enhanced by organic finishes or other protective coatings. Extensive reviews on the uses and corrosion properties of aluminum for aircraft and aerospace vehicles can be found in the articles "Corrosion in the Aircraft Industry" and "Corrosion in the Aerospace Industry" in *Corrosion,* Volume 13 of *ASM Handbook,* formerly 9th Edition *Metals Handbook.*

Electric Applications

Conductor Alloys. The use of aluminum predominates in most conductor applications. Aluminum of controlled composition is treated with trace additions of boron to remove titanium, vanadium, and zirconium, each of which increases resistivity. The use of aluminum rather than competing materials is based on a combination of low cost, high electrical conductivity, adequate mechanical strength, low specific gravity, and excellent resistance to corrosion.

The most common conductor alloy (1350) offers a minimum conductivity of 61.8% of the International Annealed Copper Standard (IACS) and from 55 to 124 MPa (8 to 18 ksi) minimum tensile strength, depending on size. When compared with IACS on a basis of mass instead of volume, minimum conductivity of hard drawn aluminum 1350 is 204.6%. Other alloys are used in bus bar, for service at slightly elevated temperatures, and in cable television installations.

Cable sheathing is achieved by extruding the sheath in final position and dimensions around the cable as it is fed through an axial orifice in the extrusion die. It can also be done by threading the cable through an oversized prefabricated tube and then squeezing the tube to final dimensions around the cable by tube reducers and draw dies.

Conductor accessories may be rolled, extruded, cast, or forged. Common forms of aluminum conductors are single wire and multiple wire (stranded, bunched, or rope layed). Each is used in overhead or other tensioned applications, as well as in nontensioned insulated applications.

Size for size, the direct current resistance of the most common aluminum conductor is from about 1.6 to 2.0 times IACS. For equivalent direct-current resistance, an aluminum wire that is two American Wire Gage sizes larger than copper wire must be used. Nevertheless, as a result of the lower specific gravity, the conductivity-based aluminum required weighs only about half as much as an equivalent copper conductor.

Aluminum conductors, steel reinforced (ACSR) consist of one or more layers of concentric-lay stranded aluminum wire around a high-strength galvanized or aluminized steel wire core, which itself may be a single wire or a group of concentric-lay strands. Electrical resistance is determined by the aluminum cross section, whereas tensile strength is determined on the composite with the steel core providing 55 to 60% of the total strength.

The ACSR construction is used for mechanical strength. Strength-to-weight ratio is usually about two times that of copper of equivalent direct-current resistance. Use of ACSR cables permits longer spans and fewer or shorter poles or towers.

Bus Bar Conductors. Commercial bus design in the United States utilizes four types of bus conductors: rectangular bar, solid round bar, tubular, and structural shapes.

Motors and Generators. Aluminum has long been used for cast rotor windings and structural parts. Rotor rings and cooling fans are pressure cast integrally with bars through slots of the laminated core in caged motor rotors.

Aluminum structural parts, such as stator frames and end shields, are often economically die cast. Their corrosion resistance may be necessary in specific environments--in motors for spinning natural and synthetic fiber, and in aircraft generators when light weight is equally important, for example.

Additional applications are field coils for direct-current machines, stator windings in motors, and transformer windings. Alloyed wire is used in extremely large turbogenerator field coils, where operating temperatures and centrifugal forces might otherwise result in creep failure.

Transformers. Aluminum windings have been extensively used in dry-type power transformers and have been adapted to secondary coil windings in magnetic-suspension type constant-current transformers. Their use decreases weight and permits the coil to float in electromagnetic suspension. In a closely associated application, aluminum is being used in concrete reactor devices that protect transformers from overloads.

Extruded shapes and punched sheet are used in radar antennas, extruded and roll-formed tubing in television antennas, rolled strips in coiled line traps; drawn or impact-extruded cans in condensers and shields, and vaporized high-purity coatings in cathode-ray tubes.

Examples of applications in which electrical properties other than magnetic are not dominant are chassis for electronic equipment, spun pressure receptacles for airborne equipment, etched name plates, and hardware such as bolts, screws, and nuts. In addition, finned shapes are used in electronic components to facilitate heat removal. Aluminum may be used as the cell base for the deposition of selenium in the manufacture of selenium rectifiers.

Lighting. Aluminum in incandescent and fluorescent lamp bases and other sheet alloys for sockets are established uses. Cast, stamped, and spun parts are used, often artistically, in table, floor, and other lighting fixtures. Aluminum reflector is common in fluorescent and other installed lighting systems.

Capacitors. Aluminum in the form of foil dominates all other metals in the construction of capacitor electrodes. Dry electrolytic and nonelectrolytic capacitors are the basic condenser types in extensive commercial use. Dry electrolytic capacitors usually employ parallel coiled or wrapped aluminum foil ribbons as electrodes. Paper saturated with an operative electrolyte, wrapped into the coil, mechanically separates the ribbons. In designs for intermittent use in alternating circuits, both electrodes are anodized in a hot boric acid electrolyte. The resulting thin anodic films constitute the dielectric element.

Only the anode foil is anodized in dry electrolytic assemblies intended for direct-current applications. Anodized electrodes are of high purity, whereas the nonanodized electrodes utilize foil ribbons of lower purity. Prior to anodizing the foil is usually, but not always, etched to increase effective surface area. Containers for dry electrolytic capacitors may be either drawn or impact extruded.

Ordinary clean foil ribbons serve as electrodes in commercial nonelectrolytic capacitors. Oil-impregnated paper separates the electrodes and adjacent coils of the wrap. Nonelectrolytic foil assemblies are packed in either aluminum alloy or steel cans.

Consumer Durables

Household Appliances. Light weight, excellent appearance, adaptability to all forms of fabrication, and low cost of fabrication are the reasons for the broad usage of aluminum in household electrical appliances. Light weight is an important characteristic in vacuum cleaners, electric irons, portable dishwashers, food processors, and blenders. Low fabricating costs depend on several properties, including adaptability to die casting and ease of finishing. Because of a naturally pleasing appearance and good corrosion resistance, expensive finishing is not necessary.

In addition to its other desirable characteristics aluminum's brazeability makes it useful for refrigerator and freezer evaporators. Tubing is placed on embossed sheet over strips of brazing alloy with a suitable flux. The assembly is then furnace brazed and the residual flux removed by successive washes in boiling water, nitric acid, and cold water. The result is an evaporator with high thermal conductivity and efficiency, good corrosion resistance, and low manufacturing cost.

With the exception of a few permanent mold parts, virtually all aluminum castings in electrical appliances are die cast. Cooking utensils may be cast, drawn, spun, or drawn and spun from aluminum. Handles are often joined to the utensil by riveting or spot welding. In some utensils, an aluminum exterior is bonded to a stainless steel interior; in others, the interior is coated with porcelain or Teflon. Silicone resin, Teflon, or other coatings enhance the utility of heated aluminum utensils. Many die castings in appliances are internal functional parts and are used without finish. Organic finishes are usually applied to external die-cast parts such as appliance housings.

Wrought forms fabricated principally from sheet, tube, and wire are used in approximately the same quantities as die castings. Wrought alloys are selected on the basis of corrosion resistance, anodizing characteristics, formability, or other engineering properties.

The natural colors some alloys assume after anodizing are extremely important for food-handling equipment. Applications include refrigerator vegetable/meat pans, ice cube trays, and wire shelves. In the production of wire shelves, full-hard wire is cold headed over extruded strips, which form the borders.

Furniture. Light weight, low maintenance, corrosion resistance, durability, and attractive appearance are the principal advantages of aluminum in furniture.

Chair bases, seat frames, and arm rests are cast, drawn or extruded tube (round, square, or rectangular), sheet, or bar. Frequently, these parts are formed in the annealed or partially heat-treated tempers, and are subsequently heat treated and aged. Designs are generally based on service requirements; however, styling often dictates overdesign or inefficient sections. Fabrication is conventional; joining is usually by welding or brazing. Various finishing procedures are used: mechanical, anodic, color anodized, anodized and dyed, enamel coated, or painted.

Tubular sections, usually round and frequently formed and welded from flat strip, are the most popular form of aluminum for lawn furniture. Conventional tube bending and mechanically fitted joints may be used. Finishing is usually by grinding and buffing and is frequently followed by clear lacquer coating.

Machinery and Equipment

Processing Equipment. In the petroleum industry, aluminum tops are used on steel storage tanks, exteriors are covered with aluminum pigmented paint, and aluminum pipelines are carriers of petroleum products. Aluminum is used extensively in the rubber industry because it resists all corrosion that occurs in rubber processing and is nonadhesive. Aluminum alloys are widely used in the manufacture of explosives because of their nonpyrophoric characteristics. Strong oxidants are processed, stored, and shipped in aluminum systems. Aluminum is especially compatible with sulfur, sulfuric acid, sulfides, and sulfates, In the nuclear energy industry, aluminum-jacketed fuel elements protect uranium from water corrosion, prevent the entry of reaction products into the cooling water, transfer heat efficiently from uranium to water, and contribute to minimizing parasitic capture of neutrons. Aluminum tanks are used to contain heavy water. The use of aluminum for each of the aforementioned industries is described in more detail in *Corrosion,* of Volume 13 *ASM Handbook,* formerly 9th Edition *Metals Handbook.*

Textile Equipment. Aluminum is used extensively in textile machinery and equipment in the form of extrusions, tube, sheet, castings, and forgings. It is resistant to many corrosive agents encountered in textile mills and in the manufacture of yarns. A high strength-to-weight ratio reduces the inertia of high-speed machine parts. Permanent dimensional accuracy with light weight improves the dynamic balance of machine members running at high speeds, and reduces vibration. Painting is usually unnecessary. Spool beamheads and cores are usually permanent mold castings and extruded or welded tube, respectively.

Paper and Printing Industries. An interesting application of aluminum is found in returnable shipping cores. Cores may be reinforced with steel end-sleeves which also constitute wear-resistant drive elements. Processing or rewinding cores are fabricated of aluminum alloys. Fourdrinier or table rolls for papermaking machines are also of aluminum construction.

Curved aluminum sheet printing plates permit higher rotary-press speeds and minimize misregister by decreasing centrifugal force. Aluminum lithographic sheet offers exceptional reproduction in mechanical and electrograined finishes.

Coal Mine Machinery. The use of aluminum equipment in coal mines has increased in recent years. Applications include cars, tubs and skips, roof props, nonsparking tools, portable jacklegs, and shaking conveyors. Aluminum is resistant to the corrosive conditions associated with surface and deep mining. Aluminum is self cleaning and offers good resistance to abrasion, vibration, splitting, and tearing.

Portable Irrigation Pipe and Tools. Aluminum is extensively used in portable sprinkler and irrigation systems. Portable tools use large quantities of aluminum in electric and gas motors and motor housings. Precision cast housings and engine components, including pistons, are used for power drills, power saws, gasoline-driven chain saws, sanders, buffing machines, screwdrivers, grinders, power shears, hammers, various impact tools, and stationary bench tools. Aluminum alloy forgings are found in many of the same applications and in manual tools such as wrenches and pliers.

Jigs, Fixtures, and Patterns. Thick cast or rolled aluminum plates and bar, precisely machined to high finish and flatness, are used for tools and dies. Plate is suitable for hydropress form blocks, hydrostretch form dies, jigs, fixtures, and other tooling. Aluminum is used in the aircraft industry for drill jigs, as formers, stiffeners and stringers for large assembly jigs, router bases, and layout tables. Used in master tooling, cast aluminum eliminates warpage problems resulting from uneven expansion of the tool due to changes in ambient temperature. Large aluminum bars have been used to replace zinc alloys as a fixture base on spar mills with weight savings of two-thirds. Cast aluminum serves as matchplate in the foundry industry.

Instruments. On the basis of combinations of strength and dimensional stability, aluminum alloys are used in the manufacture of optical, telescopic, space guidance, and other precision instruments and devices. To assure dimensional accuracy and stability in manufacturing and assembling parts for such equipment, additional thermal stress-relief treatments are sometimes applied at stages of machining, or after welding or mechanical assembly.

Other Applications

Reflectors. Reflectivity of light is as high as 95% on especially prepared surfaces of high-purity aluminum. Aluminum is generally superior to other metals in its ability to reflect infrared or heat rays. It resists tarnish from sulfides, oxides, and atmospheric contaminants, and has three to ten times the useful life of silver for mirrors in searchlights, telescopes, and similar reflectors. Heat reflectivity may be as much as 98% for a high polished surface. Performance is reduced only slightly as the metal weathers and loses its initial brilliance. When maximum reflectivity is desired, chemical or electrochemical brightening treatments are used; quick anodic treatment usually follows, sometimes finished by a coat of clear lacquer. Reflectors requiring less brightness may simply be buffed and lacquered. Etching in a mild caustic solution produces a diffuse finish, which may also be protected by clear lacquer, an anodic coating, or both.

Powders and Pastes. The addition of aluminum flakes to paint pigments exploits the intrinsic advantages of high reflectance, durability, low emissivity, and minimum moisture penetration. Other applications for powders and pastes include printing inks, pyrotechnics, floating soap, aerated concrete, thermite welding, and energy-enhancing fuel additives. Additional information can be found in *Powder Metal Technologies and Applications*, Volume 7 of the *ASM Handbook.*

Anode Materials. Highly electronegative aluminum alloys are routinely employed as sacrificial anodes, generally on steel structures or vessels such as pipelines, offshore construction, ships, and tank storage units. See the article "Cathodic Protection" in *Corrosion,* Volume 13 of *ASM Handbook,* formerly 9th Edition *Metals Handbook.* for additional information.

Alloy and Temper Designation Systems for Aluminum and Aluminum Alloys

R.B.C. Cayless, Alcan Rolled Products Company

Introduction

SYSTEMS FOR DESIGNATING aluminum and aluminum alloys that incorporate the product form (wrought, casting, or foundry ingot), and its respective temper (with the exception of foundry ingots, which have no temper classification) are covered by American National Standards Institute (ANSI) standard H35.1. The Aluminum Association is the registrar under ANSI H35.1 with respect to the designation and composition of aluminum alloys and tempers registered in the United States.

Wrought Aluminum and Aluminum Alloy Designation System

A four-digit numerical designation system is used to identify wrought aluminum and aluminum alloys. As shown below, the first digit of the four-digit designation indicates the group:

Aluminum, ≥ 99.00%	1*xxx*
Aluminum alloys grouped by major alloying element(s): Copper	2*xxx*
Manganese	3*xxx*
Silicon	4*xxx*
Magnesium	5*xxx*
Magnesium and silicon	6*xxx*
Zinc	7*xxx*
Other elements	8*xxx*
Unused series	9*xxx*

For the 2*xxx* through 7*xxx* series, the alloy group is determined by the alloying element present in the greatest mean percentage. An exception is the 6*xxx* series alloys in which the proportions of magnesium and silicon available to form magnesium silicide (Mg_2Si) are predominant. Another exception is made in those cases in which the alloy qualifies as a modification of a previously registered alloy. If the greatest mean percentage is the same for more than one element, the choice of group is in order of group sequence: copper, manganese, silicon, magnesium, magnesium silicide, zinc, or others.

Aluminum. In the 1*xxx* group, the series 10*xx* is used to designate unalloyed compositions that have natural impurity limits. The last two of the four digits in the designation indicate the minimum aluminum percentage. These digits are the same as the two digits to the right of the decimal point in the minimum aluminum percentage when expressed to the nearest 0.01%. Designations having second digits other than zero (integers 1 through 9, assigned consecutively as needed) indicate special control of one or more individual impurities.

Aluminum Alloys. In the 2*xxx* through 8*xxx* alloy groups, the second digit in the designation indicates alloy modification. If the second digit is zero, it indicates the original alloy; integers 1 through 9, assigned consecutively, indicate modifications of the original alloy. Explicit rules have been established for determining whether a proposed composition is merely a modification of a previously registered alloy or if it is an entirely new alloy. The last two of the four digits in the 2*xxx* through 8*xxx* groups have no special significance, but serve only to identify the different aluminum alloys in the group.

Cast Aluminum and Aluminum Alloy Designation System

A system of four-digit numerical designations incorporating a decimal point is used to identify aluminum and aluminum alloys in the form of castings and foundry ingot. The first digit indicates the alloy group:

Aluminum, ≥ 99.00%	1*xx.x*
Aluminum alloys grouped by major alloying element(s): Copper	2*xx.x*
Silicon, with added copper and/or magnesium	3*xx.x*
Silicon	4*xx.x*
Magnesium	5*xx.x*
Zinc	7*xx.x*
Tin	8*xx.x*
Other elements	9*xx.x*
Unused series	6*xx.x*

For 2*xx.x* though 8*xx.x* alloys, the alloy group is determined by the alloying element present in the greatest mean percentage, except in cases in which the composition being registered qualifies as a modification of a previously registered alloy. If the greatest mean percentage is common to more than one alloying element, the alloy group is determined by the element that comes first in the sequence.

The second two digits identify the specific aluminum alloy or, for the aluminum (1*xx.x*) series, indicate purity. The last digit, which is separated from the others by a decimal point, indicates the product form, whether casting or ingot. A modification of an original alloy, or of the impurity limits for unalloyed aluminum, is indicated by a serial letter preceding the numerical designation. The serial letters are assigned in alphabetical sequence starting with A but omitting I, O, Q, and X, the X being reserved for experimental alloys. Explicit rules have been established for determining whether a proposed composition is a modification of an existing alloy or if it is a new alloy.

Aluminum Castings and Ingot. For the 1*xx.x* group, the second two of the four digits in the designation indicate the minimum aluminum percentage. These digits are the same as the two digits to the right of the decimal point in the minimum aluminum percentage when expressed to the nearest 0.01%. The last digit indicates the product form: 1*xx.*0 indicates castings, and 1*xx.*1 indicates ingot.

Aluminum Alloy Castings and Ingot. For the 2*xx.x* through 9*xx.x* alloy groups, the second two of the four digits in the designation have no special significance but serve only to identify the different alloys in the group. The last digit, which is to the right of the decimal point, indicates the product form: *xxx.*0 indicates castings, and *xxx.*1 indicates ingot having limits for alloying elements the same as those for the alloy in the form of castings, except for those listed in Table 1.

Table 1 Alloying element and impurity specifications for ingots that will be remelted into sand, permanent mold, and die castings

Alloying element	**Composition, wt%**			
	Casting			**Ingot**
	Sand and permanent mold	**Die**	**All**	
Iron	≤ 0.15	. . .	. . .	Casting -0.03
	>0.15-0.25	. . .	. . .	Casting -0.05
	>0.25-0.6	. . .	. . .	Casting -0.10
	>0.6-1.0	. . .	. . .	Casting -0.2

	>1.0	. . .	. . .	Casting -0.3
	. . .	≤ 1.3	. . .	Casting -0.3
	. . .	>1.3	. . .	≤ 1.1
Magnesium	. . .	. . .	<0.50	Casting +0.05[(a)]
	. . .	. . .	≥ 0.50	Casting +0.1[(a)]
Zinc	. . .	>0.25 to 0.60	. . .	Casting -0.10
	. . .	>0.60	. . .	Casting -0.1

Source: Ref 1

(a) Applicable only when the specified range for castings is >0.15% Mg.

Designations for Experimental Alloys

Experimental alloys also are designated in accordance with the systems for wrought and cast alloys, but they are indicated by the prefix X. The prefix is dropped when the alloy is no longer experimental. During development and before they are designated as experimental, new alloys may be identified by serial numbers assigned by their originators. Use of the serial number is discontinued when the ANSI H35.1 designation is assigned.

Cross-Referencing of Aluminum and Aluminum Alloy Products

Tables 2 and 3 cross-reference aluminum wrought and ingot/cast products according to composition, per Aluminum Association, Unified Numbering System (UNS), and International Organization for Standardization (ISO) standards.

Table 2 Composition of wrought unalloyed aluminum and wrought aluminum alloys

Source: Ref 3, 4, 5

(a) Serial letter prefix indicates modification: A, B, C, D, and F.

(b) Per ISO standard No. R115 unless other standard (R164, R2147, or 3522) specified.

(c) D, die casting; P, permanent mold; s, sand. Other products may pertain to the composition shown even though not listed.

(d) The Al content for unalloyed aluminum by remelt is the difference between 100.00% and the sum of all other metallic elements present in amounts of 0.010% or more each, expressed to the second decimal before determining the sum.

(e) (Mn + Cr + Ti + V) = 0.0 25% max.

(f) Fe/Si ratio 2.5 min.

(g) Fe/Si ratio 2.0 min.

(h) Fe/Si ratio 1.5 min.

(i) 0.40 to 1.0% Ag.

(j) 0.50-1.0% Ag.

(k) Ti + Zr = 0.50 max.

(l) 0.20 to 0.30% Sb; 0.20 to 0.30% Co; 0.10 to 0.30% Zr.

(m) 0.05-0.15% V; 0.10-0.25% Zr.

(n) 0.06-0.20% V.

(o) For Fe > 0.45%, Mn content shall not be less than one-half Fe content.

(p) 0.04-0.07% Be.

(q) 0.10-0.30% Be.

(r) 0.15-0.30% Be.

(s) A*xxx*.1 ingot is used to produce *xxx*.0 and A*xxx*.0 castings.

(t) (Mn + Cr) = 0.08% max.

(u) 0.25% Pb max.

(v) 0.02-0.04% Be.

(w) 0.08-0.15% V.

(x) Use to coat steel.

(y) Use with Zn to coat steel.

(z) 0.10% Pb max.

(aa) 0.003-0.007% Be; 0.005% B max.

(bb) 0.003-0.007% B; 0.002% B max

Unified Numbering Systems. UNS numbers correlate many nationally used numbering systems currently administered by societies, trade associations, and individual users and producers of metals and alloys.

Aluminum Association International Alloy Designations. For wrought aluminum and aluminum alloys only, compositions may be registered with the Aluminum Association by number of foreign organizations. These organizations are signatories of a Declaration of Accord on the Recommendation for an International Designation System for Wrought Aluminum and Wrought Aluminum Alloys. In addition to the United States, the countries represented by signatories are Argentina, Australia, Austria, Belgium, Brazil, Denmark, Finland, France, Germany, Italy, Japan, Netherlands, Norway, Spain, Sweden, Switzerland, South Africa, and the United Kingdom. The European Aluminum Association is also a signatory.

Under ANSI standard H35.1, wrought aluminum or aluminum alloys will be registered in decreasing priority as national variations, as modifications, or as a new four-digit number. A national variation that has composition limits very close but not identical to those registered by another country is identified by a serial letter following the numerical designation.

Castings and Foundry Alloys. There is no similar international accord for these aluminum or aluminum alloy products.

Foreign Alloy Designations. Historically, all major industrialized countries developed their own standard designations for aluminum and aluminum alloys. These are now being grouped under systems of the American National Standards Institute, the International Organization for Standardization, and the European Committee for Standardization.

The International Organization for Standardization has developed its own alphanumeric designation system for wrought aluminum and its alloys, based on the systems that have been used by certain European countries. The main addition element is distinguished by specifying the required content (middle of range) rounded off to the nearest 0.5:

5052 = Al Mg2.5

5251 = Al Mg2

If required, the secondary addition elements are distinguished by specifying the required content rounded off to the nearest 0.1, for two elements at most:

6181 = Al Si1Mg0.08

The chemical symbols for addition elements should be limited to four:

7050 = Al Zn6CuMgZr

If an alloy cannot otherwise be distinguished, a suffix in brackets is used:

6063 = Al Mg0.7Si

6463 = Al Mg0.7Si(B)

and international alloy registration

6063A = Al Mg0.7Si(A)

Note that suffixes (A), (B), and so on, should not be confused with suffixes of the Aluminum Association.

The proposed ISO chemical composition standard for aluminum and its alloys references Aluminum Association equivalents as well as its own identification system. A listing of these is given in Table 4.

European Committee for Standardization. This committee (Comité Européen de Normalisation, CEN) of European Common Market members has developed a composition standard based on the ISO standard, but is proposing new designations not included in that standard. Some of these new designations are already registered as German (Deutsche Industrial-Normen, DIN) standards. The proposed standard also references Aluminum Association equivalents.

Temper Designation System for Aluminum and Aluminum Alloys

The temper designation system used in the United States for aluminum and aluminum alloys is used for all product forms (both wrought and cast), with the exception of ingot. The system is based on the sequences of mechanical or thermal treatments, or both, used to produce the various tempers. The temper designation follows the alloy designation and is separated from it by a hyphen. Basic temper designations consist of individual capital letters. Major subdivisions of basic tempers, where required, are indicated by one or more digits following the letter. These digits designate specific sequences of treatments that produce specific combinations of characteristics in the product. Variations in treatment conditions within major subdivisions are identified by additional digits. The conditions during heat treatment (such as time, temperature, and quenching rate) used to produce a given temper in one alloy may differ from those employed to produce the same temper in another alloy.

Basic Temper Designations

Designations for the common tempers, and descriptions of the sequences of operations used to produce these tempers, are given in the following paragraphs.

F, As-Fabricated. This is applied to products shaped by cold working, hot working, or casting processes in which no special control over thermal conditions or strain hardening is employed. For wrought products, there are no mechanical property limits.

O, Annealed. O applies to wrought products that are annealed to obtain lowest-strength temper and to cast products that are annealed to improve ductility and dimensional stability. The O may be followed by a digit other than zero.

H, Strain-Hardened (Wrought Products Only). This indicates products that have been strengthened by strain hardening, with or without supplementary thermal treatment to produce some reduction in strength. The H is always followed by two or more digits, as discussed in the section "System for Strain-Hardened Products" in this article.

W, Solution Heat-Treated. This is an unstable temper applicable only to alloys whose strength naturally (spontaneously) changes at room temperature over a duration of months or even years after solution heat treatment. The designation is specific only when the period of natural aging is indicated (for example, W $\frac{1}{2}$h). See also the discussion of the T*x*51, T*x*52, and T*x*54 tempers in the section "System for Heat-Treatable Alloys" in this article.

T, Solution Heat-Treated. This applies to alloys whose strength is stable within a few weeks of solution heat treatment. The T is always followed by one or more digits, as discussed in the section "System for Heat-Treatable Alloys" in this article.

System for Strain-Hardened Products

Temper designations for wrought products that are strengthened by strain hardening consist of an H followed by two or more digits. The first digit following the H indicates the specific sequence of basic operations.

H1, Strain-Hardened Only. This applies to products that are strain hardened to obtain the desired strength without supplementary thermal treatment. The digit following the H1 indicates the degree of strain hardening.

H2, Strain-Hardened and Partially Annealed. This pertains to products to products that are strain-hardened more than the desired final amount and then reduced in strength to the desired level by partial annealing. The digit following the H2 indicates the degree of strain hardening remaining after the product has been partially annealed.

H3, Strain-Hardened and Stabilized. This applies to products that are strain-hardened and whose mechanical properties are stabilized by a low-temperature thermal treatment or as a result of heat introduced during fabrication. Stabilization usually improves ductility. This designation applies only to those alloys that, unless stabilized, gradually age soften at room temperature. The digit following the H3 indicates the degree of strain hardening remaining after stabilization.

Additional Temper Designations. For alloys that age soften at room temperature, each H2*x* temper has the same minimum ultimate tensile strength as the H3*x* temper with the same second digit. For other alloys, each H2*x* temper has the same minimum ultimate tensile strength as the H1*x* with the same second digit, and slightly higher elongation.

The digit following the designations H1, H2, and H3, which indicates the degree of strain hardening, is a numerical from 1 through 9. Numeral 8 indicates tempers with ultimate tensile strength equivalent to that achieved by about 75% cold reduction (temperature during reduction not to exceed 50 °C, or 120 °F) following full annealing. Tempers between 0 (annealed) and 8 are designated by numerals 1 through 7. Material having an ultimate tensile strength approximately midway between that of the 0 temper and the 8 temper is designated by the numeral 4, midway between the 0 and 4 tempers by the numeral 2, and midway between the 4 and 8 tempers by the numeral 6. Numeral 9 designates tempers whose minimum ultimate tensile strength exceeds that of the 8 temper by 10 MPa (2 ksi) or more. For two-digit H tempers whose second digits are odd, the standard limits for strength are the arithmetic mean of the standard limits for the adjacent two-digit H tempers whose second digits are even.

For alloys that cannot be sufficiently cold-reduced to establish an ultimate tensile strength applicable to the 8 temper (75% cold reduction after full annealing), the 6-temper tensile strength may be established by cold reduction of approximately 55% following full annealing, or the 4-temper tensile strength may be established by cold reduction of approximately 35% after full annealing.

When it is desirable to identify a variation of a two-digit H temper, a third digit (from 1 to 9) may be assigned. The third digit is used when the degree of control of temper or the mechanical properties are different from but close to those for the two-digit H temper designation to which it is added, or when some other characteristic is significantly affected. The minimum ultimate tensile strength of a three-digit H temper is at least as close to that of the corresponding two-digit H temper as it is to either of the adjacent two-digit H tempers. Products in H tempers whose mechanical properties are below those of H*x*1 tempers are assigned variations of H*x*1. Some three-digit H temper designations have already been assigned for wrought products in all alloys:

Hx11 applies to products that incur sufficient strain hardening after final annealing to fail to qualify as 0 temper, but not so much or so consistent an amount of strain hardening to qualify as *Hx1* temper.

H112 pertains to products that may acquire some strain hardening during working at elevated temperature and for which there are mechanical property limits.

Patterned or Embossed Sheet. Table 5 lists the three-digit H temper designations that have been assigned to patterned or embossed sheet.

System for Heat-Treatable Alloys

The temper designation system for wrought and cast products that are strengthened by heat treatment employs the W and T designations described in the section "Basic Temper Designations" in this article. The W designation denotes an unstable temper, whereas the T designation denotes a stable temper other than F, O, or H. The T is followed by a number from 1 to 10, each number indicating a specific sequence of basic treatments.

T1, Cooled From an Elevated-Temperature Shaping Process and Naturally Aged to Substantially Stable Condition. This designation applies to products that are not cold worked after an elevated-temperature shaping process such as casting or extrusion and for which mechanical properties have been stabilized by room-temperature aging. It also applies to products are flattened or straightened after cooling from the shaping process, for which the effects of the cold work imparted by flattening or straightening are not accounted for in specified property limits.

T2, Cooled From an Elevated-Temperature Shaping Process, Cold Worked, and Naturally Aged to a Substantially Stable Condition. This variation refers to products that are cold worked specifically to improve strength after cooling from a hot-working process such as rolling or extrusion and for which mechanical properties have been stabilized by room-temperature aging. It also applies to products in which the effects of cold work, imparted by flattening or straightening, are accounted for in specified property limits.

T3, Solution Heat Treated, Cold Worked, and Naturally Aged to a Substantially Stable Condition. T3 applies to products that are cold worked specifically to improve strength after solution heat treatment and for which mechanical properties have been stabilized by room-temperature aging. It also applies to products in which the effects of cold work, imparted by flattening or straightening, are accounted for in specified property limits.

T4, Solution Heat Treated and Naturally Aged to a Substantially Stable Condition. This signifies products that are not cold worked after solution heat treatment and for which mechanical properties have been stabilized by room-temperature aging. If the products are flattened or straightened, the effects of the cold work imparted by flattening or straightening are not accounted for in specified property limits.

T5, Cooled From an Elevated-Temperature Shaping Process and Artificially Aged. T5 includes products that are not cold worked after an elevated-temperature shaping process such as casting or extrusion and for which mechanical properties have been substantially improved by precipitation heat treatment. If the products are flattened or straightened after cooling from the shaping process, the effects of the cold work imparted by flattening or straightening are not accounted for in specified property limits.

T6, Solution Heat Treated and Artificially Aged. This group encompasses products that are not cold worked after solution heat treatment and for which mechanical properties or dimensional stability, or both, have been substantially improved by precipitation heat treatment. If the products are flattened or straightened, the effects of the cold work imparted by flattening or straightening are not accounted for in specified property limits.

T7, Solution Heat Treated and Overaged or Stabilized. T7 applies to wrought products that have been precipitation heat treated beyond the point of maximum strength to provide some special characteristic, such as enhanced resistance to stress-corrosion cracking or exfoliation corrosion. It applies to cast products that are artificially aged after solution heat treatment to provide dimensional and strength stability.

T8, Solution Heat Treated, Cold Worked, and Artificially Aged. This designation applies to products that are cold worked specifically to improve strength after solution heat treatment and for which mechanical properties or

dimensional stability, or both, have been substantially improved by precipitation heat treatment. The effects of cold work, including any cold work imparted by flattening or straightening, are accounted for in specified property limits.

T9, Solution Heat Treated, Artificially Aged, and Cold Worked. This grouping is comprised of products that are cold worked specifically to improve strength after they have been precipitation heat treated.

T10, Cooled From an Elevated-Temperature Shaping Process, Cold Worked, and Artificially Aged. T10 identifies products that are cold worked specifically to improve strength after cooling from a hot-working process such as rolling or extrusion and for which mechanical properties have been substantially improved by precipitation heat treatment. The effects of cold work, including any cold work imparted by flattening or straightening, are accounted for in specified property limits.

Additional T Temper Variations. When it is desirable to identify a variation of one of the ten major T tempers described above, additional digits, the first of which cannot be zero, may be added to the designation.

Specific sets of additional digits have been assigned to stress-relieved wrought products:

Stress Relieved by Stretching, Compressing, or Combination of Stretching and Compressing. This designation applies to the following products when stretched to the indicated amounts after solution heat treatment or after cooling from an elevated-temperature shaping process:

Product form	Permanent set, %
Plate	$1\frac{1}{2}$-3
Rod, bar, shapes, and extruded tube	1-3
Drawn tube	$\frac{1}{2}$-3

- T*x*51 applies specifically to plate, to rolled or cold-finished rod and bar, to die or ring forgings, and to rolled rings. These products receive no further straightening after stretching
- T*x*510 applies to extruded rod, bar, shapes and tubing, and to drawn tubing. Products in this temper receive no further straightening after stretching
- T*x*511 refers to products that may receive minor straightening after stretching to comply with standard tolerances

This variation involves stress relief by compressing.

- T*x*52 applies to products that are stress relieved by compressing after solution heat treatment or after cooling from a hot-working process to produce a permanent set of 1 to 5%

The next designation is used for products that are stress relieved by combining stretching and compressing.

- T*x*54 applies to die forgings that are stress relieved by restriking cold in the finish die. (These same digits--and 51, 52, and 54--may be added to the designation W to indicate unstable solution-heat-treated

and stress-relieved tempers)

Temper designations have been assigned to wrought products heat treated from the O or the F temper to demonstrate response to heat treatment:

- T42 means solution heat treated from the O or the F temper to demonstrate response to heat treatment and naturally aged to a substantially stable condition
- T62 means solution heat treated from the O or the F temper to demonstrate response to heat treatment and artificially aged

Temper designations T42 and T62 and also may be applied to wrought products heat treated from any temper by the user when such heat treatment results in the mechanical properties applicable to these tempers.

System for Annealed Products

A digit following the "O" indicates a product in annealed condition having special characteristics. For example, for heat-treatable alloys, O1 indicates a product that has been heat treated at approximately the same time and temperature required for solution heat treatment and then air cooled to room temperature; this designation applies to products that are to be machined prior to solution heat treatment by the user. Mechanical property limits are not applicable.

Designation of Unregistered Tempers

The letter P has been assigned to denote H, T, and O temper variations that are negotiated between manufacturer and purchaser. The letter P follows the temper designation that most nearly pertains. The use of this type of designation includes situations where:

- The use of the temper is sufficiently limited to preclude its registration
- The test conditions are different from those required for registration with the Aluminum Association
- The mechanical property limits are not established on the same basis as required for registration with the Aluminum Association

Foreign Temper Designations

Unlike the agreement relating to wrought alloy designations, there is no Declaration of Accord for an international system of tempers to be registered with the Aluminum Association by foreign organizations. For the most part, the ANSI system is used, but because there is no international accord, reference to ANSI H35.1 properties and characteristics of aluminum alloy tempers registered with the Aluminum Association under ANSI 35.1 may not always reflect actual properties and characteristics associated with the particular alloy temper. In addition, temper designations may be created which are not registered with the Aluminum Association.

Introduction

Aluminum mill products are those aluminum products that have been subjected to plastic deformation by hot- and cold-working mill processes (such as rolling, extruding, and drawing, either singly or in combination), so as to transform cast aluminum ingot into the desired product form. The microstructural changes associated with the working and with any accompanying thermal treatments are used to control certain properties and characteristics of the worked, or wrought, product or alloy.

Typical examples of mill products include plate or sheet (which is subsequently formed or machined into products such as aircraft or building components), household foil, and extruded shape such as storm window frames. A vast difference in the mechanical and physical properties of aluminum mill products can be obtained through the control of the chemistry, processing, and thermal treatment.

Wrought Alloy Series

Aluminum alloys are commonly grouped into an alloy designation series, as described earlier in the article "Alloy and Temper Designation Systems for Aluminum and Aluminum Alloys" in this Volume. The general characteristics of the alloy groups are described below, and the comparative corrosion and fabrication characteristics and some typical applications of the commonly used grades or alloys in each group are presented in Table 1.

(a) Ratings A through E are relative ratings in decreasing order of merit, based on exposures to sodium chloride solution by intermittent spraying or immersion. Alloys with A and B ratings can be used in industrial and seacoast atmospheres without protection. Alloys with C, D, and E ratings generally should be protected at least on faying surfaces.

(b) Stress-corrosion cracking ratings are based on service experience and on laboratory tests of specimens exposed to the 3.5% sodium chloride alternate immersion test. A = No known instance of failure in service or in laboratory tests. B = No known instance of failure in service; limited failures in laboratory tests of short transverse specimens. C = Service failures with sustained tension stress acting in short transverse direction relative to grain structure; limited failures in laboratory tests of long transverse specimens. D = Limited service failures with sustained longitudinal or long transverse stress.

(c) In relatively thick sections the rating would be E.

(d) This rating may be different for material held at elevated temperature for long periods.

(e) Ratings A through D for workability (cold), and A through E for machinability, are relative ratings in decreasing order of merit.

(f) Ratings A through D for weldability and brazeability are relative ratings defined as follows: A = Generally weldable by all commercial procedures and methods. B = Weldable with special techniques or for specific applications; requires preliminary trials or testing to develop welding procedure and weld performance. C = Limited weldability because of crack sensitivity or loss in resistance to corrosion and mechanical properties. D = No commonly used welding methods have been developed.

(g) Ratings A through D and NA for solderability are relative ratings defined as follows: A = Excellent. B = Good. C = Fair. D = Poor. NA = Not applicable

1*xxx* Series. Aluminum of 99.00% or higher purity has many applications, especially in the electrical and chemical fields. These grades of aluminum are characterized by excellent corrosion resistance, high thermal and electrical conductivities, low mechanical properties, and excellent workability. Moderate increases in strength may be obtained by strain hardening. Iron and silicon are the major impurities. Typical uses include chemical equipment, reflectors, heat exchangers, electrical conductors and capacitors, packaging foil, architectural applications, and decorative trim.

2*xxx* Series. Copper is the principal alloying element in 2*xxx* series alloys, often with magnesium as a secondary addition. These alloys require solution heat treatment to obtain optimum properties; in the solution heat-treated condition, mechanical properties are similar to, and sometimes exceed, those of low-carbon steel. In some instances, precipitation heat treatment (aging) is employed to further increase mechanical properties. This treatment increases yield strength, with attendant loss in elongation; its effect on tensile strength is not as great.

The alloys in the 2*xxx* series do not have as good corrosion resistance as most other aluminum alloys, and under certain conditions they may be subject to intergranular corrosion. Therefore, these alloys in the form of sheet usually are clad with a high-purity aluminum or with a magnesium-silicon alloy of the 6*xxx* series, which provides galvanic protection of the core material and thus greatly increases resistance to corrosion.

Alloys in the 2*xxx* series are particularly well suited for parts and structures requiring high strength-to-weight ratios and are commonly used to make truck and aircraft wheels, truck suspension parts, aircraft fuselage and wing skins, and structural parts and those parts requiring good strength at temperatures up to 150 °C (300 °F). Except for alloy 2219, these alloys have limited weldability, but some alloys in this series have superior machinability.

3*xxx* Series. Manganese is the major alloying element of 3*xxx* series alloys. These alloys generally are non-heat treatable but have about 20% more strength than 1*xxx* series alloys. Because only a limited percentage of manganese (up to about 1.5%) can be effectively added to aluminum, manganese is used as major element in only a few alloys. However, three of them--3003, 3X04, and 3105--are widely used as general-purpose alloys for moderate-strength applications requiring good workability. These applications include beverage cans, cooking utensils, heat exchangers, storage tanks, awnings, furniture, highway signs, roofing, siding, and other architectural applications.

4*xxx* Series. The major alloying element in 4*xxx* series alloys is silicon, which can be added in sufficient quantities (up to 12%) to cause substantial lowering of the melting range without producing brittleness. For this reason, aluminum-silicon alloys are used in welding wire and as brazing alloys for joining aluminum, where a lower melting range than that of the base metal is required. Most alloys in this series are non-heat treatable, but when used in welding heat-treatable alloys, they will pick up some of the alloying constituents of the latter and so respond to heat treatment to a limited extent. The alloys containing appreciable amounts of silicon become dark gray to charcoal when anodic oxide finishes are applied and hence are in demand for architectural applications. Alloy 4032 has a low coefficient of thermal expansion and high wear resistance, and thus is well suited to production of forged engine pistons.

5*xxx* Series. The major alloying element in 5*xxx* series alloys is magnesium. When it is used as a major alloying element or with manganese, the result is a moderate-to-high-strength work-hardenable alloy. Magnesium is considerably more effective than manganese as a hardener, about 0.8% Mg being equal to 1.25% Mn, and it can be added in considerably higher quantities. Alloys in this series possess good welding characteristics and good resistance to corrosion in marine atmospheres. However, certain limitations should be placed on the amount of cold work and the safe operating temperatures permissible for the higher-magnesium alloys (over about 3.5% for operating temperatures above about 65 °C, or 150 °F) to avoid susceptibility to stress-corrosion cracking.

Uses include architectural, ornamental, and decorative trim; cans and can ends; household appliances; streetlight standards; boats and ships, cryogenic tanks; crane parts; and automotive structures.

6*xxx* Series. Alloys in the 6*xxx* series contain silicon and magnesium approximately in the proportions required for formation of magnesium silicide (Mg_2Si), thus making them heat treatable. Although not as strong as most 2*xxx* and 7*xxx* alloys, 6*xxx* series alloys have good formability, weldability, machinability, and corrosion resistance, with medium strength. Alloys in this heat-treatable group may be formed in the T4 temper (solution heat treated but not precipitation heat treated) and strengthened after forming to full T6 properties by precipitation heat treatment. Uses include architectural applications, bicycle frames, transportation equipment, bridge railings, and welded structures.

7*xxx* Series. Zinc, in amounts of 1 to 8% is the major alloying element in 7*xxx* series alloys, and when coupled with a smaller percentage of magnesium results in heat-treatable alloys of moderate to very high strength. Usually other

elements, such as copper and chromium, are also added in small quantities. 7*xxx* series alloys are used in airframe structures, mobile equipment, and other highly stressed parts.

Higher strength 7*xxx* alloys exhibit reduced resistance to stress corrosion cracking and are often utilized in a slightly overaged temper to provide better combinations of strength, corrosion resistance, and fracture toughness.

Types of Mill Products

Commercial wrought aluminum products are divided basically into five major categories based on production methods as well as geometric configurations. These are:

- Flat-rolled products (sheet, plate, and foil)
- Rod, bar, and wire
- Tubular products
- Shapes
- Forgings

In the aluminum industry, rod, bar, wire tubular products, and shapes are termed mill products, as they are in the steel industry, even though they often are produced by extrusion rather than by rolling. Aluminum forgings, although usually not considered mill products, are wrought products and are briefly reviewed in this section.

In addition to production method and product configuration, wrought aluminum products also may be classified into heat-treatable and non-heat-treatable alloys. Initial strength of non-heat-treatable (1*xxx*, 3*xxx*, 4*xxx*, and 5*xxx*) alloys depends on the hardening effects of elements such as manganese, silicon, iron, and magnesium, singly or in various combinations. Because these alloys are work hardenable, further strengthening is made possible by various degrees of cold working, denoted by the H series of tempers, as discussed earlier in this Volume in the article on temper designations of aluminum and aluminum alloys. Alloys containing appreciable amounts of magnesium when supplied in strain-hardened tempers usually are given a final elevated-temperature treatment, called stabilizing, to ensure stability of properties. Initial strength of heat-treatable (2*xxx*, 4*xxx*, 6*xxx*, 7*xxx*, and some 8*xxx*) alloys is enhanced by addition of alloying elements such as copper, magnesium, zinc, lithium, and silicon. Because these elements, singly or in various combinations, show increasing solid solubility in aluminum with increasing temperature, it is possible to subject them to thermal treatments that will impart pronounced strengthening.

Flat-rolled products include sheet, plate, and foil. They are manufactured by either hot or hot-and-cold rolling, are rectangular in cross section and form, and have uniform thickness.

Plate. In the United States, plate refers to a product whose thickness is greater than 0.250 in. (6.3 mm). Plate up to 8 in. (200 mm) thick is available in some alloys. It usually has either sheared or sawed edges. Plate can be cut into circles, rectangles, or odd-shape blanks. Plate of certain alloys--notably the high-strength 2*xxx* and 7*xxx* series alloys--also are available in Alclad form, which comprises an aluminum alloy core having on one or both sides a metallurgically bonded aluminum or aluminum alloy coating that is anodic to the core, thus electrolytically protecting the core against corrosion. Most often, the coating consists of a high-purity aluminum, a low magnesium-silicon alloy, or an alloy containing 1% Zn. Usually, coating thickness (one side) is from 2.5 to 5% of the total thickness. The most commonly used plate alloys are 2024, 2124, 2219, 7050, 7075, 7150, 7475, and 7178 for aircraft structures; 5083, 5086, and 5456 for marine, cryogenics, and pressure vessels; and 1100, 3003, 5052, and 6061 for general applications.

Sheet. In the United States, sheet is classified as a flat-rolled product with a thickness of 0.006 to 0.249 in. (0.15 to 0.63 mm). Sheet edges can be sheared, slit, or sawed. Sheet is supplied in flat form, in coils, or in pieces cut to length from coils. Current facilities permit production of a limited amount of extra-large sheet, for example, up to 200 in. (5 m) wide by 1000 in. (25 m) long. The term strip, as applied to narrow sheet, is not used in the U.S. aluminum industry. Aluminum sheet usually is available in several surface finishes such as mill finish, one-side bright finish, or two-side bright finish. It may also be supplied embossed, perforated, corrugated, painted, or otherwise surface treated; in some instances, it is edge conditioned. As with aluminum plate, sheet made of the heat-treatable alloys in which copper or zinc are the major alloying constituents, notably the high-strength 2*xxx* and 7*xxx* series alloys, also is available in Alclad form for increased

corrosion resistance. In addition, special composites may be obtained such as Alclad non-heat-treatable alloys for extra corrosion protection, for brazing purposes, or for special surface finishes.

With a few exceptions, most alloys in the 1*xxx*, 2*xxx*, 3*xxx*, 5*xxx*, and 7*xxx* series are available in sheet form. Along with alloy 6061, they cover a wide range of applications from builders' hardware to transportation equipment and from appliances to aircraft structures.

Foil is a product with a thickness less than 0.006 in. (0.15 mm). Most foil is supplied in coils, although it is also available in rectangular form (sheets). One of the largest end uses of foil is household wrap. There is a wider variety of surface finishes for foil than for sheet. Foil often is treated chemically or mechanically to meet the needs of specific applications. Common foil alloys are limited to the higher-purity 1*xxx* series and 3003, 5052, 5056, 8111, and 8079 (Al-1.0Fe-0.15Si).

Bar, rod, and wire are all solid products that are extremely long in relation to their cross section. They differ from each other only in cross-sectional shape and in thickness or diameter. In the United States, when the cross section is round or nearly round and over $\frac{3}{8}$ in. (10 mm) in diameter, it is called rod. It is called bar when the cross section is square, rectangular, or in the shape of a regular polygon and when at least one perpendicular distance between parallel faces (thickness) is over $\frac{3}{8}$ in. (10 mm). Wire refers to a product, regardless of its cross-sectional shape, whose diameter or greatest perpendicular distance between parallel faces is less than $\frac{3}{8}$ in. (10 mm).

Rod and bar can be produced by either hot rolling or hot extruding and brought to final dimensions with or without additional cold working. Wire usually is produced and sized by drawing through one or more dies, although roll flattening is also used. Alclad rod or wire for additional corrosion resistance is available only in certain alloys. Many aluminum alloys are available in bar, rod, and wire; among these alloys, 2011 and 6262 are specially designed for screw-machine products, 2117 and 6053 for rivets and fittings. Alloy 2024-T4 is a standard material for bolts and screws. Alloys 1350, 6101, and 6201 are extensively used as electrical conductors. Alloy 5056 is used for zippers and alclad 5056 for insect screen wire.

Tubular products include tube and pipe. They are hollow wrought products that are long in relation to their cross section and have uniform wall thickness except as affected by corner radii. Tube is around, elliptical, square, rectangular, or regular polygonal in cross section. When round tubular products are in standardized combinations of outside diameter and wall thickness, commonly designated by "Nominal Pipe Sizes" and "ANSI Schedule Numbers," they are classified as pipe.

Tube and pipe may be produced by using a hollow extrusion ingot, by piercing a solid extrusion ingot, or by extruding through a porthole die or a bridge die. They also may be made by forming and welding sheet. Tube may be brought to final dimensions by drawing through dies. Tube (both extruded and drawn) for general applications is available in such alloys as 1100, 2014, 2024, 3003, 5050, 5086, 6061, 6063, and 7075. For heat-exchanger tube, alloys 1060, 3003, alclad 3003, 5052, 5454, and 6061 are most widely used. Clad tube is available only in certain alloys and is clad only on one side (either inside or outside). Pipe is available only in alloys 3003, 6061, and 6063.

Shapes. A shape is a product that is long in relation to its cross-sectional dimensions and has a cross-sectional shape other than that of sheet, plate, rod, bar, wire, or tube. Most shapes are produced by extruding or by extruding plus cold finishing; shapes are now rarely produced by rolling because of economic disadvantages. Shapes may be solid, hollow (with one or more voids), or semihollow. The 6*xxx* series (Al-Mg-Si) alloys, because of their easy extrudability, are the most popular alloys for producing shapes. Some 2*xxx* and 7*xxx* series alloys are often used in applications requiring higher strength.

Standard structural shapes such as I beams, channels, and angles produced in alloy 6061 are made in different and fewer configurations than similar shapes and made of steel; the patterns especially designed for aluminum offer better section properties and greater structural stability than the steel design by using the metal more efficiently. The dimensions, weights, and properties of the alloy 6061 standard structural shapes, along with other information needed by structural engineers and designers, are contained in the Aluminum Construction Manual, published by the Aluminum Association, Inc.

Most aluminum alloys can be obtained as precision extrusions with good as-extruded surfaces; major dimensions usually do not need to be machined because tolerances of the as-extruded product often permit manufacturers to complete the part with simple cutoff, drilling, or other minor operations.

In many instances, long aircraft structural elements involve large attachment fittings at one end. Such elements often are more economical to machine from stepped aluminum extrusions, with two or more cross sections in one piece, rather than from an extrusion having a uniform cross section large enough for the attachment fitting.

Aluminum Alloy Forgings. Aluminum alloys can be forged into a variety of shapes and types of forgings with a broad range of final part forging design criteria based on the intended application. As a class of alloys, however, aluminum alloys are generally considered to be more difficult to forge than carbon steels and many alloy steels. Compared to the nickel/cobalt-base alloys and titanium alloys, aluminum alloys are considerably more forgeable, particularly in conventional forging-process technology, in which dies are heated to 540 °C (100 °F) or less.

Figure 1 illustrates the relative forgeability of ten aluminum alloys that constitute the bulk of aluminum alloys forging production. This arbitrary unit is principally based on the deformation per unit of energy absorbed in the range of forging temperatures typically employed for the alloys in question. Also considered in this index is the difficulty of achieving specific degrees of severity in deformation as well as the cracking tendency of the alloy under forging-process conditions. There are wrought aluminum alloys, such as 1100 and 3003, whose forgeability would be rated significantly above those presented; however, these alloys have limited application in forging because they cannot be strengthened by heat treatment.

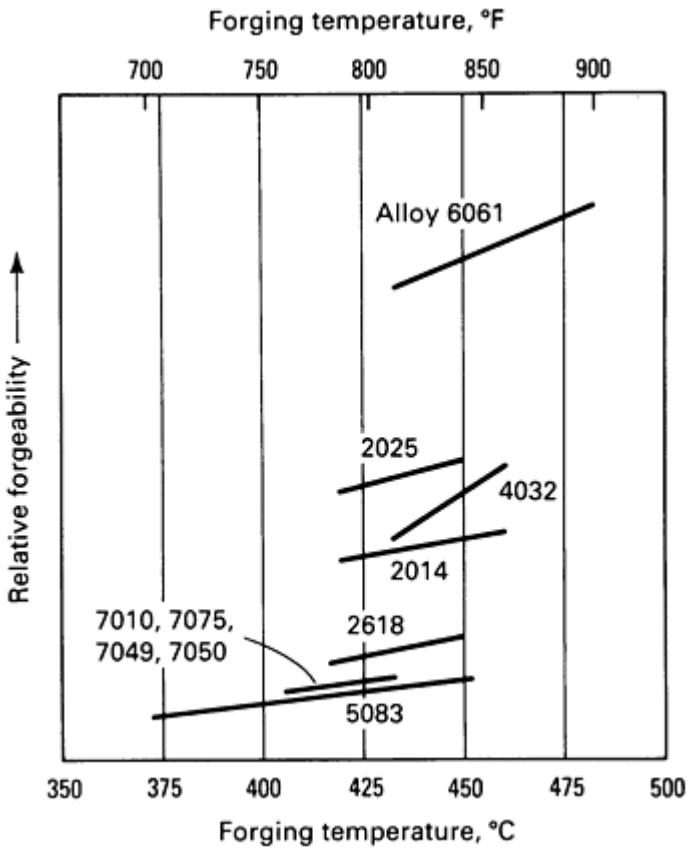

Fig. 1 Forgeability and forging temperatures of various aluminum alloys

The 15 aluminum alloys that are most commonly forged, as well as recommended temperature ranges, are listed in Table 2. All of these alloys are generally forged to the same severity, although some alloys may require more forging power and/or more forging operations than others. The forging temperature range for most alloys is relatively narrow (generally <55 °C, or 100 °F), and for no alloy is the range greater than 85 °C (155 °F). Obtaining and maintaining proper metal

temperatures in the forging of aluminum alloys is critical to the success of the forging process. Die temperature and deformation rates play key roles in the actual forging temperature achieved.

Table 2 Recommended forging temperature ranges for aluminum alloys

Aluminum alloy	Forging temperature range	
	°C	°F
1100	315-405	600-760
2014	420-460	785-860
2025	420-450	785-840
2219	425-470	800-880
2618	410-455	770-850
3003	315-405	600-760
4032	415-460	780-860
5083	405-460	760-860
6061	430-480	810-900
7010	370-440	700-820
7039	380-440	720-820
7049	360-440	680-820
7050	360-440	680-820
7075	380-440	720-820

Forging Methods. Aluminum alloys are produced by all of the current forging methods available, including open-die (or hand) forging, closed-die forging, upsetting, roll forging orbital (rotary) forging, spin forging, and mandrel forging, ring rolling, and extrusion. Selection of the optimal forging method for a given forging shape is based on the desired forged shape, the sophistication of the forged-shape design, and cost. In many cases, two or more forging methods are combined in order to achieve the desired forging shape and to obtain a thoroughly wrought structure, For example, open-die forging frequently precedes closed-die forging in order to prework the alloy (especially when cast ingot forging is being employed) and in order to preshape to preshape (or preform) the metal to conform to the subsequent closed dies and to conserve input metal.

Most aluminum alloy forgings are produced in closed dies. However, open-die forging is frequently used to produce small quantities of aluminum alloy forgings when the construction of expensive closed dies is not justified or when such quantities are needed during the prototype fabrication stages of a forging application. The quantity that warrants the use of closed dies varies considerably, depending on the size and shape of the forging and on the application for the part. However, open-die forging is by no means confined to small or prototype quantities, and in some cases, it may be the most cost-effective method of aluminum forging manufacture. For example, as many as 2000 pieces of biscuit forgings have been produced in open dies when closed dies did not provide sufficient economic benefits. Further information on the forging of aluminum alloys is given in *Forming and Forging*, Volume 14 of *ASM Handbook,* formerly 9th Edition *Metals Handbook.*

Design of Shapes

Aluminum shapes can be produced in a virtually unlimited variety of cross-sectional designs that place the metal where needed to meet functional and appearance requirements. Full utilization of this capability of the extrusion process depends principally on the ingenuity of designers in creating new and useful configurations. The cross-sectional design of an extruded shape, however, can have an important influence on its producibility, production rate, cost of tooling, surface finish, and ultimate production cost. The optimum design of an extruded shape must take into account alloy thickness or thicknesses involved, and the size, type, and complexity of the shape. Therefore, the extruder should be consulted during design to ensure adequate dimensional control, satisfactory finish, and lowest cost while retaining the desired functional and appearance characteristics.

Classification of Shapes. The complexity of a shape producible as an extrusion is a function of metal-flow characteristics of the process and the means available to control flow. Control of metal flow places a few limitations on the design features of the cross section of an extruded shape that affect production rate, dimensional and surface quality, and costs. Extrusions are classified by shape complexity from an extrusion-production viewpoint into solid, hollow, and semihollow shapes. Each hollow shape--a shape with any part of its cross section completely enclosing a void--is further classified by increasing complexity as follows:

- Class 1: A hollow shape with a round void 25 mm (1 in) or more in diameter and with its weight equally distributed on opposite sides of two or more equally spaced axes
- Class 2: Any hollow shape other than Class 1, not exceeding a 125 mm (5 in.) diam circle and having a single void of not less than 9.5 mm (0.375 in.) diam or 70 mm^2 (0.110 $in.^2$) area
- Class 3: Any hollow shape other than Class 1 or 2

A semihollow shape is a shape with any part of its cross section partly enclosing a void having the following ratios for the area of the void to the square of the width of the gap leading to the void:

Gap width		Ratio
mm	**in.**	
0.9-1.5	0.035-0.061	Over 2
1.6-3.1	0.062-0.124	Over 3
3.2-6.3	0.125-0.249	Over 4
6.4-12.6	0.250-0.499	Over 5

Alloy Extrudability. Aluminum alloys differ in inherent extrudability. Alloys selection is important because it establishes the minimum thickness for a shape and has a basic effect on extrusion cost. In general, the higher the alloy content and the strength of an alloy, the more difficult it is to extrude and the lower its extrusion rate.

The relative extrudabilities, as measured by extrusion rate, for several of the more important commercial extrusion alloys are given below:

Alloy	Extrudability, % of rate for 6063
1350	160
1060	135
1100	135
3003	120
6063	100

6061	60
2011	35
5086	25
2014	20
5083	20
2024	15
7075	9
7178	8

Actual extrusion rate depends on pressure, temperature, and other requirements for the particular shape, as well as ingot quality.

Shape and Size Factors. The important shape factor of an extrusion is the ratio of its perimeter to its weight per unit length. For a single classification, increasing shape factor is a measure of increasing complexity. Designing for minimum shape factor promotes ease of extrusion.

The size of an extruded shape affects ease of extrusion and dimensional tolerances. As the circumscribing circle size (smallest diameter that completely encloses the shape) increases, extrusion becomes more difficult. In extrusion, the metal flows fastest at the center of the die face. With increasing circle size, the tendency for different metal flow increases, and it is more difficult to design and construct extrusion dies with compensating features that provide uniform metal-flow rates to all parts of the shape.

Ease of extrusion improves with increasing thickness; shapes of uniform thickness are most easily extruded. A shape whose cross section has elements of widely differing thicknesses increases the difficulty of extrusion. The thinner a flange on a shape, the less the length of flange that can be satisfactorily extruded. Thinner elements at the ends of long flanges are difficult to fill properly and make it hard to obtain desired dimensional control and finish. Although it is desirable to produce the thinnest shape feasible for an application, reducing thickness can cause an increase in cost of extrusion that more than offsets the savings in metal cost. Extruded shapes 1 mm (0.040 in.) thick and even less can be produced, depending on alloy, shape, size, and design. Manufacturing limits on minimum practical thickness of extruded shapes are given in Table 3.

Table 3 Standard manufacturing limits (in inches) for aluminum extrusion

Diameter of circumscribing circle, in.	**Minimum wall thickness, in.**

(a) Minimum inside diameter is one-half the circumscribing diameter, but never under 1 in. for alloys in first three columns or under 2 in. for alloys in last two columns.

(b) Minimum, hole size for alloys is 0.110 sq. in. in area or 0.375 in. in diam.

Size and thickness relationships among the various elements of shape can add to its complexity. Rod, bar, and regular shapes of uniform thickness are easily produced. For example, a bar 3.2 mm (0.125 in.) thick, a rod 25 mm (1 in.) in diameter, and an angle 19 by 25 mm (0.75 by 1 in.) in cross section, and 1.6 mm (0.0625 in.) thick are readily extruded, whereas extrusion of a 75 mm (3 in.) bar-type shape with a 3.2 mm (0.125 in.) flange is more difficult.

Semihollow and channel shapes require a tongue in the extrusion die, which must have adequate strength to resist the extrusion force. Channel shapes become increasingly difficult to produce as the depth-to-width ratio increase. Wide, thin shapes are difficult to produce and make it hard to control dimension. Channel-type shapes and wide, thin shapes may be fabricated if they are not excessively thin. Thin flanges or projections from a thicker element of the shape add to the complexity of an extruded design. On thinner elements at the extremities of high flanges, it is difficult to get adequate fill to obtain desired dimensions. The greater the difference in thickness off individual elements comprising a shape, the more difficult the shape is to produce. The effect of such thickness differences can be greatly diminished by blending one thickness into the other by tapered or radiused transitions. Sharp corners should be avoided wherever possible because they reduce maximum extrusion speed and are locations of stress concentrations in the die opening that can cause premature die failure. Fillet radii of at least 0.8 mm (0.031 in.) are desirable, but corners with radii of only 0.4 mm (0.015 in.) are feasible.

In general, the more unbalanced and unsymmetrical an extruded-shape cross section, the more difficult that shape is to produce. Despite this, production of grossly unbalanced and unsymmetrical shapes is the basis of the great growth that has occurred in the use of aluminum extrusions, and such designs account for the bulk of extruded shapes produced today.

Interconnecting Shapes. It is becoming increasingly common to include an interconnecting feature in the design of an extruded shape to facilitate its assembly to a similar shape or to another product. This feature can be a simple step to provide a smooth lapping joint, or a tongue and groove for a nesting joint (see Fig. 2). Such connections can be secured by any of the common joining methods. Of special interest when the joint is to be arc welded is the fact that lapping and nesting types of interconnections can be designed to provide edge preparation and/or integral backing for the weld (see the sketch at bottom left in Fig. 2).

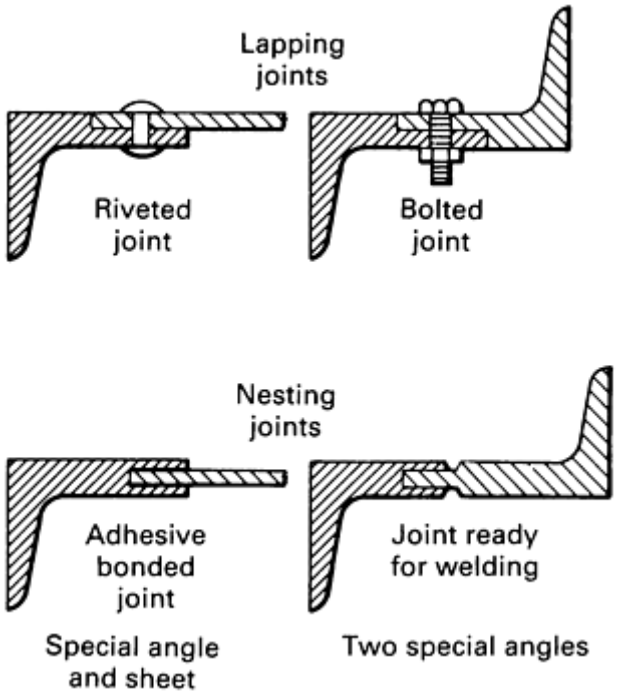

Fig. 2 Four examples of interconnecting extrusions that fit together or fit other products, and four examples of joining methods

Interlocking joints can be designed to incorporate a free-moving hinge (see top sketch in Fig. 3) when one part is slid lengthwise into the mating portion of the next extrusion. Panel-type extrusions with hinge joints have found application in conveyor belts and roll-up doors.

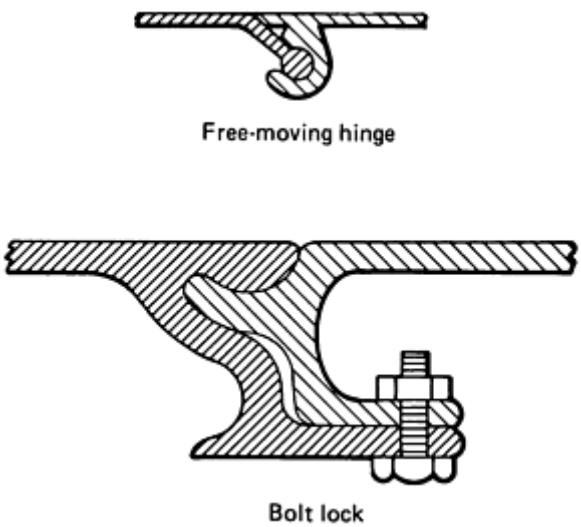

Fig. 3 Two examples of extrusions with nonpermanent interconnections

A more common type of interlocking feature used in interconnecting extrusion is the nesting type that requires rotation of one part relative to the mating part of assembly (see bottom sketch in Fig. 3). Such joints can be held together by gravity or by mechanical devices. If a nonpermanent joint is desired, a bolt or other fastener can be used, as illustrated in the bottom sketch in Fig. 3.

When a permanent joint is desired, a snapping or crimping feature can be added to intetrlocking extrusions (see Fig. 4). Crimping also can be used to make a permanent joint between an interlocking extrusion and sheet (Fig. 4). Extrusion also can be provided with longitudinal teeth or serrations, which will permanently grip smooth surfaces as well as surfaces provided with mating teeth or serrations; this is illustrated in the sketch at the bottom of Fig. 4.

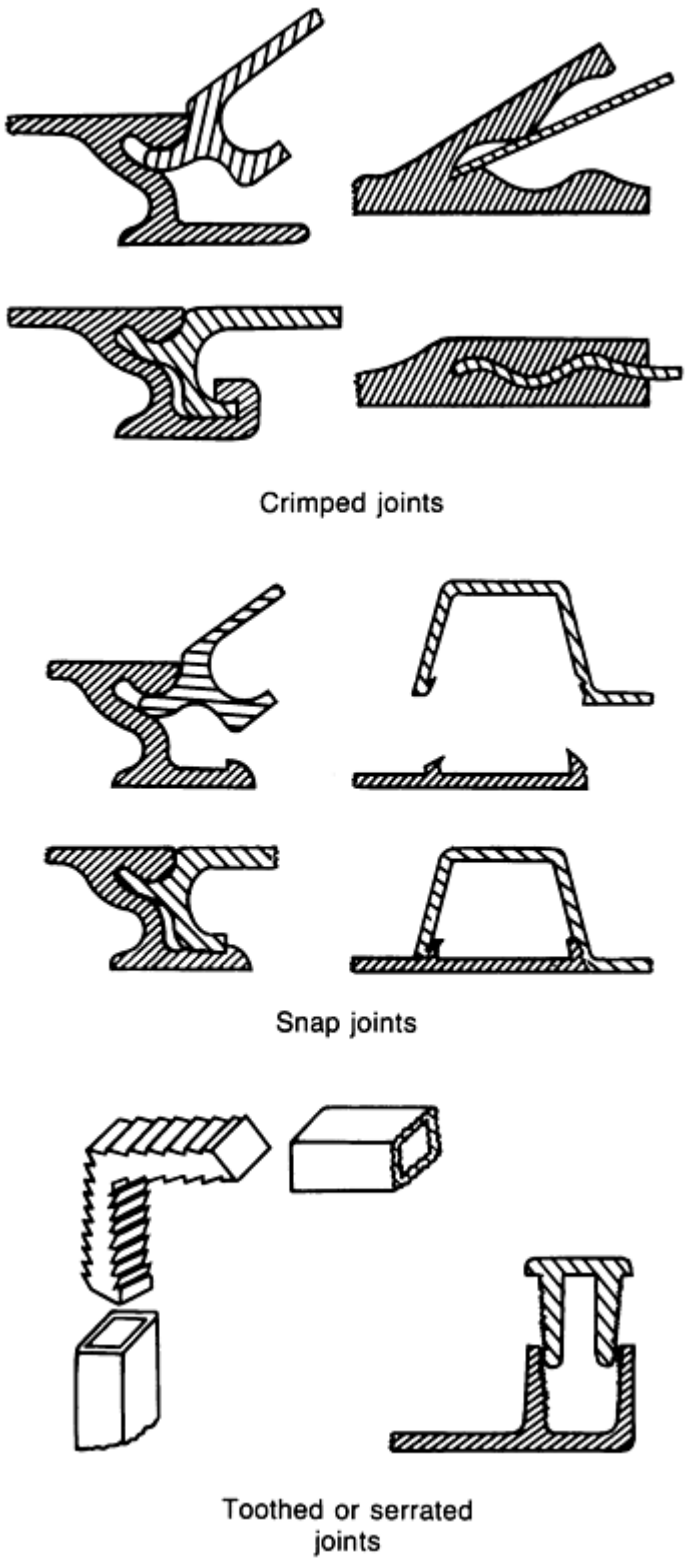

Fig. 4 Six examples of interconnecting extrusions that lock together or lock to other products

Applications for interconnecting extrusions include doors, wall, ceiling and floor panels, pallets, aircraft landing mats, highway signs, window frames, and large cylinders.

Aluminum Mill and Engineered Wrought Products

Jack W. Bray, Reynolds Metals Company

Physical Metallurgy

The principal concerns in the physical metallurgy of aluminum alloys include the effects of composition, mechanical working, and/or heat treatment on mechanical and physical properties. In terms of properties, strength improvements is a major objective in the design of aluminum alloys because the low strength of pure aluminum (about a 10 MPa, or 1.5 ksi, tensile yield strength in the annealed condition) limits its commercial usefulness. The two most common methods for increasing the strength of aluminum alloys are to:

- Disperse second-phase constituents or elements in solid solution and cold work the alloy (non-heat-treatable alloys)
- Dissolve the alloying elements into solid solution and precipitate them as coherent submicroscopic particles (heat-treatable or precipitation-hardening alloys)

The factors affecting these strengthening mechanisms and the fracture toughness and physical properties of aluminum alloys are discussed in the following portions of this section.

Phases in Aluminum Alloys

The elements that are most commonly present in commercial aluminum alloys to provide increased strength--particularly when coupled with strain hardening by cold working or with heat treatment, or both--are copper, magnesium, manganese, silicon, and zinc. These elements all have significant solid solubility in aluminum, and in all cases the solubility increases with increasing temperature (see Fig. 5).

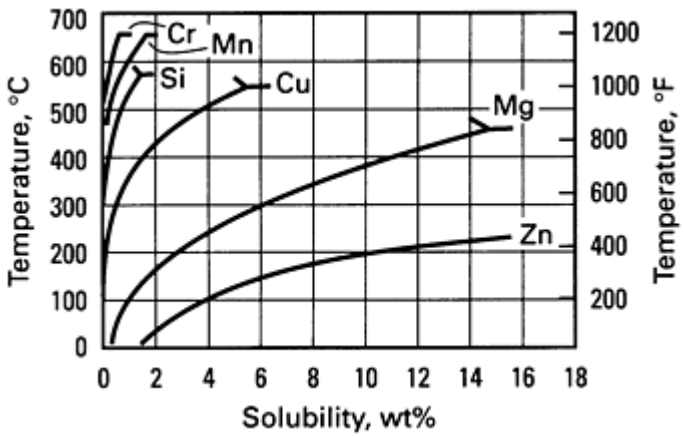

Fig. 5 Equilibrium binary solid solubility as a function of temperature for alloying elements most frequently added to aluminum

Of all the elements, zinc has the greatest solid solubility in aluminum (a maximum of 66.4 at%). In addition to zinc, the solid solubilities of silver, magnesium, and lithium are greater than 10 at% (in order of decreasing maximum solubility). Gallium, germanium, copper, and silicon (in decreasing order) have maximum solubilities of less than 10 but greater than 1 at%. All other elements are less soluble. With the one known exception of tin (which shows a retrograde solid solubility between the melting point of aluminum and the eutectic temperature, 228.3 °C, with a maximum of 0.10% at approximately 660 °C), the maximum solid solubility in aluminum alloys occurs at the eutectic, peritectic, or monotectic temperature. With decreasing temperature, the solubility limits decrease. This decrease from appreciable concentrations at elevated temperatures to relatively low concentrations at low temperatures is one fundamental characteristic that provides the basis for substantially increasing the hardness and strength of aluminum alloys by solution heat treatment and subsequent precipitation aging operations.

For those elements in concentrations below their solubility limits, the alloying elements are essentially in solid solution and constitute a single phase. However, no element is known to have complete miscibility with aluminum in the solid

state. Among the commercial alloys, only the bright-finishing alloys such as 5657, and 5252, which contain 0.8 and 2.5% Mg (nominal), respectively, with very low limits on all impurities, may be regarded as nearly pure solid solutions.

Second-Phase Constituents. When the content of an alloying element exceeds the solid-solubility limit, the alloying element produces "second-phase" microstructural constituents that may consist of either the pure alloying ingredient or an intermetallic-compound phase. In the first group are silicon, tin, and beryllium. If the alloy is a ternary or higher-order alloy, however, silicon or tin may form intermetallic-compound phases. Most of the other alloying elements form such compounds with aluminum in binary alloys and more complex phases in ternary or higher-order alloys.

Manganese and chromium are included in the group of elements that form predominantly second-phase constituents, because in commercial alloys they have very low equilibrium solid solubilities. In the case of many compositions containing manganese, this is because iron and silicon are also present and form the quaternary-phase $Al_{12}(Fe,Mn)_3Si$. In alloys containing copper and manganese, the ternary-phase $Al_{20}Cu_2Mn_3$ is formed. Most of the alloys in which chromium is present also contain magnesium, so that during solid-state heating they form $Al_{12}Mg_2Cr$, which also has very low-equilibrium solid solubility. Smelter-grade primary metal, whether in ingot or wrought-product form, contains a small volume fraction of second-phase particles, chiefly iron-bearing phases--the metastable Al_6Fe, the stable Al_3Fe, which forms from Al_6Fe on solid-state heating, and $Al_{12}Fe_3Si$. Proportions of the binary and ternary phases depend on relative iron and silicon contents.

In quaternary systems, intermetallic phases of the respective binary and ternary systems are occasionally isomorphous, forming continuous series of solid solutions in equilibrium with aluminum solid solution. An important example is in the aluminum-copper-magnesium-zinc quaternary system where there are three such pairs: $CuMg_4Al_6 + Mg_3Zn_3Al_2$, $Mg_2Zn_{11} + Cu_6Mg_2Al_5$, and $MgZn_2 + CuMgAl$. The first pair have similar lattice parameters and form extensive mutual solid solution, the others less so. Neither $Cu_6Mg_2Al_5$ nor CuMgAl are equilibrium phases in aluminum-copper-magnesium, although both Mg_2Zn_{11} and $MgZn_2$ are equilibrium phases in aluminum-magnesium-zinc. Another instance is in the aluminum-iron-manganese-silicon quaternary system; here the stable phase $(FeMn)_3Si_2Al_{15}$ (body-centered cubic) can vary from $Mn_3Si_2Al_{15}$, a = 1.2652 nm (12.652 Å) to : $(Mn_{0.1}Fe_{0.9})_3Si_2Al_{15}$, a = 1.2548 nm (12.548 Å). The stable phase of the closest composition in aluminum-iron-silicon is Fe_2SiAl_8 (hexagonal); the hexagonal-to-cubic transition is also accomplished by small additions of vanadium, chromium, molybdenum, and tungsten, and larger additions of copper (Ref 1). Such chemical stabilization effects, coupled with the metastability introduced by casting, frequently cause complex alloy structure.

Prediction of Intermetallic Phases in Aluminum Alloys. The wide variety of intermetallic phases in aluminum alloys, which occur because aluminum is highly electronegative and trivalent, has been the subject of considerable study (Ref 2, 3, 4). Details depend on ratios and total amounts of alloying elements present and require reference to the phase diagrams for prediction. It must be kept in mind, however, that metastable conditions frequently prevail that are characterized by the presence of phases that are not shown on the equilibrium diagrams. Transition metals, for example, exhibit frequent metastability, in which one phase introduced during fast solidification transforms in the solid state to another, for example, $FeAl_6 \rightarrow FeAl_3$, or a metastable variant precipitates from supersaturated solid solution such as $MnAl_{12}$.

Calculation of Phase Diagrams. Recently, considerable advances have been made in the thermodynamic evaluation of phase diagrams, particularly through the application of computer techniques (Ref 5). The available data and computational procedures have been systemized internationally since 1971 through the CALPHAD (Computer Coupling of Phase Diagrams and Thermochemistry) project (Ref 6). Application for multicomponent aluminum alloy phase diagram prediction has some inherent problems, particularly regarding the unexpected occurrence of ternary intermetallic phases, but is rapidly becoming an effective procedure. As of 1980, the following ternary aluminum-containing systems have been examined: Al-Fe-Ti, Al-Ga-Ge, Al-Ga-In, Al-Ge-Sn, Al-Li-Mg, and Al-Ni-Ti. As well as the 15 binaries required for these systems, phase diagrams of the following binary systems have also been examined: Al-Ca, Al-Ce, Al-Co, Al-Cr, Al-Cu, Al-Mn, Al-Mo, Al-Nb, Al-O, Al-P, and Al-Si (Ref 7). In principle, any ternary or quaternary combination of these binary systems can be analyzed.

Strengthening Mechanisms

The predominant objective in the design of aluminum alloys is to increase strength, hardness, and resistance to wear, creep, stress relaxation, or fatigue. Effects on these properties are specific to the different combinations of alloying elements, their alloy phase diagrams, and to the microstructures and substructures they form as a result of solidification,

thermomechanical history, heat treatment, and/or cold working. These factors, to a large extent, depend on whether the alloy is a non-heat-treatable alloy or a heat-treatable (precipitation-strengthening) alloy.

Strength at elevated temperatures is improved mainly by solid-solution and second-phase hardening because at least for temperatures exceeding those of the precipitation-hardening range--230 °C (450 °F) and over--the precipitation reactions continue into the softening regime. For supersonic aircraft and space vehicle applications subject to aerodynamic heating, the heatreatable alloys of the 2*xxx* group can be used for temperatures up to about 150 °C (300 °F).

Strengthening in non-heat-treatable alloys occurs from solid-solution formation, second-phase microstructural constituents, dispersoid precipitates, and/or strain hardening. Wrought alloys of this type are mainly those of the 3*xxx* and 5*xxx* groups containing magnesium, manganese, and/or chromium as well as the 1*xxx* aluminums and some alloys of the 4*xxx* group that contain only silicon. Non-heat-treatable casting alloys are of the 4*xx.x* or 5*xx.x* groups, containing silicon or magnesium, respectively, and the 1*xx.x* aluminums.

Solid-Solution Strengthening. For those elements that form solid solution, the strengthening effect when the element is in solution tends to increase with increasing difference in the atomic radii of the solvent (Al) and solute (alloying element) atoms. This factor is evident in data obtained from super-purity binary solid-solution alloys in the annealed state, presented in Table 4, but it is evident that other effects are involved, chief among which is an electronic bonding factor. The effects of multiple solutes in solid solution are somewhat less than additive and are nearly the same when one solute has a larger and the other a smaller atomic radius than that of aluminum as when both are either smaller or larger. Manganese in solid solution is highly effective in strengthening binary alloys. Its contribution to the strength of commercial alloys is less, because in these compositions, as a result of commercial mill fabricating operations, the manganese is largely precipitated.

Table 4 Solid-solution effects on strength of principal solute elements in super-purity aluminum

Element	Difference in atomic radii, r_x-r_{Al}, %[(a)]	Strength/addition values[(b)]							
		Yield strength/% addition[(c)]				Tensile strength/% addition[(d)]			
		MPa/at%	ksi/wt%	MPa/at%	ksi/wt%	MPa/at%	ksi/wt%	MPa/at%	ksi/wt%
Si	-3.8	9.3	1.35	9.2	1.33	40.0	5.8	39.6	5.75
Zn	-6.0	6.6	0.95	2.9	0.42	20.7	3.0	15.2	2.2
Cu	-10.7	16.2	2.35	13.8	2.0	88.3	12.8	43.1	6.25
Mn	-11.3	[(e)]	[(e)]	30.3	4.4	[(e)]	[(e)]	53.8	7.8

(a) Listed in order of increasing percent difference in atomic radii.

(b) Some property-percent addition relationships are nonlinear. Generally, the unit effects of smaller additions are greater.

(c) Increase in yield strength (0.2% offset) for 1% (atomic or weight basis) alloy addition.

(d) Increase in ultimate tensile strength for 1% (atomic or weight basis) alloy addition.

(e) 1 at% of manganese is not soluble.

The principal alloys that are strengthened by alloying elements in solid solution (often coupled with cold work) are those in the aluminum-magnesium (5*xxx*) series, ranging from 0.5 to 6 wt% Mg. These alloys often contain small additions of transition elements such as chromium or manganese, and less frequently zirconium to control the grain or subgrain structure and iron and silicon impurities that usually are present in the form of intermetallic particles. Figure 6 illustrates the effect of magnesium in solid solution on the yield strength and tensile elongation for most of the common aluminum-magnesium commercial alloys.

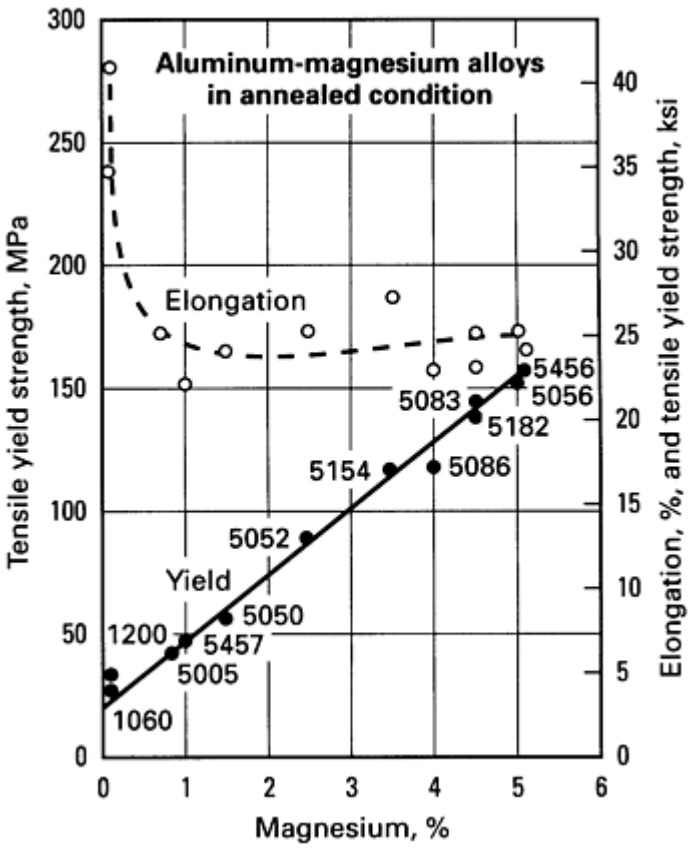

Fig. 6 Correlation between tensile yield, elongation, and magnesium content for some commercial aluminum alloys

Strengthening From Second-Phase Constituents. Elements and combinations that form predominantly second-phase constituents with relatively low solid solubility include iron, nickel, titanium, manganese, and chromium, and combinations thereof. The presence of increasing volume fractions of the intermetallic-compound phases formed by these elements and the elemental silicon constituents formed by silicon during solidification or by precipitation in the solid state during postsolidification heating also increases strength and hardness. The rates of increase per unit weight of alloying element added are frequently similar to but usually lower than those resulting from solid solution. This "second-phase" hardening occurs even though the constituent particles are of sizes readily resolved by optical microscopy. These irregularly shaped particles form during solidification and occur mostly along grain boundaries and between dendrite arms.

Grain Refinement With Dispersed Precipitates. Manganese and/or chromium additions in wrought aluminum alloys allow the formation of complex precipitates that not only retard grain growth during ingot reheating but also assist in grain refinement during rolling. This method involves rapid solidification and cooling during the casting of ingots, so that a solid-solution state is formed with concentrations of manganese and/or chromium that greatly exceed their equilibrium solubility. During reheating of the as-cast ingot for wrought processing, this supersaturated metastable solid solution is designed to cause solid-state precipitation of complex phases. This precipitation does not cause appreciable hardening, nor is intended that it should. Its purpose is to produce finely divided and dispersed particles that retard or inhibit recrystallization and grain growth in the alloy during subsequent heatings. The precipitate particles of $Al_{12}(Fe,Mn)_3Si$, $Al_{20}Cu_2Mn_3$, or $Al_{12}Mg_2Cr$ are incoherent with the matrix, and concurrent with their precipitation the original solid solution becomes less concentrated. These conditions do not provide appreciable precipitation hardening. Changes in electrical conductivity constitute an effective measure of the completeness of these precipitation reactions that occur in preheating.

The newer "in-line" or integrated processes that shorten the path from molten metal to wrought product, avoiding ingot preheating and reducing the overall time-temperature history, are changing this conventional or traditional picture. It seems very probable that in order to obtain the best results from such processes, traditional alloy compositions should be adjusted taking into account the fact that larger proportions of these elements would be expected to remain in solid solution through such abbreviated and truncated thermomechanical operations. New capabilities may be obtained with

currently standard alloys in some instances, but it would not be expected that a particular alloy would exhibit the same properties when produced by the two types of processes.

For alloys that are composed of both solid-solution and second-phase constituents and/or dispersoid precipitates, all of these components of microstructure contribute to strength, in a roughly additive manner. This is shown in Fig. 7 for Al-Mg-Mn alloys in the annealed condition.

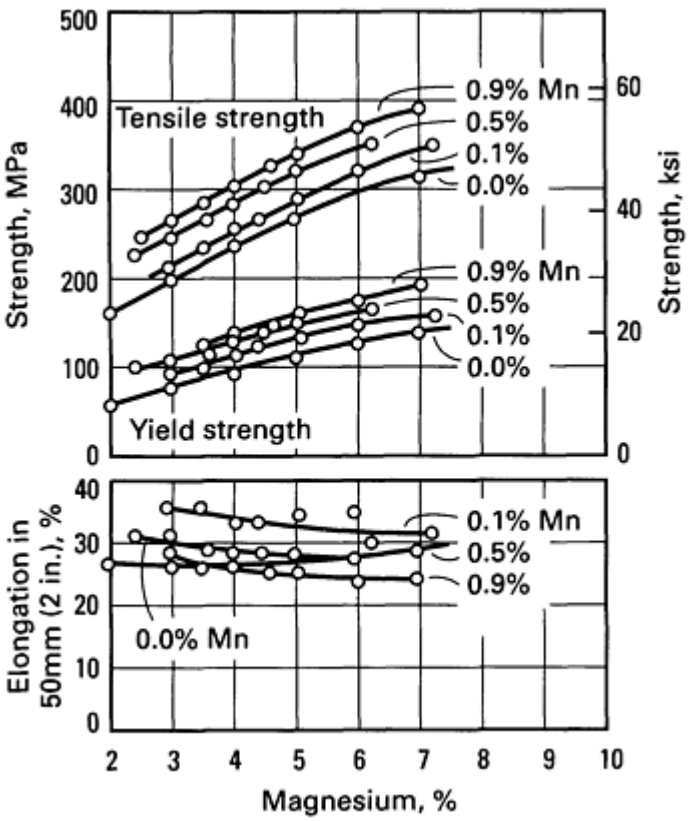

Fig. 7 Tensile properties in Al-Mg-Mn alloys in the form of annealed (O temper) plate 13 mm (0.5 in.) thick

Strain hardening by cold rolling, drawing, or stretching is a highly effective means of increasing the strength of non-heat-treatable alloys. Work- or strain-hardening curves for several typical non-heat-treatable commercial alloys (Fig. 8) illustrate the increases in strength that accompany increasing reduction by cold rolling of initially annealed temper sheet. This increase is obtained at the expense of ductility as measured by percent elongation in a tensile test and by reducing formability in operations such as bending and drawing. It is often advantageous to use material in a partially annealed (H2*x*) or stabilized (H3*x*) temper when bending, forming, or drawing is required, since material in these tempers has greater forming capability for the same strength levels that those strain-hardened only (H1*x*) material (see Table 5, for example).

Table 5 Tensile-property data illustrating typical relationships between strength and elongation for non-heat-treatable alloys in H1*x* versus H2*x* or H3*x* tempers

Alloy and temper	Tensile strength		Yield strength		Elongation, %
	MPa	ksi	MPa	ksi	
3105-H14	172	25	152	22	5
3105-H25	179	26	159	23	8

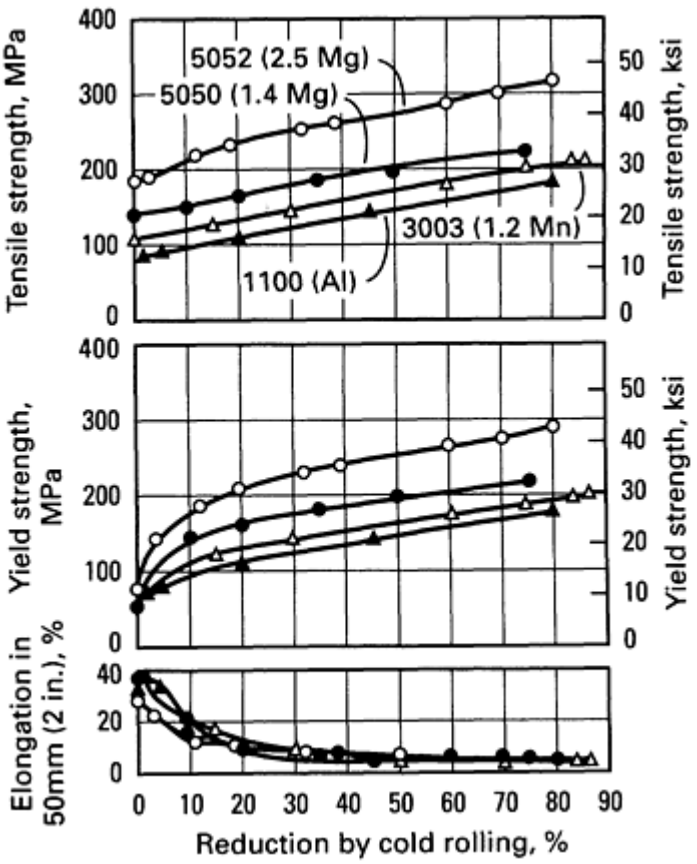

Fig. 8 Strain-hardening curves for aluminum (1100), and for Al-Mn (3003) and Al-Mg (5050 and 5052) alloys

All mill products can be supplied in the strain-hardened condition, although there are limitations on the amounts of strain that can be applied to products such as die forgings and impacts. Even aluminum castings have been strengthened by cold pressing for certain applications. The heat-treatable alloys described below can also be subjected to strain hardening.

Heat-treatable (precipitation-hardening) aluminum alloys for wrought and cast products contain elements that decrease in solubility with decreasing temperature, and in concentrations that exceed their equilibrium solid solubility at room- and moderately higher temperatures. However, these features alone do not make an alloy capable of (precipitation hardening) during heat treatment. The strengths of most binary alloys containing magnesium, silicon, zinc, chromium, or manganese alone exhibit little change from thermal treatments regardless of whether the solute is completely in solid solution, partially precipitated, or substantially precipitated.

The mechanism of strengthening by age hardening involves the formation of coherent clusters of solute atoms (that is, the solute atoms have collected into a cluster but still have the same crystal structure as the solvent phase). This causes a great deal of stain because of mismatch in size between the solvent and solute atoms. The cluster stabilizes dislocations, because dislocations tend to reduce the strain, similar to the reduction in strain energy of a single solute atom by a dislocation. When dislocations are anchored or trapped by coherent solute clusters, the alloy is considerably strengthened and hardened.

However, if the precipitates are semicoherent (sharing a dislocation-containing interface with the matrix), incoherent (sharing a disordered interface, akin to a large-angle grain boundary, with the matrix), or are incapable of reducing strain behavior because they are too strong, a dislocation can circumvent the particles only by bowing into a roughly semicircular shape between them under the action of an applied shear stress. Consequently, the presence of the precipitate particles, and even more importantly the strain fields in the matrix surrounding the coherent particles, provide higher strength by obstructing and retarding the movement of dislocations. The characteristic that determines whether a precipitate phase is coherent or noncoherent is the closeness of match or degree of disregistry between the atomic spacings on the lattice of the matrix and on that of the precipitate.

Heat treatment for precipitation strengthening includes a solution heat treatment at a high temperature to maximize solubility, followed by rapid cooling or quenching to a low temperature to obtain a solid solution supersaturated with both solute elements and vacancies. Solution heat treatments are designed to maximize the solubility of elements that participate in subsequent aging treatments. They are most effective near the solidus or eutectic temperature, where maximum solubility exists and diffusion rates are rapid. However, care must be taken to avoid incipient melting of low-temperature, eutectics and grain-boundary phases. Such melting results in quench cracks and loss in ductility. The maximum temperature may also be set with regard to grain growth, surface effects, and economy of operation. The minimum temperature should be above the solvus, or the desired properties derived from aging will not be realized. The optimum heat-treatment range may be quite small, with a margin of safety sometimes only ±5 K.

The high strength is produced by the finely dispersed precipitates that form during aging heat treatments (which may include either natural aging or artificial aging as described below). This final step must be accomplished not only below the equilibrium solvus temperature, but below a metastable miscibility gap called the Guinier-Preston (GP) zone solvus line. The supersaturation of vacancies allows diffusion, and thus zone formation, to occur much faster than expected from equilibrium diffusion coefficients. In the precipitation process, the saturated solid solution first develops solute clusters,

which then become involved in the formation of transitional (nonequilibrium) precipitates. The final structure consists of equilibrium precipitates, which do not contribute to age hardening (precipitation strengthening).

Natural aging refers to the spontaneous formation of a G-P zone structure during exposure at room temperature. Solute atoms either cluster or segregate to selected atomic lattice planes, depending on the alloy system, to form the G-P zones, which are more resistant to movement of dislocations through the lattice, and hence are stronger. Curves showing the changes in tensile yield strength with time at room temperature (natural aging curves) for three wrought commercial heat-treatable alloys of different alloy systems are shown in Fig. 9. The magnitudes of increase in this property are considerably different for the three alloys, and the differences in rate of change with time are of practical importance. Because 7075 and similar alloys never become completely stable under these conditions, they are rarely used in the naturally aged tamper. On the other hand, 2024 is widely used in this condition.

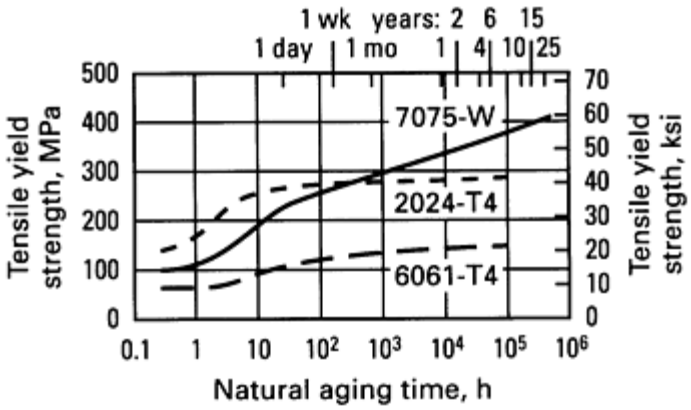

Fig. 9 Natural aging curves for three solution heat-treated wrought aluminum alloys

Of the binary alloys, aluminum-copper alloys exhibit natural aging after being solution heat treated and quenched. The amounts by which strength and hardness increase become larger with time of natural aging and with the copper content of the alloy from about 3% to the limit of solid solubility (5.65%). Natural aging curves for slowly quenched, high-purity Al-Cu alloys with 1 to 4.5% Cu are shown in Fig. 10. The rates and amounts of the changes in strength and hardness can be increased by holding the alloys at moderately elevated temperatures (for alloys of all types, the useful range is about 120 to 230 °C, or 250 to 450 °F). This treatment is called precipitation heat treating or artificial aging. In the Al-Cu system, alloys with as little as 1% Cu, again slowly quenched, start to harden after about 20 days at a temperature of 150 °C, or 300 °F (see Fig. 11). The alloys of this system, having less than about 3% Cu, show little or no natural aging after low-cooling-rate quenching, which introduces little stress.

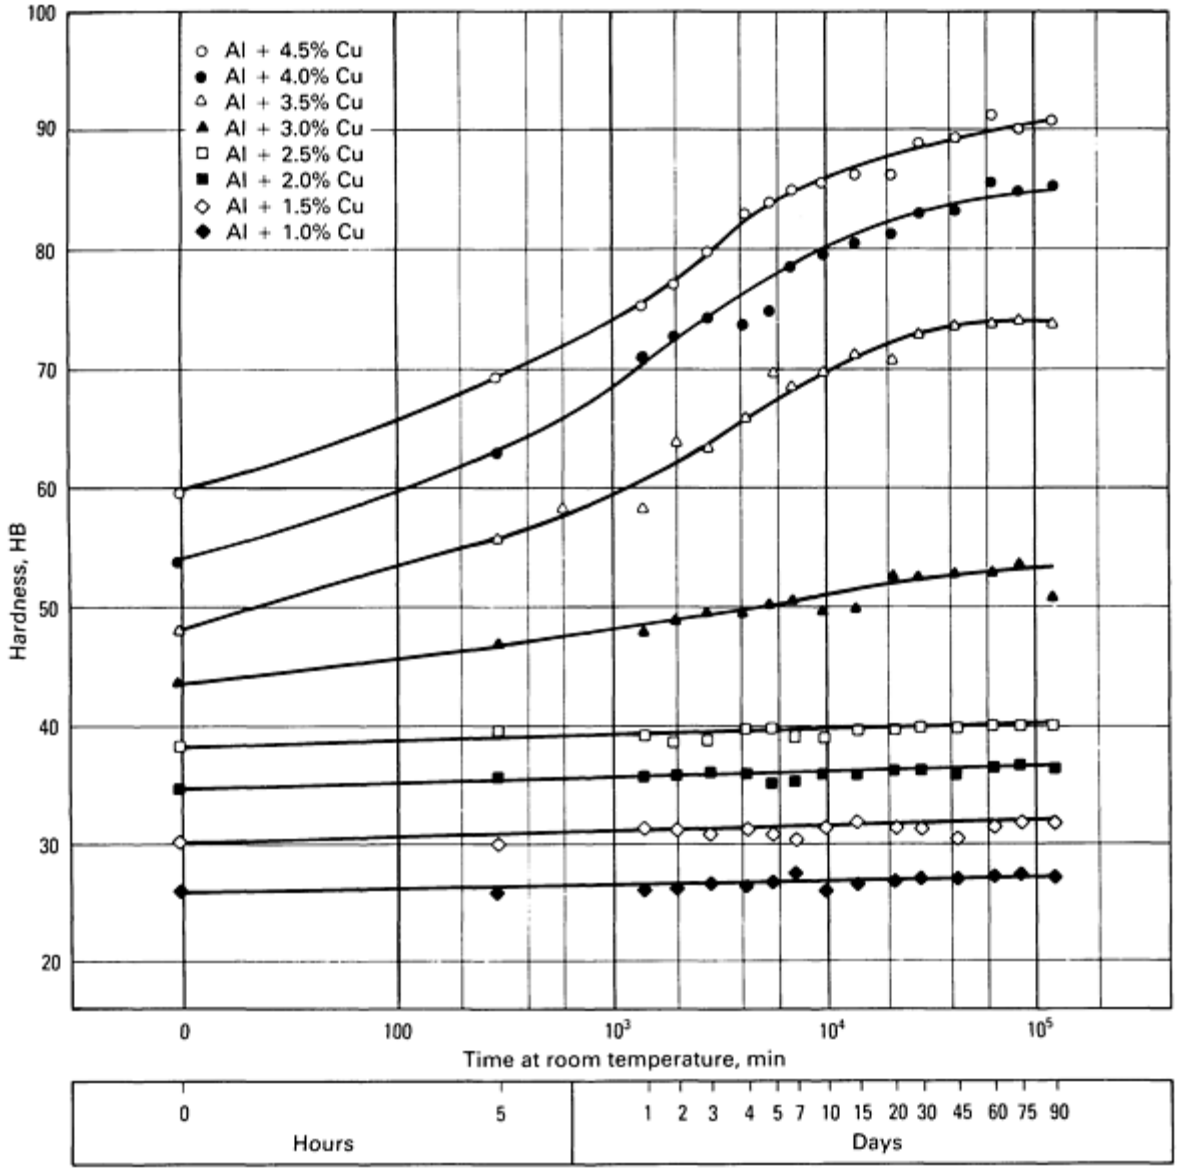

Fig. 10 Natural aging curves for binary Al-Cu alloys quenched in water at 100 °C (212 °F)

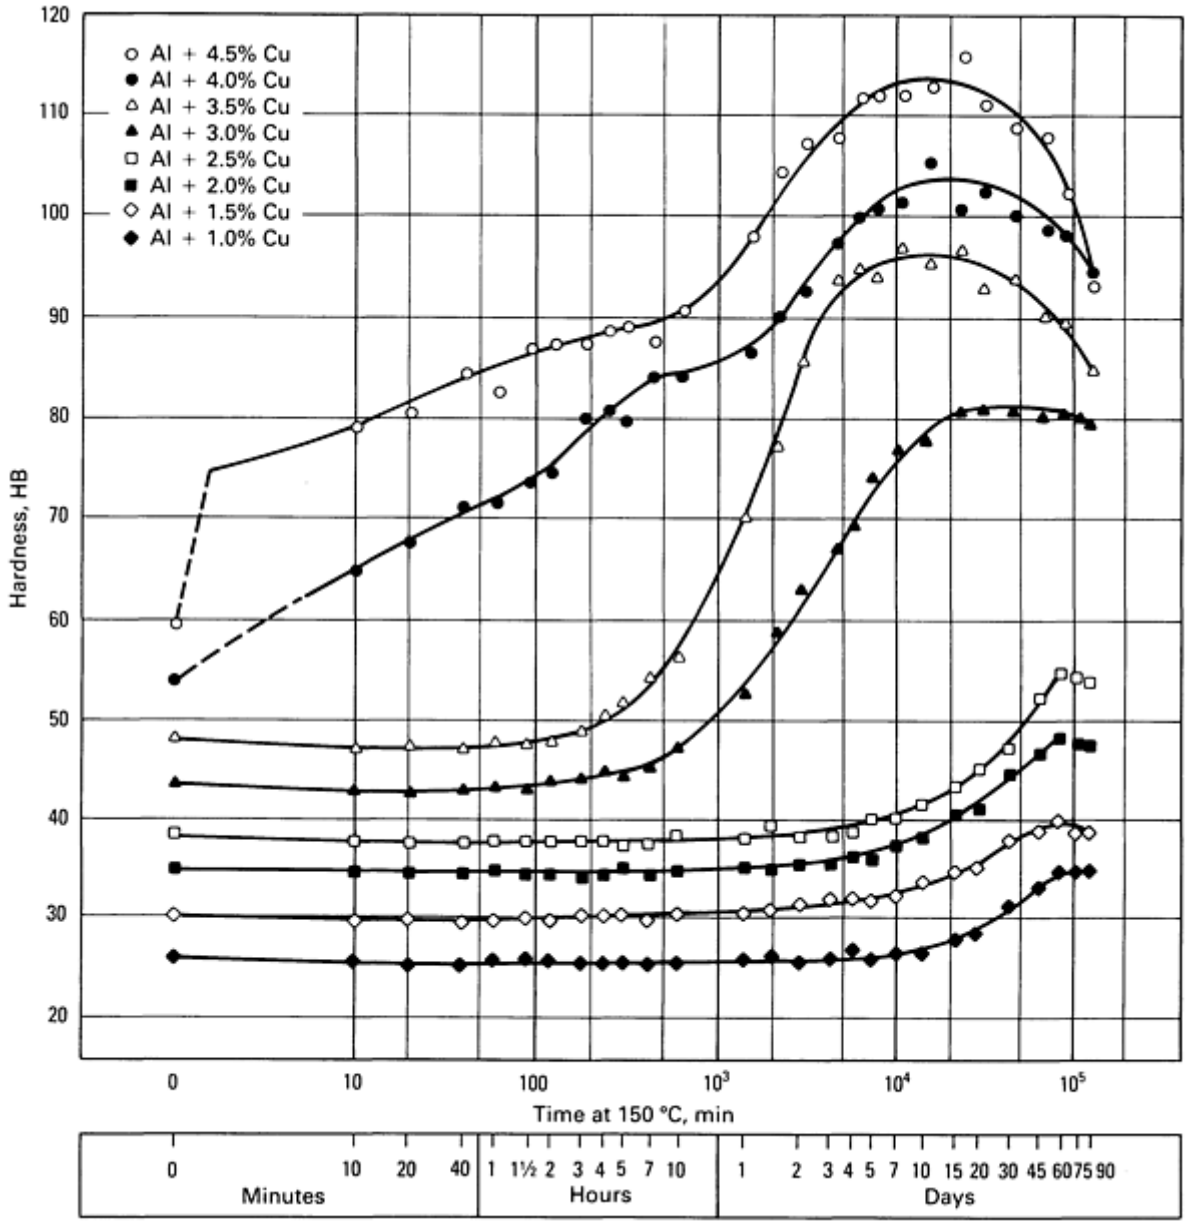

Fig. 11 Precipitation hardening curves for binary Al-Cu alloys quenched in water at 100 °C (212 °F) and aged at 150 °C (300 °F)

Artificial aging includes exposure at temperatures above room temperature so as to produce the transitional (metastable) forms of the equilibrium precipitate of a particular alloy system. These transitional precipitates remain coherent with the solid-solution matrix and thus contribute to precipitation strengthening. With further heating at temperatures that cause strengthening or at higher temperatures, the precipitate particles grow, but even more importantly convert to the equilibrium phases, which generally are not coherent. These changes soften the material, and carried further, produce the softest or annealed condition. Even at this stage, the precipitate particles are still too small to be clearly resolved by optical microscopy, although etching effects are readily observed--particularly in alloys containing copper.

Precipitation heat treatment or artificial aging curves for the Al-Mg-Si wrought alloy 6061 (which is widely used for structural shapes) are shown in Fig. 12. This is a typical family of curves showing the changes in tensile yield strength that accrue with increasing time at each of a series of temperatures. In all cases, the material had been given a solution heat treatment followed by a quench just prior to the start of the precipitation heat treatment. For detailed presentation of heat-treating operations, parameters, and practices, see *Heat Treating,* Volume 4 of *ASM Handbook.*

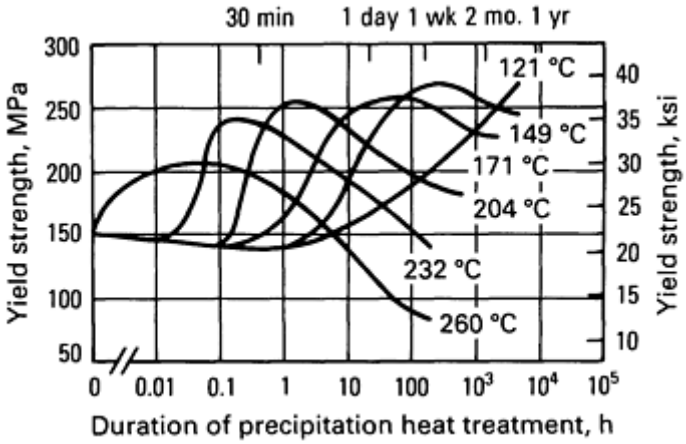

Fig. 12 Precipitation heat treatment or artificial aging curves for solution heat-treated aluminum alloy 6061

The commercial heat-treatable aluminum alloys are, with few exceptions, based on ternary or quaternary systems with respect to the solutes involved in developing strength by precipitation. The most prominent systems are: Al-Cu-Mg, Al-Cu-Si, and Al-Cu-Mg-Si, alloys of which are in the 2*xxx* and 2*xx.x* groups (wrought and casting alloys, respectively); Al-Mg-Si (6*xxx* wrought alloys); Al-Si-Mg, Al-Si-Cu, and Al-Si-Mg-Cu (3*xx.x* casting alloys); and Al-Zn-Mg and Al-Zn-Mg-Cu (7*xxx* wrought and 7*xx.x* casting alloys). In each case the solubility of the multiple-solute elements decreases with decreasing temperature.

These multiple alloying additions of both major solute elements and supplementary elements employed in commercial alloys are strictly functional and serve with different heat treatments to provide the many different combinations of properties--physical, mechanical, and electrochemical--that are required for different applications. Some alloys, particularly those for foundry production of castings, contain amounts of silicon far in excess of the amount that is soluble or needed for strengthening alone. The function here is chiefly to improve casting soundness and freedom from cracking, but the excess silicon also serves to increase wear resistance, as do other microstructural constituents formed by manganese, nickel, and iron. Parts made of such alloys are commonly used in gasoline and diesel engines (pistons, cylinder blocks, and so forth). The system of numerical nomenclature used to designate the alloys, and that for the strain-hardened and heat-treated tempers, is described in the article "Alloy and Temper Designation Systems for Aluminum and Aluminum Alloys" in this Volume.

Alloys containing the elements silver, lithium, and germanium are also capable of providing high strength with heat treatment, and in the case of lithium, both increased elastic modulus and lower density, which are highly advantageous--particularly for aerospace applications (see the article "Aluminum-Lithium Alloys" in this Volume). Commercial use of alloys containing these elements has been restricted either by cost or by difficulties encountered in producing them. Such alloys are used to some extent, however, and research is being directed toward overcoming their disadvantages.

In the case of alloys having copper as the principal alloying ingredient and no magnesium, strengthening by precipitation can be greatly increased by adding small fractional percentages of tin, cadmium, or indium, or combinations of these elements. Alloys based on these effects have been produced commercially but not in large volumes because of costly special practices and limitations required in processing, and in the case of cadmium, the need for special facilities to avoid health hazards from formation and release of cadmium vapor during alloying. Such alloys, as well as those containing silver, lithium, or other particle-forming elements, may be used on a selective basis in the future.

Effects on Physical and Electrochemical Properties. The above description of the precipitation processes in commercial heat-treatable aluminum alloys (as well as the heat-treatable binary alloys, none of which is used commercially) affect not only mechanical properties but also physical properties (density and electrical and thermal conductivities) and electrochemical properties (solution potential). On the microstructural and submicroscopic scales, the electrochemical properties develop point-to-point nonuniformities that account for changes in corrosion resistance.

Measurements of changes in physical and electrochemical properties have played an important role in completely describing precipitation reactions and are very useful in analyzing or diagnosing whether heat-treatable products have been properly or improperly heat treated. Although they may be indicative of the strength levels of products, they cannot be relied upon to determine whether or not the product meets specified mechanical-property limits. Since elements in solid solution are always more harmful to electrical conductivity than the same elements combined with others as intermetallic compounds, thermal treatments are applied to ingots used for fabrication of electrical conductor parts. These thermal treatments are intended to precipitate as much as possible of the dissolved impurities. Iron is the principal element involved, and although the amount precipitated is only a few hundredths of a percent, the effect on electrical conductivity of the wire, cable, or other product made from the ingot is of considerable practical importance. These alloys may or may not be heat treatable with respect to mechanical properties. Electrical conductor alloys 6101 and 6201 are heat treatable. These alloys are used in tempers in which their strengthening precipitate, the transition form of Mg_2Si, is largely out of solid solution to optimize both strength and conductivity.

Metallurgical Factors of Other Mechanical Properties

Forming. The formability of a material is the extent to which it can be deformed in a particular process before the onset of failure. Aluminum sheet or aluminum shapes usually fail by localized necking or by ductile fracture. Necking is governed largely by bulk material properties such as work hardening and strain-rate hardening and depends critically on the strain path followed by the forming process. In dilute alloys, the extent of necking or limit strain is reduced by cold work, age hardening, gross defects, a large grain size, and the presence of alloying elements in solid solution. Ductile fracture occurs as a result of the nucleation and linking of microscopic voids at particles and the concentration of strain in narrow shear bands. Fracture usually occurs at larger strains than does localized necking and therefore is usually important only when necking is suppressed. Common examples where fracture is encountered are at small radius bends and at severe drawing, ironing, and stretching near notches or sheared edges.

Considerable advances have been made in developing alloys with good formability, but in general, an alloy cannot be optimized on this basis alone. The function of the formed part must also be considered and improvements in functional characteristics, such as strength and ease of machining, often tend to reduce the formability of the alloy.

The principal alloys that are strengthened by alloying elements in solid solution (often coupled with cold work) are those in the aluminum-magnesium (5*xxx*) series, ranging from 0.5 to 6 wt% Mg. Figure 6 illustrates the effect of magnesium in solid solution on the yield strength and tensile elongation for most of the common aluminum-magnesium commercial alloys. Note the large initial reduction in the tensile elongation with the addition of small amounts of magnesium.

The reductions in the forming limit produced by additions of magnesium and copper appear to be related to the tendency of the solute atoms to migrate to dislocations (strain age). This tends to increase work hardening at low strains, where dislocations are pinned by solute atoms, but produces a decrease in work hardening at large strains. Small amounts of magnesium or copper also reduce the strain-rate hardening, which will reduce the amount of useful diffuse necking that occurs after the uniform elongation. Zinc in dilute alloys has little effect on work hardening or necking, and it does not cause strain aging.

Elements that have low solid solubilities at typical processing temperatures, such as iron, silicon, and manganese, are present in the form of second-phase particles and have little influence on either strain hardening or strain-rate hardening and thus a relatively minor influence on necking behavior. Second-phase particles do, however, have a large influence on fracture, as is shown in Fig. 13 and 14. In these examples an increase in the iron, nickel, or manganese content produces an increase in the number of microscopic particles that promote fracture. The addition of magnesium promotes an additional reduction in fracture strain because the higher flow stresses aid in the formation and growth of voids at the intermetallic particles. Magnesium in solid solution also promotes the localization of strain into shear bands, which concentrates the voids in a thin plane of highly localized strain.

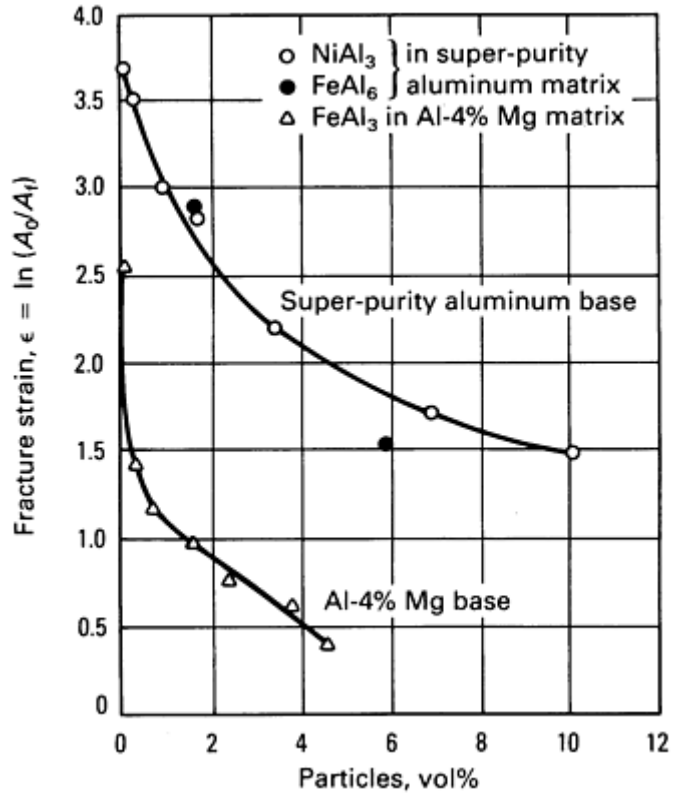

Fig. 13 Effect of volume percent fraction of micron-size intermetallic particles and composition of the matrix on the fracture strain of 5 mm (0.2 in.) diam tensile specimens. A_0 is initial cross-sectional area. A_f is area of fracture.

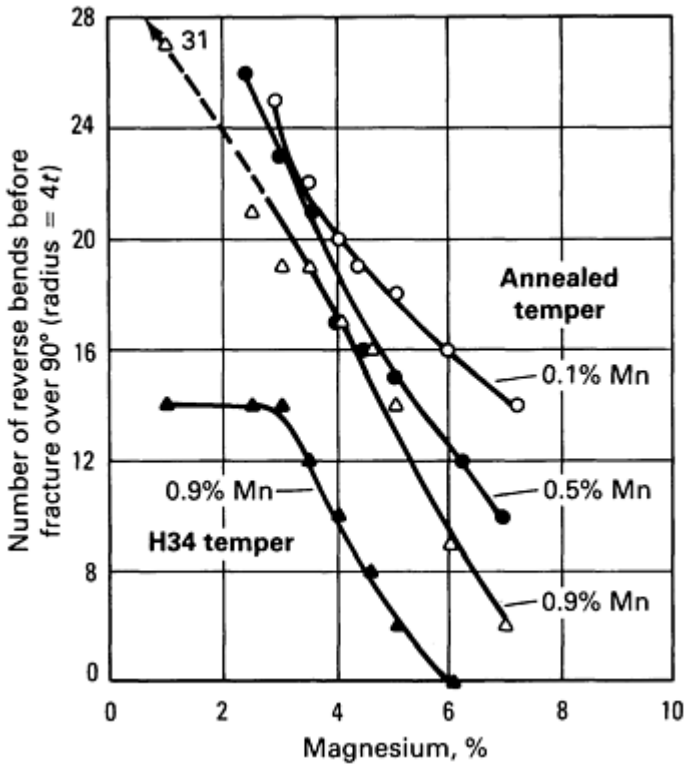

Fig. 14 Effect of magnesium and manganese on the formability of aluminum alloys in the annealed and H34

tempers; 1.6 mm (0.064 in.) thick sheet

Precipitation-strengthened alloys are usually formed in the naturally aged (T4) condition, or in the annealed (O) condition, but only very rarely in the peak strength (T6) condition where both the necking and fracture limits are low. In Fig. 15 the effect of a wide range of precipitate structures on some of the forming properties is illustrated for alloy 2036 (2.5% Cu-0.5% Mg). Curves similar in shape can be drawn for most of the precipitation-strengthened alloys in the 2*xxx* and 6*xxx* series. The properties in Fig. 15 were obtained from sheet tensile specimens first solution heat treated, then aged at temperatures ranging from room temperature to 350 °C (660 °F). This produced a full range of structures from solid solution (as-quenched) through T4 and T6 tempers to various degrees of overaging and precipitate agglomeration.

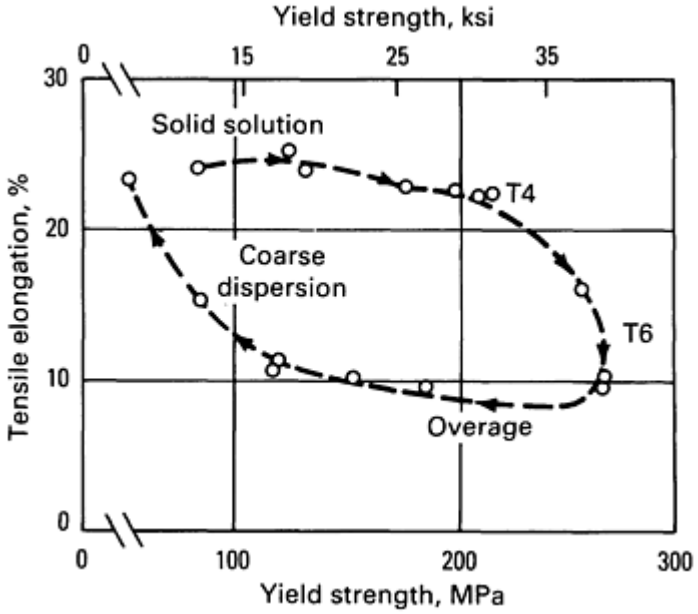

Fig. 15 Effect of precipitation on yield strength and elongation in alloy 2036

Fracture toughness and fatigue behavior, which are important characteristics of the high-strength aluminum alloys used in aerospace applications, are known to be influenced by the following three types of constituent particles:

Type	Size		Typical examples
	µm	mil	
Constituent particles	2-50	0.08-2	Cu_2FeAl_7, $CuAl_2$, $FeAl_6$
Dispersoid particles	0.01-0.5	0.0004-0.02	$ZrAl_3$, $CrMg_2Al_{12}$
Strengthening precipitates	0.001-0.5	0.00004-0.02	Guinier-Preston zones

Consequently, the design of damage-tolerant aluminum alloys such as 7475, 7050, or 2124 has been primarily based upon the control of microstructure through composition and fabrication practice.

Effect of Second-Phase Constituents on Fracture Toughness. It is generally accepted that the fracture of brittle constituent particles leads to preferential paths for crack advance and reduced fracture toughness. Consequently, an often-used approach to improve the toughness of high-strength aluminum alloys has been the reduction of iron and silicon levels. The recent development of improved alloys such as 7475, 7050, and 2124 has hinged, in large part, upon the use of higher-purity base metal than 7075 or 2024. Figure 16 illustrates the influence of base metal purity on the fracture resistance of alloy 7475 sheet. The partially soluble constituents exert a similar effect on the fracture behavior of other high-strength alloys. Figure 17 shows the reduction in toughness experienced as the volume fraction of Al_2CuMg is increased in alloy 7050 plate.

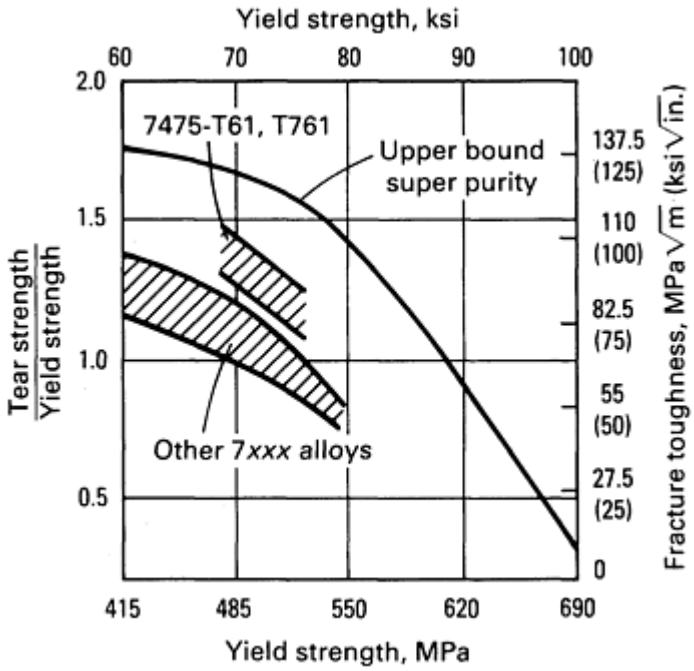

Fig. 16 Tear strength and yield strength ratio of alloy 7475 sheet

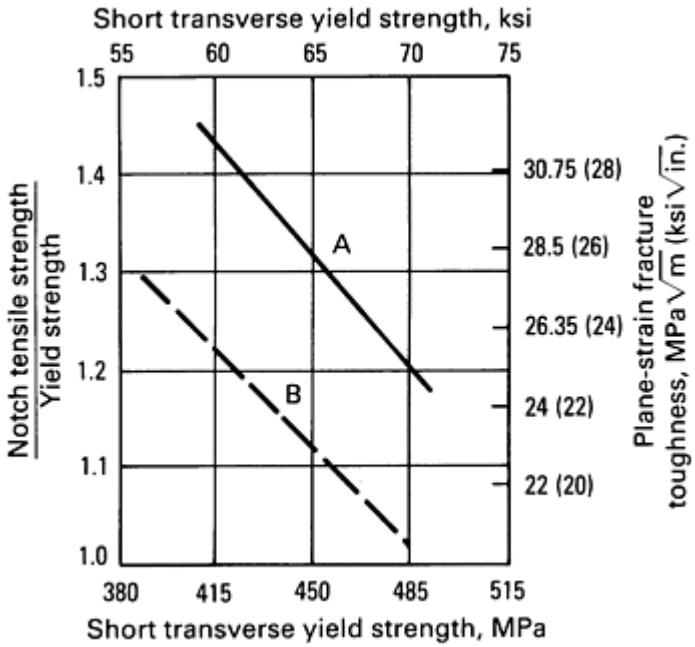

Fig. 17 Effects of amount of Al_2CuMg constituent on the toughness of 7050 plate

For superior toughness, the amount of dispersoid-forming element should be held to the minimum required for control of grain structure, mechanical properties, or resistance to stress-corrosion cracking. Results for 7*xxx* alloy sheet (Fig. 18) show the marked decrease in unit propagation energy as chromium is increased. Substitution of other elements, such as zirconium or manganese, for chromium can also influence fracture toughness. However, the observed effects of the different dispersoids on fracture toughness can quite possibly be related to the particular toughness parameter chosen and the influence of the dispersoid on the grain structure of the wrought product.

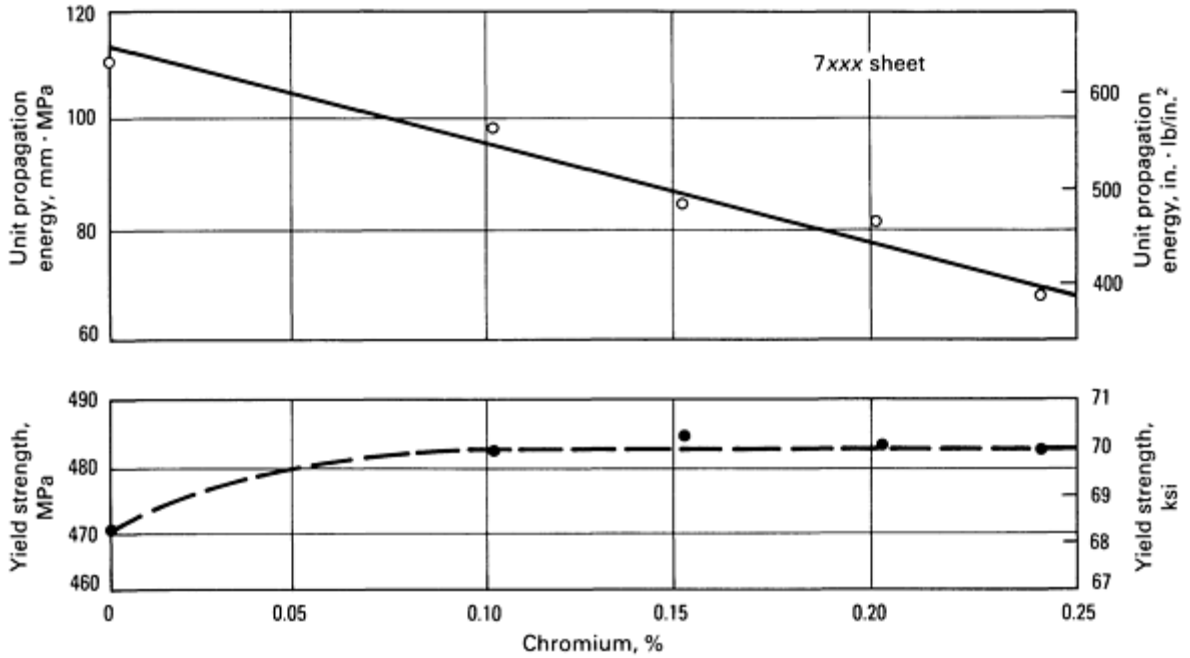

Fig. 18 Effect of chromium content on unit crack propagation energy and yield strength on a Zn-Mg-Cu aluminum alloy (5.5 Zn, 2.4 Mg, 1.4 Cu, 0.30 Fe, 0.08 Si, 0.03 Ti, 0.01 Mn)

The primary effect of hardening precipitates on fracture toughness of high-strength aluminum alloys is through the increase in yield strength and depends upon the particular working and heat-treatment practices applied to the wrought products. However, composition changes, particularly magnesium level, can produce significant effects on toughness of 7*xxx* alloys. These variations in composition do not alter the basic character of the hardening precipitates, but exert a subtle influence on the overall precipitate structure.

Effect of Second-Phase Constituents on Fatigue Behavior. Although the three types of constituent particles may influence fatigue behavior, the effect of constituent particles on fatigue behavior is highly dependent upon the type of fatigue test or the stress regime chosen for evaluation. Consequently, the design of aluminum alloys to resist failure by fatigue mechanisms has not proceeded to the same extent as for fracture toughness. In the case of large constituent particles, for example, reduced iron and silicon contents do not always result in improved fatigue resistance commensurate with the previously described improvements in fracture toughness. Increased purity level does not, for instance, produce any appreciable improvement in notched or smooth *S-N* fatigue strength.

In terms of fatigue crack growth (FCG) rates, no consistent differences have been observed for low- and high-purity 7*xxx* alloy variants at low to intermediate ΔK levels. However, at high stress-intensity ranges, FCG rates are notably reduced for low iron and silicon alloys. The reason for the observed improvement is undoubtedly related to the higher fracture toughness of high-purity metals. At high stress-intensity ranges, where crack growth per cycle (da/dN) values are large, localized fracture and void nucleation at constituent particles become the dominant FCG mechanism. For samples subjected to periodic spike overloads, low-purity alloys were shown to exhibit slower overall FCG rates than higher-

purity materials. This effect was attributed to localized crack deviation induced by the insoluble constituents. Secondary cracks at these particles acted to lower crack tip stress-intensity values and to reduce measured FCG rates.

No clear-cut influence of dispersoid particles on the fatigue behavior of aluminum alloys has emerged. Two separate studies have concluded that dispersoid type has little effect on either FCG resistance or notched fatigue resistance of 7*xxx* alloys. The only expected effect of dispersoid type on fatigue performance should occur for high ΔK fatigue crack growth, where mechanisms similar to those for fracture toughness predominate.

Within a given alloys system, slight changes in composition that influence hardening precipitates have not been shown to influence the *S-N* fatigue resistance of aluminum alloys. However, significant differences have been observed in comparison of alloys of different systems. For instance, 2024-T3 is known to outperform 7075-T6 at stresses where fatigue lives are short (: 10^5 cycles). The superior fatigue performance of alloy 2024-T3 in the 10^5 cycle range has led most aircraft designers to specify it in preference to 7075-T6 in applications where tension-tension loads are predominant.

Alloy 2024-T3 shows a similar advantage over 7075-T6 and other 7*xxx* alloys in fatigue crack growth. The superior performance for 2024-T3 plate versus 7075-T6 extends over the entire *da*/*dN*-ΔK range, as shown in Fig. 19. Within the 7*xxx* alloy system, increasing copper content improves FCG performance in high humidity. This result was attributed to an increased resistance of the high-copper alloy to corrosion in the moist environment.

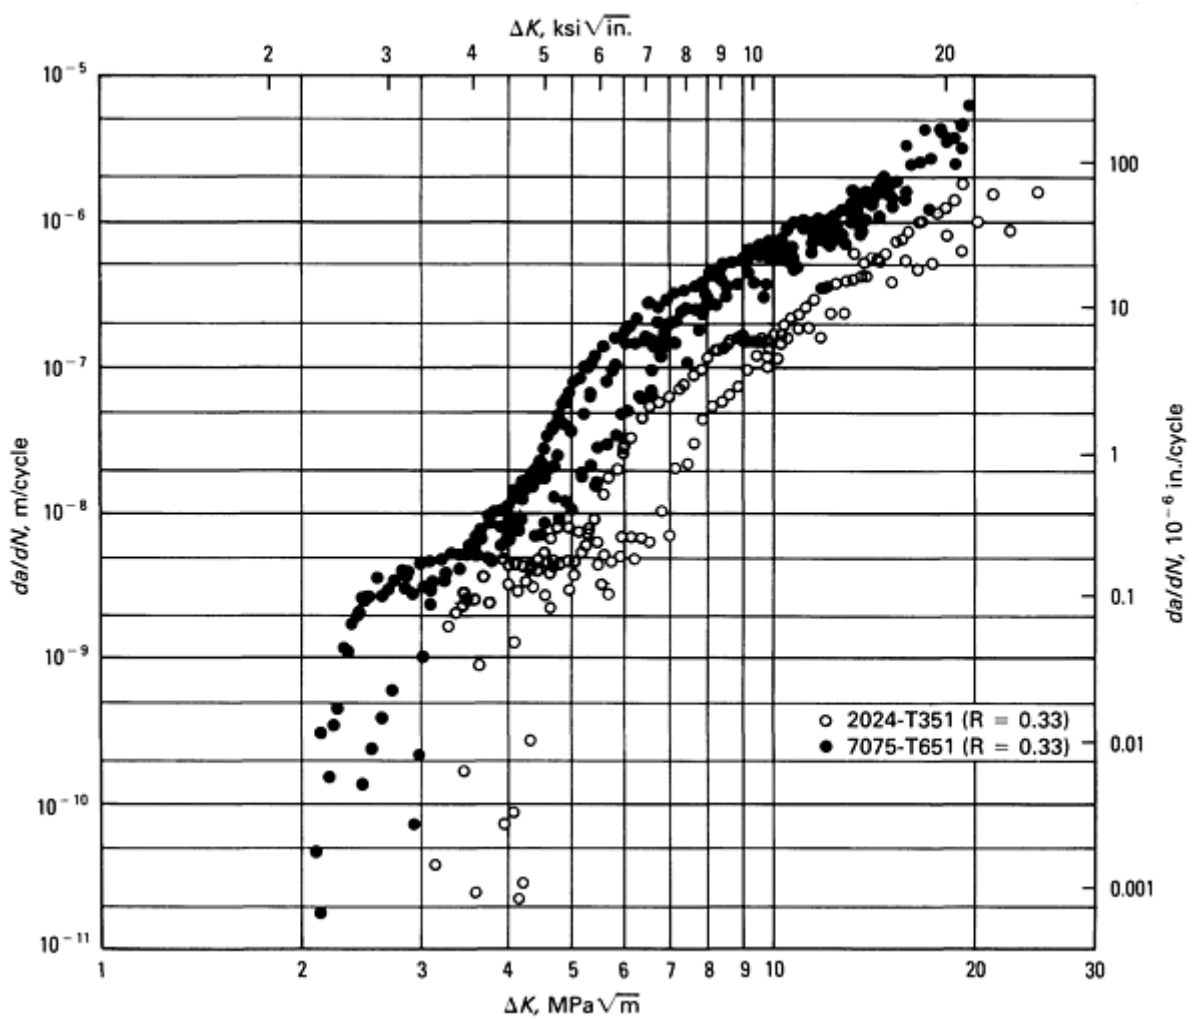

Fig. 19 Fatigue crack growth of 2024-T3 versus 7075-T6 plate over entire *da*/*dN*-ΔK range

Fatigue designers are currently beginning to use increasingly complex "spectrum" FCG tests to predict the performance of materials in service. Early work in the area of spectrum fatigue showed that high-toughness alloy 7475-T76 performed better than either 2024-T3 or 7075-T6.

General Effects of Alloying

Although the predominant reason for alloying is to increase strength, alloying also has important effects on other characteristics of aluminum alloys. Some of these effects are discussed below. Effects of specific elements are discussed in the section "Specific Alloying Elements and Impurities" in this article.

Alloy Effects on Physical Properties. Most of the physical properties--density, melting-temperature range, heat content, coefficient of thermal expansion, and electrical and thermal conductivities--are changed by addition of one or more alloying elements. The rates of change in these properties with each incremental addition are specific for each element and depend, in many cases drastically, on whether a solid solution or a second phase is formed. In those cases in which the element or elements may be either dissolved or precipitated by heat treatment, certain of these properties, particularly density and conductivity, can be altered substantially by heat treatment. Density and conductivity of such alloys show relatively large differences from one temper to another.

Electrochemical properties and corrosion resistance are strongly affected by alloying elements that form either solid solutions, or additional phases, or both. For those systems exhibiting substantial changes in solid solubility with temperature, these properties may change markedly with heat-treated tempers, and although infrequently, even with room-temperature aging (for example, the stress-corrosion resistance of high-Mg 5*xxx* alloys in strain-hardened tempers). The strongest electrochemical effects are from copper or zinc in solid solution. Additions of copper in solid solution change the electrochemical solution potential in the cathodic direction at the rate of 0.047 V/wt% (0.112 V/at%), and additions of zinc change it in the anodic direction at the rate of 0.063 V/wt% (0.155 V/at%). These potentials are those measured in aqueous solution of 53 g NaCl + 3 g H_2O_2 per liter. Magnesium and silicon, which are the basis for the 4*xxx,* 5*xxx,* and 6*xxx* series wrought alloys and the 3*xx.x,* 4*xx.x,* and 5*xx.x* series casting alloys, and which are prominent in the compositions of many other alloys, have relatively mild effects on solution potential and are not detrimental to corrosion resistance.

Although aluminum is a thermodynamically reactive metal, it has excellent resistance to corrosion in most environments, which may be attributed to the passivity afforded by a protective film of aluminum oxide. This film is strongly bonded to the surface of the metal, and if damaged re-forms almost immediately. The continuity of the film is affected by the microstructure of the metal--in particular, by the presence and volume fraction of second-phase particles. Corrosion resistance is affected by this factor and by the solution-potential relationships between the second-phase particles or constituents and the solid-solution matrix in which they occur. In most environments, resistance to corrosion of unalloyed aluminum increases with increasing purity. The resistance of an alloys depends not only on the microstructural relationships involving the specific types, amounts, and distributions of the second-phase constituents but even more strongly on the nature of the solid solutions in which they are present. Copper reduces corrosion resistance despite the fact that when in solid solution it makes the alloy more cathodic (less active thermodynamically). This is explained by the fact that copper ions taken into solution in aqueous, corroding media replate on the aluminum alloy surface as minute particles of metallic copper, forming even more active corrosion couples because metallic copper is highly cathodic to the alloy. Manganese, which in solid solution changes solution potential in the cathodic direction as strongly as does copper, does not impair corrosion resistance of commercial alloys that contain it, because that amounts left in solid solution in commercial products, which undergo extensive solid-state heating in process, are very small, and the manganese does not replate from solution as does copper.

The differences in solution potential among alloys of different compositions are used to great advantage in the composite Alclad products. In these products, the structural component of the composite, usually a strong or heat-treatable alloy, is made the core of the product and is covered by a cladding alloy of a composition that not only is highly corrosion resistant but also has a solution potential that is anodic to that of the core. Analogous to the protection of the underlying steel afforded by zinc on the surfaces of galvanized steel products, the aluminum alloy core is protected electrolytically by the more-anodic cladding. The composition of the cladding material is designed specifically to protect the core alloy, so that, for those containing copper as the principal alloying ingredient (2*xxx* type), the more-anodic unalloyed aluminum (1*xxx* type) serves to protect the core electrolytically. In the case of the strong alloys containing zinc along with magnesium and copper (such as 7049, 7050, 7075, and 7178), an aluminum-zinc alloy (7072) or an aluminum-zinc-magnesium alloy (7008 or 7011) provides protection. The latter provides higher strength.

Impurity Effects. Although major differences in properties and characteristics are usually associated with alloying additions of one to several percent, many alloying elements produce highly significant effects when added in small fractions of 1% or when increased by such small amounts. With respect to mechanical properties, this is particularly true for combinations of certain elements. The interactions are quite complex, and a given element may be either highly

beneficial or highly detrimental depending on the other elements involved and on the property or combination of properties needed.

The presence or absence of amounts on the order of one thousandth of one percent of certain impurities--sodium and calcium, for example--may make the difference between success of complete failure in fabricating high-magnesium 5*xxx* alloy ingots into useful wrought products. There are many other examples of equal practical importance. Impurity limits specified for commercial alloys reflect some of these effects, but producers of mill products must adhere to even more restrictive limits in many cases to ensure good product recovery.

Silicon-Modifying Additions. Additions of similarly small percentages of both metallic and nonmetallic substances--sodium and phosphorus, for example--are used to enhance the mechanical and machining properties of silicon-containing casting alloys.

Grain-Refining Additions. Most alloys produced as "fabricating ingots" for fabricating wrought products, as well as those in the form of foundry ingot, have small additions of titanium or boron, or combinations of these two elements, in controlled proportions. The purpose of these additions is to control grain size and shape in the as-cast fabricating ingot or in castings produced from the foundry ingot. These grain-refining additions have little effect on changes in grain size that occur during or as a result of working or recrystallization. Welding filler alloys and casting alloys generally have higher contents of the grain-refining elements to ensure highest resistance to cracking during solidification of welds and castings.

The elements that have relatively great and controlling effects on grain sizes and shapes produced by the mechanical working required to produce wrought products (their thermomechanical history) are manganese, chromium, and zirconium. Small amounts (fractional percentages) of these elements, singly or in combination, are included in the compositions of many alloys to control grain size and recrystallization behavior through fabrication and heat treatment. Such grain control has many purposes, which include ensuring good resistance to stress-corrosion cracking (SCC), high fracture toughness, and good forming characteristics. In specific alloys, these elements have highly significant supplementary beneficial effects on strength, resistance to fatigue, or strength at elevated temperatures. In order to fulfill their grain-control functions, these elements must be precipitated as finely distributed particles termed dispersoids. Their precipitation is accomplished primarily by the high-temperature, solid-state heating involved in ingot pre-heating.

Secondary Aluminum. Aluminum recovered from scrap (secondary aluminum) has been an important contributor to the total metal supply for many years. For some uses, secondary aluminum alloys may be treated to remove certain impurities or alloying elements. Chief among the alloying elements removed is magnesium, which is frequently present in greater amounts in secondary metal than in the alloys to be produced from it. Magnesium is usually removed by fluxing with chlorine gas or halide salts.

Specific Alloying Elements and Impurities

The important alloying elements and impurities are listed here alphabetically as a concise review of major effects. Some of the effects, particularly with respect to impurities, are not well documented and are specific to particular alloys or conditions.

Antimony is present in trace amounts (0.01 to 0.1 ppm) in primary commercial-grade aluminum. Antimony has a very small solid solubility in aluminum (<0.01%). It has been added to aluminum-magnesium alloys because it was claimed that by forming a protective film of antimony oxychloride, it enhances corrosion resistance in salt water. Some bearing alloys contain up to 4 to 6% Sb. Antimony can be used instead of bismuth to counteract hot cracking in aluminum-magnesium alloys.

Arsenic. The compound AsAl is a semiconductor. Arsenic is very toxic (as AsO_3) and must be controlled to very low limits where aluminum is used as foil for food packaging.

Beryllium is used in aluminum alloys containing magnesium to reduce oxidation at elevated temperatures. Up to 0.1% Be is used in aluminizing baths for steel to improve adhesion of the aluminum film and restrict the formation of the deleterious iron-aluminum complex. The mechanism of protection is attributed to beryllium diffusion to the surface and the formation of a protective layer.

Oxidation and discoloration of wrought aluminum-magnesium products are greatly reduced by small amounts of beryllium because of the diffusion of beryllium to the surface and the formation of an oxide of high-volume ratio.

Beryllium does not affect the corrosion resistance of aluminum. Beryllium is generally held to <8 ppm in welding filler metal, and its content should be limited in wrought alloys that may be welded.

Beryllium poisoning is an allergic disease, a problem of individual hypersensitivity that is related to intensity and duration of exposure. Inhalation of dust containing beryllium compounds may lead to acute poisoning. Beryllium is not used in aluminum alloys that may contact food or beverages.

Bismuth. The low-melting-point metals such as bismuth, lead, tin, and cadmium are added to aluminum to make free-machining alloys. These elements have a restricted solubility in solid aluminum and form a soft, low-melting phase that promotes chip breaking and helps to lubricate the cutting tool. An advantage of bismuth is that its expansion on solidification compensates for the shrinkage of lead. A 1-to-1 lead-bismuth ratio is used in the aluminum-copper alloy, 2011, and in the aluminum-Mg_2Si alloy, 6262. Small additions of bismuth (20 to 200 ppm) can be added to aluminum-magnesium alloys to counteract the detrimental effect of sodium on hot cracking.

Boron is used in aluminum and its alloys as a grain refiner and to improve conductivity by precipitating vanadium, titanium, chromium, and molybdenum (all of which are harmful to electrical conductivity at their usual impurity level in commercial-grade aluminum). Boron can be used alone (at levels of 0.005 to 0.1%) as a grain refiner during solidification, but becomes more effective when used with an excess of titanium. Commercial grain refiners commonly contain titanium and boron in a 5-to-1 ratio. Boron has a high neutron capture cross section and is used in aluminum alloys for certain atomic energy applications, but its content has to be limited to very low levels in alloys used in reactor areas where this property is undesirable.

Cadmium is a relatively low-melting element that finds limited use in aluminum. Up to 0.3% Cd may be added to aluminum-copper alloys to accelerate the rate of age hardening, increase strength, and increase corrosion resistance. At levels of 0.005 to 0.5%, it has been used to reduce the time of aging of aluminum-zinc-magnesium alloys. It has been reported that traces of Cd lower the corrosion resistance of unalloyed aluminum. In excess of 0.1%, cadmium causes hot shortness in some alloys. Because of its high neutron absorption, cadmium has to be kept very low for atomic energy use. It has been used to confer free-cutting characteristics, particularly to aluminum-zinc-magnesium alloys; it was preferred to bismuth and lead because of its higher melting point. As little as 0.1% provides an improvement in machinability. Cadmium is used in bearing alloys along with silicon. The oral toxicity of cadmium compounds is high. In melting, casting, and fluxing operations cadmium oxide fume can present hazards.

Calcium has very low solubility in aluminum and forms the intermetallic $CaAl_4$. An interesting group of alloys containing about 5% Ca and 5% Zn have superplastic properties. Calcium combines with silicon to form $CaSi_2$, which is almost insoluble in aluminum and therefore will increase the conductivity of commercial-grade metal slightly. In aluminum-magnesium-silicon alloys, calcium will decrease age hardening. Its effect on aluminum-silicon alloys is to increase strength and decrease elongation, but it does not make these alloys heat treatable. At the 0.2% level, calcium alters the recrystallization characteristics of 3003. Very small amounts of calcium (10 ppm) increase the tendency of molten aluminum alloys to pick up hydrogen.

Carbon may occur infrequently as an impurity in aluminum in the form of oxycarbides and carbides, of which the most common is Al_4C_3, but carbide formation with other impurities such as titanium is possible. Al_4C_3 decomposes in the presence of water and water vapor, and this may lead to surface pitting. Normal metal transfer and fluxing operations usually reduce carbon to the ppm level.

Cerium, mostly in the form of mischmetal (rare earths with 50 to 60% Ce), has been added experimentally to casting alloys to increase fluidity and reduce die sticking. In alloys containing high iron (>0.7%), it is reported to transform acicular $FeAl_3$ into a nonacicular compound.

Chromium occurs as a minor impurity in commercial-purity aluminum (5 to 50 ppm). It has a large effect on electrical resistivity. Chromium is a common addition to many alloys of the aluminum-magnesium, aluminum-magnesium-silicon, and aluminum-magnesium-zinc groups, in which it is added in amounts generally not exceeding 0.35%. In excess of these limits, it tends to form very coarse constituents with other impurities or additions such as manganese, iron, and titanium. This limit is decreased as the content of transition metals increases. In casting alloys, excess chromium will produce a sludge by peritectic precipitation on holding.

Chromium has a low diffusion rate and forms fine dispersed phase in wrought products. The dispersed phase inhibit nucleation and grain growth. Chromium is used to control grain structure, to prevent grain growth in aluminum-

magnesium alloys, and to prevent recrystallization in aluminum-magnesium-silicon or aluminum-magnesium-zinc alloys during hot working or heat treatment. The fibrous structures that develop reduce stress corrosion susceptibility and/or improve toughness. Chromium in solid solution and as a finely dispersed phase increases the strength of alloys slightly. The main drawback of chromium in heat-treatable alloys is the increase in quench sensitivity when the hardening phase tends to precipitate on the preexisting chromium-phase particles. Chromium imparts a yellow color to the anodic film.

Cobalt is not a common addition to aluminum alloys. It has been added to some aluminum-silicon alloys containing iron, where it transforms the acicular β(aluminum-iron-silicon) into a more rounded aluminum-cobalt-iron phase, thus improving strength and elongation. Aluminum-zinc-magnesium-copper alloys containing 0.2 to 1.9% Co are produced by powder metallurgy.

Copper. Aluminum-copper alloys containing 2 to 10% Cu, generally with other additions, form important families of alloys. Both cast and wrought aluminum-copper alloys respond to solution heat treatment and subsequent aging with an increase in strength and hardness and a decrease in elongation. The strengthening is maximum between 4 and 6% Cu, depending upon the influence of other constituents present. The properties of aluminum-copper alloy sheet in a number of thermal conditions are assembled in Fig. 20. The aging characteristics of binary aluminum-copper alloys have been studied in greater detail than any other system, but there are actually very few commercial binary aluminum-copper alloys. Most commercial alloys contain other alloying elements.

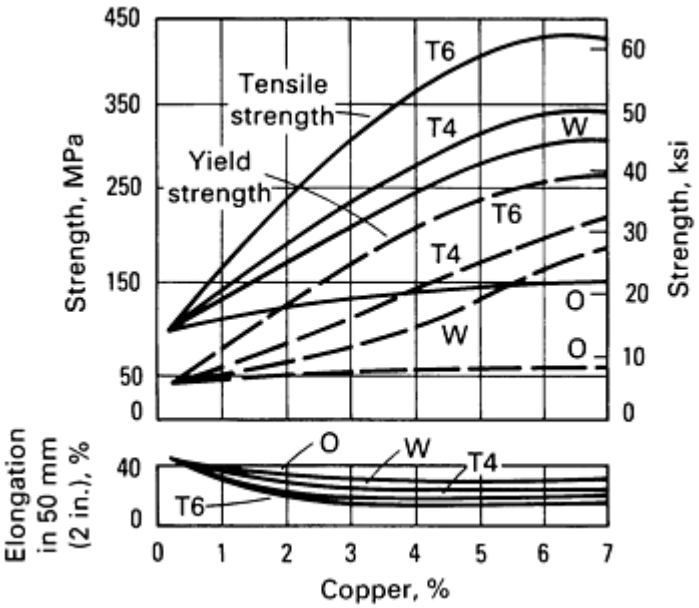

Fig. 20 Tensile properties of high-purity, wrought aluminum-copper alloys. Sheet specimen was 13 mm (0.5 in.) wide and 1.59 mm (0.0625 in.) thick. O, annealed; W, tested immediately after water quenching from a solution heat treatment; T4, as in W, but aged at room temperature; T6, as in T4, followed by precipitation treatment at elevated temperature

Copper-Magnesium. The main benefit of adding magnesium to aluminum-copper alloys is the increased strength possible following solution heat treatment and quenching. In wrought material of certain alloys of this type, an increase in strength accompanied by high ductility occurs on aging at room temperature. On artificial aging, a further increase in strength, especially in yield strength, can be obtained, but at a substantial sacrifice in tensile elongation.

On both cast and wrought aluminum-copper alloys, as little as about 0.5% Mg is effective in changing aging characteristics. In wrought products, the effect of magnesium additions on strength can be maximized in artificially aged materials by cold working prior to aging (Fig. 21). In naturally aged materials, however, the benefit to strength from magnesium additions can decrease with cold working (Fig. 22). The effect of magnesium on the corrosion resistance of aluminum-copper alloys depends on the type of product and the thermal treatment.

Copper-Magnesium Plus Other Elements. The cast aluminum-copper-magnesium alloys containing iron are characterized by dimensional stability and improved bearing characteristics, as well as by high strength and hardness at elevated temperatures. However, in a wrought Al-4%Cu-0.5%Mg alloy, iron in concentrations as low as 0.5% lowers the tensile properties in the heat-treated condition, if the silicon content is less than that required to tie up the iron as the αFeSi constituent. In this event, the excess iron unites with copper to form the Cu_2FeAl_7 constituent, thereby reducing the amount of copper available for heat-treating effects. When sufficient silicon is present to combine with the iron, the properties are unaffected. Silicon also combines with magnesium to form Mg_2Si precipitate and contributes in the age-hardening process.

Silver substantially increased the strength of heat-treated and aged aluminum-copper-magnesium alloys. Nickel improves the strength and hardness of cast and wrought aluminum-copper-magnesium alloys at elevated temperatures. Addition of about 0.5% Ni lowers the tensile properties of the heat-treated, wrought Al-4%Cu-0.5%Mg alloy at room temperature.

The alloys containing manganese form the most important and versatile system of commercial high-strength wrought aluminum-copper-magnesium alloys. The substantial effect exerted by manganese on the tensile properties of aluminum-copper alloys containing 0.5% Mg is shown in Fig. 23. It is apparent that no one composition offers both maximum strength and ductility. In general, tensile strength increases with separate or simultaneous increases in magnesium and manganese, and the yield strength also increases, but to a lesser extent. Further increases in tensile and particularly yield strength occur on cold working after heat treatment. Additions of manganese and magnesium decrease the fabricating characteristics of the aluminum-copper alloys, and manganese also causes a loss in ductility; hence, the concentration of this element does not exceed about 1% in commercial alloys. Additions of cobalt, chromium, or molybdenum to the wrought Al-4%Cu-0.5%Mg type of alloy increase the tensile properties on heat treatment, but none offers a distinct advantage over manganese.

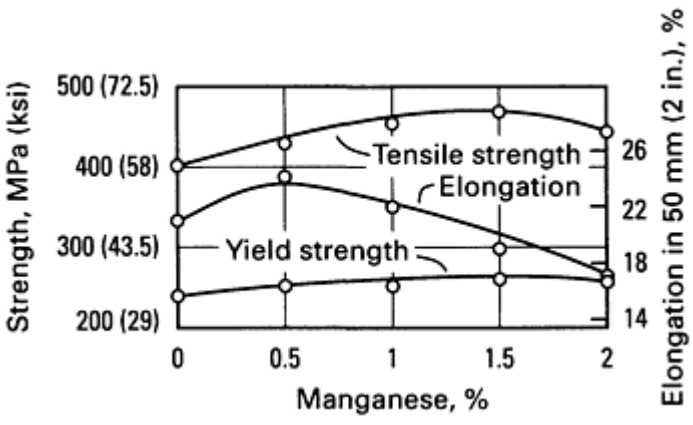

Fig. 23 Relationship between tensile properties and manganese content of Al-4%Cu-0.5%Mg alloy, heat treated at 525 °C (980 °F)

Alloys with lower copper content than the conventional 2024 and 2014 type alloys were necessary to provide the formability required by the automobile industry. Copper-magnesium alloys developed for this purpose are 2002, AU2G, and 2036 variations. These have acceptable formability, good spot weldability, reasonable fusion weldability, good corrosion resistance, and freedom from Lüder lines. The paint-baking cycle serves as a precipitation treatment to give final mechanical properties.

Copper and Minor Additions. In the wrought form, an alloy family of interest is the one containing small amounts of several metals known to raise the recrystallization temperature of aluminum and its alloys, specifically manganese, titanium, vanadium, or zirconium. An alloy of this nature retains its properties well at elevated temperatures, fabricates readily, and has good casting and welding characteristics. Figure 24 illustrates the effect of 3 to 8% Cu on an alloy of Al-0.3% Mn-0.2% Zr-0.1% V at room temperature and after exposure at 315 °C (600 °F) for two different periods of time. The stability of the properties should be noted, as reflected in the small reduction in strength with time at this temperature.

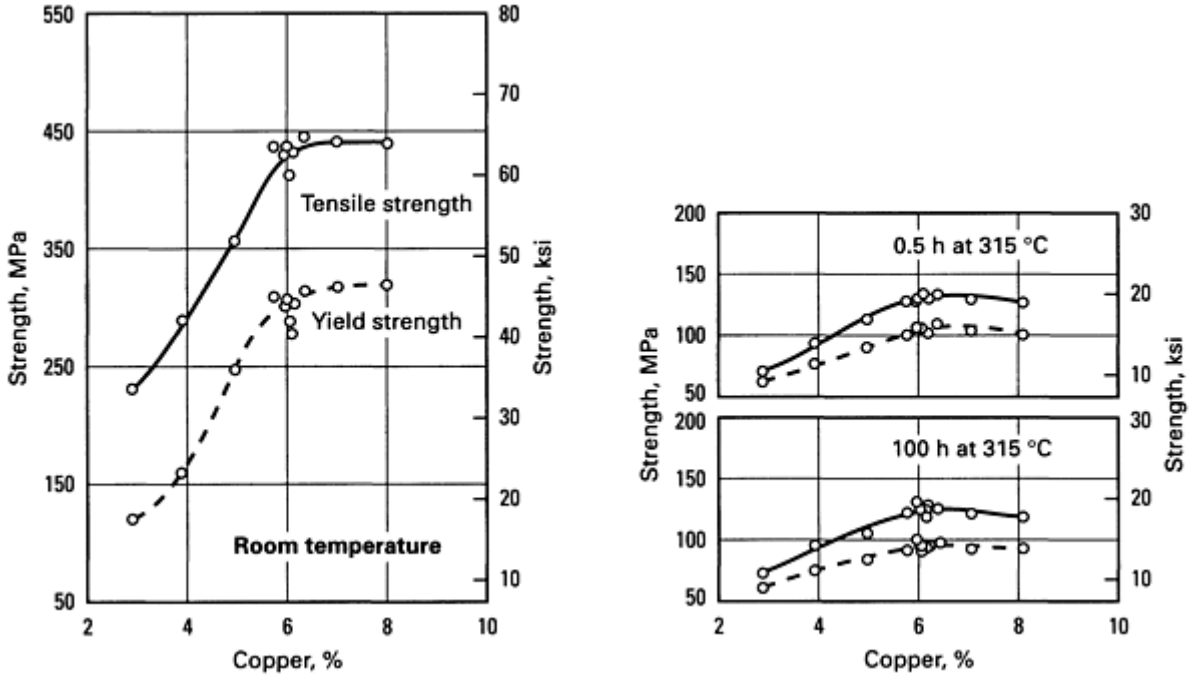

Fig. 24 Variation of tensile properties with copper content in Al-0.3% Mn-0.2% Zr-0.1% V alloy in the T6 temper

Gallium is an impurity in aluminum and is usually present at levels of 0.001 to 0.02%. At these levels its effect on mechanical properties is quite small. At the 0.2% level, gallium has been found to affect the corrosion characteristics and the response to etching and brightening of some alloys. Liquid gallium metal penetrates very rapidly at aluminum grain boundaries and can produce complete grain separation. In sacrificial anodes, an addition of gallium (0.01 to 0.1%) keeps the anode from passivating.

Hydrogen has a higher solubility in the liquid state at the melting point than in the solid at the same temperature. Because of this, gas porosity can form during solidification. Hydrogen is produced by the reduction of water vapor in the atmosphere by aluminum and by the decomposition of hydrocarbons. Hydrogen pickup in both solid and liquid aluminum is enhanced by the presence of certain impurities, such as sulfur compounds, on the surface and in the atmosphere. Hydride-forming elements in the metal increase the pickup of hydrogen in the liquid. Other elements such as beryllium, copper, tin, and silicon decrease hydrogen pickup.

In addition to causing primary porosity in casting, hydrogen causes secondary porosity, blistering, and high-temperature deterioration (advanced internal gas precipitation) during heat treating. It probably plays a role in grain-boundary decohesion during SCC. Its level in melts is controlled by fluxing with hydrogen-free gases or by vacuum degassing.

Indium. Small amounts (0.05 to 0.2%) of indium have a marked influence on the age hardening of aluminum-copper alloys, particularly at low copper contents (2 to 3% Cu). In this respect, indium acts very much like cadmium in that it reduces room-temperature aging but increases artificial aging. The addition of magnesium decreases the effect of indium. Small amounts of indium (0.03 to 0.5%) are claimed to be beneficial in aluminum-cadmium-bearing alloys.

Iron is the most common impurity found in aluminum. It has a high solubility in molten aluminum and is therefore easily dissolved at all molten stages of production. The solubility of iron in the solid state is very low (: 0.04%) and therefore, most of the iron present in aluminum over this amount appears as an intermetallic second phase in combination with aluminum and often other elements. Because of its limited solubility, it is used in electrical conductors in which it provides a slight increase in strength (Fig. 25) and better creep characteristics at moderately elevated temperatures.

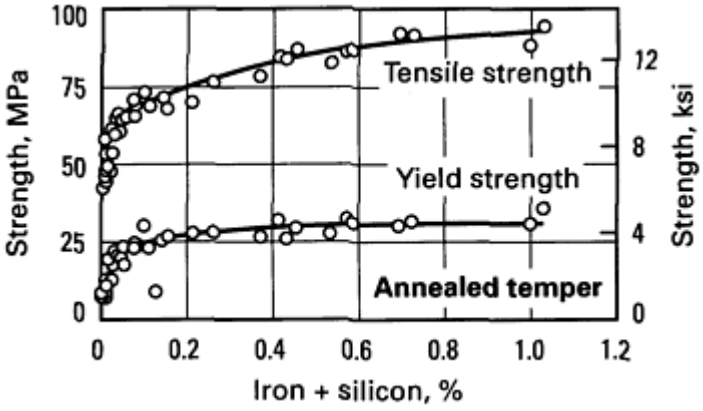

Fig. 25 Effect of iron plus silicon impurities on tensile strength and yield strength of aluminum

Iron reduces the grain size in wrought products. Alloys of iron and manganese near the ternary eutectic content, such as 8006, can have useful combinations of strength and ductility at room temperature and retain strength at elevated temperatures. The properties are due to the fine grain size that is stabilized by the finely dispersed iron-rich second phase. Iron is added to the aluminum-copper-nickel group of alloys to increase strength at elevated temperatures.

Lead. Normally present only as a trace element in commercial-purity aluminum, lead is added at about the 0.5% level with the same amount as bismuth in some alloys (2011 and 6262) to improve machinability. Additions of lead may be troublesome to the fabricator as it will tend to segregate during casting and cause hot shortness in aluminum-cooper-magnesium alloys. Lead compounds are toxic.

Lithium. The impurity level of lithium is of the order of a few ppm, but at a level of less than 5 ppm it can promote the discoloration (blue corrosion) of aluminum foil under humid conditions. Traces of lithium greatly increase the oxidation rate of molten aluminum and alter the surface characteristics of wrought products. Binary aluminum-lithium alloys age harden but are not used commercially. Present interest is on the aluminum-copper-magnesium-lithium alloys, which can be heat treated to strengths comparable to present aircraft alloys (see the article "Aluminum-Lithium Alloys" in this Volume). In addition, the density is decreased and the modulus is increased. This type of alloy has a high volume fraction of coherent, ordered $LiAl_3$ precipitate. In addition to increasing the elastic modulus, the fatigue crack growth resistance is increased at intermediate levels of stress intensity.

Magnesium is the major alloying element in the 5*xxx* series of alloys. Its maximum solid solubility in aluminum is 17.4%, but the magnesium content in current wrought alloys does not exceed 5.5%. Magnesium precipitates preferentially at grain boundaries as a highly anodic phase (Mg_5Al_3 or Mg_5Al_8), which produces susceptibility to intergranular cracking and to stress corrosion. Wrought alloys containing up to 5% Mg properly fabricated are stable under normal usage. The addition of magnesium markedly increases the strength of aluminum without unduly decreasing the ductility. Corrosion resistance and weldability are good. In the annealed condition, magnesium alloys form Lüder lines during deformation.

Magnesium-Manganese. In wrought alloys, this system has high strength in the work-hardened condition, high resistance to corrosion, and good welding characteristics. Increasing amounts of either magnesium or manganese intensify the difficulty of fabrication and increase the tendency toward cracking during hot rolling, particularly if traces of sodium are present. The two main advantages of manganese additions are that the precipitation of the magnesium phase is more general throughout the structure, and that for a given increase in strength, manganese allows a lower magnesium content and ensures a greater degree of stability to the alloy.

The tensile properties of 13 mm (0.5 in.) plate at various magnesium and manganese concentrations are shown in Fig. 26 for the O temper and in Fig. 27 for a work-hardened temper. Increasing magnesium raises the tensile strength by about 35 MPa (5 ksi) for each 1% increment; manganese is about twice as effective as magnesium.

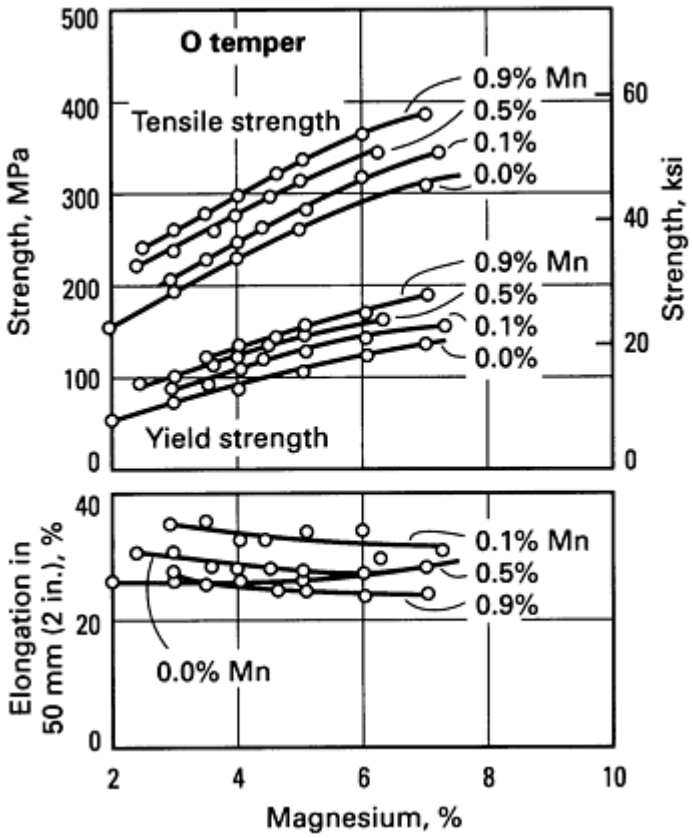

Fig. 26 Tensile properties of 13 mm (0.5 in.) aluminum-magnesium-manganese plate in O temper

Magnesium-Silicide. Wrought alloys of the 6*xxx* group contain up to 1.5% each of magnesium and silicon in the approximate ratio to form Mg_2Si, that is, 1.73:1. The maximum solubility of Mg_2Si is 1.85%, and this decreases with temperature. Precipitation upon age hardening occurs by formation of Guinier-Preston zones and a very fine precipitate. Both confer an increase in strength to these alloys, though not as great as in the case of the 2*xxx* or the 7*xxx* alloys.

Al-Mg_2Si alloys can be divided into three groups. In the first group, the total amount of magnesium and silicon does not exceed 1.5%. These elements are in a nearly balanced ratio or with a slight excess of silicon. Typical of this group is 6063, widely used for extruded architectural sections. This easily extrudable alloy nominally contains 1.1% Mg_2Si. Its solution heat-treating temperature of just over 500 °C (930 °F) and its low quench sensitivity are such that this alloy does not need a separate solution treatment after extrusion but may be air quenched at the press and artificially aged to achieve moderate strength, good ductility, and excellent corrosion resistance.

The second group nominally contains 1.5% or more of magnesium + silicon and other additions such as 0.3% Cu, which increases strength in the T6 temper. Elements such as manganese, chromium, and zirconium are used for controlling grain structure. Alloys of this group, such as the structural alloy 6061, achieve strengths about 70 MPa (10 ksi) higher than in the first group in the T6 temper. Alloys of the second group require a higher solution-treating temperature than the first and the quench sensitive. Therefore, they generally require a separate solution treatment followed by rapid quenching and artificial aging.

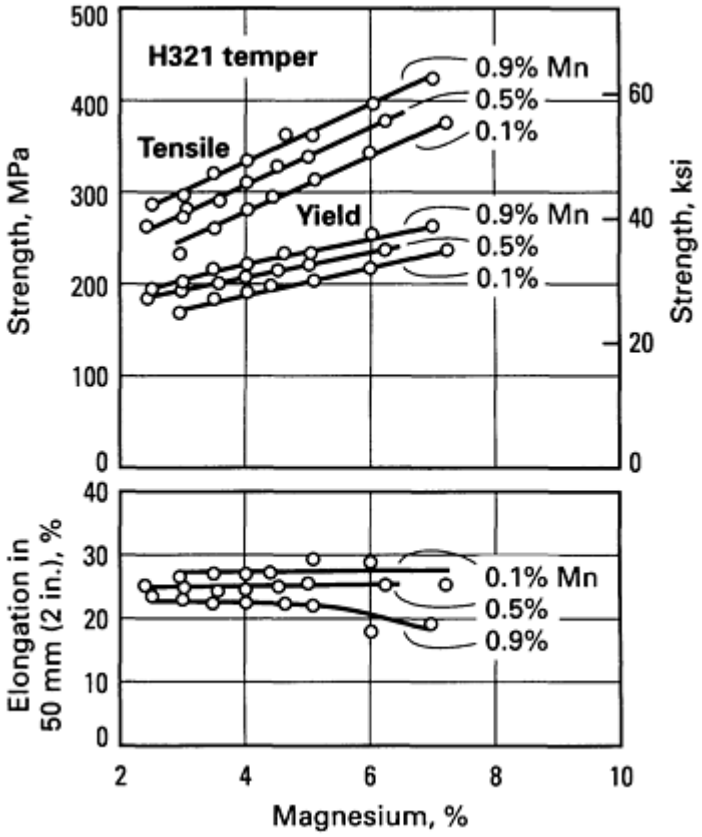

Fig. 27 Tensile properties of 13 mm (0.5 in.) aluminum-magnesium-manganese plate in H321 temper

The third group contains an amount of Mg_2Si overlapping the first two but with a substantial excess silicon. An excess of 0.2% Si increases the strength of an alloy containing 0.8% Mg_2Si by about 70 MPa (10 ksi). Larger amounts of excess silicon are less beneficial. Excess magnesium, however, is of benefit only at low Mg_2Si contents because magnesium lowers the solubility of Mg_2Si. In excess silicon alloys, segregation of silicon to the boundary causes grain-boundary fracture in recrystallized structures. Additions of manganese, chromium, or zirconium counteract the effect of silicon by preventing recrystallization during heat treatment. Common alloys of this group are 6351 and the more recently introduced alloys 6009 and 6010. Additions of lead and bismuth to an alloy of this series (6262) improves machinability. This alloy has a better corrosion resistance than 2011, which also is used as a free-machining alloy.

Manganese is a common impurity in primary aluminum, in which its concentration normally ranges from 5 to 50 ppm. It decreases resistivity. Manganese increases strength either in solid solution or as a finely precipitated intermetallic phase. It has no adverse effect on corrosion resistance. Manganese has a very limited solid solubility in aluminum in the presence of normal impurities but remains in solution when chill cast so that most of the manganese added is substantially retained in solution, even in large ingots. As an addition, it is used to increase strength and to control the grain structure (Fig. 28). The effect of manganese is to increase the recrystallization temperature and to promote the formation of fibrous structure upon hot working. As a dispersed precipitate it is effective in slowing recovery and in preventing grain growth. The manganese precipitate increases the quench sensitivity of heat-treatable alloys.

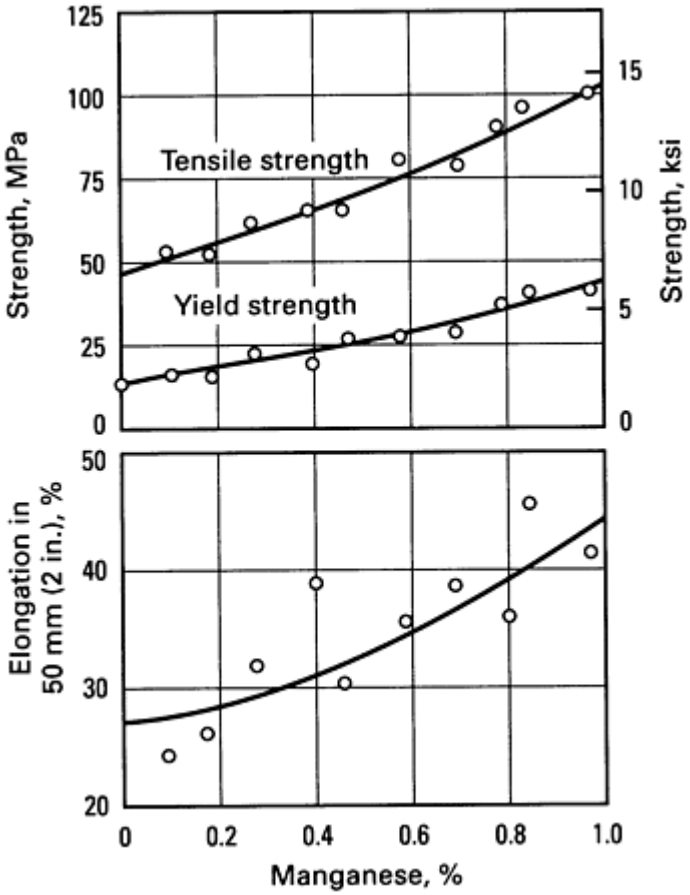

Fig. 28 Effect of manganese on tensile properties of wrought 99.95% Al, 1.6 mm (0.064 in.) thick specimens, quenched in cold water from 565 °C (1050 °F)

Manganese is also used to correct the shape of acicular or of platelike iron constituents and to decrease their embrittling effect. Up to the 1.25% level, manganese is the main alloying addition of the 3*xxx* series of alloys, in which it is added alone or with magnesium. This series of alloys is used in large tonnages for beverage containers and general utility sheet. Even after high degrees of work hardening, these alloys are used to produce severely formed can bodies.

The combined content of manganese, iron, chromium, and other transition metals must be limited, otherwise large primary intermetallic crystals precipitate from the melt in the transfer system or in the ingot sump during casting. In alloys 3003 and 3004 the iron plus manganese content should be kept below about 2.0 and 1.7%, respectively, to prevent the formation of primary $(Fe,Mn)Al_6$ during casting.

Mercury has been used at the level of 0.05% in sacrificial anodes used to protect steel structures. Other than for this use, mercury in aluminum or in contact with it as a metal or a salt will cause rapid corrosion of most aluminum alloys. The toxic properties of mercury must be kept in mind when adding it to aluminum alloys.

Molybdenum is a very low level (0.1 to 1.0 ppm) impurity in aluminum. It has been used at a concentration of 0.3% as a grain refiner, because the aluminum end of the equilibrium diagram is peritectic, and also as a modifier for the iron constituents, but it is not in current use for these purposes.

Nickel. The solid solubility of nickel in aluminum does not exceed 0.04%. Over this amount, it is present as an insoluble intermetallic, usually in combination with iron. Nickel (up to 2%) increases the strength of high-purity aluminum but reduces ductility. Binary aluminum-nickel alloys are no longer in use, but nickel is added to aluminum-copper and to aluminum-silicon alloys to improve hardness and strength at elevated temperatures and to reduce the coefficient of expansion. Nickel promotes pitting corrosion in dilute alloys such as 1100. It is limited in alloys for atomic reactor use, due to its high neutron absorption, but in other areas it is a desirable addition along with iron to improve corrosion resistance to high-pressure steam.

Niobium. As with other elements forming a peritectic reaction, niobium would be expected to have a grain refining effect on casting. It has been used for this purpose, but the effect is not marked.

Phosphorus is a minor impurity (1 to 10 ppm) in commercial-grade aluminum. Its solubility in molten aluminum is very low (**:** 0.01% at 660 °C, or 1220 °F) and considerably smaller in the solid. Phosphorus is used as a modifier for hypereutectic aluminum-silicon alloys where aluminum-phosphide acts as nucleus for primary silicon, thus refining silicon and improving machinability. The aluminum-phosphorus compound reacts with water vapor to give phosphine (PH_3), but the level of phosphorus in aluminum is sufficiently low that this does not constitute a health hazard if adequate ventilation is used when machining phosphorus-nucleated castings. Phosphine can be a problem in furnace teardowns where phosphate-bonded refractories are used.

Silicon, after iron, is the highest impurity level in electrolytic commercial aluminum (0.01 to 0.15%). In wrought alloys, silicon is used with magnesium at levels up to 1.5% to produce Mg_2Si in the 6*xxx* series of heat-treatable alloys.

High-purity aluminum-silicon alloys are hot short up to 3% Si, the most critical range being 0.17 to 0.8% Si, but additions of silicon (0.5 to 4.0%) reduce the cracking tendency of aluminum-copper-magnesium alloys. Small amounts of magnesium added to any silicon-containing alloy will render it heat treatable, but the converse is not true as excess

magnesium over that required to form Mg_2Si sharply reduces the solid solubility of this compound. Modification of the silicon can be achieved through the addition of sodium in eutectic and hypoeutectic alloys and by phosphorus in hypereutectic alloys. Up to 12% Si is added in wrought alloys used as cladding for brazing sheet. Alloys containing about 5% Si acquire a black color when anodized and are used for ornamental purposes.

Silver has an extremely high solid solubility in aluminum (up to 55%). Because of cost, no binary aluminum-silver alloys are in use, but small additions (0.1 to 0.6% Ag) are effective in improving the strength and stress-corrosion resistance of aluminum-zinc-magnesium alloys.

Strontium. Traces of strontium (0.01 to 0.1 ppm) are found in commercial-grade aluminum.

Sulfur. As much as 0.2 to 20 ppm sulfur are present in commercial-grade aluminum. It has been reported that sulfur can be used to modify both hypo- and hypereutectic aluminum-silicon alloys.

Tin is used as an alloying addition to aluminum--from concentrations of 0.03 to several percent in wrought alloys, to concentrations of about 25% in casting alloys. Small amounts of tin (0.05%) greatly increase the response of aluminum-copper alloys to artificial aging following a solution heat treatment. The result is an increase in strength and an improvement in corrosion resistance. Higher concentrations of tin cause hot cracking in aluminum-copper alloys. If small amounts of magnesium are present, the artificial aging characteristics are markedly reduced, probably because magnesium and tin form a noncoherent second phase.

The aluminum-tin bearing alloys, with additions of other metals such as copper, nickel, and silicon are used where bearings are required to withstand high speeds, loads, and temperatures. The copper, nickel, and silicon additions improve load-carrying capacity and wear resistance, and the soft tin phase provides antiscoring properties.

As little as 0.01% Sn in commercial-grade aluminum will cause surface darkening on annealing and increase the susceptibility to corrosion, which appears to be due to migration of tin to the surface. This effect may be reduced by small additions (0.2%) of copper. Aluminum-zinc alloys with small additions of tin are used as sacrificial anodes in salt water.

Titanium. Amounts of 10 to 100 ppm Ti are found in commercial-purity aluminum. Titanium depresses the electrical conductivity of aluminum, but its level can be reduced by the addition of boron to the melt to form insoluble TiB_2. Titanium is used primarily as a grain refiner of aluminum alloy castings and ingots. When used alone, the effect of titanium decreases with time of holding in the molten state and with repeated remelting. The grain-refining effect is enhanced if boron is present in the melt or if it is added as a master alloy containing boron largely combined as TiB_2. Titanium is a common addition to weld filler wire; it refines the weld structure and prevents weld cracking. It is usually added alone or with TiB_2 during the casting of sheet or extrusion ingots to refine the as-cast grain structure and to prevent cracking.

Vanadium. There is usually 10 to 200 ppm V in commercial-grade aluminum, and because it lowers conductivity, it generally is precipitated from electrical conductor alloys with boron. The aluminum end of the equilibrium diagram is peritectic, and therefore the intermetallic VAl_{11} would be expected to have a grain-refining effect upon solidification, but it is less efficient than titanium and zirconium. The recrystallization temperature is raised by vanadium.

Zinc. The aluminum-zinc alloys have been known for many years, but hot cracking of the casting alloys and the susceptibility to stress-corrosion cracking of the wrought alloys curtailed their use. Aluminum-zinc alloys containing other elements offer the highest combination of tensile properties in wrought aluminum alloys. Efforts to overcome the aforementioned limitations have been successful, and these aluminum-zinc base alloys are being used commercially to an increasing extent. The presence of zinc in aluminum increases its solution potential, hence its use in protective cladding (7072) and in sacrificial anodes.

Zinc-Magnesium. The addition of magnesium to the aluminum-zinc alloys develops the strength potential of this alloy system, especially in the range of 3 to 7.5% Zn. Magnesium and zinc form $MgZn_2$, which produces a far greater response to heat treatment than occurs in the binary aluminum-zinc system.

The strength of the wrought aluminum-zinc alloys also is substantially improved by the addition of magnesium. Increasing the $MgZn_2$ concentration from 0.5 to 12% in cold-water quenched 1.6 mm (0.062 in.) sheet continuously increases the tensile and yield strengths. The addition of magnesium in excess (100 and 200%) of that required to form $MgZn_2$ further increases tensile strength, as shown in Fig. 29.

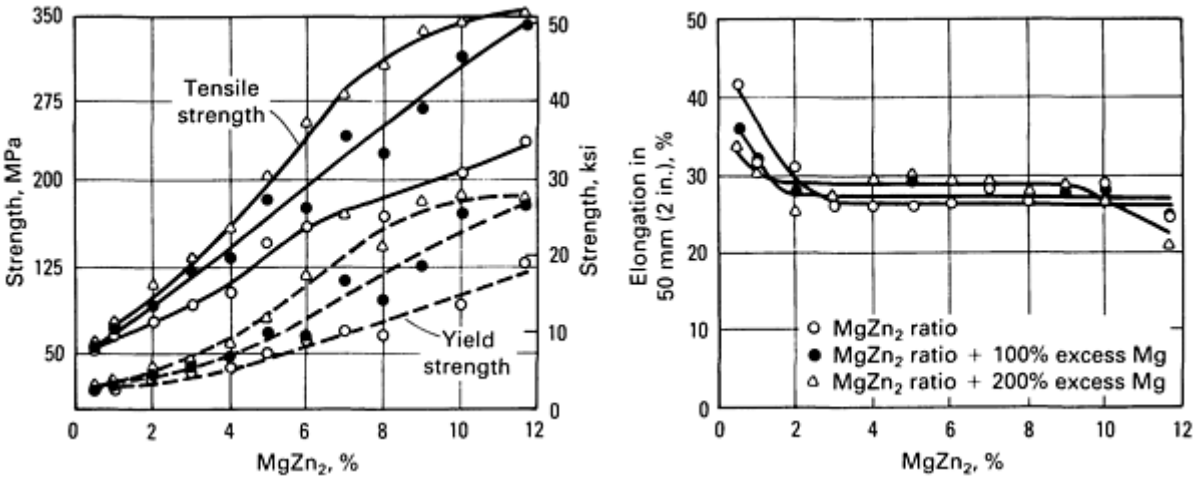

Fig. 29 Effect of $MgZn_2$ and $MgZn_2$ with excess magnesium on tensile properties of wrought 95% Al; 1.59 mm (0.0625 in.) specimens, quenched in cold water from 470 °C (875 °F)

On the negative side, increasing additions of both zinc and magnesium decrease the overall corrosion resistance of aluminum to the extent that close control over the microstructure, heat treatment, and composition are often necessary to maintain adequate resistance to stress corrosion and to exfoliatory attack. For example, depending upon the alloy, stress corrosion is controlled by some or all of the following:

- Overaging
- Cooling rate after solution treatment
- Maintaining a nonrecrystallized structure through the use of additions such as zirconium
- Copper or chromium additions (see zinc-magnesium-copper alloys)
- Adjusting the zinc-magnesium ratio closer to 3:1

Zinc-Magnesium-Copper. The addition of copper to the aluminum-zinc-magnesium system, together with small but important amounts of chromium and manganese, results in the highest-strength aluminum-base alloys commercially available. The properties of a representative group of these compositions, after one of several solution and aging treatments to which they respond, are shown in Fig. 30.

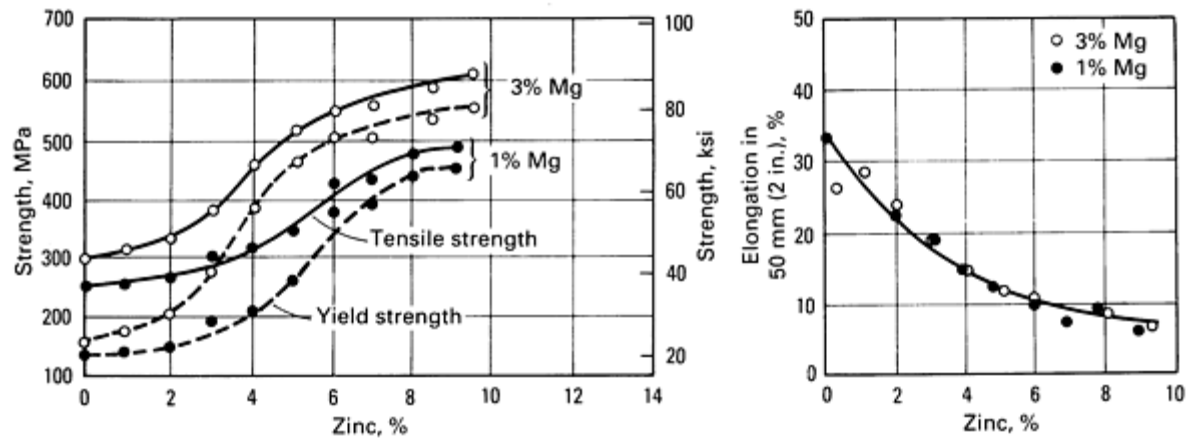

Fig. 30 Effect of zinc on aluminum alloy containing 1.5% Cu and 1 and 3% Mg; 1.6 mm (0.064 in.) thick sheet. Alloy with 1% Mg heat treated at 495 °C (920 °F); that with 3% Mg heat treated at 460 °C (860 °F). All

specimens quenched in cold water, aged 12 h at 135 °C (275 °F)

In this alloy system, zinc and magnesium control the aging process. The effect of copper is to increase the aging rate by increasing the degree of supersaturation and perhaps through nucleation of the $CuMgAl_2$ phase. Copper also increases quench sensitivity upon heat treatment. In general, copper reduces the resistance to general corrosion of aluminum-zinc-magnesium alloys, but increases the resistance to stress corrosion. The minor alloy additions, such as chromium and zirconium, have a marked effect on mechanical properties and corrosion resistance.

Zirconium additions in the range 0.1 to 0.3% are used to form a fine precipitate of intermetallic particles that inhibit recovery and recrystallization. An increasing number of alloys, particularly in the aluminum-zinc-magnesium family, use zirconium additions to increase the recrystallization temperature and to control the grain structure in wrought products. Zirconium additions leave this family of alloys less quench sensitive than similar chromium additions. Higher levels of zirconium are employed in some superplastic alloys to retain the required fine substructure during elevated-temperature forming. Zirconium additions have been used to reduce the as-cast grain size, but its effect is less than that of titanium. In addition, zirconium tends to reduce the grain-refining effect of titanium plus boron additions so that it is necessary to use more titanium and boron to grain refine zirconium-containing alloys.

Properties of Wrought Aluminum Alloys

Property data on aluminum alloys are of two basic types:

- Typical property values
- Property limits

The data on wrought aluminum alloys presented in this section are primarily typical property values, although sources and tabular data for some mechanical property limits are also mentioned.

Typical values are considered nominal or representative values. Physical properties (Tables 6 and 7), for example, are median values determined in laboratory tests of representative commercial products. Typical mechanical properties (Table 8) are average or median values, near the peaks of distribution curves derived from routine quality-control tests of commercial products processed by standard mill procedures. The values listed are representative of products of moderate cross section or thickness, and are most useful for demonstrating relationships between alloys and tempers. These data are not intended to be used for critical design purposes. Static-strength values from tensile tests listed as typical do not represent the somewhat higher values (5 to 10% higher) obtained in tests (longitudinal direction) of extruded products of moderate section thickness nor do they represent the lower values expected in tests of very thick, heat-treated products.

Table 6 Typical physical properties of aluminum alloys

Alloy	Average coefficient of thermal expansion[a]		Approximate melting range[b][c]		Temper	Thermal conductivity at 25 °C (77 °F)		Electrical conductivity at 20 °C (68 °F), %IACS		Electrical resistivity at 20 °C (68 °F)

(a) Coefficient from 20 to 100 °C (68 to 212 °F).

(b) Melting ranges shown apply to wrought products of 6.35 mm ($\frac{1}{4}$ in.) thickness or greater.

(c) Based on typical composition of the indicated alloys.

(d) Eutectic melting can be completely eliminated by homogenization.

(e) Eutectic melting is not eliminated by homogenization.

(f) Although not formerly registered, the literature and some specifications have used T736 as the designation for this temper.

(g) Homogenization may raise eutectic melting temperature 10 to 20 °C (20 to 40 °F) but usually does not eliminate eutectic melting.

(a) 500 kg load and 10 mm ball.

(b) Based on 500,000,000 cycles of completely reversed stress using the R.R. Moore type of machine and specimen.

(c) Average of tension and compression moduli. Compression modulus is about 2% greater than tension modulus.

(d) 1350-O wire will have an elongation of approximately 23% in 250 mm (10 in.).

(e) 1350-H19 wire will have an elongation of approximately $1\frac{1}{2}$% in 250 mm (10 in.).

(f) Tempers T361 and T861 were formerly designated T36 and T86, respectively.

(g) Based on 10^7 cycles using flexural type testing of sheet specimens.

(h) T7451, although not previously registered, has appeared in literature and in some specifications as T73651.

Mechanical property limits are established on a statistical "A"-value basis, whereby 99% of the material is expected to conform at a confidence of 0.95. In most instances limits are based on a normally distributed database of a minimum of 100 tests from at least 10 different lots of material. Mechanical property limits are typically used for design or lot acceptance. The distinction between metric and English unit property limits can be important because of rounding from metric to English or vice versa.

Typical physical-property values (Table 6) are given only as a basis for comparing alloys and tempers and should not be specified as engineering requirements or used for design purposes. They are not guaranteed values, since in most cases they are averages for various sizes, product forms, and methods of manufacture and may not be exactly representative of any particular size or product. Density values for the annealed (O) temper are listed in Table 7.

Typical Mechanical Properties. Typical tensile strengths (ultimate and yield), tensile elongations, ultimate shear strengths, fatigue strengths (endurance limits), hardnesses, and elastic moduli are given in Table 8. As typical properties they are for comparative purposes and not design, as discussed previously. The table lists both heat-treatable and non-heat-treatable alloys, and in most cases the properties are averages for various sizes, product forms, and methods of manufacture.

Tensile property limits for various wrought aluminum alloys are given in the article "Properties of Wrought Aluminum and Aluminum Alloys" in this Volume. In addition, the current edition of *Aluminum Standards and Data*, published biennially by The Aluminum Association, provides tensile property limits for most alloy tempers and product forms.

Bend Properties. Recommended minimum 90° cold bend radii for sheet and plate are given in Table 9. Additional forming characteristics (Olsen ball, *n*, *r*, minimum bend radii painted sheet, bend radii bus bar) may be found in *Aluminum Standards and Data*, published by The Aluminum Association.

Table 9 Recommended minimum bend radii for 90 °C cold forming of sheet and plate

(a) The radii listed are the minimum recommended for bending sheets and plates without fracturing in a standard press brake with air bend dies. Other types of bending operations may require larger radii or permit smaller radii. The minimum permissible radii will also vary with the design and condition of the tooling.

(b) Alclad sheet in the heat-treatable alloys can be bent over slightly smaller radii than the corresponding tempers of the bare alloy.

(c) Heat-treatable alloys can be formed over appreciably smaller radii immediately after solution heat treatment.

(d) The H112 temper (applicable to non-heat-treatable alloys) is supplied in the as-fabricated condition without special property control but usually can be formed over radii applicable to the H14 (or H34) temper or smaller.

(e) (e) Tempers T361 and T861 formerly designated T36 and T86, respectively

Classification of Alloys for Fracture Toughness. Fracture toughness is rarely, if ever, a design consideration in the 1000, 3000, 4000, 5000, and 6000 series alloys. The fracture toughness of these alloys is sufficiently high that thicknesses beyond those commonly produced would be required to obtain a valid test. Therefore, these alloys are

excluded from further consideration in this article. Among the alloys for which fracture toughness is a meaningful design-related parameter, controlled-toughness high-strength alloys and conventional high-strength alloys merit discussion.

Controlled-toughness high-strength alloys were developed for their high fracture toughness and range in measured K_{Ic} values from about 20 MPa $\sqrt{m}$ (18 ksi $\sqrt{in}$) upward. The alloys and tempers currently identified as controlled-toughness high-strength products include:

Alloy	Condition	Product form
2048	T8	Sheet and plate
2124	T3, T8	Sheet and plate
2419	T8	Sheet, plate, extrusions, and forgings
7049	T7	Plate, forgings, and extrusions
7050	T7	Sheet, plate, forgings, and extrusions
7150	T6	Sheet and plate
7175	T6, T7	Sheet, plate, forgings, and extrusions
7475	T6, T7	Sheet and plate

Typical applications include 2419-T851 used in the lower wing skins of the B-1 bomber and 7475-T7351 and 2124-T851 in the F-16 aircraft.

Conventional High-Strength Alloys. Although these alloys, tempers, and products are not used for fracture-critical components, fracture toughness can be a meaningful design parameter. Conventional aerospace alloys for which fracture toughness minimums may be useful in design include 2014, 2024, 2219, 7075, and 7079. These alloys have toughness levels that are inferior to those of their controlled-toughness counterparts. Consequently, toughness is not guaranteed.

Controlled-toughness alloys are often derivatives of conventional alloys. For example, 7475 alloy is a derivative of 7075 with maximum compositional limits on some elements that were found to decrease toughness.

Fracture toughness quality control and material procurement minimums are appropriate for controlled-toughness, high-strength alloys, tempers, and products, because checks on composition and tensile properties are inadequate assurances that the proper levels of toughness have been achieved. If the minimum specified fracture toughness value is not attained, the material is not acceptable.

Minimum and typical room-temperature plane-strain fracture toughness is listed for selected high-strength aluminum alloys in Table 10. The effect of alloying elements and microstructural constituents on fracture toughness is discussed in the section "Fracture Toughness and Fatigue Behavior" in this article.

Table 10 Minimum and typical room-temperature plane-strain fracture-toughness values for several high-strength aluminum alloys

Product form	Alloy and temper	Thickness		Plane-strain fracture toughness (K_{Ic})

(a) L-T, crack plane and growth direction perpendicular to the rolling direction.

(b) T-L, crack plane and growth direction parallel to the rolling direction.

(c) S-L, short transverse fracture toughness

Fatigue and Fatigue Crack Growth. Aluminum does not generally exhibit the sharply defined fatigue limit typically shown by low-carbon steel in *S-N* tests. For smooth or notched coupon tests, where lifetime is governed primarily by crack initiation, the fatigue resistance is expressed as a fatigue strength (stress) for a given number of cycles. Table 8 gives typical data on the fatigue strength of various aluminum alloys.

In tests where fatigue crack growth is of interest, the performance of aluminum is measured by recording the crack growth rate (da/dN) as a function of stress intensity range (ΔK). This type of FCG test is currently of prime importance for alloys used in aerospace applications. Fatigue crack growth can be influenced by alloy composition and microstructure, the presence of oxygen, temperature, load ratio (R), material thickness (or thickness in relation to plastic zone size), stress intensity range, and the processes used in preparing the alloys. It is recognized that the interactions among these variables complicate the proper interpretation and extrapolation of experimental data and introduce additional uncertainties with respect to damage-tolerant design and failure analysis.

Elevated-Temperature Properties. Tables 11(a), 11(b), and 11(c) list typical tensile properties of various aluminum alloys at elevated temperatures. The 7*xxx* series of age-hardenable alloys that are based on the Al-Zn-Mg-Cu system develop the highest room-temperature tensile properties of any aluminum alloys produced from conventionally cast ingots. However, the strength of these alloys declines rapidly if they are exposed to elevated temperatures (Fig. 31), due mainly to coarsening of the fine precipitates on which the alloys depend for their strength. Alloys for the 2*xxx* series such as 2014 and 2024 perform better above these temperatures but are not normally used for elevated-temperature applications.

Table 11(a) Ultimate tensile strengths of various aluminum alloys at cryogenic and elevated temperatures

(a) These data are based on a limited amount of testing and represent the lowest strength during 10,000 h of exposure at testing temperature under no load; stress applied at 34 MPa/min (5000 psi/min) to yield strength and then at strain rate of 0.05 mm/mm/min (0.05 in./in./min) to failure. Under some conditions of temperature and time, the application of heat will adversely affect certain other properties of some alloys.

(a) These data are based on a limited amount of testing and represent the lowest strength during 10,000 h of exposure at testing temperature under no load; stress applied at 34 MPa/min (5000 psi/min) to yield strength and then at strain rate of 0.05 mm/mm/min (0.05 in./in./min) to failure. Under some conditions of temperature and time, the application of heat will adversely affect certain other properties of some alloys.

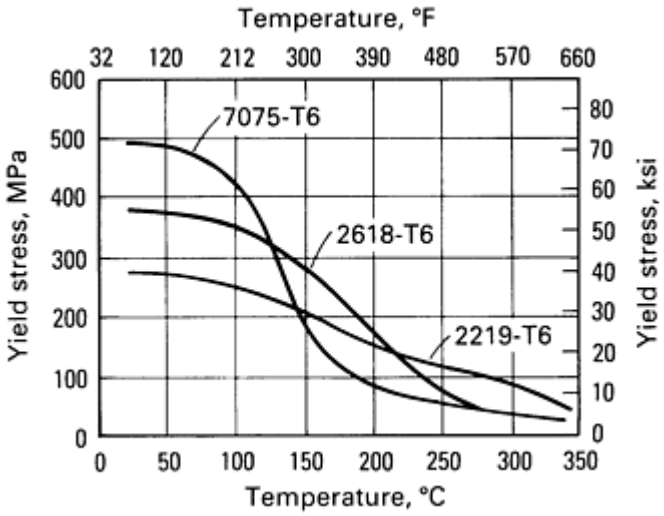

Fig. 31 Values of 0.2% yield stress of aluminum alloys after exposure for 1000 h at temperatures between 0 and 350 °C

Strength at temperatures above about 100 to 200 °C (200 to 400 °F) is improved mainly by solid-solution strengthening or second-phase hardening. Another approach to improve the elevated-temperature performance of aluminum alloys has been the use of rapid solidification technology to produce powders or foils containing high supersaturations of elements such as iron or chromium that diffuse slowly in solid aluminum. In this regard, several experimental materials are now available that have promising creep properties up to 350 °C (650 °F). An experimental Al-Cu-Mg alloy with silver

additions has also resulted in improved creep properties (Fig. 32). Iron is also used to improve creep properties (see the heading "Iron" in this article).

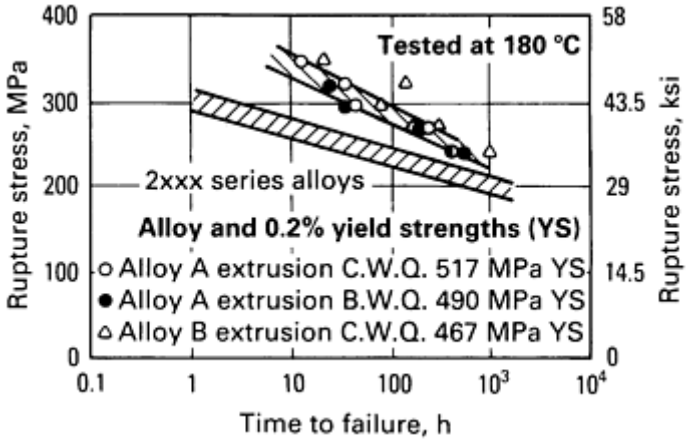

Fig. 32 Stress-rupture results for creep tests at 180 °C (355 °F) on aluminum alloys with silver additions compared with those for 2*xxx* series alloys. Alloy A: 6.3% Cu, 0.5% Mg, 0.5% Ag, 0.5% Mn, and 0.2% Zr. Alloy B: 6.0% Cu, 0.45% Mg, 0.5% Ag, 0.5% Mn, and 0.14% Zr. CWQ, cold-water quenched before aging; BWQ, boiling-water quenched before aging. Low-Temperature Properties. Aluminum alloys represent a very important class of structural metals for subzero-temperature applications and are used for structural parts for operation at temperatures as low as -270 °C (-450 °F). Below zero, most aluminum alloys show little change in properties; yield and tensile strengths may increase; elongation may decrease slightly; impact strength remains approximately constant. Consequently, aluminum is a useful material for many low-temperature applications; the chief deterrent is its relatively low elongation compared with certain austenitic ferrous alloys. This inhibiting factor affects principally industries that must work with public safety codes. A notable exception to this has been the approval, in the ASME unfired pressure vessel code, to use alloys 5083 and 5456 for pressure vessels within the range from -195 to 65 °C (-320 to 150 °F). With these alloys, tensile strength increases 30 to 40%, yield strength 5 to 10%, and elongation 60 to 100% between room temperature and -195 °C (-320 °F).

The wrought alloys most often considered for low-temperature service are alloys 1100, 2014, 2024, 2219, 3003, 5083, 5456, 6061, 7005, 7039, and 7075. Alloy 5083-O, which is the most widely used aluminum alloy for cryogenic applications, exhibits the following increases in tensile properties when cooled from room temperature to the boiling point of nitrogen (-195.8 °C, or -320.4 °F):

- About 40% in ultimate tensile strength
- About 10% in yield strength
- Sixty percent in elongation

Typical tensile properties of various aluminum alloys at cryogenic temperatures are given in Tables 11(a), 11(b), and 11(c).

Retention of toughness also is of major importance for equipment operating at low temperature. Aluminum alloys have no ductile-to-brittle transition; consequently, neither ASTM nor ASME specifications require low-temperature Charpy or Izod tests of aluminum alloys. Other tests, including notch-tensile and tear tests, assess the notch-tensile and tear toughness of aluminum alloys at low temperatures. The low-temperature characteristics of welds in the weldable aluminum alloys parallel those described above for unwelded material.

Fracture Toughness. Data on fracture toughness of several aluminum alloys at room and subzero temperatures are summarized in Table 12. Of the alloys listed in Table 12, 5083-O has substantially greater toughness than the others. Because this alloy is too tough for obtaining valid K_{Ic} data, the values shown for 5083-O were converted from J_{Ic} data. The fracture toughness of this alloy increases as exposure temperature decreases. Of the other alloys, which were all evaluated in various heat-treated conditions, 2219-T87 has the best combination of strength and fracture toughness, both at room temperature and at -196 °C (-320 °F), of all the alloys that can be readily welded.

Table 12 Fracture toughness of aluminum alloy plate

Alloy and condition	Room temperature yield strength		Specimen design	Orientation	Fracture toughness, K_{Ic} or $K_{Ic}(J)$ at:

(a) 2124 is similar to 2024 but with higher-purity base and special processing to improve fracture toughness.

(b) $K_{Ic}(J)$.

Alloy 6061-T651 has good fracture toughness at room temperature and at -196 °C (-320 °F), but its yield strength is lower than that of alloy 2219-T87. Alloy 7039 also is weldable and has a good combination of strength and fracture toughness at room temperature and at -196 °C (-320 °F). Alloy 2124 is similar to 2024 but with a higher-purity base and special processing for improved fracture toughness. Tensile properties of 2124-T851 at subzero temperatures can be expected to be similar to those for 2024-T851.

Several other aluminum alloys, including 2214, 2419, 7050, and 7475, have been developed in order to obtain room-temperature fracture toughness superior to that of other 2000 and 7000 series alloys. Information on subzero properties of these alloys is limited, but it is expected that these alloys also would have improved fracture toughness at subzero temperatures as well as at room temperature.

Fatigue Strength. Results of axial and flexural fatigue tests at 10^6 cycles on aluminum alloy specimens at room temperature and at subzero temperatures are presented in Table 13. These data indicate that, for a fatigue life of 10^6 cycles, fatigue strength is higher at subzero temperatures than at room temperature for each alloy. This trend is not necessarily valid for tests at higher stress levels and shorter fatigue lives, but at 10^6 cycles results are consistent with the effect of subzero temperatures on tensile strength.

Table 13 Results of fatigue-life tests on aluminum alloys

Alloy and condition	Stressing mode	Stress ratio, *R*	K_t	Fatigue strength at 10^6 cycles, at:					
				24 °C (75 °F)		-196 °C (-320 °F)		-253 °C (-423 °F)

1050
99.5 Al min

Specifications

ASTM. B 491

UNS number. A91050

Foreign. Canada: CSA 9950. France: NF A5. United Kingdom: BS 1B. West Germany: DIN A 199.5

Chemical Composition

Composition limits. 99.50 Al min, 0.25 Si max, 0.40 Fe max, 0.05 Cu max, 0.05 Mn max, 0.05 Mg max, 0.05 V max, 0.03 max other (each)

Applications

Typical uses. Extruded coiled tube for equipment and containers for food, chemical, and brewing industries; collapsible tubes; pyrotechnic powder

Mechanical Properties

Tensile properties. See Table 1.

Table 1 Typical mechanical properties of 1050 aluminum

Temper	Tensile strength		Yield strength		Elongation, %	Shear strength	
	MPa	ksi	MPa	ksi		MPa	ksi
O	76	11	28	4	39	62	9
H14	110	16	103	15	10	69	10
H16	131	19	124	18	8	76	11

Mass Characteristics

Density. 2.705 g/cm^3 (0.0977 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperatures. 657 °C (1215 °F)

Solidus temperature. 646 °C (1195 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.8	12.1
20 to 100	68 to 212	23.6	13.1
20 to 200	68 to 392	24.5	13.6
20 to 300	68 to 572	25.5	14.2

Volumetric: 68.1 × 10^{-6} m^3/m^3 · K (3.78 × 10^{-5} in.^{3}/in.^{3} · °F)

Specific heat. 900 J/kg · K (0.215 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. O temper, 231 W/m · K (133 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric. O temper, 61.3% IACS at 20 °C (68 °F)

Electrical resistivity. O temper: 28.1 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Government. QQ-A-1876

Chemical Composition

Composition limits. 99.45 Al min, 0.55 Si max + Fe, 0.05 Cu max, 0.05 Mn max, 0.05 Mg max, 0.05 Zn max, 0.05 V max, 0.03 Ti max, 0.03 max other (each)

Applications

Typical uses. Foil for packaging, insulating, and heat exchangers

Mechanical Properties

Tensile properties. See Table 9.

Table 9 Tensile properties of 1145 aluminum foil

Temper	Tensile strength		Yield strength		Elongation, %
	MPa	ksi	MPa	ksi	
Typical properties					
O	75	11	34	5	40
H18	145	21	117	17	5
Tensile strength limits[(a)]					
O	95 max	14 max	. . .	. . .	. . .

(a) Unmounted foil 0.02 to 0.15 mm (0.0007 to 0.0059 in.) thick

Mass Characteristics

Density. 2.705 g/cm^3 (0.0977 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 657 °C (1215 °F)

Solidus temperature. 646 °C (1195 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.8	12.1

20 to 100	68 to 212	23.6	13.1
20 to 200	68 to 392	24.5	13.6
20 to 300	68 to 572	25.5	14.1

Volumetric: 68×10^{-6} $m^3/m^3 \cdot K$ (3.8×10^{-5} $in.^3/in.^3 \cdot °F$)

Specific heat. 904 J/kg · K (0.216 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. AT 20 °C (68 °F): O temper, 230 W/m · K (133 Btu/ft) · h · °F); H18 temper, 227 W/m · K (131 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric at 20 °C (68 °F): O temper, 61% IACS; H18 temper, 60% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 28.3 nΩ · m; H18 temper, 28.7 nΩ · m. Temperature coefficient at 20 °C: O and H18 tempers, 0.1 nΩ · m per K

Optical Properties

Reflectance. 95 to 97% for λ= 0.3 to 10 μm

Emittance. 3 to 5% for λ= 9.3 μm at 20 °C (68 °F)

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F)

1199
99.99 Al min

Commercial Names

Trade name. Super-purity aluminum, Raffinal

Common name. Super-purity aluminum, refined aluminum

Chemical Composition

Composition limits. 99.99 Al min, 0.006 Si max, 0.006 Fe max, 0.006 Cu max, 0.002 Mn max, 0.006 Mg max, 0.006 Zn max, 0.002 Ti max, 0.005 V max, 0.005 Ga max, 0.002 max other (each)

Consequence of exceeding impurity limit. See Fig. 3.

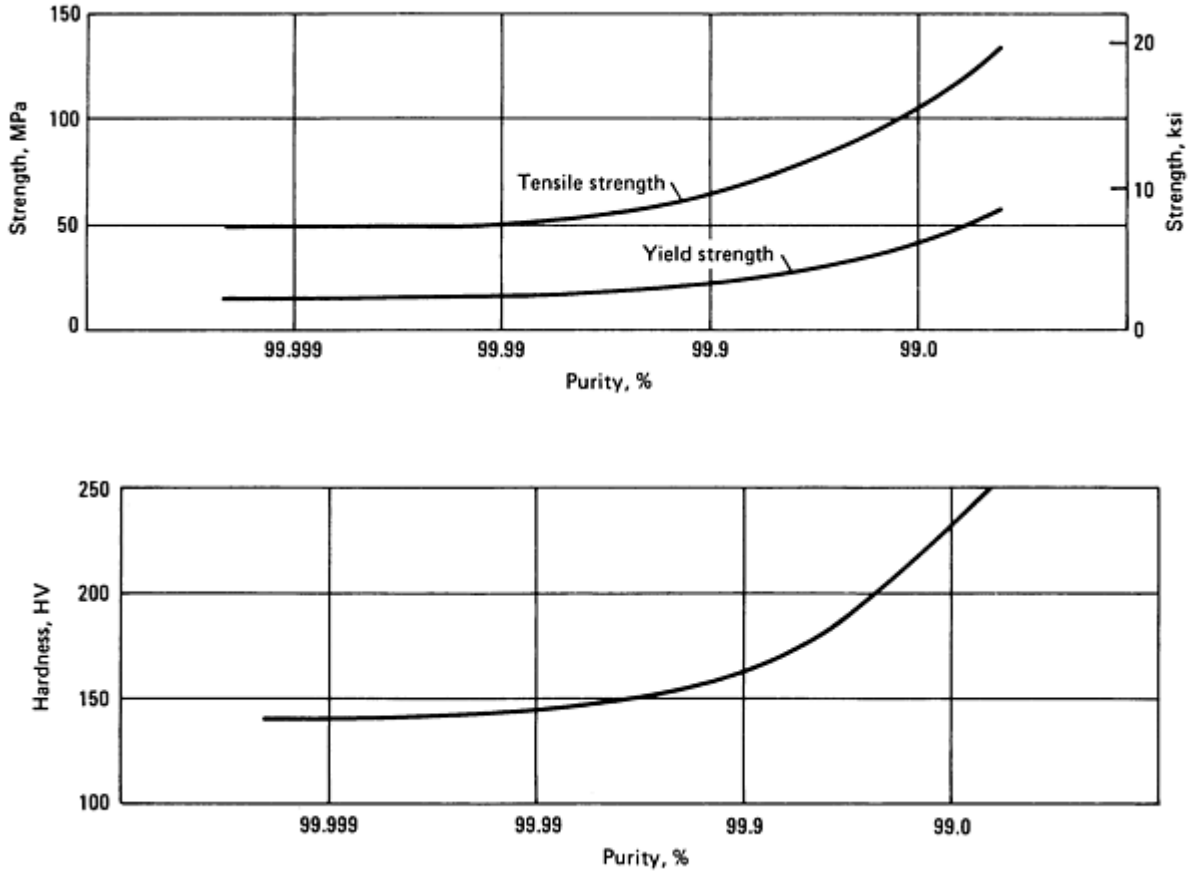

Fig. 3 Effect of purity on strength and hardness of unalloyed aluminum

Applications

Typical uses. Electrolytic capacitor foil, vapor deposited coatings for optically reflecting surfaces

Mechanical Properties

Tensile properties. See Table 10 and Fig. 3.

Table 10 Typical tensile properties of 1199 aluminum

Reduction by cold rolling, %	Tensile strength		Yield strength		Elongation, %
	MPa	ksi	MPa	ksi	
0 (annealed)	45	6.5	10	1.5	50
10	59	8.6	57	8.2	40
20	77	11.1	75	10.8	15
40	96	13.9	91	13.2	11

60	110	15.9	105	15.1	6
75	120	17.5	113	16.4	5

Hardness. O temper, 15 HB; H18 temper, 27 HB. (500 kg load; 10 mm diam ball). See also Fig. 3.

Elastic modulus. Tension, 62 GPa (9.0×10^6 psi); shear, 25.0 GPa (3.62×10^6 psi)

Mass Characteristics

Density. 2.70 g/cm^3 (0.0975 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Melting point. 660 °C (1220 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	**°F**	**µ/m · K**	**µin./in. · °F**
-50 to 20	-58 to 68	21.8	12.1
20 to 100	68 to 212	23.6	13.1
20 to 200	68 to 392	24.5	13.6
20 to 300	68 to 572	25.5	14.2

Specific heat. 900 J/kg · K at 25 ° (77 °F)

Heat of fusion. 390 kJ/kg · K

Thermal conductivity. O temper, 243 W/m · K (140 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O temper: 64.5% IACS at 20 °C (68 °F)

Electrical resistivity. O temper: 26.7 nΩ · m at 20 °C (68 °F); temperature coefficient, O temper: 0.1 nΩ · m per K at 20 °C (68 °F)

Optical Properties

Reflectivity. 85 to 90% to visible light for an electrolytically brightened surface

1350
99.50 Al min

Commercial Names

Common name. Electrical conductor grade (EC)

Specifications

ASTM. Aluminum conductor steel reinforced B 232, B 401. Bus conductors: B 236. Communication wire: B 314. Rolled redraw rod: B 233. Round wire: B 230, B 609, Wire, rectangular and square: B 324. Round solid conductors: B 544. Stranded conductors: B 231, B 400

Foreign. France: NF A5/L. Spain: UNE AL99.5E. United Kingdom: BSIE. West Germany: DIN E-A199.5

Chemical Composition

Composition limits. 99.50 Al min, 0.10 Si max, 0.40 Fe max, 0.05 Cu max, 0.01 Mn max, 0.01 Cr max, 0.05 Zn max, 0.03 Ga max, 0.02 V max + Ti, 0.05 B max, 0.03 max other (each), 0.10 max others (total)

Consequence of exceeding impurity limits. Impurity elements in excess of limits degrade electrical conductivity.

Applications

Typical uses. Wire, stranded conductors, bus conductors, transformer strip

Mechanical Properties

Tensile properties. Typical, see Table 11; property limits, see Tables 12 and 13.

Table 11 Typical mechanical properties of 1350 aluminum

Temper	Tensile strength		Yield strength		Elongation[(a)], %	Shear strength	
	MPa	ksi	MPa	ksi		MPa	ksi

0.2101-0.2600	155	22.5	162	23.5	2.2	2.3

(a) Minimum value for any test in a given lot.

(b) Minimum value for average of all tests for a given lot.

(c) In 250 mm (10 in.)

Shear strength. See Table 11.

Poisson's ratio. 0.33 at 20 °C (68 °F)

Elastic modulus. Tension, 69 GPa (10×10^6 psi)

Fatigue strength. H19 temper, 48 MPa (7 ksi) at 5×10^8 cycles in an R.R. Moore type test

Mass Characteristics

Density. 2.705 g/cm^3 (0.0977 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 657 °C (1215 °F)

Solidus temperature. 646 °C (1195 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µ/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.8	12.1
20 to 100	68 to 212	23.6	13.1
20 to 200	68 to 392	24.5	13.6
20 to 300	68 to 572	25.5	14.2

Volumetric: 68×10^{-6} $m^3/m^3 \cdot K$ (3.8×10^{-5} $in.^3/in.^3 \cdot °F$)

Specific heat. 900 J/kg · K (0.215 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. O temper, 234 W/m · K (135 Btu/ft · h · °F); H19 temper, 230 W/m · K (133 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F). O temper, 61.8% IACS min; H1*x* tempers, 61.0% IACS min

Electrical resistivity. O temper, 27.9 nΩ · m max at 20 °C (68 °F); H1*x* tempers, 28.2 nΩ · m max at 20 °C. Temperature coefficient, all tempers: 0.1 nΩ · m per K at 20 °C

Electrolytic solution potential. --0.84 V versus 0.1 *N* calomel electrode in aqueous solution of 53 g NaCl plus 3 g H_2O_2 per liter at 25 °C (77 °F)

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F)

2011
5.5Cu-0.4Pb-0.4Bi

Specifications

ASTM. Drawn, seamless tube: B 210. Rolled or cold finished wire, rod, and bar: B 211

SAE. J454

UNS number. A92011

Government. Rolled or cold finished wire, rod, and bar: QQ-A-225/3

Foreign. Canada: CSA CB60. France: NF A-U4Pb. United Kingdom: BS FCI. Germany: DINAL CuBiPb

Chemical Composition

Composition limits. 0.40 Si max, 0.7 Fe max, 5.0 to 6.0 Cu, 0.30 Zn max, 0.20 to 0.6 Pb, 0.05 max other (each), 0.15 others (total), bal Al

Applications

Typical uses. Wire, rod, and bar for screw machine products. Applications where good machinability and good strength are required

Mechanical Properties

Tensile properties. See Tables 14 and 15

Table 14 Room-temperature mechanical properties of alloy 2011

Temper	Tensile strength		Yield strength[a]		Elongation, %	Hardness[b], HB	Shear strength	
	MPa	ksi	Mpa	ksi			MPa	ksi
Typical properties								
T3[c]	379	55	296	43	15[d]	95	221	32
T8[c]	407	59	310	45	12[d]	100	241	35
Property limits (minimum values for rolled or cold finished wire, rod, and bar)								
T3								
0.125 to 1.500 in. thick	310	45	260	38	10[a],[e]	. . .	. . .	. . .
1.501 to 2.000 in. thick	295	43	235	34	12[a],[e]	. . .	. . .	. . .
2.001 to 3.250 in. thick	290	42	205	30	14[a],[e]	. . .	. . .	. . .
T4, T451 0.375 to 8.000 in. thick	275	40	125	18	16	. . .	. . .	. . .
T8	370	54	275	40	10	. . .	. . .	. . .

(a) Yield strength and elongation limits not applicable to wire less than 3.2 mm (0.125 in.) in thickness or diameter.

(b) 500 kg (1100 lb) load; 10 mm diam ball.

(c) Strengths and elongations generally unchanged or improved at low temperatures.

(d) 13 mm ($\frac{1}{2}$ in.) diam specimen.

(e) In 2 in. or 4*d*, where *d* is diameter of reduced section of tensile test specimen

Table 15 Typical tensile properties of alloy 2011-T3

Temperature		Tensile strength		Yield strength (0.2% offset)		Elongation, %
°C	°F	MPa	ksi	MPa	ksi	
24	75	379	55	296	43	15
100	212	324	47	234	34	16
149	300	193	28	131	19	25
204	400	110	16	76	11	35
260	500	45	6.5	26	3.8	45
316	600	21	3.1	12	1.8	90
371	700	16	2.3	10	1.4	125

Lowest strength for exposures up to 10,000 h at temperature, no load; test loading applied at 35 MPa/min (6 ksi/min) to yield strength

Comprehensive yield strength. . Approximately equal to tensile yield strength

Hardness. See Table 14.

Poisson's ratio. 0.33 at 20 °C (68 °F)

Elastic modulus. Tension, 70 GPa (10.2×10^6 psi); shear, 26 GPa (3.8×10^6 psi)

Fatigue strength. At 5×10^8 cycles, R.R. Moore type test: T3 and T8 tempers, 124 MPa (18 ksi)

Mass Characteristics

Density. 2.82 g/cm^3 (0.102 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 638 °C (1180 °F)

Solidus temperature. 541 °C (1005 °F)

Incipient melting temperature. 535 °C (995 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	μm/m · K	μin./in. · °F
-50 to 20	-58 to 68	21.4	11.9
20 to 100	68 to 212	23.1	12.8
20 to 200	68 to 392	24.0	13.3
20 to 300	68 to 572	25.0	13.9

Volumetric: 67 x 10^{-6} m^3/m^3 · K (3.72 × 10^{-5} $in.^3/in.^3$ · °F) at 20 °C (68 °F)

Specific heat. 864 J/kg · K (0.206 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 20 °C (68 °F): T3 and T4 tempers, 152 W/m · K (87.8 Btu/ft · h · °F); T8 temper, 173 W/m · K (99.9 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): T3 and T4 tempers, 39% IACS; T8 temper, 45% IACS

Electrical resistivity. At 20 °C (68 °F): T3 and T4 tempers, 44 nΩ · m; T8 temper, 38 nΩ · m; temperature coefficient. T3, T4, and T8 tempers, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. At 25 °C (77 °F): -0.69 (T3 and T4 tempers), -0.83 V (T8 temper) versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 413 °C (775 °F)

Solution temperature. 524 °C (975 °F)

Aging temperature. T8 temper, 160 °C (320 °F); 14 h at temperature

(a) In 50 mm (2 in.) or 4*d*, where *d* is diameter of reduced section of tensile test specimen. Where a range of values appears in this column, specified minimum elongation varies with thickness of the mill product.

(b) Upon artificial aging, T451 temper material develops properties applicable to T651 temper.

(c) 6% elongation for products over 19 mm (0.750 in.) in diameter or thickness and over 160 through 205 cm^2 (25 through 32 $in.^2$) in cross-sectional area.

(d) Value slightly lower for material over 160 through 205 cm^2 (25 through 32 $in.^2$) in cross-sectional area.

(e) Test bar machined from sample forging.

(f) 16% for test bar taken from separately forged coupon.

(g) 8% for test bar taken from separately forged coupon.

(h) 2% for forgings over 25 through 50 mm (1 through 2 in.) thick

Compressive yield strength. Approximately the same as tensile yield strength

Hardness. O temper: 87 to 98 HRH; 45 HB. T4 temper: 65 to 73 HRB; 105 HB. T6 temper: 80 to 86 HRB; 135 HB. HB values obtained using 500 kg load and 10 mm diam ball

Poisson's ratio. 0.33 at 20 °C (68 °F)

Elastic modulus. Tension: 2014, 72.4 GPa (10.5×10^6 psi); Alclad 2014, 71.7 GPa (10.4×10^6 psi). Shear: 2014 and Alclad 2014, 28 GPa (4.0×10^6 psi). Compression: 2014, 73.8 GPa (10.7×10^6 psi); Alclad 2014, 73.1 GPa (10.6×10^6 psi)

Fatigue strength. O temper, 90 MPa (13 ksi); T4 temper, 140 MPa (20 ksi); T6 temper, 125 MPa (18 ksi); all at 5×10^8 cycles in an R.R. Moore type test

Mass Characteristics

Density. 2.80 g/cm^3 (0.101 $lb/in.^3$) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 638 °C (1180 °F)

Solidus temperature. 507 °C (945 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm · K	µin./in. · °F
-50 to 20	-58 to 68	20.8	11.5
20 to 100	68 to 212	22.5	12.5

20 to 200	68 to 392	23.4	13.0
20 to 300	68 to 572	24.4	13.6

Volumetric: 65.1 × 10^{-6} m^3/m^3 · K (3.62 × 10^{-5} $in.^3/in.^3$ · °F)

Thermal conductivity. At 20 °C (68 °F); O temper, 192 W/m · K (111 Btu/ft · h · °F); T3, T4, T451 tempers, 134 W/m · K (77.4 Btu/ft · h · °F); T6, T651, T652 tempers, 155 W/m · K (89.5 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. At 20 °C (68 °F): O temper, 50% IACS, T3, T4, T451 tempers, 34% IACS; T6, T651, T652 tempers, 40% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 34 nΩ · m; T3, T4, T451 tempers, 51 nΩ · m; T6, T651, T652 tempers, 43 nΩ · m. Temperature coefficient: O, T3, T4, T451, T6, T651, T652 tempers, 0.1 nΩ · m per K at 20 °C (68 °F).

Electrolytic solution potential. At 25 °C (77 °F): -0.68 V (T3, T4, T451 tempers) or -0.78 V (T6, T651, T652 tempers) versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 413 °C (775 °F)

Solution temperature. 502 °C (935 °F)

Aging temperature. T6 temper. Sheet, plate, wire, rod, bar, shapes, and tube: 160 °C (320 °F) for 18 h at temperature. Forgings: 171 °C (340 °F) for 10 h at temperature

2017
4.0Cu-0.6Mg-0.7Mn-0.5Si

Specifications

ASTM. B 211 and B 316

SAE. J454

ANSI. H38.4 and H38.12

UNS number. A92017

Government. QQ-A-222/5, QQ-A-430, MIL-R-430

Foreign. France: A-U46. Germany: AlCuMg1 and 3.1325. Great Britain: L18 and 150A. Canada: CM41. Austria: AlCuMg1. ISO: AlCuMgSi

Chemical Composition

Composition limits. 0.20 to 0.80 Si, 0.7 max Fe, 3.5 to 4.5 Cu, 0.4 to 0.80 Mg, 0.40 to 1.0 Mn, 0.10 max Cr, 0.15 max Ti, 0.25 max Zn, 0.05 other (each), 0.15 others (total); bal Al

Applications

Typical uses. Alloy 2017, which was the first alloy developed in the Al-Cu-Mg series, is now in rather limited use, chiefly for rivets. Used in components for general engineering purposes, structural applications in construction and transportation, screw machine products, and fittings.

General characteristics. Age-hardenable wrought aluminum alloy with medium strength and ductility, good machinability, good formability, and fair resistance to atmospheric corrosion. Welding is not recommended unless heat treatment after welding is practicable. Its service temperature is below 100 °C (212 °F).

Forms available. Forgings, extrusions, bars, rods, wire, shapes, and rivets

Mechanical Properties

Tensile properties. See Tables 20 and 21.

Table 20 Typical room-temperature mechanical properties of 2017

Property	Temper condition	
	O	T4, T451
Tensile strength, MPa (ksi)	180 (26)	427 (62)
Yield strength (0.2% offset), MPa (ksi)	70 (10)	275 (40)
Elongation in 50 mm (2 in.)[(a)], %	22	22
Hardness, HB[(b)]	45	105
Shear strength, MPa (ksi)	125 (18)	262 (38)

(a) Specimens 13 mm ($\frac{1}{2}$ in.) diameter.

(b) 500 kg load, 10 mm ball

Table 21 Typical tensile properties of 2017 (T4 and T451 tempers) at various temperatures

Test temperature[(a)]		Tensile strength		Yield strength (0.2% offset)		Elongation in 50 mm (2 in.), %
°C	°F	MPa	ksi	MPa	ksi	
-196	-320	550	80	365	53	28

149	300	275	40	207	30	15
204	400	110	16	90	13	35
260	500	62	9	52	7.6	45
316	600	40	6	35	5	65
371	700	30	4.3	24	3.5	70

(a) Tested after holding 10,000 h at temperature

Hardness. See Table 20.

Shear strength. See Table 20.

Modulus of elasticity. 72.4 GPa (10.5×10^6 psi) average of tension and compression; modulus is about 2% greater for compression than tension

Modulus of rigidity. 27.5 GPa (4×10^6 psi)

Fatigue strength. See Table 20.

Mass Characteristics

Density. 2.80 g/cm^3 (0.101 lb/in.^{3})

Thermal Properties

Liquidus temperature. 640 °C (1185 °F)

Solidus temperature. 513 °C (955 °F)

Thermal conductivity. At 25 °C (77 °F): 193 W/m · °C (1340 Btu · in./ft^2 · h · °F) with an O temper and 134 W/m · °C (930 Btu · in./ft^2 · h · °F) with a T4 temper

Coefficient of thermal expansion. From 20 to 100 °C (68 to 212 °F): 23.6 μm/m · °C (13.1 μin./in. · °F)

Electrical Properties

Electrical conductivity. At 20 °C (68 °F): 50% IACS on a volume basis (159% IACS) on weight basis) with an O temper; 34% IACS on a volume basis (108% IACS on a weight basis) with a T4 temper

Electrical resistivity. At 20 °C (68 °F): 0.035 Ω· mm^2/m (21 Ω· circ mil/ft)with an O temper and 0.05 Ω· mm^2/m (30 Ω· circ mil/ft) with a T4 temper

Fabrication Characteristics

Annealing temperature. 415 °C (775 °F) for a heat-treated anneal and 340 to 350 °C (640 to 660 °F) for cold-work anneal

Solution temperature. 500 to 510 °C (930 to 950 °F)

Aging temperature. Room temperature

Machinability. Fair to good in the annealed condition and excellent in the solution treated and naturally aged condition (T4 temper)

Workability. Has good formability. In the annealed condition (O temper) its formability is equal to or superior to 2024-O. In the T4 temper condition, it forms as readily as 2024-T3 or 2024-T4.

Weldability. Because of the effect of heating on corrosion resistance, welding is rarely recommended except where heat treatment after welding is practicable. The inert gas method and resistance welding have given satisfactory results. Gas welding, brazing, and soldering are not successful. This alloy is so sensitive to cracking during welding that other aluminum alloys, joint design, fixtures, and so on must be arranged so as to put a minimum stress on the joint during cooling. The best filler material is parent metal.

Corrosion Resistance

2017 has a fair resistance to atmospheric corrosion, depending on its thermal treatment. Quenching slowly from the solution-treatment temperature lowers the resistance to corrosion and makes this alloy susceptible to intergranular attack. The same result is obtained by heating the alloy after solution treatment. If, however, the alloy has been slowly quenched, artificial aging tends to restore the normal resistance to attack; in fact, for material that is to be artificially aged, a mild quench may be preferable. For thicker sections, the rate of cooling even by immersion in cold water is not great enough to produce complete freedom from susceptibility to intergranular attack. In thin sections the solution treated material, being aged at room temperature, is more resistant to corrosion than the fully aged material, while in heavy sections the latter is more resistant because of the beneficial effect of artificial aging on more slowly cooled material.

ASME. Rolled or drawn wire, rod, and bar: SB211. Extrusions: SB221

ASTM. See Table 22.

SAE. J454

UNS number. A92024

Government. See Table 22.

Foreign. Austria: Önorm AlCuMg2. Canada: CSA CG42. France: NF A-U4G1. Italy: UNI P-AlCu4.5MgMn; Alclad 2024, P-AlCu4.5MgMn placc. Spain: UNE L-314. Germany: DIN AlCuMg2

Chemical Composition

Composition limits. 0.5 Si max, 0.50 Fe max, 3.8 to 4.9 Cu, 0.30 to 0.9 Mn, 1.2 to 1.8 Mg, 0.10 Cr max, 0.25 Zn max, 0.15 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Composition limits of Alclad 2024. 1230 cladding--99.30 Al min, 0.7 Si max + Fe, 0.10 Cu max, 0.05 Mn max, 0.05 Mg max, 0.10 Zn max, 0.05 V max, 0.013 Ti max, 0.03 max other (each)

Applications

Typical uses. Aircraft structures, rivets, hardware, truck wheels, screw machine products, and other miscellaneous structural applications

Mechanical Properties

Tensile properties. See Tables 23, 24, and 25.

Table 23 Typical tensile properties of alloy 2024

(a) In 50 mm (2 in.) or 4*d*, where *d* is diameter of reduced section of tension-test specimen. Where a range of values appears in this column, the specified minimum elongation varies with thickness of the mill product.

(b) For plate 12.7 mm (0.500 in.) or over in thickness, listed properties apply to core material only. Tensile and yield strengths of composite plate are slightly lower than the listed value, depending on thickness of the cladding.

(c) Minimum yield strength of coiled wire and rod, 276 MPa (40 ksi).

(d) Applicable to rod only.

(e) Full section specimen; minimum elongation is 10 to 12% for cut-out specimen

Shear strength. See Table 24.

Hardness. See Table 24.

Poisson's ratio. 0.33 at 20 °C (68 °F)

Elastic modulus. Tension, 72.4 GPa (10.5×10^6 psi); shear , 28.0 GPa (4.0×10^6 psi); compression, 73.8 GPa (10.7×10^6 psi)

Fatigue strength. See Table 24.

Elevated-temperature strengths. See Fig. 4.

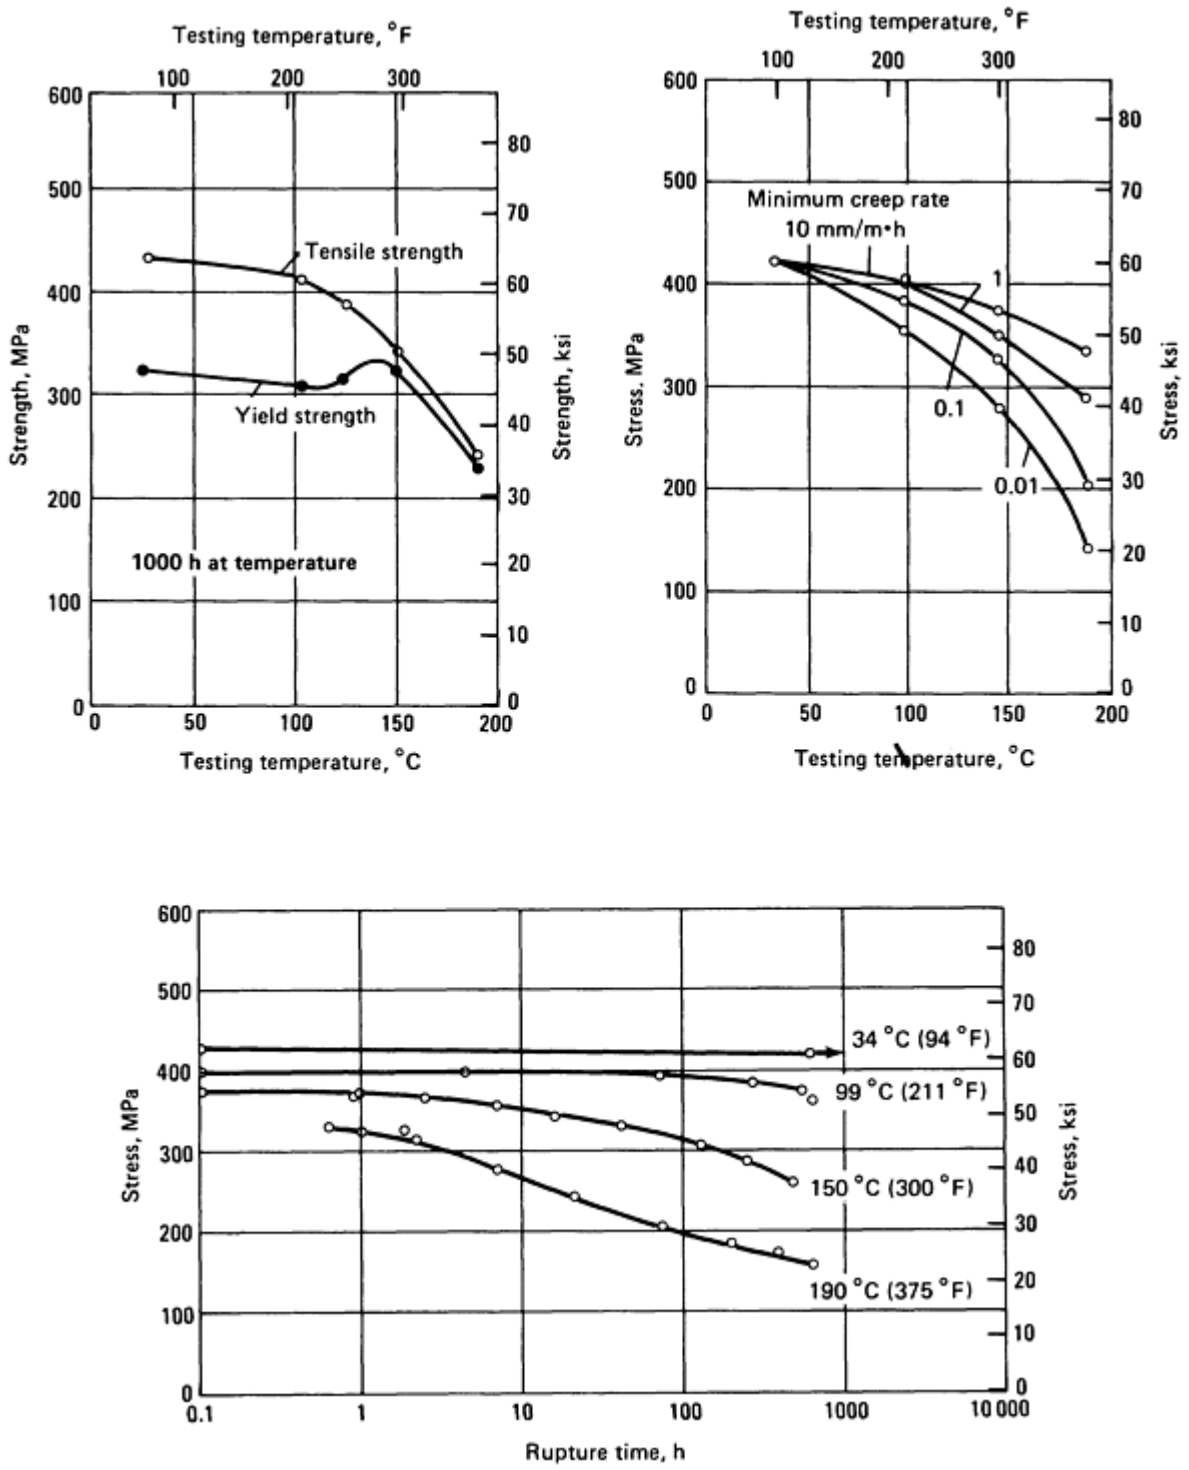

Fig. 4 Effect of temperature on tensile properties of Alclad 2024-T3. Sheet was 1.0 mm (0.04 in.) thick.

Mass Characteristics

Density. 2.77 g/cm^3 (0.100 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 638 °C (1180 °F)

Solidus temperature. 502 °C (935 °F)

Incipient melting temperature. 502 °C (935 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	**°F**	**µm/m · K**	**µin./in. · °F**
-50 to 20	-58 to 68	21.1	11.7

Fabrication Characteristics

Annealing temperature. 413 °C (775 °F)

Solution temperature. 493 °C (920 °C)

Aging temperature. T6 and T8 tempers: 191 °C (375 °F) for 8 to 16 h at temperature

2036
2.6Cu-0.45Mg-0.25Mn

Specifications

UNS number. A92036M

Chemical Composition

Composition limits. 0.50 Si max, 0.50 Fe max, 2.2 Cu max, 0.10 to 0.40 Mn, 0.30 to 0.6 Mg, 0.10 Cr max, 0.25 Zn max, 0.15 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Sheet for auto body panels

Mechanical Properties

Tensile properties. Typical, for 0.64 to 3.18 mm (0.025 to 0.125 in.) flat sheet, T4 temper: tensile strength, 340 MPa (49 ksi); yield strength, 195 MPa (28 ksi); elongation, 24% in 50 mm (2 in.). Minimum, for 0.64 to 3.18 mm flat sheet, T4 temper: tensile strength, 290 MPa (42 ksi); yield strength, 160 MPa (23 ksi); elongation, 20% in 50 mm (2 in.)

Hardness. Typical, T4 temper: 80 HR15T

Strain-hardening exponent. 0.23

Elastic modulus. Tension, 70.3 GPa (10.2×10^6 ksi); compression, 71.7 GPa (10.4×10^6 ksi)

Fatigue strength. Typical, T4 temper: 124 MPa (18 ksi) at 10^7 cycles for flat sheet tested in reversed flexure

Mass Characteristics

Density. 2.75 g/cm^3 (0.099 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 650 °C (1200 °F)

Solidus temperature. 554 °C (1030 °F)

Incipient melting temperature. 510 °C (950 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F

-50 to 20	-58 to 68	21.6	12.0
20 to 100	68 to 212	23.4	13.0
20 to 200	68 to 392	24.3	13.5
20 to 300	68 to 572	25.2	14.0

Volumetric: 67.5×10^{-6} $m^3/m^3 \cdot K$ (3.75×10^{-5} $in.^3/in.^3 \cdot °F$) at 20 °C (68 °F)

Specific heat. 882 J/kg · K (0.211 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 20 °C (68 °F): O temper, 198 W/m · K (114 Btu/ft · h · °F); T4 temper, 159 W/m · K (91.8 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): O temper, 52% IACS; T4 temper, 41% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 33.2 nΩ · m; T4 temper, 42.1 nΩ · m. Temperature coefficient, at 20 °C (68 °F): O and T4 tempers, 0.1 nΩ · m per K

Electrolytic solution potential. At 25 °C (77 °F): -0.75 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Weldability. Arc welding with inert gas limited due to crack sensitivity, loss of mechanical properties, and/or loss in resistance to corrosion. When used for automotive parts, can be resistance welded with very good results

Annealing temperature. 385 °C (725 °F); hold 2 to 3 h at temperature for sheet

Solution temperature. 500 °C (930 °F)

2048
3.3Cu-1.5Mg-0.40Mn

Specifications

UNS number. A92048

Chemical Composition

Composition limits. 0.15 Si max, 0.20 Fe max, 2.8 to 3.8 Cu, 0.20 to 0.6 Mn, 1.2 to 1.8 Mg, 0.25 Zn max, 0.10 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Sheet and plate in structural components for aerospace application and military equipment

Mechanical Properties

Tensile properties. See Table 26 and Fig. 5.

(a) Stress to produce 0.2% plastic extension in the indicated time

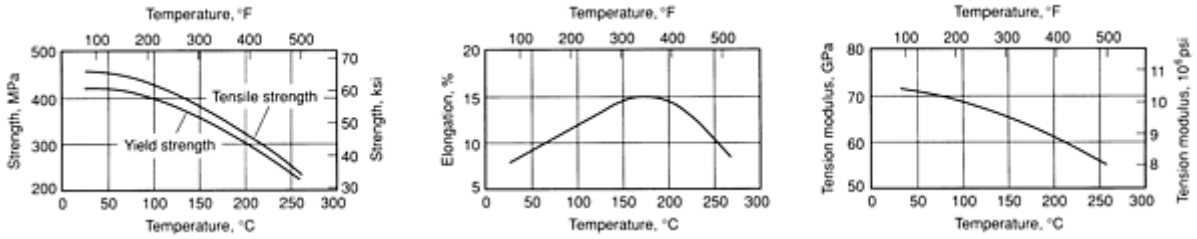

Fig. 5 Typical tensile properties of alloy 2048-T851 plate

Shear strength. Longitudinal, 271 MPa (39.3 ksi); transverse, 270 MPa (39.2 ksi)

Compressive properties. See Table 26 and Fig. 6.

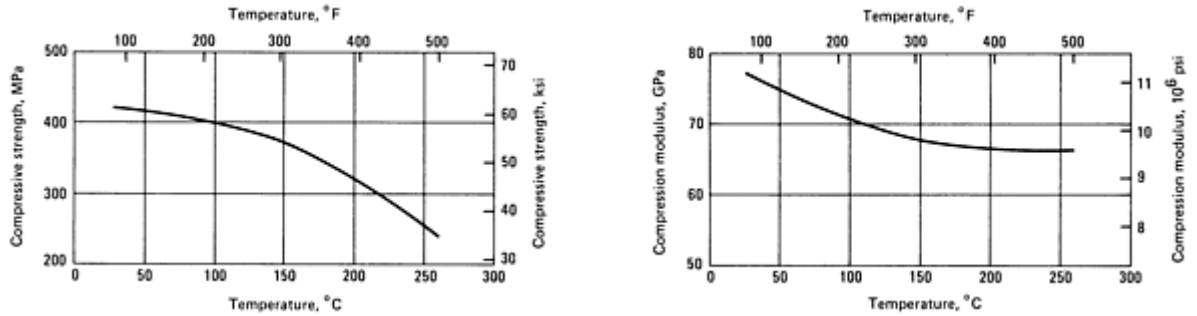

Fig. 6 Typical compressive properties of alloy 2048-T851 plate

Elastic modulus. See Fig. 5 and 6.

Impact strength. Charpy V-notch: longitudinal, 10.3 J (7.6 ft · lbf); transverse, 6.1 J (4.5 ft · lbf)

Fatigue strength. See Table 26 and Fig. 7, 8, , and 9 10.

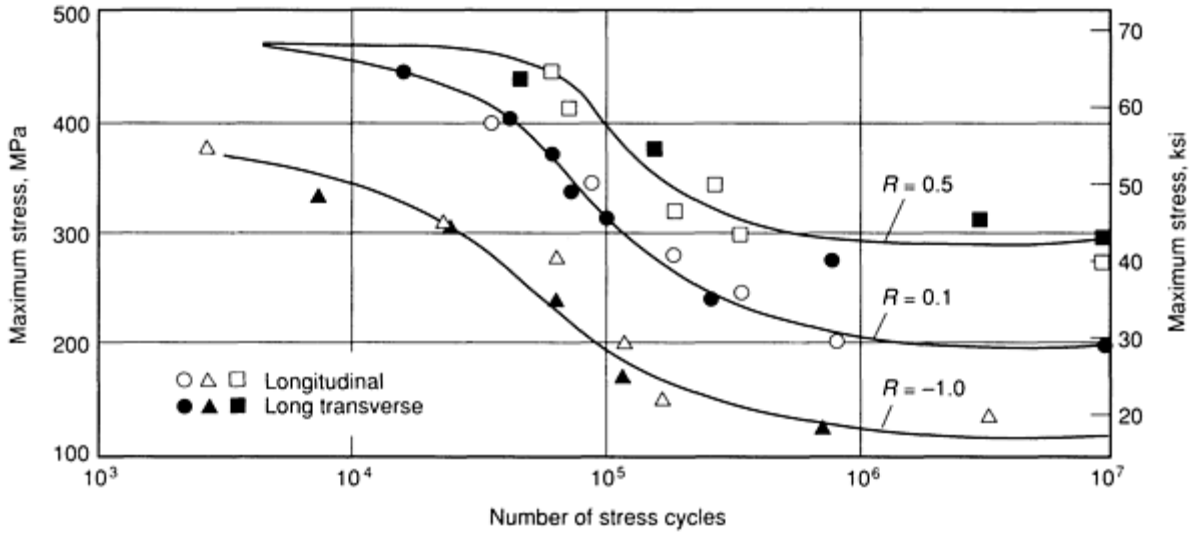

Fig. 7 Axial fatigue curves for unnotched specimens of alloy 2048-T851 plate

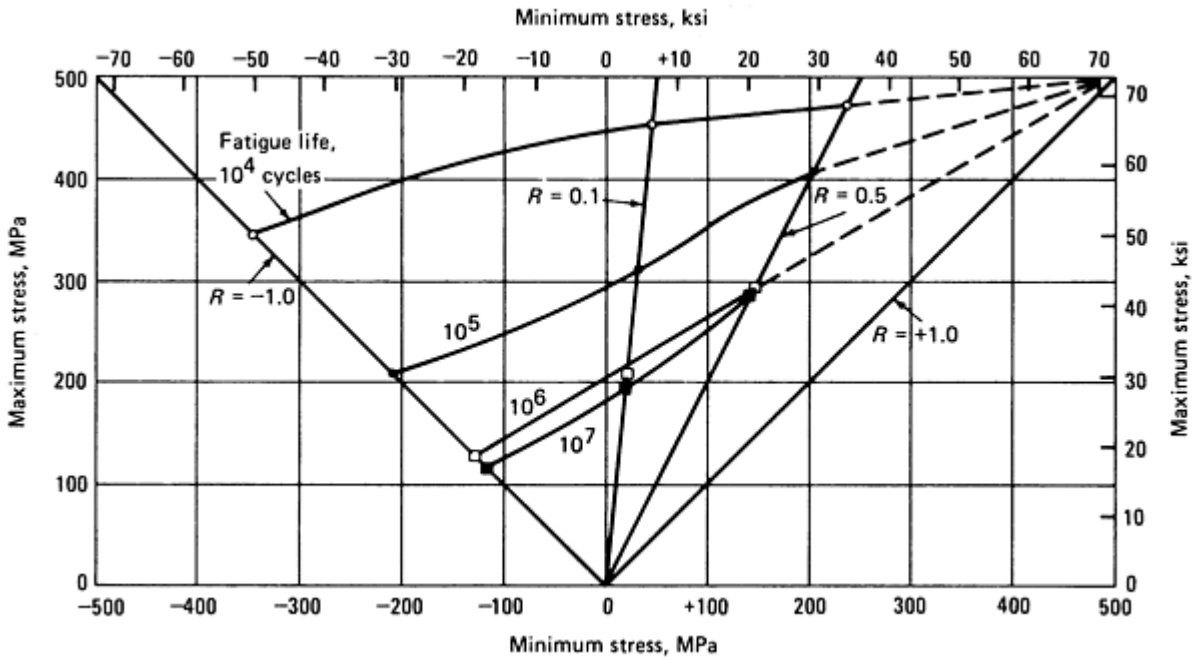

Fig. 8 Modified Goodman diagram for axial fatigue of unnotched specimens of alloy 2048-T851 plate

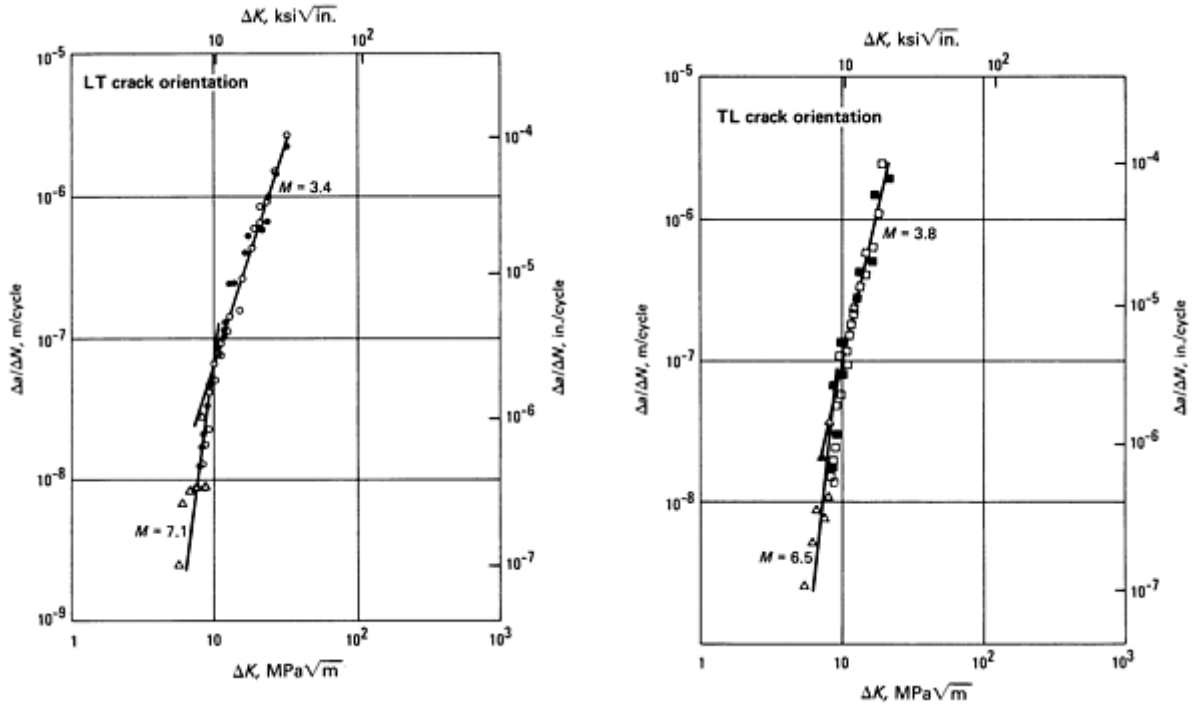

Fig. 9 Fatigue-crack propagation in alloy 2048-T851 plate

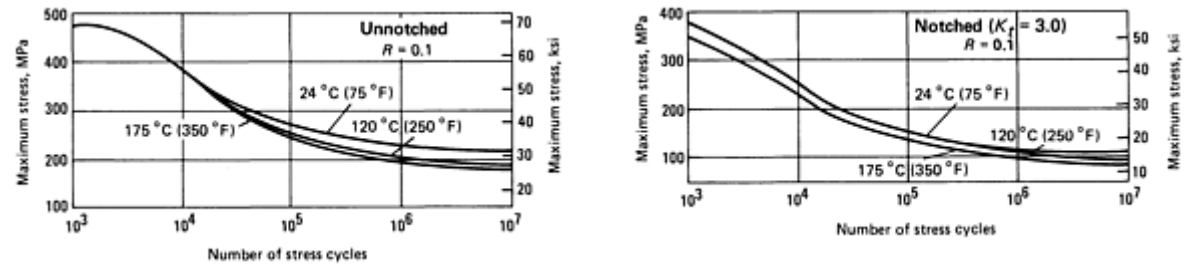

Fig. 10 Axial fatigue of alloy 2048-T851 plate

Plane-strain fracture toughness. L-T crack orientation, 35.2 MPa $\sqrt{m}$ (32.0 ksi $\sqrt{in}$); T-L crack orientation, 31.9 MPa $\sqrt{m}$ (29.1 ksi $\sqrt{in}$

Creep-rupture characteristics. See Table 26 and Fig. 11.

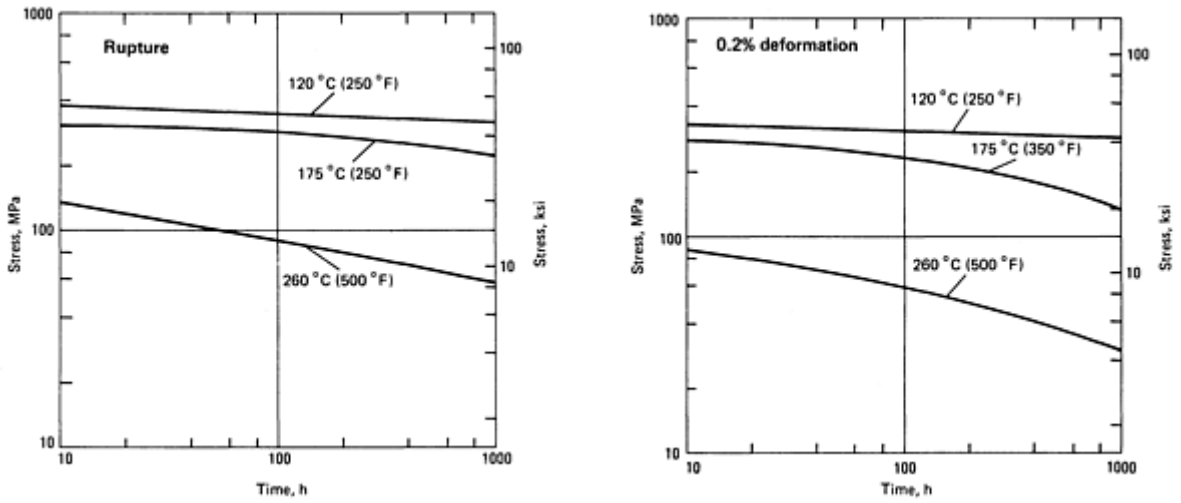

Fig. 11 Creep-rupture curves for alloy 2048-T851 plate, longitudinal orientation

Mass Characteristics

Density. 2.75 g/cm^3 (0.099 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Coefficient of thermal expansion. Linear, 23.5 μm/m · K (13.0 μin./in. · °F) at 21 to 104 °C (70 to 220 °F)

Specific heat. 926 J/kg · K (0.221 Btu/lb · °F) at 100 °C (212 °F)

Thermal conductivity. T851 temper, 159 W/m · K (92 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, T851 temper: 42% IACS at 20 °C (68 °F)

Electrical resistivity. T851 temper, 40 nΩ · m at 20 °C (68 °F)

2124
4.4Cu-1.5Mg-0.6Mn

Specifications

AMS. 4101

ASTM. B 209

UNS number. A92124

Government. QQ-A-250/29

Chemical Composition

Composition limits. 0.20 Si max, 0.30 Fe max, 3.8 to 4.9 Cu, 0.30 to 0.9 Mn, 1.2 to 1.8 Mg, 0.10 Cr max, 0.25 Zn max, 0.15 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Consequence of exceeding impurity limits. Degrades fracture toughness

Applications

Typical uses. Plate in thicknesses of 40 to 150 mm (1.5 to 6.0 in.) for aircraft structures

Mechanical Properties

Tensile properties. See Tables 27 and 28.

Table 27 Typical tensile properties of alloy 2124-T851

Specimen orientation	Tensile strength		Yield strength		Elongation, %
	MPa	ksi	MPa	ksi	
1.500-2.000 in. thick

Mass Characteristics

Density. 2.77 g/cm^3 (0.100 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 638 °C (1180 °F)

Solidus temperature. 502 °C (935 °F)

Incipient melting temperature. 502 °C (935 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.1	11.7
20 to 100	68 to 212	22.9	12.7
20 to 200	68 to 392	23.8	13.2
20 to 300	68 to 572	24.7	13.7

Volumetric: 66.0 × 10^{-6} m^3/m^3 · K (3.6 × 10^{-5} $in.^3/in.^3$ · °F) at 20 °C (68 °F)

Specific heat. 882 J/kg · K (0.210 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 20 °C (68 °F): O temper, 191 W/m · K (110 Btu/ft · h · °F); T851, 152 W/m · K (87.8 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): O temper, 50% IACS; T851, 39% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 34.5 nΩ · m. Temperature coefficient, O and T851 tempers: 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. T851 temper, -0.80 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter 25 °C (77 °F)

Fabrication Characteristics

Annealing temperature. 413 °C (775 °F)

Solution temperature. 493 °C (920 °F)

Aging temperature. 191 °C (375 °F)

2218
4.0Cu-2.0Ni-1.5Mg

Specifications

AMS. Forgings and forging stock: 4142

SAE. J454

UNS. A92218

Government. Forgings and forging stock:

QQ-A-367

Foreign. France: NF A-U4N. Spain: UNE

L-315. Switzerland: VSM Al-Cu-Ni

Chemical Composition

Composition limits. 0.9 Si max, 1.0 Fe max, 3.5 to 4.5 Cu, 0.20 Mn max, 1.2 to 1.8 Mg, 0.10 Cr max, 1.7 to 2.3 Ni, 0.25 Zn max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Forgings; aircraft and diesel engine pistons; aircraft engine cylinder heads; jet engine impellers and compressor rings

Mechanical Properties

Tensile properties. See Tables 30 and 31.

Table 30 Typical mechanical properties of alloy 2218

Temper	Tensile strength		Yield strength		Elongation, %	Hardness[(a)], HB
	MPa	ksi	MPa	ksi		
T61	407	59	303	44	13	115
T71	345	50	276	40	11	105

(a) 500 kg load; 10 mm diam ball

Table 31 Tensile properties of alloy 2218-T61

Temperature		Tensile strength[(a)]		Yield strength[(a)]		Elongation, %
°C	°F	MPa	ksi	MPa	ksi

Mass Characteristics

Density. 2.80 g/cm^3 (0.101 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 635 °C (1175 °F)

Solidus temperature. 532 °C (990 °F)

Incipient melting temperature. 504 °C (940 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	20.7	11.5
20 to 100	68 to 212	22.4	12.4
20 to 200	68 to 392	23.3	12.9
20 to 300	68 to 572	24.2	13.4

Volumetric: 6.5 × 10^{-5} m^3/m^3 · K (3.6 × 10^{-5} in./in. · °F) at 20 °C (68 °F)

Specific heat. 871 J/kg · K (0.208 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 20 °C (68 °F): T61 temper, 148 W/m · K (85.5 Btu/ft · h · °F); T72 temper, 155 W/m · K (89.6 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric: T61 temper, 38% IACS; T72 temper, 40% IACS

Electrical resistivity. T61 temper, 45.0 nΩ · m; T72 temper, 43.0 nΩ · m. Temperature coefficient, T61 and T72 tempers: 0.1 nΩ · m per K at 20 °C (68 °F)

Fabrication Characteristics

Solution temperature. 510 °C (950 °F)

Aging temperature. T61 temper, 170 °C (340 °F) for 10 h at temperature; T72 temper, 240 °C (460 °F) for 6 h at temperature

2219, Alclad 2219
6.3Cu-0.3Mn-0.18Zr-0.10V-0.06Ti

Specifications

AMS. Sheet and plate: 4031. Extruded wire, rod, bar, shapes, and tube: 4162, 4163. Forgings: 4143, 4144. Alclad 2219, sheet and plate: 4094, 4095, 4096

ASTM. Sheet and plate: B 209. Rolled or cold finished wire, rod, and bar: B 211. Extruded wire, rod, bar, shapes, and tube: B 221. Extruded, seamless tube: B 241. Forgings: B 247. Alclad 2219, sheet and plate: B 209

SAE. J454

UNS. A92219

Government. Sheet and plate: QQ-A-250/30. Forgings: QQ-A-367, MIL-A-22771. Armor plate: MIL-A-46118. Rivet wire and rod: QQ-A-430

Foreign. France: NF A-U6MT. United Kingdom: DTD 5004

Chemical Composition

Composition limits for 2219. 0.20 Si max, 0.30 Fe max, 5.8 to 6.8 Cu, 0.20 to 0.40 Mn, 0.02 Mg max, 0.10 Zn max, 0.05 to 0.15 V, 0.02 to 0.10 Ti, 0.10 to 0.25 Zr, 0.05 max other (each), 0.15 max others (total), bal Al

Composition limits for Alclad 2219. 7072 cladding--0.10 Cu max, 0.10 Mn max,0.70 Si max + Fe, 0.80 to 1.3 Zn, 0.10 Mg max, 0.05 max other (each), 0.15 max others (total)

Applications

Typical uses. Welded space booster oxidizer and fuel tanks, supersonic aircraft skin and structure components. Readily weldable and useful for applications over temperature range of -270 to 300 °C (-450 to 600 °F). Has high fracture toughness, and the T8 temper is highly resistant to stress-corrosion cracking

Mechanical Properties

Tensile properties. See Tables 34, 35, and 36.

(a) In 50 mm (2 in.) or 4*d*, where *d* is diameter of reduced section of tensile test specimen. Where a range of values appears in this column, specified minimum elongation varies with thickness of the mill product.

(b) Sheet only.

(c) For plate 12.7 mm (0.500 in.) or greater in thickness, property limits apply to core material only. Tensile and yield strengths of composite plate slightly lower depending on thickness of cladding.

(d) Plate only.

(e) Specimen taken from forging.

(f) 10% for specimen taken from separately forged coupon.

(g) Maximum cross-sectional area 1650 cm^2 (256 $in.^2$). These properties not applicable to upset biscuit forgings or rolled rings.

(h) Only applicable to rings having ratio of outside diameter to wall thickness equal to or greater than 10

Table 36 Typical tensile properties of alloy 2219 at various temperatures

Mass Characteristics

Density. 2.84 g/cm^3 (0.103 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 643 °C (1190 °F)

Incipient melting temperature. 543 °C (1010 °F)

Coefficient of thermal expansion. Linear:

Temperature range		**Average coefficient**	
°C	**°F**	**µ/m · K**	**µin./in. · °F**
-50 to 20	-58 to 68	20.8	11.5
20 to 100	68 to 212	22.5	12.5
20 to 200	68 to 349	23.4	13.0
20 to 300	68 to 572	24.4	13.6

Volumetric: 6.5 × 10^{-5} m^3/m^3 · K (3.62 × 10^{-5} in.^{3}/in.^{3} · °F)

Specific heat. 864 J/kg · K (0.206 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. O temper, 170 W/m · K (98.2 Btu/ft · h · °F); T31, T37 tempers, 116 W/m · K (67.0 Btu/ft · h · °F); T62, T81, T87 tempers, 130 W/m · K (75.1 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): O temper, 44% IACS; T31, T37, T351 tempers, 28% IACS; T62, T81, T87, T851 tempers, 30% IACS

Electrical resistivity. At 20 °C (68 °F); O temper, 39 nΩ · T31, T37, T351 tempers, 62 nΩ · m; T62, T81, T87, T851 tempers, 57 nΩ · m. Temperature coefficient, all tempers: 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. T31, T37, T351 tempers, -0.64 V and T62, T81, T87, T851 tempers, -0.80 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter at 25 °C (77 °F)

Fabrication Characteristics

Annealing temperature. 415 °C (775 °F)

Solution temperature. 535 °C (995 °F)

Aging temperature. 165 to 190 °C (325 to 375 °F) from 18 to 36 h at temperature. Appropriate combination of aging time and temperature is different for different tempers.

2319
5.3Cu-0.3Mn-0.18Zr-0.15Ti-0.10V

Specifications

UNS. A922319

Government. QQ-R-566, MIL-E-16053

Chemical Composition

Composition limits. 5.8 to 6.8 Cu, 0.20 to 0.40 Mn, 0.10 to 0.25 Zr, 0.10 to 0.20 Ti, 0.05 to 0.15 V, 0.20 Si max, 0.30 Fe max, 0.02 Mg max, 0.10 Zn max, 0.0008 Be max, 0.05 max other (each), 0.15 max others (total)

Applications

Typical uses. Electrodes and filler wire for welding 2219

Mass Characteristics

Density. 2.83 g/cm^3 (0.103 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 643 °C (1190 °F)

Incipient melting temperature. 543 °C (1010 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	20.8	11.5
20 to 100	68 to 212	22.5	12.5
20 to 200	68 to 392	23.4	13.0
20 to 300	68 to 572	24.4	13.6

Volumetric: 6.5×10^{-5} $m^3/m^3 \cdot K$ (3.62×10^{-5} $in.^3/in.^3 \cdot °F$) at 20 °C (68 °F)

Specific heat. 864 J/kg · K (0.206 Btu/lb · °F)

Thermal conductivity . O temper: 170 W/m · K (98.2 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric: O temper, 44% IACS at 20 °C (68 °F)

Electrical resistivity. O temper, 39 nΩ · at 20 °C (68 °F)

Temperature coefficient. 2.94×10^{-3}/K

Fabrication Characteristics

Annealing temperature. 413 °C (775 °F)

2618
2.3Cu-1.6Mg-1.1Fe-1.0Ni-0.18Si-0.07Ti

Specifications

AMS. Forging and forging stock: 4132

ASTM. Forging: B 247

SAE. J454

Government. Forgings: QQ-A-367; MIL-A-22771

Foreign. France: NF A-U2Gn. United Kingdom: BS H12

Chemical Composition

Composition limits. 0.10 to 0.25 Si, 0.9 to 1.3 Fe, 1.9 to 2.7 Cu, 1.3 to 1.8 Mg, 0.9 to 1.2 Ni, 0.10 Zn max, 0.04 to 0.10 Ti, 0.05 max other (each), 0.15 others (total), bal Al

Applications

Typical uses. Die and hand forgings. Pistons and rotating aircraft engine parts for operation at elevated temperatures. Tire molds

Mechanical Properties

Tensile properties. See Tables 39 and 40 and Fig. 12.

Table 39 Tensile properties of alloy 2618-T61

Product and orientation	Tensile strength		Yield strength		Elongation[a], %
	MPa	ksi	MPa	ksi	
Typical					
All products	440	64	372	54	10[b]
Property limits					
Die forgings, thickness ≤4 in.[c]					
Axis parallel to grain flow	400	58	310	45	4[d][e]
Axis not parallel to grain flow	380	55	290	42	4[d]
Hand forgings					
Thickness ≤2.000 in.[c][f]					
Longitudinal	400	58	325	47	7
Long transverse	380	55	290	42	5
Short transverse	360	52	290	42	4
2.001-3.000 in.					
Longitudinal	395	57	315	46	7
Long transverse	380	55	290	42	5

Short transverse	360	52	290	42	4
3.001-4.000 in.					
Longitudinal	385	56	310	45	7
Long transverse	365	53	275	40	5
Short transverse	350	51	270	39	4
Rolled rings, thickness ≤2.500 in.[g]					
Tangential	380	55	285	41	6
Axial	380	55	285	41	5

(a) In 50 mm (2 in.) or 4 *d*, where *d* is diameter of reduced section of tensile test specimen.

(b) 12.5 mm ($\frac{1}{2}$ in.) diameter specimen.

(c) Properties also apply to forgings machined prior to heat treatment, provided machined thickness is not less than $\frac{1}{2}$ original (as-forged) thickness.

(d) Specimen taken from forgings.

(e) Elongation 6% min for specimen taken from separately forged coupon.

(f) Maximum cross-sectional area 930 cm^2 (1 ft^2). Not applicable to upset biscuit forgings or to rolled rings.

(g) Applicable only to rings having ratio of outside diameter to wall thickness equal to or greater than 10

Table 40 Typical tensile properties of alloy 2618-T61 at various temperatures

Temperature		**Tensile strength**		**Yield strength (0.2% offset)**		**Elongation, %**
°C	**°F**	**MPa**	**ksi**	**MPa**	**ksi**	
-196	-320	538	78.0	421	61.0	12

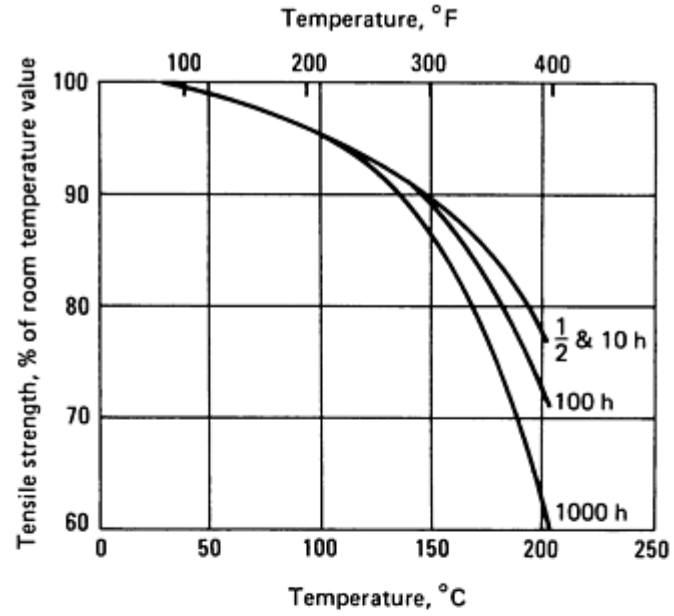
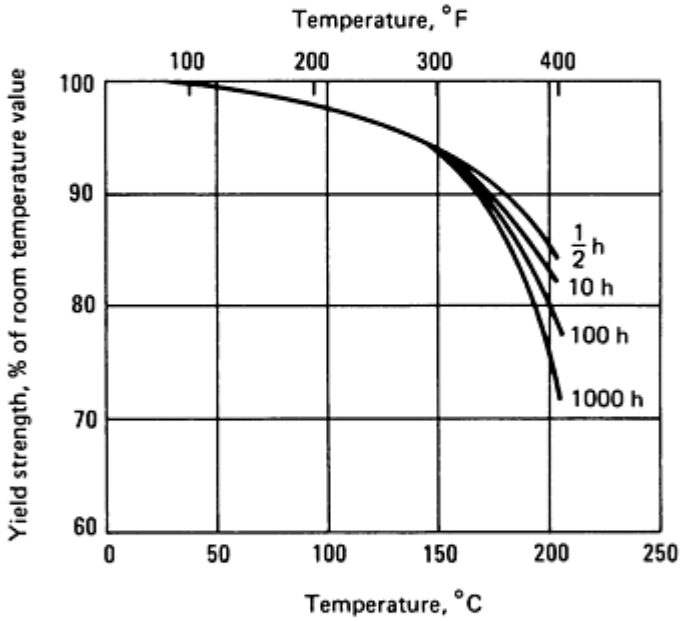
371	700	34	5.0	24	3.5	120





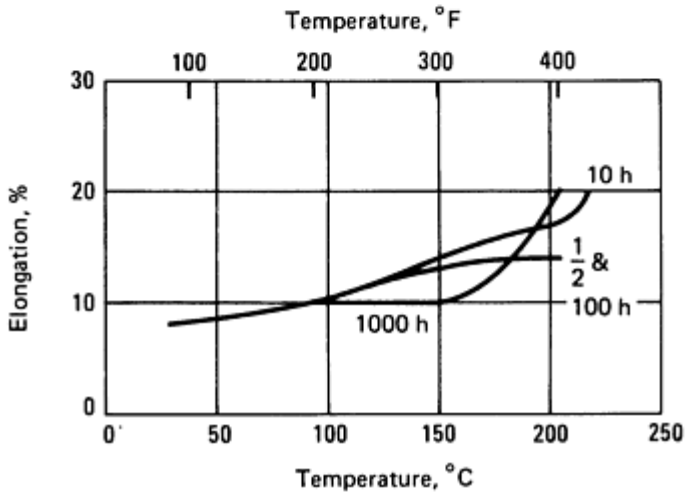


Fig. 12 Influence of prolonged holding at elevated temperature on tensile properties of alloy 2618-T61 hand-

forged billets. Properties determined at temperature after holding for the indicated time under no load. Tensile and yield strengths plotted as percentage of corresponding room-temperature value. Elongation plotted as value determined at temperature

Shear strength. T61 temper, 260 MPa (38 ksi)

Compressive yield strength. Approximately the same as the tensile yield strength. See also Fig. 13.

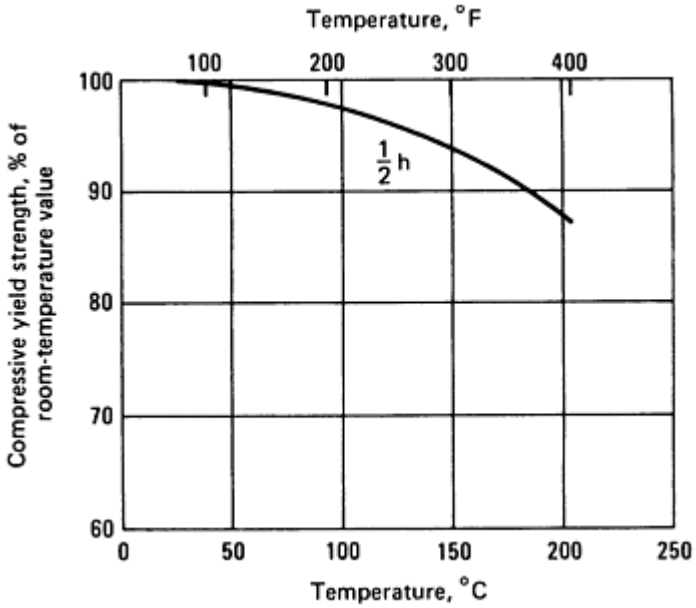

Fig. 13 Influence of temperature on compressive yield strength of alloy 2618-T61 hand-forged billets. Compressive yield strength determined at temperature after holding $\frac{1}{2}$ h under no load. Value plotted as percentage of corresponding room-temperature value

Hardness. Die forgings, T61 temper 115 HB min

Poisson's ratio. 0.33 at 20 °C (68 °F)

Elastic modulus, Tension, 74.4 GPa (10.8×10^6 psi); shear, 28.0 GPa (4.0×10^6 psi)

Fatigue strength. T61 temper, 125 MPa (18 ksi) at 5×10^8 cycles; R.R. Moore type test

Creep-rupture characteristics. See Table 41.

Table 41 Creep-rupture properties of alloy 2618

Temperature		Time under stress, h	Rupture stress		Stress for creep of							
					1.0%		0.5%		0.2%		0.1%

		1000	20	2.9	17	2.5	14	2.1	. . .	. . .	. . .	. . .

Mass Characteristics

Density. 2.76 g/cm^3 (0.100 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 638 °C (1180 °F)

Solidus temperature. 549 °C (1020 °F)

Incipient melting temperature. 502 °C (935 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	20.6	11.4
20 to 100	68 to 212	22.3	12.4
20 to 200	68 to 392	23.2	12.9
20 to 300	68 to 572	24.1	13.4

Volumetric: 6.45 × 10^{-5} m^3/m^3 · K (3.6 × 10^{-5} in.^{3}/in.^{3} · °F) at 20 °C (68 °F)

Specific heat. 875 J/kg · K at 20 °C (68 °F)

Thermal conductivity. T61 temper, 146 W/m · K (84 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, T61 temper, 37% IACS at 20 °C (68 °F)

Electrical resistivity. T61 temper, 41 nΩ · m at 20 °C (68 °F); temperature coefficient, T61 temper: 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. At 25 °C (77 °F): T61 temper, -0.80 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Solution temperature. 530 °C (985 °F)

Aging temperature. T61, 200 °C (390 °F) for 20 h at temperature

ASME. See Table 42.

ASTM. See Table 42.

SAE. J454

UNS number. 3003: A93003

Government. See Table 42.

Foreign. Canada. CSA MC10. France: NF A-M1. United Kingdom: BS N3. West Germany: DIN AlMn. ISO: AlMn1Cu

Chemical Composition

Composition limits of 3003: 0.6 Si max, 0.7 Fe max, 0.05 to 0.20 Cu, 1.0 to 1.5 Mn, 0.10 Zn max, 0.05 max other (each), 0.15 max others (total), bal Al

Composition limits of Alclad 3003. 7072 cladding--0.10 Cu max, 0.10 Mg max, 0.10 Mn max, 0.7 Fe max + Si, 0.8 to 1.3 Zn, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses of 3003. Applications where good formability, very good resistance to corrosion or good weldability, or all three, are required, and where more strength is desired than is provided by unalloyed aluminum. Cooking utensils, food and chemical handling and storage equipment, tanks, trim in transportation equipment, lithographic sheet pressure vessels and piping

Typical uses of Alclad 3003. Farm roofing and siding

Mechanical Properties

Tensile properties. See Table 43 and 44. Directional characteristics: tensile strength and elongation of sheet in any of the H tempers are slightly lower in transverse direction

Table 43 Mechanical properties of alloy 3003

400	752	18	2.6	12	1.7	75

(a) Lowest strengths for exposures up to 10,000 h at temperature, no load; test load applied at 35 MPa/min (5 ksi/min) to yield strength and then at strain rate of 5%/min to fracture

Compressive yield strength. Approximately the same as tensile yield strength

Shear yield strength. Approximately 55% of the tensile strength

Hardness. See Table 43.

Poisson's ratio. 0.33 at 20 °C (68 °F)

Elastic modulus. Tension, 70 GPa (10.2×10^6 psi); shear, 25 GPa (3.6×10^6 psi)

Fatigue strength. See Table 43.

Mass Characteristics

Density. 2.73 g/cm^3 (0.099 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 654 °C (1210 °F)

Solidus temperature. 643 °C (1190 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.5	11.9
20 to 100	68 to 212	23.2	12.9
20 to 200	68 to 392	24.1	13.4
20 to 300	68 to 572	25.1	13.9

Volumetric: 67×10^{-6} m^3/m^3 · K (3.72×10^{-5} in.^{3}/in.^{3} · °F) at 20 °C (68 °F)

Specific heat. 893 J/kg · K (0.213 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 20 °C (68 °F):

Temper	Conductivity	
	W/m · K	Btu/ft · h · °F
O	193	112
H12	163	94.1
H14	159	91.9

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F):

Temper	Conductivity, % IACS
O	50
H12	42
H14	41
H18	40

Electrical resistivity. At 20 °C (68 °F):

Temper	Resistivity, nΩ · m
O	34
H12	41

H14	42
H18	43

Temperature coefficient, all tempers: 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. 3003 and core of Alclad 3003, -0.83 V; 7072 cladding, -0.96 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Magnetic Properties

Magnetic susceptibility. Mass: 0.8×10^{-6} (cgs/g) at 25 °C (77 °F)

Fabrication Characteristics

Annealing temperature. 415 °C (775 °F). Commercial practice: 400 to 600 °C (750 to 1100 °F); higher temperatures used only for flash annealing

---

3004, Alclad 3004
1.2Mn-1.0Mg

Specifications

ASTM. 3004: sheet and plate, B 209; extruded tube, B 221; welded tube, B 313, B 547. Alclad 3004: sheet and plate, B 209; welded tube, B 313; culvert pipe, B 547

SAE. J454

UNS number. A93004

Government. Culvert pipe: WW-P-402

Foreign. Australia: A3004. France: NF A-M1G. West Germany: DIN AlMn1Mg1

Chemical Composition

Composition limits of 3004. 0.25 Cu max, 0.30 Si max, 0.70 Fe max, 1.0 to 1.5 Mn, 0.8 to 1.3 Mg, 0.25 Zn max, 0.05 max other (each), 0.15 max others (total), bal Al

Composition limits of Alclad 3004. 7072 cladding--0.10 Cu max, 0.10 Mg max, 0.10 Mn max, 0.7 Fe max + Si, 0.8 to 1.3 Zn, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses of 3004. Drawn and ironed rigid containers (cans), chemical handling and storage equipment, sheet metal work, builders' hardware, incandescent and fluorescent lamp bases and similar applications requiring good formability and higher strength than provided by 3003

Typical uses of Alclad 3004. Siding, culvert pipe, industrial roofing

Mechanical Properties

Tensile properties. See Tables 45 and 46.

Table 45 Mechanical properties of alloy 3004

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.5	11.9
20 to 100	68 to 212	23.2	12.9
20 to 200	68 to 392	24.1	13.4
20 to 300	68 to 572	25.1	13.9

Volumetric: 67×10^{-6} m^3/m^3 · K (3.72×10^{-5} in.^{3}/in.^{3} · °F) at 20 °C (68 °F)

Specific heat. 893 J/kg · K (0.213 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. O temper: 162 W/m · K (93.6 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O temper: 42% IACS at 20 °C (68 °F)

Electrical resistivity. O temper: 41.0 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.84 V; 3004 and core of Alclad 3004, 7072 cladding; -0.96 V (cladding) versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Magnetic Properties

Magnetic susceptibility. Mass: 0.8×10^{-6} (cgs/g) at 25 °C (68 °F)

Fabrication Characteristics

Annealing temperature. 415 °C (775 °F)

3105
0.55Mn-0.50Mg

Specifications

ASTM. B 209

SAE. J454

Chemical Composition

Composition limits. 0.6 Si max, 0.7 Fe max, 0.30 Cu max, 0.20 to 0.80 Mn, 0.20 to 0.80 Mg, 0.20 Cr max, 0.40 Zn max, 0.10 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Residential siding, mobile home sheet, gutters and downspouts, sheet metal work, bottle caps and closures

Mechanical Properties

Tensile properties. See Table 47.

Table 47 Mechanical properties of alloy 3105 sheet

Temper	Tensile strength				Yield strength		Elongation, %	Shear strength	
	MPa	ksi	MPa	ksi	MPa	ksi		MPa	ksi
Typical properties									

O	115	17	. . .	. . .	55	8	24	83	12

H25 (0.013-0.080 in. thick)	160	23	. . .	. . .	130	19	2-6	. . .	. . .

Poisson's ratio. 0.33

Elastic modulus. Tension, 69 GPa (10×10^6 psi); shear, 25 GPa (3.6×10^6 psi)

Mass Characteristics

Density. 2.71 g/cm^3 (0.098 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 657 °C (1215 °F)

Solidus temperature. 638 °C (1180 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.8	12.1
20 to 100	68 to 212	23.6	13.1
20 to 200	68 to 392	24.5	13.6
20 to 300	68 to 572	25.5	14.2

Volumetric: 68×10^{-6} $m^3/^3 \cdot K$ (3.77×10^{-5} $in.^3/in.^3 \cdot °F$) at 20 °C (68 °F)

Specific heat. 897 J/kg · K (0.214 Btu/lb · °F) at 20 °F (68 °F)

Thermal conductivity. 173 W/m · K (99.9 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O temper: 45% IACS at 20 °C (68 °F)

Electrical resistivity. O temper: 38.3 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.84 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Magnetic Properties

Magnetic susceptibility. Mass: 0.7×10^{-6} (cgs/g) at 20 °C (68 °F)

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F)

4032
12.2Si-1.0Mg-0.9Cu-0.9Ni

Specifications

AMS. Forgings and forging stock: 4145

ASTM. Forgings: B 247

SAE. J454

UNS number. A94032

Government. Forgings: QQ-A-367

Foreign. Canada: CSA SG121. France: NF A-S12UN. Italy: UNI P-AlSi12MgCuNi

Chemical Composition

Composition limits. 11.0 to 13.5 Si, 1.0 Fe max, 0.50 to 1.30 Cu, 0.8 to 1.3 Mg, 0.10 Cr max, 0.50 to 1.3 Ni, 0.25 Zn max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Pistons and other high-temperature service parts

Mechanical Properties

Tensile properties. T6 temper: tensile strength, 380 MPa (55 ksi); yield strength, 315 MPa (46 ksi); elongation, 9% in 50 mm (2 in.). For typical properties at various temperatures, see Table 48.

Table 48 Typical mechanical properties of alloy 4032-T6 at various temperatures

Temperature		Tensile strength		Yield strength		Elongation, %
°C	°F	MPa	ksi	MPa	ksi	
-200	-328	460	67	337	49	11
-100	-148	415	60	325	47	10

		1000	83	12	76	11	69	10	. . .	. . .

Mass Characteristics

Density. 2.68 g/cm^3 (0.097 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 571 °C (1060 °F)

Eutectic temperature. 532 °C (990 °F)

Incipient melting temperature. 532 °C (990 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	18.0	10.0
20 to 100	68 to 212	19.5	10.8
20 to 200	68 to 392	20.2	11.2
20 to 300	68 to 572	21.0	11.7

Volumetric: 56×10^{-6} m^3/m^3 · K (3.11×10^{-5} in.^{3}/in.^{3} · °F) at 20 °C (68 °F)

Specific heat. 864 J/kg · K (0.206 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 20 °C (68 °F): O temper, 155 W/m · K (89.6 Btu/ft · h · °F); T6 temper, 141 W/m · K (81.5 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): O temper, 40% IACS; T6 temper, 36% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 43.1 nΩ · m; T6 temper, 47.9 nΩ · m. Temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Fabrication Characteristics

Annealing temperature. 415 °C (775 °F); 2 to 3 h at temperature then furnace cooled to 260 °C (500 °F) at 25 °C (50 °F) per h max

Solution temperature. 505 to 515 °C (940 to 960 °F). Hold 4 min at temperature then quench in cold water; for heavy or complicated forgings, quench in water at 65 to 100 °C (150 to 212 °F)

Aging temperature. 170 to 175 °C (335 to 345 °F); 8 to 12 h at temperature

Hot-working temperature. 315 to 480 °C (600 to 900 °F)

4043
5.2Si

Specifications

AMS. Bare welding rod and electrodes: 4190

SAE. J454

Government. Bare welding rod and electrodes: QQ-R-566, MIL-E-16053; spray gun wire: MIL-W-6712

Foreign. Australia: B4043. Canada: CSA S5. France: NF A-S5. United Kingdom: BS N21. Germany: DIN AlSi5, Werstoff-Nr. 3.2245

Chemical Composition

Composition limits. 4.5 to 6.0 Si, 0.8 Fe max, 0.30 Cu max, 0.05 Mn max, 0.05 Mg max, 0.10 Zn max, 0.20 Ti max, 0.05 max other (each), 0.15 max others (total), 0.0008 Be max for welding electrode only, bal Al

Applications

Typical uses. General purpose weld filler alloy (rod or wire) for welding all wrought and foundry alloys except those rich in magnesium.

Mechanical Properties

Tensile properties. See Table 51.

Table 51 Typical tensile properties of alloy 4043 welding wire

Wire diameter		Temper	Tensile strength		Yield strength (0.2% offset)		Elongation, %
mm	in.		MPa	ksi	MPa	MPa	
5.0	0.20	H16	205	30	180	26	1.7
3.2	0.12	H14	170	25	165	24	1.3

1.6	0.06	O	145	21	65	10	22
1.2	0.05	O	110	16	55	8	29

Mass Characteristics

Density. 2.68 g/cm^3 (0.097 lb/in.^{3})

Thermal Properties

Liquidus temperature. 630 °C (1170 °F)

Solidus temperature. 575 °C (1065 °F)

Coefficient of thermal expansion. Linear, 22.0 μm/m · K (12.2 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Electrical Properties

Electrical conductivity. Volumetric, O temper: 42% IACS at 20 °C (68 °F)

Electrical resistivity. O temper: 41 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Annealing temperature. 350 °C (660 °F)

5005
0.8Mg

Specifications

ASTM. Sheet and plate: B 209. Wire, H19 temper: B 396. Stranded conductor: B 397. Rivet wire and rod: B 316. Rolled rod: B 531. Drawn tube: B 210, B 483

SAE. J454

UNS number. A95005

Government. Rivet wire and rod: QQ-A-430

Foreign. France: NF A-G0.6. United Kingdom: BS N41. Germany: DIN AlMg1. ISO: AlMg1

Chemical Composition

Composition limits. 0.30 Si max, 0.7 Fe max, 0.20 Cu max, 0.20 Mn max, 0.50 to 1.1 Mg, 0.10 Cr max, 0.25 Zn max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Electrical conductor wire, cooking utensils, appliances, and architectural applications. Medium strength and good resistance to corrosion are two characteristics of 5005 similar to those of 3003. When anodized, film on 5005 is clearer and lighter than on 3003 and gives better color match with 6063 architectural extrusions.

Mechanical Properties

Tensile properties. See Tables 52 and 53. Tensile strength and elongation are slightly lower in transverse direction than in longitudinal direction.

Table 52 Typical mechanical properties of alloy 5005

Temper	Tensile strength[(a)]		Yield strength[(a)]		Elongation [(a)(b)], %	Hardness[(c)], HB	Shear strength	
	MPa	ksi	MPa	ksi			MPa	ksi
O	124	18	41	6	25	28	76	11

(a) In 50 mm (2 in.) or 5*d*, where *d* is diameter or reduced section of tensile test specimen. Where a range of values appears in this column, the specified minimum elongation varies with thickness of the mill product.

Shear yield strength. Approximately 55% of tensile yield strength

Compressive yield strength. Approximately the same as tensile yield strength

Hardness. See Table 52.

Poisson's ratio. 0.33

Elastic modulus. Tension. 68.2 GPa (9.90×10^6); shear, 25.9 GPa (3.75×10^6 psi); compression, 69.5 GPa (10.1×10^6 psi)

Mass Characteristics

Density. 2.70 g/cm^3 (0.097 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 652 °C (1205 °F)

Solidus temperature. 632 °C (1170 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.9	12.2
20 to 100	68 to 212	23.7	13.2
20 to 200	68 to 392	24.6	13.7
20 to 300	68 to 572	25.6	14.2

Volumetric: 68×10^{-6} m^3/m^3 · K (3.77×10^{-5} in.^{3}/in.^{3} · °F) at 20 °C (68 °F)

Specific heat. 900 J/kg · K (0.215 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 205 W/m · K (118 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O and H38 tempers: 52% IACS at 20 °C (68 °F)

Electrical resistivity. O and H38 tempers: 33.2 nΩ · m at 30 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.83 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F); holding at temperature not required

Hot-working temperature. 260 to 510 °C (500 to 950 °F)

5050
1.4Mg

Specifications

ASTM. Sheet and plate: B 209. Drawn, seamless tube: B 210. Drawn tube: B 483. Welded tube: B 313, B 547

(a) Lowest strengths for exposures up to 10,000 h at temperature; no load; test loading applied at 35 MPa/min (5 ksi/min) to yield strength and then at strain rate of 5%/min to fracture

Table 56 Tensile-property limits for alloy 5050

Temper	Tensile strength (min)		Yield strength (min)		Elongation (min), %[(a)]
	MPa	ksi	MPa	ksi	

O	125	18	41	6	16-20
H32	150	22	110	16	4-6
H34	170	25	138	20	3-5
H36	185	27	151	22	2-4
H38	200	29	. . .	. . .	2-4

(a) Where a range of values appears in this column, specified minimum elongation varies with thickness of the mill product.

Shear yield strength. Approximately 55% of the tensile yield strength

Compressive yield strength. Approximately the same as tensile yield strength

Hardness. See Table 54.

Poisson's ratio. 0.33

Elastic modulus. Tension, 68.9 GPa (10.0×10^6 psi); shear, 25.9 GPa (3.75×10^6 psi)

Mass Characteristics

Density. 2.69 g/cm^3 (0.097 lb/in.^{3} at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 652 °C (1205 °F)

Solidus temperature. 627 °C (1160 °F)

Coefficient of thermal expansion. Linear:

Temperature range		**Average coefficient**	
°C	**°F**	**µm/m · K**	**µin./in. · °F**
-50 to 20	-58 to 68	21.8	12.1
20 to 100	68 to 212	23.8	13.2

20 to 200	68 to 392	24.7	13.7
20 to 300	68 to 572	25.6	14.2

Specific heat. 900 J/kg · K (0.215 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 191 W/m · K (110 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O and H38 tempers: 50% IACS at 20 °C (68 °F)

Electrical resistivity. O and H38 tempers: 34 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.83 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F); holding at temperature not required

Hot-working temperature. 260 to 510 °C (500 to 950 °F)

5052
2.5Mg-0.25Cr

Specifications

AMS. See Table 57.

Table 57 Standard specifications for alloy 5052

Mill form	Specification No.	
	AMS	ASTM

Rivet wire and rod	. . .	B 316
Foil	4004	. . .

ASTM. See Table 57.

SAE. J454

UNS number. A95052

Government. Sheet and plate: QQ-A-250/8 Foil: MIL-A-81596. Rolled or cold finished wire, rod, and bar: QQ-A-225/7. Drawn, seamless tube: WW-T-700/4. Rivet wire and rod: QQ-A430, Rivets: MIL-R-24243

Foreign. Canada: CSA GR20. France: NF A-G2.5C. Italy: UNI P-AlMg2.5. Germany: DIN AlMg2.5 ISO: AlMg2.5

Chemical Composition

Composition limits. 0.25 Si max, 0.40 Fe max, 0.10 Cu max, 0.10 Mn max, 2.2 to 2.8 Mg, 0.15 to 0.35 Cr, 0.10 Zn max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Aircraft fuel and oil lines, fuel tanks, miscellaneous marine and transport applications, sheet metal work, appliances, street light standards, rivets, and wire. Applications where good workability, very good resistance to corrosion, high fatigue strength, weldability, and moderate static strength are desired

Mechanical Properties

Tensile properties. See Tables 58 and 59.

Table 58 Typical mechanical properties of alloy 5052

Temper	Tensile	Yield	Elongation, %[(a)]	Hardness,	Shear	Fatigue

	strength[a]		strength[a]				HB[b]	strength		strength[c]	
	MPa	ksi	MPa	ksi	1.6 mm ($\frac{1}{16}$ in.) thick	12.5 mm ($\frac{1}{2}$ in.) diam		MPa	ksi	MPa	ksi
O	195	28	90	13	25	27	47	125	18	110	16

	100	212	276	40	248	36	16
	149	300	234	34	193	28	24

Shear yield strength. Approximately 55% of tensile yield strength

Compressive yield strength. Approximately the same as tensile yield strength

Hardness. See Table 58.

Poisson's ratio. 0.33

Elastic modulus. Tension, 69.3 GPa (10.1×10^6 psi); shear, 25.9 GPa (3.75×10^6 psi); compression, 70.7 GPa (10.3×10^6 psi)

Mass Characteristics

Density. 2.68 g/cm^3 (0.097 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 649 °C (1200 °F)

Solidus temperature. 607 °C (1125 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	22.1	12.3
20 to 100	68 to 212	23.8	13.2
20 to 200	68 to 392	24.8	13.8
20 to 300	68 to 572	25.7	14.3

Volumetric: 69×10^{-6} m^3/m^3 · K (3.83×10^{-5} in.^{3}/in.^{3} · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O and H38 tempers: 35% IACS at 20 °C (68 °F)

Electrical resistivity. O and H38 tempers: 49.3 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.85 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F); holding at temperature not required

Hot-working temperature. 260 to 510 °C (500 to 950 °F)

5056, Alclad 5056
5.0Mg-0.1Mn-0.1Cr

Specifications

AMS. Rolled or cold finished wire, rod, and bar: 4182. Foil: 4005

ASTM. Rivet wire and rod: B 316. Rolled or cold finished wire, rod, and bar: B 211. Alclad, rolled or cold finished wire, rod, and bar: B 211

SAE. J454

UNS number. A95056

Government. Rivet wire and rod: QQ-A430. Foil: MIL-A-81596

Foreign. Austria: AlMg5. Canada: CSA-GM50R. United Kingdom: BS N6 2L.58. Germany: DIN AlMg5. ISO: AlMg5

Chemical Composition

Composition limits of 5056. 0.30 Si max, 0.40 Fe max, 0.10 Cu max, 0.05 to 0.20 Mn, 4.5 to 5.6 Mg, 0.20 Cr max, 0.10 Zn max, 0.05 max other (each), 0.15 max others (total), bal Al

Composition limits of Alclad 5056. 6253 cladding--Si, 45 to 65% of Mg content, 0.50 Fe max, 0.10 Cu max, 1.0 to 1.5 Mg, 0.15 to 0.35 Cr, 1.6 to 2.4 Zn, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Rivets for use with magnesium alloy and cable sheathing; zipper stock, nails; also Alclad wire is extensively used in fabrication of insect screens and other applications where wire products with good resistance to corrosion are required

Mechanical Properties

Tensile properties. See Tables 60, 61, and 62. Elongation, O temper: 20% in 50 mm (2 in.) or 4*d*, where *d* is diameter of reduced section of tension test specimen

Table 60 Typical mechanical properties of alloy 5056

Temper	Tensile strength[(a)]		Yield strength[(a)]		Elongation [(a)(b)], %	Hardness[(c)], HB	Shear strength		Fatigue strength[(d)]	
	MPa	ksi	MPa	ksi			MPa	ksi	MPa	ksi
O	290	42	152	22	35	65	179	26	138	20
H18	434	63	407	59	10	105	234	34	152	22

(a) Strengths and elongations are unchanged or improved at low temperatures.

(b) 12.5 mm ($\frac{1}{2}$ in.) diam; round specimen.

(c) 500 kg load; 10 mm diam ball.

(d) At 5×10^8 cycles, R.R. Moore type test

Table 61 Typical tensile properties of alloy 5056

Temper	Temperature		Tensile strength[(a)]		Yield strength[(a)]		Elongation, %
	°C	°F	MPa	ksi	MPa	ksi	
O	24	75	290	42	150	22	35
	149	300	214	31	117	17	55
	204	400	152	22	90	13	65
	260	500	110	16	69	10	80
	316	600	76	11	48	7	100
	371	700	41	6	28	4	130
H38	24	75	414	60	345	50	15
	149	300	262	38	214	31	30
	204	400	179	26	124	18	50
	260	500	110	16	69	10	80
	316	600	76	11	48	7	100

(a) Lowest strengths for exposures up to 10,000 h at temperature, no load; test loading applied at 35 MPa/min (5 ksi/min) to yield strength and then at strain rate of 5%/min to fracture

Table 62 Mechanical-property limits for alloy 5056--rolled or cold finished wire, rod, and bar

Temper	Tensile strength (min)	
	MPa	ksi
Bare 5056		
O	315 (max)	46 (max)
H111	305	44
H12	315	46
H32	305	44
H14	360	52
H34	345	50
H18	400	58
H38	380	55
H192	415	60
H392	400	58
Alclad 5056		
H192	360	52
H392	345	50
H393	370[(a)]	54

(a) Yield strength (min), 325 MPa (47 ksi)

Shear yield strength. Approximately 55% of tensile yield strength

Compressive yield strength. Approximately the same as the tensile yield strength

Hardness. See Table 60.

Poisson's ratio. 0.33

Elastic modulus. Tension, 71.7 GPa (10.4×10^6 psi): shear, 25.9 GPa (3.75×10^6 psi); compression, 73.1 GPa (10.6×10^6 psi)

Mass Characteristics

Density. 2.64 g/cm^3 (0.095 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 638 °C (1180 °F)

Solidus temperature. 568 °C (1055 °F)

Coefficient of thermal expansion. Linear, O temper:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	22.5	12.5
20 to 100	68 to 212	24.1	13.7
20 to 200	68 to 392	25.2	14.0
20 to 300	68 to 572	26.1	14.5

Volumetric: 70×10^{-6} m^3/m^3 · K (3.89×10^{-5} in.^{3}/in.^{3} · °F) at 20 °C (68 °F)

Specific heat. 904 J/kg · K (0.216 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 20 °C (68 °F): O temper, 120 W/m · K (69.3 Btu/ft · h · °F); H38 temper, 112 W/m · K (64.7 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): O temper, 29% IACS; H38 temper, 27% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 59 nΩ · m, H38 temper, 64 nΩ · m. Temperature coefficient, O and H38 temperatures: 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.87 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 415 °C (775 °F); holding at temperature not required

Hot-working temperature. 315 to 480 °C (600 to 900 °F)

5083
4.4Mg-0.7Mn-0.15Cr

Specifications

AMS. Sheet and plate: 4056, 4057, 4058, 4059

ASTM. Sheet and plate: B 209. Extruded wire, rod, bar, shapes, and tube: B 221. Extruded seamless tube: B 241. Drawn seamless tube: B 210. Welded tube: B 547. Forgings: B 247. Gas and oil transmission pipe: B 345

SAE. J454

UNS number. A95083

Government. Sheet and plate: QQ-A-250/6. Extruded wire, rod, bar, shapes, and tube: QQ-A-200/4. Forgings: QQ-A-367. Armor plate: MIL-A-46027. Extruded armor: MIL-A-46083. Forged armor: MIL-A-45225

Foreign. Canada: CSA GM41. United Kingdom: BS N8. Germany: DIN AlMg4.5Mn; Werstoff-Nr. 3.3547. ISO: AlMg4.5Mn

Chemical Composition

Composition limits. O.40 Si max, 0.40 Fe max, 0.10 Cu max, 0.40 to 1.0 Mn, 4.0 to 4.9 Mg, 0.05 to 0.25 Cr, 0.25 Zn max, 0.15 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Marine, auto, and aircraft applications, unfired welded pressure vessels, cryogenics, TV towers, drilling rigs, transportation equipment, missile components, armor plate. Applications requiring a weldable moderate-strength alloy having good corrosion resistance

Mechanical Properties

Tensile properties. See Tables 63, 64, and 65.

Table 63 Typical tensile properties of alloy 5083

Temper	Tensile strength[a]		Yield strength		Elongation[a, b], %
	MPa	ksi	MPa	ksi

20 to 100	68 to 212	24.2	13.4
20 to 200	68 to 392	25.0	13.9
20 to 300	68 to 572	26.0	14.4

Volumetric: 70×10^{-6} m^3/m^3 · K (3.89×10^{-5} in.^{3}/in.^{3} · °F) at 20 °C (68 °F)

Specific heat. 900 J/kg · K (0.215 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 120 W/m · K (69.3 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, average of all tempers: 29% IACS at 20 °C (68 °F)

Electrical resistivity. 59.5 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.91 versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 415 °C (775 °F); holding at temperature not required

Hot-working temperature. 315 to 480 °C (600 to 900 °F)

5086, Alclad 5086
4.0Mg-0.4Mn-0.15Cr

Specifications

ASTM. Sheet and plate; B 209. Extruded wire, rod, bar, shapes, and tube: B 221. Extruded seamless tube: B 241. Drawn, seamless tube: B 210. Welded tube: B 313, B 547. Gas and oil transmission pipe: B 345. Alclad 5086, sheet and plate: B 209

SAE. J454

UNS number. A95086

Government. Sheet and plate: QQ-A-250/7, QQ-A-250/19. Extruded wire, rod, bar, shapes, and tube: QQ-A-200/5. Drawn, seamless tube: WW-T-700/5

Foreign. France: NF A-G4MC. Germany: DIN AlMg4. ISO: AlMg4

Chemical Composition

Composition limits. 0.40 Si max, 0.50 Fe max, 0.20 to 0.7 Mn, 3.5 to 4.5 Mg, 0.25 Zn max, 0.15 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Marine, automotive, and aircraft parts, cryogenics, TV towers, drilling rigs, transportation equipment, missile components, armor plate. Applications requiring weldable moderate-strength alloy having comparatively good corrosion resistance

Mechanical Properties

Tensile properties. See Tables 66 and 67. Tensile strength and elongation are approximately equal in the longitudinal and transverse directions.

Table 66 Tensile properties alloy 5086

Temper	Tensile strength				Yield strength		Elongation[(a)], %

(a) In 50 mm (2 in.) or 4*d*, where *d* is diameter of reduced section of tensile test specimen. Where a range of values appears in this column, specified minimum elongation varies with thickness of the mill product.

Table 67 Typical tensile properties of alloy 5086-O at various temperatures

Temperature	Tensile strength[(a)]	Yield strength (0.2% offset)[(a)]	Elongation, %

°C	°F	MPa	ksi	MPa	ksi	
-196	-320	379	55	131	19	46
-80	-112	269	39	117	17	35
-28	-18	262	38	117	17	32
24	75	262	38	117	17	30
100	212	262	38	117	17	36
149	300	200	29	110	16	50
204	400	152	22	103	15	60
260	500	117	17	76	11	80
316	600	76	11	52	7.5	110
371	700	41	6	29	4.2	130

(a) Lowest strengths for exposures up to 10,000 h at temperature, no load; test loading applied at 35 MPa/min (5 ksi/min) to yield strength and then at strain rate of 5%/min to fracture

Shear properties. Shear strength: O temper, 160 MPa (23 ksi); H34 temper, 185 MPa (27 ksi). Shear yield strength: approximately 55% of tensile yield strength

Compressive yield strength. Approximately the same as tensile yield strength

Poisson's ratio. 0.33

Elastic modulus. Tension, 71.0 GPa (10.3×10^6 psi); shear, 26.4 GPa (3.83×10^6 psi); compression, 72.4 GPa (10.5×10^6 psi)

Mass Characteristics

Density. 2.66 g/cm^3 (0.096 lb/in.^{3} at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 640 °C (1184 °F)

Solidus temperature. 585 °C (1085 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	22.0	12.2
20 to 100	68 to 212	23.8	13.2
20 to 200	68 to 392	24.7	13.7
20 to 300	68 to 572	25.8	14.3

Volumetric: 69×10^{-6} $m^3/m^3 \cdot K$ (3.83×10^{-5} $in.^3/in.^3 \cdot °F$)

Specific heat. 900 J/kg · K (0.215 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 127 W/m · K (73.4 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, average of all tempers: 31% IACS at 20 °C (68 °F)

Electrical resistivity. Average of all tempers: 56 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.88 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F); holding at temperature not required

Hot-working temperature. 315 to 480 °C (600 to 900 °F)

5154
3.5Mg-0.25Cr

Specifications

AMS. Sheet and plate: 4018, 4019

ASTM. Sheet and plate: B 209. Rolled or cold finished wire, rob, and bar: B 211. Extruded wire, rod, bar, shapes, and tube: B 221. Drawn, seamless tube: B 210. Welded tube: B 313, B 547

SAE. J454

UNS number. A95154

Foreign. Canada: CSA GR40. France: NF A-G3C. United Kingdom: BS N5. ISO: AlMg3.5

Chemical Composition

Composition limits. 0.25 Si max, 0.40 Fe max, 0.10 Cu max, 0.10 Mn max, 3.1 to 3.9 Mg, 0.15 to 0.35 Cr, 0.20 Zn max, 0.20 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Welded structures, storage tanks, pressure vessels, marine structures, transportation trailer tanks

Mechanical Properties

Tensile properties. See Tables 68 and 69. Tensile strength and elongation are approximately equal in the longitudinal and transverse directions.

Table 68 Mechanical properties of alloy 5154

371	700	41	6	29	4.2	130

(a) In 50 mm (2 in.) or 4*d*, where *d* is diameter of reduced section of tensile test specimen

Shear properties. Shear strength: see Table 68. Shear yield strength: approximately 55% of tensile yield strength

Compressive yield strength. Approximately the same as tensile yield strength

Hardness. See Table 68.

Poisson's ratio. 0.33

Elastic modulus. Tension, 69.3 GPa (10.1×10^6 psi); shear, 25.9 GPa (3.75×10^6 psi); compression, 70.7 Gpa (10.3×10^6 psi)

Fatigue Strength. See Table 68.

Mass Characteristics

Density. 2.66 g/cm^3 (0.096 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 643 °C (1190 °F)

Solidus temperature. 593 °C (1100 °F)

Coefficient of thermal expansion. Linear:

Temperature range		**Average coefficient**	
°C	**°F**	**µm/m · K**	**µin./in. · °F**
-50 to 20	-58 to 68	22.1	12.3
20 to 100	68 to 212	23.9	13.3
20 to 200	68 to 392	24.9	13.8
20 to 300	68 to 572	25.9	14.4

Volumetric: 69×10^{-6} m^3/m^3 · (3.83×10^{-5} in.^{3}/in.^{3} · °F) at 20 °C (68 °F)

Specific heat. 900 J/kg · K (0.215 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 127 W/m · K (73.3 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, average of all tempers: 32% IACS at 20 °C (68 °F)

Electrical resistivity. Average of all tempers: 53.9 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.86 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F); holding at temperature not required

Hot-working temperature. 260 to 510 °C (500 to 950 °F)

5182
4.5Mg-0.35Mn

Specifications

UNS number. A95182

Chemical Composition

Composition limits. 0.20 Si max, 0.35 Fe max, 0.15 Cu max, 0.20 to 0.50 Mn, 4.0 to 5.0 Mg, 0.10 Cr max, 0.25 Zn max, 0.10 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Sheet used for container ends, automotive body panels and reinforcement members, brackets, and parts

Mechanical Properties

Tensile properties. See Table 70.

Table 70 Typical tensile properties of alloy 5182

Temper	Tensile strength[a]		Yield strength[a]		Elongation[a],[b], %
	MPa	ksi	MPa	ksi	
O	276	40	138	19	25
H32	317	46	234	34	12
H34	338	49	283	41	10

H19[(c)]	421	61	393	57	4

(a) Strengths and elongations are unchanged or increased at low temperatures.

(b) 1.6 mm ($\frac{1}{16}$ in.) thick specimen.

(c) Properties of this temper are for container end stock 0.25 to 0.38 mm (0.010 to 0.015 in.) thick.

Shear properties. Shear strength: O temper, 152 MPa (22 ksi). Shear yield strength: approximately 55% of tensile yield strength

Compressive yield strength. Approximately the same as tensile yield strength

Hardness. O temper, 58 HB with 200 kg load, 10 mm diam ball

Poisson's ratio. 0.33

Elastic modulus. Tension, 69.6 GPa (10.1×10^6 psi); compression, 70.9 GPa (10.3×10^6 psi)

Fatigue strength. O temper, 138 MPa (20 ksi) at 5×10^8 cycles in an R.R. Moore type rotating-beam test

Mass Characteristics

Density. 2.65 g/cm^3 (0.096 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 638 °C (1180 °F)

Solidus temperature. 577 °C (1070 °F)

Coefficient of thermal expansion. Linear:

Temperature range		**Average coefficient**	
°C	**°F**	**µm/m · K**	**µin./in. · °F**
-50 to 20	-58 to 68	22.2	12.3
20 to 100	68 to 212	24.1	13.4

20 to 200	68 to 392	25.0	13.9
20 to 300	68 to 572	26.0	14.4

Volumetric: 70×10^{-6} $m^3/m^3 \cdot K$ (3.89×10^{-5} $in.^3/in.^3 \cdot °F$) at 20 °C (68 °F)

Specific heat. 904 J/kg · K (0.216 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 123 W/m · K (71.1 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 31% IACS at 20 °C (68 °F)

Electrical resistivity. 55.6 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F)

Hot-working temperature. 260 to 510 °C (500 to 950 °F)

5252
2.5 Mg

Specifications

ASTM. Sheet: B 209

SAE. J454

UNS number. A95252

Chemical Composition

Composition limits. 0.08 Si max, 0.10 Fe max, 0.10 Cu max, 0.10 Mn max, 2.2 to 2.8 Mg, 0.05 Zn max, 0.05 V max, 0.03 max other (each), 0.10 max others (total), bal Al

Applications

Typical uses. Automotive and appliance trim where greater strength is required than in other trim alloys. Can be bright dipped or anodized to give a bright, clear finish

Mechanical Properties

Tensile properties. See Table 71.

Table 71 Tensile properties of alloy 5252

Temper	Tensile strength	Yield strength	Elongation, %

	MPa	ksi	MPa	ksi	MPa	ksi	%
Typical properties							
H25	235	34	. . .	. . .	170	25	11[(a)]

(a) 500 kg load; 10 mm ball.

(b) At 5×10^8 cycles; R.R. Moore type test.

(c) Strengths and elongations are unchanged or increased at low temperatures.

(d) In 50 mm (2 in.) or 4*d*, where *d* is diameter of reduced section of test specimen. Where a range of values appears in this column, specified minimum elongation varies with thickness of the mill product.

Table 73 Typical tensile properties of alloy 5254-O at various temperatures

Temperature		**Tensile strength**[(a)]		**Yield strength**[(a)]		**Elongation, %**
°C	**°F**	**MPa**	**ksi**	**MPa**	**ksi**	
-196	-320	360	52	130	19	46
-80	-112	250	36	115	17	35
-28	-18	240	35	115	17	32
24	75	240	35	115	17	30
100	212	240	35	115	17	36
149	300	200	29	110	16	50
204	400	150	22	105	15	60
260	500	115	17	75	11	80
316	600	75	11	50	7.5	110

(a) Lowest strengths for exposure up to 10,000 h at temperature, no load; test loading applied at 35 MPa/min (5 ksi/min) to yield strength and

then at strain rate of 5%/min to fracture

Shear yield strength. Approximately 55% of tensile yield strength

Compressive yield strength. Approximately the same at tensile yield strength

Hardness. See Table 72.

Elastic modulus. 70.3 GPa (10.2×10^6 psi); compression, 70.9 GPa (10.3×10^6 psi)

Fatigue strength. See Table 72.

Mass Characteristics

Density. 2.66 g/cm^3 (0.096 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 643 °C (1190 °F)

Solidus temperature. 593 °C (1100 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	22.1	12.3
20 to 100	68 to 212	24.0	13.3
20 to 200	68 to 392	24.9	13.8
20 to 300	68 to 572	25.9	14.4

Volumetric: 69×10^{-6} m^3/m^3 · K (3.83×10^{-5} in.^{3}/in.^{3} · °F) at 20 °C (68 °F)

Specific heat. 900 J/kg · K (0.215 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 127 W/m · K (73.4 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 32% IACS at 20 °C (68 °F)

Electrical resistivity. 54 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.86 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F); holding at temperature not required

Hot-working temperature. 260 to 510 °C (500 to 950 °F)

5356
5.0Mg-0.12Mn-0.12Cr

Specifications

UNS number. A95356

Government. QQ-R-566, MIL-E-16053

Foreign. Canada. CSA GM50P. France: NF A-G5

Chemical Composition

Composition limits. 0.25 Si max, 0.40 Fe max, 0.10 Cu max, 0.05 to 0.20 Mn, 4.5 to 5.5 Mg, 0.05 to 0.20 Cr, 0.10 Zn max, 0.06 to 0.20 Ti, 0.05 max other (each), 0.15 max others (total), 0.0008 Be max, bal Al

Applications

Typical uses. Welding electrodes and filler wire for base metals with high magnesium content (>3% Mg)

Mass Characteristics

Density. 2.64 g/cm^3 (0.0954 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 638 °C (1180 °F)

Solidus temperature. 574 °C (1065 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	22.3	12.3

20 to 100	68 to 212	24.2	13.4
20 to 200	68 to 392	25.1	13.9
20 to 300	68 to 572	26.1	14.5

Volumetric: 70×10^{-6} $m^3/m^3 \cdot K$ (3.89×10^{-5} $in.^3/in.^3 \cdot °F$) at 20 °C (68 °F)

Specific heat. 904 K/kg · K (0.216 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 116 W/m · K (67 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O temper: 29% IACS at 20 °C (68 °F)

Electrical resistivity. O temper; 59.4 nΩ · m at 20 °C (68 °F). Temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.87 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F); holding at temperature not required

Hot-working temperature. 260 to 510 °C (500 to 950 °F)

(a) 12.5 mm ($\frac{1}{2}$ in.) diam specimen.

(b) Material in this temper not recommended for applications requiring exposure to seawater.

(c) H116 designation also applies to the condition previously designated H117.

(d) Elongations in 50 mm (2 in.) apply to thicknesses through 12.5 mm ($\frac{1}{2}$ in.); elongation in $5d(5.65\sqrt{A})$, where d is diameter and A is cross-sectional area of tensile test specimen, apply to material over 12.5 mm ($\frac{1}{2}$ in.) thick.

(e) Material in this temper required to pass an exfoliation corrosion test administered by the purchaser

Shear strength. H321, H116 tempers: 207 MPa (30 ksi)

Hardness. H321, H116 tempers: 90 HB

Elastic modulus. Tension, 70.3 GPa (10.2×10^6 psi); compression, 71.7, GPa (10.4×10^6 psi)

Mass Characteristics

Density. 2.66 g/cm^3 (0.096 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 638 °C (1180 °F)

Solidus temperature. 570 °C (1055 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	22.1	12.3

20 to 100	68 to 212	23.9	13.3
20 to 200	68 to 392	24.8	13.8
20 to 300	68 to 572	25.9	14.4

Volumetric: 69×10^{-6} $m^3/m^3 \cdot K$ (3.83×10^{-5} $in.^3/in.^3 \cdot °F$) at 20 °C (68 °F)

Specific heat. 900 J/kg · K (0.215 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 116 W/m · K (67 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, average of all tempers: 29% IACS at 20 °C (68 °F)

Electrical resistivity. Average of all tempers: 59.5 nΩ · at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.87 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 343 °C (650 °F); holding at temperature not required

Hot-working temperature. 260 to 510 °C (500 to 950 °F)

5457
1.0Mg-0.30Mn

Specifications

ASTM. Sheet: B 209

UNS number. A95457

Chemical Composition

Composition limits. 0.08 Si max, 0.10 Fe max, 0.20 Cu max, 0.15 to 0.45 Mn, 0.08 to 1.2 Mg, 0.05 Zn max, 0.05 V max, 0.03 max other (each), 0.10 max others (total), bal Al

Applications

Typical uses. Brightened and anodized automotive and appliance trim

Precautions in use. Fine grain size required for most applications of this alloy

Mechanical Properties

Tensile properties. Tensile strength: min, 110 MPa (16 ksi); max, 150 MPa (22 ksi). Elongation, 20% in 50 mm (2 in.). See also Table 77.

Table 77 Typical mechanical properties of alloy 5457

Temper	Tensile strength[a]		Yield strength[a]		Elongation[a],[b], %	Hardness[c], HB	Shear strength	
	MPa	ksi	MPa	ksi			MPa	ksi
O	130	19	50	7	22	32	85	12
H25	180	26	160	23	12	48	110	16

(a) Strengths and elongations are unchanged or improved at lower temperatures.

(b) 1.6 mm ($\frac{1}{16}$ in.) thick specimen.

(c) 500 kg load; 10 mm ball

Shear strength: See Table 77.

Compressive yield strength. Approximately the same as tensile yield strength

Hardness. See Table 77

Poisson's ratio. 0.33 at 20 °C (68 °F)

Elastic modulus. Tension, 68.2 GPa (10.0×10^6 psi); shear, 25.9 GPa (3.75×10^6 psi); compression, 69.6 GPa (10.1×10^6 psi)

Mass Characteristics

Density. 2.69 g/cm^3 (0.0972 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 654 °C (1210 °F)

Solidus temperature. 629 °C (1165 °F)

Coefficient of thermal expansion. Linear:

Temperature	Average coefficient

°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.9	12.2
20 to 100	68 to 212	23.7	13.2
20 to 200	68 to 392	24.6	13.7
20 to 300	68 to 572	25.6	14.2

Volumetric: 68×10^{-6} $m^3/m^3 \cdot K$ (3.77×10^{-5} $in.^3/in.^3 \cdot °F$) at 20 °C (68 °F)

Specific heat. 900 J/kg · (0.215 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 177 W/m · K (102 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, average of all tempers: 46% IACS at 20 °C (68 °F)

Electrical resistivity. 37.5 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.84 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Formability. Readily formed in both annealed and H25 tempers

Annealing temperature. 343 °C (650 °F); holding temperature not required

Hot-working temperature. 260 to 510 °C (500 to 950 °F)

UNS number. A95652

Chemical Composition

Composition limits. 0.40 Si max + Fe, 0.04 Cu max, 0.01 Mn max, 2.2 to 2.8 Mg, 0.15 to 0.35 Cr, 0.10 Zn max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Storage vessels for hydrogen peroxide and other chemicals

Mechanical Properties

Tensile properties. See Table 78.

Table 78 Mechanical properties of alloy 5652

Temper	Tensile strength				Yield strength		Elongation[(a)], %	Hardness[(b)], HB	Shear strength		Fatigue strength[(c)]

(a) In 50 mm (2 in.) or 4*d*, where *d* is diameter of reduced section of tension-test specimen. Where a range of values appears in this column, the specified minimum elongation varies with thickness of the mill product.

(b) 500 kg load; 10 mm ball.

(c) At 5×10^8 cycles; R.R. Moore type test

Shear strength. See Table 78.

Compressive yield strength. Approximately the same as tensile yield strength

Hardness. See Table 78.

Poisson's ratio. 0.33

Elastic modulus. Tension, 68.2 GPa (9.89×10^6 psi); shear, 25.9 GPa (3.75×10^6 psi); compression, 69.6 GPa (10.1×10^6 psi)

Fatigue strength. See Table 78.

Mass Characteristics

Density. 2.68 g/cm^3 (0.097 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 649 °C (1200 °F)

Solidus temperature. 607 °C (1125 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	22.0	12.2
20 to 100	68 to 212	23.8	13.2
20 to 200	68 to 392	24.7	13.7
20 to 300	68 to 572	25.8	14.3

Volumetric: 69 × 10^{-6} m^3/m^3 · K (3.83 × 10^{-5} $in.^3/in.^3$ · °F) at 20 °C (68 °F)

Specific heat. 900 J/kg · K (0.215 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 137 W/m · K (79.1 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, average of all tempers: 35% IACS at 20 °C (68 °F)

Electrical resistivity. 49 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.85 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F); holding at temperature not required

Hot-working temperature. 260 to 510 °C (500 to 950 °F)

5657
0.8Mg

Specifications

ASTM. B 209

UNS number. A 95657

Foreign. Italy: P-AlMg0.9

Chemical Composition

Composition limits. 0.08 Si max, 0.10 Fe max, 0.10 Cu max, 0.03 Mn max, 0.6 to 1.0 Mg, 0.05 Zn max, 0.03 Ga max, 0.05 V max, 0.02 max other (each), 0.05 max others (total), bal Al

Applications

Typical uses. Brightened and anodized automotive and appliance trim

Precautions in use. Fine grain size essential for almost all applications of this alloy

Mechanical Properties

Tensile properties. See Table 79.

Table 79 Tensile properties of alloy 5657

Temper	Tensile strength				Yield strength		Elongation[(a)], %
	MPa	ksi	MPa	ksi	MPa	ksi	

Typical Properties[b]							
H25	160	23	. . .	. . .	140	20	12
H28, H38	195	28	. . .	. . .	165	24	7
Property limits	**Minimum**		**Maximum**				**Minimum**
H241[c]	125	18	180	26	. . .	. . .	13
H25	140	20	195	28	. . .	. . .	8
H26	150	22	205	30	. . .	. . .	7
H28	170	25	. . .	. . .	. . .	. . .	5

(a) In 50 mm (2 in.) or 4*d*, where *d* is diameter of reduced section of tension-test specimen.

(b) Strengths and elongations are unchanged or increased at low temperatures.

(c) Material in this temper subject to some recrystallization and attendant loss of brightness

Shear strength. H25 temper: 95 MPa (14 ksi); H28, H38 tempers; 105 MPa (15 ksi)

Compressive yield strength. Approximately the same as tensile yield strength.

Hardness. H25 temper: 40 HB. H28 and H38 tempers: 50 HB. All hardness values obtained with 500 kg load, 10 mm diam ball, and 30 s duration of loading

Poisson's ratio. 0.33

Elastic modulus. Tension, 68.2 GPa (9.89×10^6 psi); shear, 25.9 GPa (3.75×10^6 psi); compression, 69.6 GPa (10.1×10^6 psi)

Mass Characteristics

Density. 2.69 g/cm^3 (0.097 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 657 °C (1215 °F)

Solidus temperature. 638 °C (1180 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.9	12.2
20 to 100	68 to 212	23.7	13.2
20 to 200	68 to 392	24.6	13.7
20 to 300	68 to 572	25.6	14.2

Volumetric: 68×10^{-6} $m^3/m^3 \cdot K$ (3.77×10^{-5} $in.^3/in.^3 \cdot °F$) at 20 °C (68 °F)

Specific heat. 900 J/kg · K (0.215 Btu/lb · °F)

Electrical Properties

Electrical conductivity. Volumetric, 54% IACS at 20 °C (68 °F)

Electrical resistivity. 32 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F); holding at temperature not required

Hot-working temperature. 260 to 510 °C (500 to 950 °F)

6005
0.8Si-0.5Mg

Specifications

ASTM. Extruded wire, rod, bar, shapes, and tube: B 221

SAE. J454

UNS. A96005

Chemical Composition

Composition limits. 0.6 to 0.9 Si, 0.35 Fe max, 0.10 Cu max, 0.10 Mn max, 0.40 to 0.6 Mg, 0.10 Cr max, 0.10 Zn max, 0.10 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Extruded shapes and tubing for commercial applications requiring strength greater than that of 6063; ladders and TV antennas are among the more common products

Precautions in use. Not recommended for applications requiring resistance to impact loading

Mechanical Properties

Tensile properties. Tensile strength (minimum): T1 temper, 172 MPa (25 ksi); T5 temper, 262 MPa (38 ksi). Yield strength (minimum): T1 temper, 103 MPa (15 ksi); T5 temper: 241 MPa (35 ksi). Elongation (minimum): T1 temper, 16%; T5 temper, 8 to 10%, specific value varies with thickness of mill product

Shear strength. T5 temper; 205 MPa (30 ksi)

Hardness. T5 temper: 95 HB

Elastic modulus. Tension, 69 GPa (10×10^6 psi)

Fatigue strength. (minimum). 97 MPa (14 ksi) at 5×10^8 cycles; R.R. Moore type test

Mass Characteristics

Density. 2.7 g/cm^3 (0.098 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 654 °C (1210 °F)

Solidus temperature. 607 °C (1125 °F)

Coefficient of thermal expansion. Linear, 23.4 μm/m · K (13.0 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Thermal conductivity. T5 temper: 167 W/m · K (97 Btu/ft · h · °F) at 25 °C (77 °F)

Electrical Properties

Electrical conductivity. Volumetric, T5 temper: 49% IACS at 20 °C (68 °F)

Electrical resistivity. T5 temper: 35 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Annealing temperature. 415 °C (778 °F); hold at temperature for 2 to 3 h

Solution temperature. 547 °C (1015 °F)

Aging temperature. 175 °C (346 °F), hold at temperature for 8 h

---

6009
0.80Si-0.60Mg-0.50Mn-0.35Cu

Specifications

UNS. A96009

Chemical Composition

Composition limits. 0.6 to 1.0 Si, 0.50 Fe max, 0.15 to 0.6 Cu, 0.20 to 0.8 Mn, 0.40 to 0.8 Mg, 0.10 Cr max, 0.25 Zn max, 0.10 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Automobile body sheet

Mechanical Properties

Tensile properties. See Table 80.

Table 80 Typical tensile properties of alloy 6009 automobile body sheet

Orientation	Tensile strength		Yield strength		Elongation, %
	MPa	ksi	MPa	ksi	
T4 temper					
Longitudinal	234	34	131	19	24
Transverse and 45°	228	33	124	18	25
T6 temper					
Longitudinal	345	50	324	47	12

Yield stretch. Following simulated forming and a paint bake cycle consisting of 1 h at 175 °C (350 °F). T4 temper: no stretch, 228 MPa (33 ksi); 5% stretch, 262 MPa (38 ksi); 10% stretch, 290 MPa (42 ksi)

Shear strength. Auto body sheet, T4 temper: 152 MPa (22 ksi)

Hardness. T4 temper, auto body sheet: 70 HR15T

Poisson's ratio. 0.33

Elastic modulus. Tension, 69 GPa (10×10^6 psi); shear, 25.4 GPa (3.75×10^6 psi)

Fatigue strength. T4 temper: 117 MPa (17 ksi) at 10×10^6 cycles; sheet flexural specimens

Mass Characteristics

Density. 2.71 g/cm^3 (0.098 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 650 °C (1202 °F)

Solidus temperature. 560 °C (1040 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.6	12.0
20 to 100	68 to 212	23.4	13.0
20 to 200	68 to 392	24.3	13.5
20 to 300	68 to 572	25.2	14.0

Volumetric: 67×10^{-6} $m^3/m^3 \cdot K$ (3.72×10^{-5} $in.^3/in.^3 \cdot °F$) at 20 °C (68 °F)

Specific heat. 897 J/kg · K (0.214 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 20 °C (68 °F): O temper, 205 W/m · K (118 Btu/ft · h · °F); T4 temper, 172 W/m · K (99 Btu/ft · h · °F); T6 temper, 180 W/m · K (104 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): O temper, 54% IACS; T4 temper, 44% IACS; T6 temper: 47% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 31.9 nΩ · m; T4 temper, 39.2 nΩ · m; T6 temper, 36.7 nΩ · m. Temperature coefficient, 0.1 Ω· m per K at 20 °C (68 °F)

Fabrication Characteristics

Formability. Auto body sheet, T4 temper. $\frac{1}{2}t$ radius required for 90° bending or for flanging material 0.80 to 1.30 mm (0.032 to 0.050 in.) thick. Standard hems, which are made by bending 180° over 1*t* interface thickness, also can be made in auto body sheet 0.80 to 1.30 mm thick. Olsen cup height, typically 0.38 in. when tested using a 25 mm (1 in.) diam top die, 15 MPa (2.2 ksi) hold-down pressure and polyethylene film as a lubricant. Strain-hardening exponent (*n*) typically 0.23; plastic strain ratio (*r*) typically 0.70

Annealing temperature. 415 °C (775 °F)

Solution temperature. 555 °C (1030 °F)

Aging temperature. 175 °C (350 °F)

6010
1.0Si-0.8Mg-0.5Mn-0.35Cu

Specifications

UNS. A96010

Chemical Composition

Composition limits. 0.8 to 1.2 Si, 0.50 Fe max, 0.15 to 0.6 Cu, 0.20 to 0.8 Mn, 0.60 to 1.0 Mg, 0.10 Cr max, 0.25 Zn max, 0.10 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Automobile body sheet

Mechanical Properties

Tensile properties. Typical. T4 temper: tensile strength, 290 MPa (42 ksi); yield strength, 172 MPa (25 ksi); elongation, 24% in 50 mm (2 in.). See also Table 81.

Table 81 Typical tensile properties of alloy 6010 automobile body sheet

Orientation	Tensile strength		Yield strength		Elongation, %
	MPa	ksi	MPa	ksi	
T4 temper					
Longitudinal	296	43	186	27	23
Transverse and 45°	290	42	172	25	24
T6 temper					
Longitudinal	386	56	372	54	11

Yield stretch. Following simulated forming and a paint bake cycle consisting of 1 h at 175 °C (350 °F). T4 temper: no stretch, 255 MPa (37 ksi); 5% stretch, 295 MPa (43 ksi); 10% stretch, 324 MPa (47 ksi)

Hardness. T4 temper: 76 HR15T

Poisson's ratio. 0.33

Elastic modulus. Tension, 69 GPa (10×10^6 psi); shear, 25.4 GPa (3.75×10^6 psi)

Fatigue strength. T4 temper: 117 MPa (17 ksi) at 10×10^6 cycles; sheet flexural specimens

Mass Characteristics

Density. 2.70 g/cm^3 (0.098 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 650 °C (1200 °F)

Solidus temperature. 585 °C (1085 °F)

Incipient melting temperature. 577 °C (1070 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.5	11.9
20 to 100	68 to 212	23.2	12.9
20 to 200	68 to 392	24.1	13.4
20 to 300	68 to 572	25.1	13.9

Volumetric: 67 × 10^{-6} m^3/m^3 · K (3.72 × 10^{-5} in.^{3}/in.^{3} · °F) at 20 °C (68 °F)

Specific heat. 897 J/kg · K (0.214 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 20 °C (68 °F): O temper, 202 W/m · K (117 Btu/ft · h · °F); T4 temper, 151 W/m · K (87.3 Btu/ft · h · °F); T6 temper, 180 W/m · K (104 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): O temper, 53% IACS; T4 temper, 39% IACS; T6 temper, 44% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 32.5 nΩ · m; T4 temper, 44.2 nΩ · m; T6 temper, 39.2 nΩ · m. Temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Fabrication Characteristics

Formability. Auto body sheet, T4 temper, 1*t* radius required for 90° bending, 1*t* for flanging material 0.80 to 1.30 mm (0.032 to 0.050 in.) thick. Only roped hems, which are made by bending 180° over 2*t* interface thickness, can be made in auto body sheet 0.80 to 1.30 mm (0.0315 to 0.05 in.) thick. Olsen cup height, typically 9.1 mm (0.36 in.) when tested using a 25 mm (1 in.) diam top die, 15 MPa (2200 psi) hold-down pressure and polyethylene film as a lubricant. Strain-hardening exponent (*n*) typically 0.22; plastic strain ratio (*r*) typically 0.70

Annealing temperature. 415 °C (775 °F)

Solution temperature. 565 °C (1050 °F)

Aging temperature. 175 °C (350 °F)

316	600	32	4.6	19	2.7	85
371	700	24	3	12	1.8	95

(a) Lowest strength for exposures up to 10,000 h at temperature, no load; test loading applied at 35 MPa/min (5 ksi/min) to yield strength and then at strain rate of 5%/min to fracture

Shear strength. See Table 83.

Hardness. O temper: 30 HB; T4, T451 tempers: 65 HB; T6, T651 tempers: 95 HB. Data obtained using 500 kg load, 10 mm diam ball, and 30 s duration of loading

Elastic modulus. Tension, 68.9 GPa (10.0×10^6 psi); compression, 69.7 GPa (10.1×10^6 psi)

Fatigue strength. O temper: 62 MPa (9 ksi). T4, T451, T6, and T651 tempers: 97 MPa (14 ksi). Data correspond to 5×10^8 cycles of completely reversed stress in R.R. Moore type tests.

Mass Characteristics

Density. 2.70 g/cm^3 (0.098 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 652 °C (1206 °F)

Solidus temperature. 582 °C (1080 °F)

Coefficient of thermal expansion. Linear, 23.6 μm/m · K (13.1 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Specific heat. 896 J/kg · K (0.214 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 25 °C (77 °F): O temper, 180 W/m · K (104 Btu/ft · h · °F); T4 temper, 154 W/m · K (89.0 Btu/ft · h · °F); T6 temper, 167 W/m · K (96.5 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric at 20 °C (68 °F): O temper, 47% IACS; T4 temper, 40% IACS; T6 temper: 43% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 37 nΩ · m; T4 temper, 43 nΩ · m; T6 temper, 40 nΩ · m

Fabrication Characteristics

Solution temperature. 530 °C (985 °F)

Aging temperature. Rolled or drawn products: 160 °C (320 °F); hold at temperature for 18 h. Extrusions or forgings: 175 °C (350 °F); hold at temperature for 8 h

6063
0.7Mg-0.4Si

Specifications

AMS. Extruded wire, rod, bar, shapes, and tube: 4156

ASME. Extruded wire, rod, bar, shapes, and tube: SB221. Pipe: SB241

ASTM. See Table 85.

Table 85 ASTM specifications for alloy 6063

Mill form and condition	ASTM No.
Wire, rod, bar, shapes, and tube (extruded)	B 221
Tube (extruded, seamless); pipe	B 241
Tube (extruded, coiled)	B 491
Tube (drawn)	B 483
Tube (drawn, seamless)	B 210
Pipe (gas and oil transmission)	B 345
Structural pipe and tube (extruded)	B 429

SAE. J454

UNS. A96063

Government. QQ-A-200/9, MIL-P-25995

Foreign. Austria: Önorm AlMgSi0,5. Canada: CSA GS10. France: NF A-GS. Italy: UNI P-AlSi0.4Mg. United Kingdom: BS H19; DTD 372B. Germany: DIN AlMgSi0.5; Werkstoff-Nr. 3.3206. ISO: AlMgSi

Chemical Composition

Composition limits. 0.20 to 0.6 Si, 0.35 Fe max, 0.10 Cu max, 0.10 Mn max, 0.45 to 0.9 Mg, 0.10 Cr max, 0.10 Zn max, 0.10 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Pipe, railings, furniture, architectural extrusions, truck and trailer flooring, doors, windows, irrigation pipes

Mechanical Properties

Tensile properties. See Tables 86 and 87.

Table 86 Typical mechanical properties of alloy 6063

Temper	Tensile strength		Yield strength		Elongation, %	Hardness[a], HB	Shear strength		Fatigue strength[b]	
	MPa	ksi	MPa	ksi			MPa	ksi	MPa	ksi

316	600	23	3.3	17	2.5	80
371	700	16	2.3	14	2	105

(a) Lowest strength for exposures up to 10,000 h at temperature, no load; test loading applied at 35 MPa/min (5 ksi/min) to yield strength and then at strain rate of 5%/min to fracture.

(b) T1 temper formerly T42

Hardness. See Table 86.

Poisson's ratio. 0.33

Elastic modulus. Tension, 68.3 GPa (9.91×10^6; shear, 25.8 GPa (3.75×10^6 psi); compression, 69.7 GPa (10.1×10^6 psi)

Mass Characteristics

Density. 2.69 g/cm^3 (0.097 lb/in.^{3})

Thermal Properties

Liquidus temperature. 655 °C (1211 °F)

Solidus temperature. 615 °C (1139 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
50 to 20	-58 to 68	21.8	12.1
20 to 100	68 to 212	23.4	13.0
20 to 200	68 to 392	24.5	13.6
20 to 300	68 to 572	25.6	14.2

Specific heat. 900 J/kg · K (0.215 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 25 °C (77 °F):

Temper	Conductivity	
	W/m · K	Btu/ft · h · °F
O	218	126
T1 (formerly T42)	193	112
T5	209	121

Electrical Properties

Electrical conductivity. At 20 °C (68 °F):

Temper	Conductivity, % IACS	
	Equal volume	Equal weight

O	58	191
T1 (formerly T42)	50	165
T5	55	181
T6, T83	53	175

Electrical resistivity. At 20 °C (68 °F):

Temper	Resistivity, nΩ · m
O	30
T1 (formerly T42)	35
T5	32
T6, T83	33

Chemical Properties

General corrosion resistance. Highly resistant to all types of corrosion

Fabrication Characteristics

Machinability. Fair, depending on temper

Weldability. For all commercial processes, excellent weldability and brazeability

Annealing temperature. 415 °C (775 °F); hold at temperature 2 to 3 h; cool at 28 °C (50 °F) per h from 415 °C (775 °F) to 260 °C (500 °F)

Solution temperature. 520 °C (970 °F)

Aging temperature. T5 temper: 205 °C (400 °F), hold at temperature for 1 h; or 182 °C (360 °F), hold at temperature for 1 h. All other artificially aged tempers: 175 °C (350 °F), hold at temperature for 8 h

---

6066
1.4Si-1.1Mg-1.0Cu-0.8Mn

Specifications

ASTM. Extruded wire, rod, bar, shapes, and tube: B 221

SAE. J454

UNS number. A96066

Government. Extruded wire, rod, bar, shapes, and tube: QQ-A-200/10. Forgings: QQ-A-367

Foreign. United Kingdom: BS H11

Chemical Composition

Composition limits. 0.9 to 1.8 Si, 0.50 Fe max, 0.7 to 1.2 Cu, 0.6 to 1.1 Mn, 0.8 to 1.4 Mg, 0.40 Cr max, 0.25 Zn max, 0.20 Ti max, 0.50 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Forgings and extrusions for welded structures

Mechanical Properties

Tensile properties. See Table 88.

Table 88 Tensile properties of alloy 6066

Temper	Tensile strength		Yield strength (0.2% offset)		Elongation[(a)], %
	MPa	ksi	MPa	ksi	
Typical properties					
O	150	22	83	12	18
T4, T451	360	52	207	30	18
T6, T651	395	57	359	52	12
Property limits (extrusions)					
O	200 max	29 max	125 max	18 max	16 min
T4, T4510, T4511	275 min	40 min	170 min	25 min	14 min
T42	275 min	40 min	165 min	24 min	14 min
T6, T6510, T6511	345 min	50 min	310 min	45 min	8 min
T62	345 min	50 min	290 min	42 min	8 min

Property limits (die forgings)					
T6	345 min	50 min	310 min	45 min	. . .

(a) In 50 mm (2 in.) or 4*d*, where *d* is diameter of reduced section of tensile test specimen

Shear strength. Typical. O temper: 97 MPa (14 ksi); T4 and T451 tempers: 200 MPa (29 ksi); T6 and T651 tempers: 234 MPa (34 ksi)

Hardness. O temper: 43 HB; T4 and T451 tempers: 90 HB; T6 and T651 tempers: 120 HB

Elastic modulus. Tension, 69 GPa (10×10^6 psi)

Fatigue strength. T6 and T651 tempers, 110 MPa (16 ksi). Data correspond to 5×10^8 cycles in R.R. Moore type test.

Mass Characteristics

Density. 2.71 g/cm^3 (0.098 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 645 °C (1195 °F)

Solidus temperature. 563 °C (1045 °F)

Coefficient of thermal expansion. Linear, 23.2 μm/m · K (12.9 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Specific heat. 887 J/kg · K (0.212 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. T6 temper, 147 W/m · K (85 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): O temper, 40% IACS; T6 temper, 37% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 43 nΩ · m; T6 temper, 47 nΩ · m

Fabrication Characteristics

Annealing temperature. 415 °C (778 °F); hold at temperature 2 to 3 h

Solution temperature. 530 °C (990 °F); followed by quenching

Aging temperature. 175 °C (350 °F); hold at temperature 8 h

6070
1.4Si-0.8Mg-0.7Mn-0.3Cu

Specifications

ASTM. Gas and oil transmission pipe: B 345

SAE. J454

Government. Extruded rod, bar, shapes, and tube: MIL-A-46104. Impacts: MIL-A-12545

Chemical Composition

Composition limits. 1.0 to 1.7 Si, 0.50 Fe max, 0.15 to 0.40 Cu, 0.40 to 1.0 Mn, 0.50 to 1.2 Mg, 0.10 Cr max, 0.25 Zn max, 0.15 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Heavy duty welded structures, pipelines, extruded structural components for automobiles

Mechanical Properties

Tensile properties. Typical. Tensile strength: O temper, 145 MPa (21 ksi); T4 temper, 317 MPa (46 ksi); T6 temper, 379 MPa (55 ksi). Yield strength: O temper, 69 MPa (10 ksi); T4 temper, 172 MPa (25 ksi); T6 temper, 352 MPa (51 ksi). Elongation: O and T4 tempers, 20%; T6 temper, 10%

Shear strength. Typical. O temper: 97 MPa (14 ksi); T4 temper: 206 MPa (30 ksi); T6 temper: 234 MPa (34 ksi)

Hardness. O temper: 35 HB; T4 temper: 90 HB; T6 temper: 120 HB. Data obtained using 500 kg load, 10 mm diam ball, and 30 s duration of loading.

Elastic modulus. Tension, 68 GPa (9.9×10^6 psi)

Fatigue strength. O temper: 62 MPa (9 ksi); T4 temper: 90 MPa (13 ksi); T6 temper: 97 MPa (14 ksi). Data correspond to 5×10^8 cycles of completely reversed stress in an R.R. Moore type test

Mass Characteristics

Density. 2.71 g/cm^3 (0.098 lb/in.^{3})

Thermal Properties

Liquidus temperature. 649 °C (1200 °F)

Solidus temperature. 566 °C (1050 °F)

Specific heat. 891 J/kg · K (0.213 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. T6 temper: 172 W/m · K (99.1 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, T6 temper: 44% IACS at 20 °C (68 °F)

Electrical resistivity. 39 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Solution temperature. 545 °C (1015 °F); followed by quenching

Annealing temperature. T4 temper: 545 °C (1015 °F)

Aging temperature. 160 °C (320 °F); hold at temperature for 18 h

6101
0.6Mg-0.5Si

Specifications

ASTM. Bus conductor: B 317

SAE. J454

UNS number. A96101

Foreign. Austria: Önorm E-AIMgSi. France: NF A-GS/L. Italy: UNI P-AlSi0.5Mg. Switzerland: VSM Al-Mg-Si. United Kingdom: BS 91E. Germany: E-AlMgSi0.5; Werkstoff-Nr. 3.3207

Chemical Composition

Composition limits. 0.30 to 0.7 Si, 0.50 Fe max, 0.10 Cu max, 0.03 Mn max, 0.35 to 0.8 Mg, 0.03 Cr max, 0.10 Zn max, 0.06 B max, 0.03 max other (each), 0.10 max others (total), bal Al

Applications

Typical uses. High strength bus bars, electrical conductors, heat sinks

Mechanical Properties

Tensile properties. Typical. Tensile strength, 221 MPa (32 ksi); yield strength, 193 MPa (28 ksi); elongation, 15%. See also Tables 89 and 90.

Table 89 Typical tensile properties of alloy 6101-T6 at various temperatures

Temperature		Tensile strength[a]		Yield strength (0.2% offset)[a]		Elongation[b], %
°C	°F	MPa	ksi	MPa	ksi	
-196	-320	296	43	228	33	24

T63	186	27	152	22	56
T64	103	15	55	8	59.5

(a) Single entries are minimum values.

Shear strength. 138 MPa (20 ksi)

Hardness. 71 HB with 500 kg load, 10 mm diam ball

Elastic modulus. Tension, 68.9 GPa (10.0×10^6 psi); compression, 70.3 GPa (10.2×10^6 psi)

Mass Characteristics

Density. 2.69 g/cm^3 (0.097 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 654 °C (1210 °F)

Solidus temperature. 621 °C (1150 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.7	12.0
20 to 100	68 to 212	23.5	13.0
20 to 200	68 to 392	24.4	13.5
20 to 300	68 to 572	25.4	14.1

Specific heat. 895 J/kg · K (0.214 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 218 W/m · K (126 Btu/ft · h · °F) at 25 °C (77 °F)

Electrical Properties

Electrical conductivity and resistivity at 20 °C (68 °F):

Temper	Electrical conductivity, %IACS	Electrical resistivity, nΩ · m
T6	57	30.2
T61	59	29.2
T63	58	29.7

T64	60	28.7
T65	58	29.7

Fabrication Characteristics

Solution temperature. 510 °C (950 °F); hold for 1 h at temperature

Aging temperature. 175 °C (350 °F); hold for 6 to 8 h at temperature

Hot-working temperature. 260 to 510 °C (500 to 950 °F)

6151
0.9Si-0.6Mg-0.25Cr

Specifications

AMS. Forgings: 4125

SAE. J454

UNS number. A96151

Government. Forgings and forging stock: QQ-A-367; MIL-A-22771

Foreign. Canada: CSA SG11P

Chemical Composition

Composition limits. 0.6 to 1.2 Si, 1.0 Fe max, 0.35 Cu max, 0.20 Mn max, 0.45 to 0.8 Mg, 0.15 to 0.35 Cr, 0.25 Zn max, 0.15 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Die forgings and rolled rings for crank cases, fuses, and machine parts. Applications requiring good forgeability, good strength, and resistance to corrosion

Mechanical Properties

Tensile properties. See Tables 91 and 92.

Table 91 Tensile-property limits for alloy 6151

Temper	Tensile strength		Yield strength		Elongation[(a)], %
	MPa	ksi	MPa	ksi	
Die forgings, T6					
Axis parallel to grain flow	303	44	255	37	14 (coupon) 10 (forging)

Axis not parallel to grain flow	303	44	255	37	6 (forging)
Rolled rings, T6 and T652					
Tangential	303	44	255	37	5
Axial	303	44	241	35	4
Radial	290	42	241	35	2

(a) In 50 mm (2 in.) or 4*d*, where *d* is diameter of reduced section of tensile test specimen

20 to 300	68 to 572	25.0	13.9

Specific heat. 895 J/kg · K (0.214 Btu/lb · °F)

Thermal conductivity. At 20 °C (68 °F): O temper, 205 W/m · K (118 Btu/ft · h · °F); T4 temper, 163 W/m · K (94 Btu/ft · h · °F); T6 temper, 175 W/m · K (101 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): O temper, 54% IACS; T4 temper, 42% IACS; T6 temper, 45% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 32 nΩ · m; T4 temper, 41 nΩ · m; T6 temper, 38 nΩ · m

Electrolytic solution potential. -0.83 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature. 413 °C (775 °F); hold at temperature 2 to 3 h; furnace cool to 260 °C (500 °F) at 27 °C (50 °F) per h max

Solution temperature. 510 to 525 °C (950 to 975 °F); hold at temperature 4 min, quench in cold water; heavy or complicated forgings, quench in water at 65 to 100 °C (150 to 212 °F)

Aging temperature. 165 to 175 °C (300 to 345 °F), hold at temperature 8 to 12 h

Hot-working temperature. 260 to 480 °C (500 to 900 °F)

6201
0.7Si-0.8Mg

Specifications

ASTM. Wire, B 398. Stranded conductor, T81 temper: B 399

SAE. J454

UNS. A96201

Chemical Composition

Composition limits. 0.50 to 0.95 Si, 0.50 Fe max, 0.10 Cu max, 0.03 Mn max, 0.6 to 0.9 Mg, 0.03 Cr max, 0.10 Zn max, 0.06 B max, 0.03 max other (each), 0.10 max others (total), bal Al

Applications

Typical uses. Rod and wire for high strength electrical conductors

Mechanical Properties

Tensile properties. Typical. T81 temper: tensile strength, 331 MPa (48 ksi); yield strength, 310 MPa (45 ksi); elongation, 6% in 250 mm (10 in.)

Property limits for T81 temper wire with 1.6 to 3.2 mm ($\frac{1}{16}$ to $\frac{1}{8}$ in.) diameter. Min tensile strength (individual), 315 MPa (46 ksi); min tensile strength (average), 330 MPa (48 ksi)

Property limits for T81 temper wire with 3.2 to 4.8 mm ($\frac{1}{8}$ to $\frac{3}{16}$ in.) diameter. Min tensile strength (individual), 305 MPa (44 ksi); min tensile strength (average), 315 MPa (46 ksi). Min elongation, 3% in 250 mm (10 in.) for all diameters

Mass Characteristics

Density. 2.69 g/cm^3 (0.097 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 654 °C (1210 °F)

Solidus temperature. 607 °C (1125 °F)

Coefficient of thermal expansion:

Temperature range	Average coefficient

°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.6	12.0
20 to 100	68 to 212	23.4	13.0
20 to 200	68 to 392	24.3	13.5
20 to 300	68 to 572	25.2	14.0

Specific heat. 895 J/kg · K (0.214 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. T8 temper: 205 W/m · K (118 Btu/ft · h · °F) at 25 °C (77 °F)

Electrical Properties

Electrical conductivity. Volumetric, T81 temper: 54% IACS at 20 °C (68 °F)

Electrical resistivity. T81 temper: 32 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Solution temperature. 510 °C (950 °F)

Aging temperature. 150 °C (300 °F); hold at temperature approximately 4 h

316	600	32	4.6	19	2.7	85

371	700	24	3	12	1.8	95

(a) Lowest strength for exposures up to 10,000 h at temperature, no load; test loading applied at 35 MPa/min (5 ksi/min) to yield strength and then at strain rate of 5%/min to fracture

Shear strength. Typical, T9 temper: 241 MPa (35 ksi)

Hardness. Typical, T9 temper: 120 HB with 500 kg load, 10 mm diam ball

Fatigue strength. Typical, T9 temper: 90 MPa (13 ksi) at 5×10^8 cycles; R.R. Moore type test

Mass Characteristics

Density. 2.71 g/cm^3 (0.098 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 650 °C (1205 °F)

Solidus temperature. 585 °C (1080 °F)

Coefficient of thermal expansion. Linear, 23.4 μm/m · K (13.0 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Thermal conductivity. T9 temper: 172 W/m · K (99.1 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, T9 temper: 44% IACS at 20 °C (68 °F)

Electrical resistivity. T9 temper: 39 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Annealing temperature. 415 °C (780 °F); hold at temperature 2 to 3 h

Solution temperature. 540 °C (1000 °F); hold at temperature 8 to 12 h

Aging temperature. 170 °C (340 °F); hold at temperature 8 to 12 h

---

6351
1.0Si-0.6Mg-0.6Mn

Specifications

ASTM. Gas and oil transmission pipe: B 345. Extruded wire, rod, bar, shapes, and tube: B 221

UNS. A96351

Chemical Composition

Composition limits. 0.7 to 1.3 Si, 0.50 Fe max, 0.10 Cu max, 0.40 to 0.8 Mn, 0.40 to 0.8 Mg, 0.20 Zn max, 0.20 Ti max, 0.05 max other (each), 0.15 others (total), bal Al

Applications

Typical uses. Extruded structures used in road vehicles and railroad stock; tubing and pipe for carrying water, oil, or gasoline

Mechanical Properties

Tensile properties. Typical. T4 temper: tensile strength, 248 MPa (36 ksi); 0.2% yield strength, 152 MPa (22 ksi); elongation, 20%. T6 temper; tensile strength, 310 MPa (45 ksi); 0.2% yield strength, 283 MPa (41 ksi); elongation, 14%. Property limits for extrusions, T54 temper; tensile strength (min), 207 MPa (30 ksi); 0.2% yield strength (min), 138 MPa (20 ksi); elongation (min), 10%

Shear strength. T6 temper, 200 MPa (29 ksi)

Hardness. T6 temper, 95 HB with 500 kg load, 10 mm diam ball

Fatigue strength. Typical, T6 temper: 90 MPa (13 ksi) at 5×10^8 cycles in R.R. Moore type test

Mass Characteristics

Density. 2.71 g/cm^3 (0.098 lb/in.^{3})

Thermal Properties

Liquidus temperature. 650 °C (1202 °F)

Solidus temperature. 555 °C (1030 °F)

Coefficient of thermal expansion. Linear, 23.4 μm/m · K (13.0 μin./in. · °F) at 20 to 80 °C (68 to 176 °F)

Thermal conductivity. 176 W/m · K (102 Btu/ft · h · °F) at 25 °F (77 °F)

Electrical Properties

Electrical conductivity. Volumetric, T6 temper: 46% IACS at 20 °C (68 °F)

Electrical resistivity. 38 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Annealing temperature. 350 °C (660 °F); hold at temperature for about 4 h

Solution temperature. 505 °C (940 °F)

Aging temperature. 170 °C (338 °F); hold at temperature 6 h

6463
0.40Si-0.7Mg

Specifications

ASTM. Extruded wire, rod, bar, shapes, and tube: B 221

SAE. J454

UNS number. A96463

Foreign. United Kingdom: BS E6

Chemical Composition

Composition limits. 0.20 to 0.6 Si, 0.15 Fe max, 0.20 Cu max, 0.05 Mn max, 0.45 to 0.9 Mg, 0.05 Zn max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Architectural, appliance, and bright anodized automotive extrusions

Mechanical Properties

Tensile properties. Typical. Tensile strength. T1 temper, 152 MPa (22 ksi); T5 temper, 186 MPa (27 ksi); T6 temper, 241 MPa (35 ksi). 0.2% yield strength: T1 temper, 90 MPa (13 ksi); T5 temper, 145 MPa (21 ksi); T6 temper: 214 MPa (31 ksi). *Elongation:* T1 temper, 20%; T5 and T6 tempers: 12%

Shear strength. T1 temper, 97 MPa (14 ksi); T5 temper, 117 MPa (17 ksi); T6 temper, 152 MPa (22 ksi)

Hardness. T1 temper, 42 HB; T5 temper, 60 HB; T6 temper, 74 HB. Values obtained with 500 kg load and 10 mm diam ball

Fatigue strength. All tempers: 69 MPa (10 ksi) at 5×10^8 cycles; R.R. Moore type test

Mass Characteristics

Density. 2.69 g/cm^3 (0.097 lb/in.^{3})

Thermal Properties

Liquidus temperature. 654 °C (1210 °F)

Solidus temperature. 621 °C (1150 °F)

Coefficient of thermal expansion. Linear, 23.4 μm/m · K (13.0 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Thermal conductivity. At 25 °C (77 °F): T1 temper, 192 W/m · K (111 Btu/ft · h · °F); T5 temper, 209 W/m · K (121 Btu/ft · h · °F); T6 temper, 201 W/m · K (116 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F); T1 temper, 50% IACS; T5 temper, 55% IACS; T6 temper, 53% IACS

Electrical resistivity. At 20 °C (68 °F); T1 temper, 34 nΩ · m; T5 temper, 31 nΩ · m; T6 temper, 33 nΩ · m

Fabrication Characteristics

Annealing temperature. 415 °C (780 °F)

Solution temperature. 520 °C (968 °F)

Aging temperature. To produce T6 temper: 175 °C (350 °F), hold at temperature 8 h; can also use 180 °C (360 °F), hold at temperature 6 h. To produce T5 temper: 205 °C (400 °F), hold at temperature 1 h; can also use 180 °C (360 °F), hold at temperature 3 h

7005
4.6Zn-1.4Mg-0.5Mn-0.1Cr-0.1Zr-0.03Ti

Specifications

ASTM. Extruded wire, rod, bar, shapes, and tube: B 221

UNS number. A97005

Chemical Composition

Composition limits. 0.10 Cu max, 1.0 to 1.8 Mg, 0.20 to 0.70 Mn, 0.35 Si max, 0.40 Fe max, 0.06 to 0.20 Cr, 0.01 to 0.06 Ti, 4.0 to 5.0 Zn, 0.08 to 0.20 Zr, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Extruded structural members such as frame rails, cross members, corner posts, side posts, and stiffeners for trucks, trailers, cargo containers, and rapid transit cars. Welded or brazed assemblies requiring moderately high strength and high fracture toughness, such as large heat exchangers, especially where solution heat treatment after joining is impractical. Sports equipment such as tennis racquets and softball bats

Precautions in use. To avoid stress-corrosion cracking, stresses in the transverse direction should be avoided at exposed machined or sawed surfaces. Parts should be cold formed in O temper, then heat treated; alternatively, parts may be cold formed in W temper, followed by artificial aging. In parts intended for service in aggressive electrolytes such as seawater, selective attack along the heat-affected zone in a weldment or torch-brazed assembly can be avoided by postweld aging. When the service environment is conducive to galvanic corrosion, 7005 should be coupled or joined only to aluminum alloy components having similar electrolytic solution potentials; alternatively, joint surfaces should be protected or insulated.

Mechanical Properties

Tensile properties. Typical. Tensile strength: O temper, 193 MPa (28 ksi); T53 temper, 393 MPa (57 ksi); T6, T63, T6351 tempers, 372 MPa (54 ksi). Yield strength: O temper, 83 MPa (12 ksi); T53 temper, 345 MPa (50 ksi); T6, T63, T6351 tempers, 317 MPa (46 ksi). Elongation in 50 mm (2 in.) or 4*d* where *d* is diameter of tensile test specimen: O temper, 20%; T53 temper, 15%; T6, T63, T6351 tempers, 12%. See also Tables 94 and 95.

Table 94 Minimum mechanical properties of alloy 7005

Temper	Tensile strength		Yield strength		Elongation[(a)], %	Compressive yield strength		Shear strength		Shear yield strength		Bearing strength		Bearing yield strength	
	MPa	ksi	MPa	ksi		MPa	ksi	MPa	ksi	MPa	ksi	MPa	ksi	MPa	ksi

149	300	165	24	145	21	35
204	400	97	14	83	12	60

(a) Lowest strength for exposures up to 10,000 h at temperature, no load; test loading applied at 35 MPa/min (5 ksi/min) to yield strength and then at strain rate of 5%/min to fracture

Shear strength. Typical. O temper: 117 MPa (17 ksi); T53 temper: 221 MPa (32 ksi); T6, T63, T6351 tempers: 214 MPa (31 ksi); see also Table 94.

Compressive strength. See Table 94.

Elastic modulus. Tension, 71 GPa (10.3×10^6 psi); shear, 26.9 GPa (3.9×10^6 psi); compression, 72.4 GPa (10.5×10^6 psi)

Fatigue strength. Rotating beam at 10^8 cycles. T6351 plate: smooth specimens, 115 to 130 MPa (17 to 19 ksi); 60° notched specimens, 20 to 50 MPa (3 to 7 ksi). T53 extrusions: smooth specimens, 130 to 150 MPa (19 to 22 ksi); 60° notched specimens, 24 to 40 MPa (3.5 to 6 ksi). Axial ($R = 0$) at 10^8 cycles, smooth specimens. T6351 plate: 195 MPa (28 ksi). T53 extrusions: 231 MPa (33.5 ksi)

Plane-strain fracture toughness. Typical, T6351 temper. L-T orientation: 51.3 MPa $\sqrt{m}$ (46.7 ksi $\sqrt{in}$); data from 75 mm (3 in.) thick notch bend specimens. T-L orientation: 44 MPa $\sqrt{m}$ (40 ksi $\sqrt{in}$); data from 75 mm (3 in.) thick notch bend specimens. S-L orientation: 30.3 MPa $\sqrt{m}$ (27.6 ksi $\sqrt{in}$); data from 25 to 32 mm (1 to $1\frac{1}{4}$ in.) thick compact tensile specimens

Mass Characteristics

Density. 2.78 g/cm^3 (0.100 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 643 °C (1190 °F)

Solidus temperature. 604 °C (1120 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.4	11.9
20 to 100	68 to 212	23.1	12.8
20 to 200	68 to 392	24.0	13.3
20 to 300	68 to 572	25.0	13.9

Volumetric: 67.0 × 10^{-6} m^3/m^3 · K (3.72 × 10^{-5} $in.^3/in.^3$ · °F) at 20 °C (68 °F)

Specific heat. 875 J/kg · K (0.209 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 20 °C (68 °F); O temper, 166 W/m · K (96 Btu/ft · h · °F); T53, T5351, T63, T6351, T63, T6351 tempers, 148 W/m · K (86 Btu/ft · h · °F); T6 temper, 137 W/m · K (79 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): O temper, 43% IACS; T53, T5351, T63, T6351 tempers, 38% IACS; T6 temper, 35% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 40.1 nΩ · m; T53, T5351, T63, T6351 tempers, 45.4 nΩ · m; T6 temper, 49.3 nΩ · m. Temperature coefficient, all tempers: 0.1 nΩ · m per K at 20 °C (68 °F)

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F)

Solution temperature. 400 °C (750 °F)

Heat treatment. T53: Press quench from hot working temperature, naturally age 72 h at room temperature, then two-stage artificially age 8 h at 100 to 110 °C (212 to 230 °F) plus 16 h at 145 to 155 °C (290 to 310 °F)

7039
4Zn-2.8Mg-0.25Mn-0.20Cr

Specifications

Military. MIL-A-22771, MIL-A-45225, MIL-A-46063

UNS number. A97039

Chemical Composition

Composition limits. 2.3 to 3.3 Mg, 3.5 to 4.5 Zn, 0.10 to 0.40 Mn, 0.15 to 0.25 Cr, 0.30 max Si, 0.10 max Cu, 0.40 max Fe, 0.10 max Ti, 0.50 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Cryogenic storage tanks, unfired pressure vessels, ordnance tanks, armor plate, missile structures, low-temperature processing equipment, and storage tanks.

Forms available. Plates, forgings, extrusions, and sometimes sheet

Mechanical Properties

Tensile properties. See Table 96.

Table 96 Typical mechanical properties of 7039

Property	Property value[(a)] at temper:

Mass Characteristics

Density. 2.73 g/cm^3 (0.0988 lb/in.^{3}

Thermal Properties

Liquidus temperature. 638 °C (1180 °F)

Solidus temperature. 482 °C (900 °F)

Coefficient of thermal expansion. From 20 to 100 °C (68 to 212 °F): 23.4 μm/m · °C (13 μin./in. · °F)

Thermal conductivity. 125 to 155 W/m · °C (0.30 to 0.37 cal/cm · s · °C)

Electrical Properties

Electrical conductivity. 32 to 40% IACS (volumetric)

Fabrication Characteristics

Solution treatment. Heat to 460 to 500 °C (860 to 930 °F), soak 2 h, quench in cold water. Sheet stock should be quenched from 490 to 500 °C (910 to 930 °F), while extruded stock should be quenched from 460 to 470 °C (860 to 880 °F).

Aging treatment. T6 temper: reheat to 120 °C (250 °F), hold at temperature for 20 to 24 h, air cool

Annealing treatment. O temper: heat to 415 to 455 °C (775 to 850 °F), soak for 2-3 h, air cool, reheat at 230 °C (450 °F), hold at temperature for 4 h, air cool. Or heat to 355 to 370 °C (670 to 700 °F), air cool

Stress-relief anneal. Heat to 355 to 370 °C (670 to 700 °F), soak for 2 h, air cool to room temperature

Weldability. Readily weldable by the direct-current inert-gas tungsten-arc (TIG) and by the metal-arc-inert-gas (MIG) process, using a weld-filler alloy of aluminum X5039 or 5183 rod. Has considerably better weld strength and ductility than 5083. Readily welded over a wide range of thicknesses with no decrease in weld ductility. Shows very good crack resistance in restrained plate weldments when joined with X5039 filler wire. Room temperature weld strength averages 360 MPa (52 ksi) and increases to 448 MPa (65 ksi) at -195 °C (-320 °F). No special pre-weld or post-weld heat treatment is required.

Machinability. Good machinability in the annealed state. Soluble oil emulsions, kerosene, and kerosene-lard oil mixtures are recommended for most machining operations, but high viscosity lubricants are recommended for tapping operations.

Workability. Best formed in its freshly quenched condition. In the soft temper, the alloy can be successfully formed on all types of equipment. Because of its higher strength, a greater allowance for springback will have to be made than when working with other aluminum alloys. Use of heat up to 120 °C (250 °F) during forming in the annealed condition is beneficial in certain swaging, spinning, and drop hammer operations. In the solution treated condition the properties are intermediate between those of O and T6 temper, but definitely higher than O temper condition during the first few hours after quenching. Then formability gradually lessens as age-hardening increases. In the solution treated and aged T6 temper condition, the material exhibits very poor forming qualities. Due to the elaborate annealing and stabilizing treatment required, severe forming in its annealed O temper condition would be impractical. Rubber forming or streaking is usually conducted at 120 to 230 °C (250 to 450 °F).

Corrosion Resistance

The general corrosion resistance characteristics of 7039-T64 are comparable to such highly resistant aluminum-magnesium alloys as 5052, 5086, and 5083. Resistance to general corrosion is very much superior to that of most heat-treatable alloys. Under standard 6% NaCl immersion test for 6 mo or 5% NaCl salt fog, the alloy evidenced a slight superficial staining and a mild and shallow pitting attack with no measurable loss in strength. In a sodium chloride-hydrogen peroxide test, no evidence of intergranular corrosion was observed.

7049
7.6Zn-2.5Mg-1.5Cu-0.15Cr

Specifications

AMS. Extrusions: 4157, 4159. Forgings: 4111

UNS number. A97049

Government. Forgings: QQ-A-367, MIL-H-6088

Chemical Composition

Composition limits. 1.2 to 1.9 Cu, 2.0 to 2.9 Mg, 0.20 Mn max, 0.25 Si max, 0.35 Fe max, 0.10 to 0.22 Cr, 7.2 to 8.2 Zn, 0.10 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Forged aircraft and missile fittings, landing gear cylinders, and extruded sections. Used where static strengths approximately the same as forged 7079-T6 and high resistance to stress-corrosion cracking are required. Fatigue characteristics about equal to those of 7075-T6 products, toughness somewhat higher

Precautions in use. Poor general corrosion resistance

Mechanical Properties

Tensile property limits. See Table 98.

(a) Single values are minimum values.

(b) In 50 mm (2 in.) or 4*d*, where *d* is diameter of reduced section of tensile test specimen. Where a range appears in this column, the specified minimum elongation varies with thickness of mill product.

(c) $e/d = 2.0$, where *e* is edge distance and *d* is pin diameter

Shear strength. See Table 98.

Compressive strength. See Table 98.

Bearing strength. See Table 98.

Hardness. 135 HB min with 500 kg load, 10 mm diam ball

Poisson's ratio. 0.33

Elastic modulus. Forgings, typical: tension, 70 GPa (10.2×10^6 psi). Extrusions, typical: tension, 72.5 GPa (10.5 ksi); shear, 27.6 GPa (4.0 ksi); compression, 76 GPa (11 ksi)

Fatigue strength. Axial fatigue at stress ratio *R* of 1.0 for material in the T73 temper. Smooth specimens from 125 mm (5 in.) thick forgings: 275 to 315 MPa (40 to 46 ksi) at 10^7 cycles for temperatures from room temperature to 175 °C (350 °F). Notched specimens from 75 mm (3 in.) thick forgings: 390 MPa (56 ksi) for K_t of 1.0; 115 MPa (17 ksi) for K_t of 3.0; both at 10^7 cycles

Plane-strain fracture toughness. K_Q values from compact tension tests of 7049-T73 die forgings: L-S orientation, 32 to 36 MPa $\sqrt{m}$ (29 to 33 ksi $\sqrt{in}$); L-T orientation, 31 to 40 MPa $\sqrt{m}$ (28 to 37 ksi $\sqrt{in}$); S-L orientation, 21 to 27 MPa $\sqrt{m}$ (19 to 25 ksi $\sqrt{in}$)

Mass Characteristics

Density. 2.82 g/cm^3 (0.102 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 627 °C (1160 °F)

Solidus temperature. 477 °C (890 °F)

Coefficient of thermal expansion. Linear, 23.4 μm/m · K (13.0 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Specific heat. 960 J/kg · K (0.23 Btu/lb · °F) at 100 °C (212 °F)

Thermal conductivity. 154 W/m · K (89 Btu/ft · h · °F) at 25 °C (77 °F)

Electrical Properties

Electrical conductivity. Volumetric, 40% IACS min at 20 °C (68 °F)

Electrical resistivity. 43 nΩ · m

7050
6.2Zn-2.3Md-2.3Cu-0.12Zr

Specifications

AMS. 4050, 4107, 4108

UNS number. A97050

Chemical Composition

Composition limits. 2.0 to 2.6 Cu, 1.9 to 2.6 Mg, 0.10 Mn max, 0.12 Si max, 0.15 Fe max, 0.04 Cr max, 0.08 to 0.15 Zr, 5.7 to 6.7 Zn, 0.06 Ti max, 0.05 max other (each), 0.15 max others (total)

Consequence of exceeding impurity limits. Excess Fe and Si degrade fracture toughness. Increased sensitivity to quenching rate due to excess Mn and Cr results in low strength in thick sections.

Applications

Typical uses. Plate, extrusions, hand and die forgings in aircraft structural parts. Other applications requiring very high strength coupled with high resistance to exfoliation corrosion and stress-corrosion cracking, high fracture toughness and fatigue resistance

Mechanical Properties

Tensile properties. See Tables 99, 100, and 101.

Mass Characteristics

Density. 2.83 g/cm^3 (0.102 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 635 °C (1175 °F)

Solidus temperature. 524 °C (957 °F)

Incipient melting temperature. 488 °C (910 °F) for homogenized (solution treated) wrought material

Eutectic temperature. 465 °C (870 °F) for unhomogenized wrought or as-cast material

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.7	12.1
20 to 100	68 to 212	23.5	13.1
20 to 200	68 to 392	24.4	13.6
20 to 300	68 to 572	25.4	14.1

Volumetric: 68.0×10^{-6} $m^3/m^3 \cdot K$ (3.78×10^{-5} $in.^3/in.^3 \cdot °F$) at 20 °C (68 °F)

Specific heat , 860 J/kg · K (0.206 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 20 °C (68 °F): O temper, 180 W/m · K (104 Btu/ft · h · °F); T76, T7651 tempers, 154 W/m · K (89 Btu/ft · h · °F); T736, T 73651 tempers, 157 W/m · K (91 Btu/ft · h · F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): O temper, 47% IACS; T76, T7651 tempers, 39.5% IACS; T736, T73651 temper, 40.5% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 36.7 nΩ · m; T76 tempers, 43.6 nΩ · m;T736, T73651 tempers, 42.6 nΩ · m. Temperature coefficient, all tempers: 0.1 nΩ · m per K at 20 °C (68 °F)

Fabrication Characteristics

Annealing temperature. 415 °C (775 °F)

Solution temperature. 475 °C (890 °F)

Aging temperature. 120 to 175 °C (250 to 350 °F)

7072
1.0Zn

Specifications

ASTM. B 209

SAE. J454

UNS number. A97072

Chemical Composition

Composition limits. 0.10 Cu max, 0.10 Mg max, 0.10 Mn max, 0.7 Si max + Fe, 0.8 to 1.3 Zn, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Fin stock. Cladding alloy for Alclad sheet, plate, and tube products with the following core alloys: 2219, 3003, 3004, 5050, 5052, 5154, 6061, 7075, 7475, 7178

Mechanical Properties

Tensile properties. See Table 105

Table 105 Mechanical-property limits for alloy 7072 fin stock

Temper	Tensile strength				Yield strength (min)		Elongation (min), % [(a)]
	Minimum		Maximum				
	MPa	ksi	MPa	ksi	MPa	ksi	
O	55	8.0	90	13.0	21	3	15-20
H14	97	14.0	131	19.0	83	12	1-3
H18	131	19.0	. . .	. . .	. . .	. . .	1-2
H19	145	21.0	. . .	. . .	. . .	. . .	1
H25	107	15.5	148	21.5	83	12	2-3

(a) In 50 mm (2 in.). Where a range of values appears in this column, specified minimum elongation varies with thickness of the mill product

Shear strength. O temper, 55 MPa (8 ksi); H12 temper, 62 MPa (9 ksi); H14 temper, 69 MPa (10 ksi)

Hardness. O temper, 20 HB; H12 temper, 28 HB; H14 temper, 32 HB; all values obtained with 500 kg load, 10 mm diam ball, and 30 s duration of loading

Poisson's ratio. 0.33

Elastic modulus. Tension, 68 GPa (9.9×10^6 psi); compression, 70 GPa (10.1×10^6 psi)

Mass Characteristics

Density. 2.72 g/cm^3 (0.098 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 657 °C (1215 °F)

Solidus temperature. 641 °C (1185 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.8	12.1
20 to 100	68 to 212	23.6	13.1
20 to 200	68 to 392	24.5	13.6
20 to 300	68 to 572	25.5	14.2

Volumetric: 68×10^{-3} $m^3/m^3 \cdot K$ (3.78×10^{-5} $in.^3/in.^3 \cdot °F$) at 20 °C (68 °F)

Specific heat. 893 J/kg · K (0.213 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. O temper: 227 W/m · K (131 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O temper: 60% IACS at 20 °C (68 °F)

Electrical resistivity. 28.7 nΩ · m at 20 °C (68 °F); temperature coefficient, 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. -0.96 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter at 25 °C (77 °F)

Chemical Properties

General corrosion behavior. High resistance to general corrosion. Provides galvanic protection when used as cladding on several different alloys

Fabrication Characteristics

Annealing temperature. 345 °C (650 °F)

7075, Alclad 7075
5.6Zn-2.5Mg-1.6Cu-0.23Cr

ASTM. See Table 106.

SAE. J454

UNS number. A97075

Government. See Table 106.

Foreign. Austria: Önorm AlZnMg-Cu1.5. Canada: CSA ZG62, ZG62Alclad. France: NF A-Z5GU. Spain: UNE L-371. Switzerland: VSM Al-Zn-Mg-Cu; Alclad, Al-Zn-Mg-Cu-pl. United Kingdom: BS L.95, L.96. Germany: DIN AlZnMgCu1.5; Werkstoff-Nr. 3.4365. ISO: AlZn6MgCu

Chemical Composition

Composition limits of 7075. 1.20 to 2.0 Cu, 2.1 to 2.9 Mg, 0.30 Mn max, 0.40 Si max, 0.50 Fe max, 0.18 to 0.28 Cr, 5.1 to 6.1 Zn, 0.20 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Composition limits of Alclad 7075. 7072 cladding--0.10 Cu max, 0.10 Mg max, 0.10 Mn max, 0.7 Si max + Fe, 0.8 to 1.3 Zn, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Aircraft structural parts and other highly stressed structural applications where very high strength and good resistance to corrosion are required

Precautions in use. Caution should be exercised in T6 temper applications where sustained tensile stresses are encountered, either residual or applied, particularly in the transverse grain direction. In such instances, the T73 temper should be considered, at some sacrifice in tensile strength.

Mechanical Properties

Tensile properties. See Tables 107 and 108.

Table 107 Typical tensile properties for alloy 7075 at various temperatures

Temperature	Tensile strength [(a)]	Yield strength (0.2% offset) [(a)]	Elongation[(b)], %

(a) In 50 mm (2 in.) or 4*d*, where *d* is diameter of reduce section of tensile test specimen. Where a range appears in this column, the specified minimum elongation varies with thickness of the mill product.

(b) For plate 13 mm (0.500 in.) or over in thickness, listed properties apply to core material only. Tensile and yield strengths of composite plate are slightly lower than listed value, depending on thickness of cladding.

Shear strength. Bare and Alclad products, O temper: 152 MPa (22 ksi). Bare products--T6, T651 tempers: 331 MPa (48 ksi); Alclad T6, T651: 317 MPa (46 ksi)

Hardness. O temper, 60 HB; T6, T651 temper, 150 HB; data obtained using 500 kg load, 10 mm diam ball, and 30 s duration of loading

Poisson's ratio. 0.33

Elevated-temperature effects. See Fig. 15 and 16.

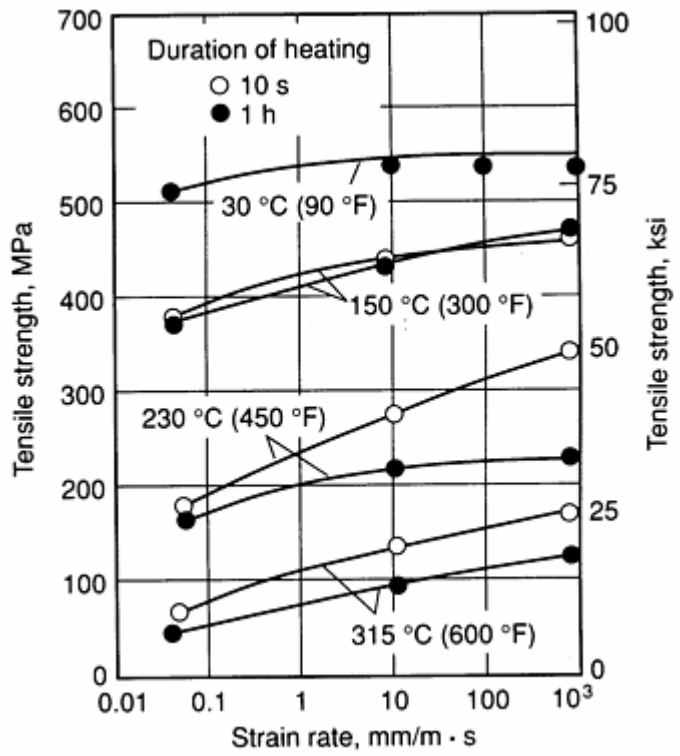

Fig. 15 Effect of strain rate and temperature on tensile strength of alloy 7075-T6

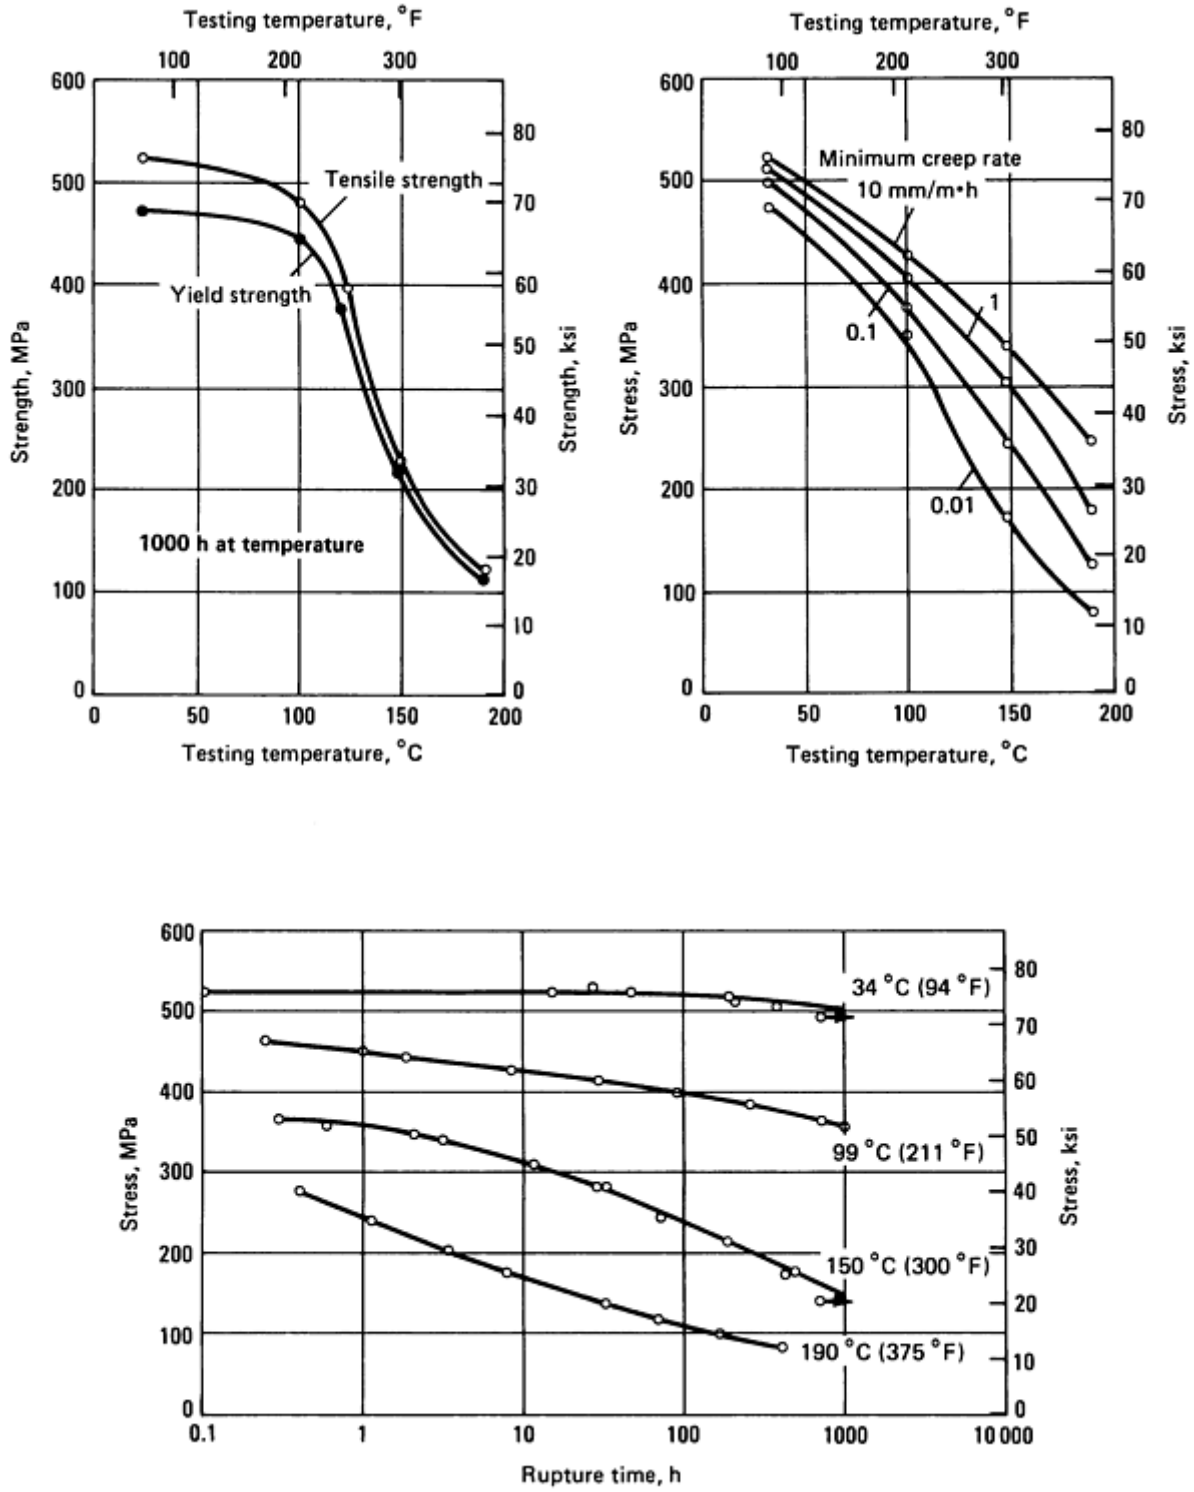

Fig. 16 Effect of temperature on tensile properties of Alclad 7075-T6

Elastic modulus. Tension, 71.0 GPa (10.3×10^6 psi); shear, 26.9 GPa (3.9×10^6 psi); compression, 72.4 GPa (10.5×10^6 psi)

Fatigue strength. T6, T651, T73 tempers: 159 MPa (23 ksi) at 5×10^8 cycles in R.R. Moore type test of smooth (unnotched) specimens

Plane-strain fracture toughness. See Table 109.

Table 109 Typical plane-strain fracture toughness of alloy 7075

Directional properties. Transverse mechanical properties of many products, particularly tensile strength and ductility in the short transverse direction, are less than those in the longitudinal direction.

Mass Characteristics

Density. 2.80 g/cm^3 (0.101 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 635 °C (1175 °F)

Solidus temperature. 477 °C (890 °F); eutectic temperature for nonhomogeneous as-cast or wrought material that has not been solution heat treated

Incipient melting temperature. 532 °C (990 °F) for homogenized (solution heat treated) wrought material

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.6	12.0
20 to 100	68 to 212	23.4	13.0
20 to 200	68 to 392	24.3	13.5
20 to 300	68 to 572	25.2	14.0

Volumetric: 68×10^{-6} $m^3/m^3 \cdot K$ (3.78×10^{-5} $in.^3/in.^3 \cdot °F$) at 20 °C (68 °F)

Specific heat. 960 J/kg · K (0.23 Btu/lb · °F) at 100 °C (212 °F)

Thermal conductivity. At 20 °C (68 °F). T6, T62, T651, T652 tempers: 130 W/m · (75 Btu/ft · h · °F). T76, T7651 tempers: 150 W/m · K (87 Btu/ft · h · °F). T73, T7351, T7352 tempers: 155 W/m · K (90 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F). T6, T62, T651, T652 tempers: 33% IACS. T76, T7651 tempers: 38.5% IACS. T73, T7351, T7352 tempers: 40% IACS

Electrical resistivity. At 20 °C (68 °F). T6, T62, T651, T652 tempers: 52.2 nΩ · m. T76, T7651 tempers: 44.8 nΩ · m. T73, T7351, T7352 tempers: 43.1 nΩ · m. Temperature coefficient, all tempers: 0.1 nΩ · m per K at 20 °C (68 °F)

Fabrication Characteristics

Annealing temperature. 415 °C (775 °F)

Solution temperature. 465 to 480 °C (870 to 900 °F), depending on product

Aging temperature. T6 temper: 120 °C (250 °F); T7 temper: two-stage treatment--107 °C (225 °F) followed by 163 to 177 °F (325 to 350 °F), depending on product

---

7076
7.5Zn-1.6Mg-0.55Mn-0.65Cu

Specifications

AMS. 4137

ASTM. B 247

Government. QQ-A-367, MIL-A-8097

Chemical Composition

Composition limits. 7.0 to 8.0 Zn, 1.2 to 2.0 Mg, 0.30 to 0.80 Mn, 0.3 to 1.0 Cu, 0.40 Si max, 0.60 Fe max, 0.20 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Aircraft propellers

Available forms. Forgings

Mechanical Properties

Tensile properties. T61 temper: tensile strength of 485 MPa (70 ksi), yield strength (0.2% offset) of 415 MPa (60 ksi), and elongation of 14% in 50 mm (12 in.)

Hardness. T61 temper: 140 HB (500 kg load).

Modulus of elasticity. 67 GPa (9.7×10^6 psi)

Physical Properties

Density. 2.82 g/cm^3 (0.102 lb/in.^{3})

Coefficient of thermal expansion. 21.6 μm/m · °C (12 μin./in. · °F) from 21 to 100 °C (70 to 212 °F)

Electrical conductivity. 35% IACS (volumetric)

Fabrication Characteristics

Solution anneal. T4 temper: heat to 493 °C (920 °F), quench in water.

Precipitation treatment. T6 temper: after solution anneal, heat at 120 °C (250 °F) for 24 h, air cool

Annealing treatment. O temper; heat to 415 to 455 °C (775 to 850 °F), soak for 2 h, air cool, reheat at 232 °C (450 °F), hold at temperature for 4 h, air cool. Or heat to 355 to 370 °C (670 to 700 °F), soak for 2 h, air cool to 232 °C (450 °F), soak 4 h, at 232 °C (450 °F), air cool

Stress-relief anneal. Heat to 355 to 370 °C (670 to 700 °F), soak for 2 h, air cool to room temperature.

7175
5.6Zn-2.5Mg-1.6Cu-O.23Cr

Commercial Names

Trade name. AA7175

Specifications

AMS. 4109, 4148, 4149, 4179

UNS number. A97175

Chemical Composition

Composition limits. 1.2 to 2.0 Cu, 2.1 to 2.9 Mg, 0.10 Mn max, 0.15 Si max, 0.20 Fe max, 0.18 to 0.28 Cr, 5.1 to 6.1 Zn, 0.10 Ti max, 0.05 max other (each), 0.15 max others (total)

Consequence of exceeding impurity limits. Degraded fracture toughness

Applications

Typical uses. Die and hand forgings for structural parts requiring very high strength, such as aircraft components. T736 tempers supply high strength, resistance to exfoliation corrosion and stress-corrosion cracking, high fracture toughness, and good fatigue resistance.

Mechanical Properties

Tensile properties. Typical. Tensile strength: T66 temper, 593 MPa (86 ksi); T736 temper, 524 MPa (76 ksi). Yield strength: T66 temper, 524 MPa (76 ksi); T736 temper, 455 MPa (66 ksi). Elongation: 11% in 50 mm (2 in.). See also Table 110.

Table 110 Typical mechanical properties of alloy 7175-T736 die forgings up to 75 mm (3 in.) thick

(a) In 50 mm (2 in.)

Shear strength. Typical. T66 temper: 324 MPa (47 ksi); T736 temper: 290 MPa (42 ksi)

Hardness. Typical. T66 temper, 150 HB; T736 temper, 145 HB; data obtained with 500 kg load, 10 mm diam ball, and 30 s duration of loading

Poisson's ratio. 0.33

Elastic modulus. Tension, 72 GPa(10.4×10^6 psi)

Fatigue strength. Typical. T66 and T736 tempers: 159 MPa (23 ksi)

Plane-strain fracture toughness. See Table 111.

Table 111 Plane-strain fracture toughness of alloy 7175-T736 forgings

Temper and orientation	**Plane-strain fracture toughness**			
	Minimum		**Average**

S-L	23.1	21	26.4	24

Mass Characteristics

Density. 2.80 g/cm^3 (0.100 lb/in.^{3}

Thermal Properties

Liquidus temperature. 635 °C (1175 °F)

Incipient melting temperature. 532 °C (990 °F) for homogenized (solution heat treated) wrought material

Eutectic temperature. 477 °C (890 °F) for nonhomogeneous as cast or wrought material that has not been solution heat treated

Coefficient of the thermal expansion. Linear:

Temperature range		**Average coefficient**	
°C	**°F**	**µm/m · K**	**µin./in. · °F**
-50 to 20	-58 to 68	21.6	12.0
20 to 100	68 to 212	23.4	13.0
20 to 200	68 to 392	24.3	13.5
20 to 300	68 to 572	25.2	14.0

Volumetric: 68 × 10^{-6} m^3/m^3 · K (3.78 × 10^{-5} in.^{3}/in.^{3} · °F) at 20 °C (68 °F)

Specific heat. 864 J/kg · K (0.206 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 20 °C (68 °F): O temper, 177 W/m · K (102 Btu/ft · h · °F); T66 temper, 142 W/m · K (82 Btu/ft · h · °F) T736, T73652 tempers, 155 W/m · K (90 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): O temper, 46% IACS; T66 temper, 36% IACS; T736, T73652 tempers, 40% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 37.5 nΩ · m; T66 temper, 47.9 nΩ · m, T736, T73652 tempers, 43.1 nΩ · m. Temperature coefficient, all tempers: 0.1 nΩ · m per K at 20 °C (68 °F)

Fabrication Characteristic

Annealing temperature. 415 °C (775 °F)

Solution temperature. 515 °C (960 °F); must be preceded by soak at 477 to 485 °C (890 to 905 °F). Quench from lower temperature.

Aging temperature. 120 to 175 °C (250 to 350 °F)

7178, Alclad 7178
6.8Zn-2.7Mg-2.0Cu-0.3Cr

Specifications

AMS. Extruded wire, rod, bar, shapes, and tube, 4158. Alclad 7178, sheet and plate: 4051, 4052

ASTM. See Table 112.

Table 112 Standard specifications for alloy 7178

Mill form and condition	Specification number	
	ASTM	Government
Sheet and plate	B 209	QQ-A-250/14
	. . .	QQ-A-250/21
Wire, rod, bar, shapes, and tube (extruded)	B 221	QQ-A-200/13
	. . .	QQ-A-200/14
Rivet wire	B 316	. . .
Tube (extruded, seamless)	B 241	. . .
Alclad sheet and plate	B 209	QQ-A-250/15
	. . .	QQ-A-250/22

SAE. J454

UNS number. A97178

Government. See Table 112.

Chemical Composition

Composition limits of 7178. 1.6 to 2.4 Cu, 2.4 to 3.1 Mg, 0.30 Mn max, 0.40 Si max, 0.50 Fe max, 0.18 to 0.35 Cr, 6.3 to 7.3 Zn, 0.20 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Composition limits of Alclad 7178. 7011 cladding--0.05 Cu max, 1.0 to 1.6 Mg, 0.10 to 0.30 Mn, 0.15, Si max, 0.20 Fe max, 0.08 to 0.20 Cr, 4.0 to 5.5 Zn, 0.05 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al. 7072 cladding--0.10 max Cu, 0.10 Mg max, 0.10 Mn max, 0.70 Si max + Fe, 0.8 to 1.3 Zn, 0.05 max other (each), 0.15 max others (total), bal Al

Applications

Typical uses. Aircraft and aerospace applications where high compressive yield is design criteria

Precautions in use. T6 temper is highly susceptible to exfoliation corrosion. T76 temper has mechanical properties comparable to 7075-T6 and provides improved resistance to exfoliation corrosion.

Mechanical Properties

Tensile properties. See Table 113.

Table 113 Typical tensile properties of alloy 7178

Temperature		Tensile strength [(a)]		Yield strength (0.2% offset) [(a)]		Elongation[(b)], %

(a) Lowest strength for exposures up to 10,000 h at temperature, no load; test loading applied at 35 MPa/min (5 ksi/min) to yield strength and then at strain rate of 5%/min to fracture.

(b) In 50 mm (2 in.)

Shear strength. T6, T6510, T6511 tempers: 305 MPa (44 ksi). T76, T76510, T76511 tempers: 295 MPa (43 ksi)

Compressive strength. T6, T6510, T6511 tempers: 530 MPa (77 ksi) at 0.1% permanent set. T76, T76510, T76511 tempers: 460 MPa (67 ksi) at 0.1% permanent set

Bearing properties. T6, T6510, T6511 tempers; bearing strength, 1035 to 110 MPa (150 to 160 ksi); bearing yield strength, 680 to 730 MPa (99 to 106 ksi). T76, T76510, T76511 tempers: bearing strength, 965 MPa (140 ksi); bearing yield strength, 740 MPa (107 ksi). All data for e/d ratio of 2.0, where e is edge distance and d is pin diameter *Poisson's ratio.* 0.33

Elastic modulus. Tension, 71.7 GPa (10.4×10^6 psi); shear, 27.5 GPa (4.0×10^6 psi); compression, 73.7 GPa (10.7×10^6 psi)

Fatigue strength. T76 type tempers: 200 to 290 MPa (29 to 42 ksi) at 10^7 cycles in axial fatigue tests (R = 0.0) of smooth specimens; 130 to 195 MPa (19 to 28 ksi) at 10^8 cycles in rotating beam tests (R = -1.0) of polished specimens; 28 to 55 MPa (4 to 8 ksi) at 10^8 cycles in rotating beam tests (R = -1.0) of 60° V-notched specimens (K_t = 3.0)

Creep-rupture characteristics. See Table 114.

Table 114 Creep-rupture properties of alloy 7178-T6

Temperature		Time under stress, h	Rupture stress		Stress for creep of:							
					1.0%		0.5%		0.2%		0.1%

		1000	28	4	23	3.4	. . .	. . .	. . .	. . .	. . .	. . .

Mass Characteristics

Density. 2.83 g/cm^3 (0.102 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 629 °C (1165 °F)

Eutectic temperature. 477 °C (890 °F)

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in · ° F
-50 to 20	-58 to 68	21.7	12.1
20 to 100	68 to 212	23.5	13.1
20 to 200	68 to 392	24.4	13.6
20 to 300	68 to 572	25.4	14.1

Volumetric: 68 × 10^{-6} m^3/m^3 · K (3.78 × 10^{-5} in.^{3}/in.^{3} · °F)

Specific heat. 856 J/kg · K (0.205 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. At 20 °C (68 °F): O temper, 180 W/m · K (104 Btu/ft · h · °F); T6, T651 tempers, 127 W/m · K (73 Btu/ft · h · °F); T76, T7651 tempers, 152 W/m · K (88 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): O temper, 46% IACS; T6, T651 tempers, 32% IACS; T76, T7651 tempers, 39% IACS

Electrical resistivity. At 20 °C (68 °F): O temper, 37.5 nΩ · m; T6, T651 tempers, 53.9 nΩ · m; T76, T7651 tempers, 44.2 nΩ · m. Temperature coefficient, all tempers: 0.1 nΩ · m per K at 20 °C (68 °F)

Electrolytic solution potential. T6 temper: -0.81 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Annealing temperature: 415 °C (775 °F)

Solution temperature: 468 °C (875 °F)

Aging temperature. T6 and T7 tempers, 121 °C (250 °F) for 24 h

---

7475
5.7Zn-2.3Mg-1.5Cu-0.022Cr

Specifications

AMS. 4084, 4085, 4089, 4090

UNS number. A94475

Chemical Composition

Composition limits. 1.2 to 1.9 Cu, 1.9 to 2.6 Mg, 0.06 Mn max, 0.18 to 0.25 Cr, 0.12 Fe max, 0.10 Si max, 5.2 to 6.2 Zn, 0.06 Ti max, 0.05 max other (each), 0.15 max others (total), bal Al

Consequence of exceeding impurity limits. Degrades fracture toughness

Applications

Typical uses. Bare and Alclad sheet and plate for aircraft fuselage and wing skins, spars, and bulkheads. Other structural applications requiring a combination of high strength and high fracture toughness

Mechanical Properties

Tensile properties. See Table 115.

Table 115 Typical tensile properties of alloy 7475 at various temperatures

Temperature		Time at temperature, h	At indicated temperature					At room temperature after heating				
			Tensile strength		Yield strength		Elongation[(a)] %	Tensile strength		Yield strength		Elongation[(a)] %

(a) In 50 mm (2 in.)

Shear strength. Plate: T651 temper, 296 MPa (43 ksi); T7351, T7651 tempers, 269 MPa (39 ksi)

Compressive strength. At 0.1% permanent set. Plate: T651 temper, 476 MPa (69 ksi); T7351 temper, 379 MPa (55 ksi); T7651 temper, 414 MPa (60 ksi)

Bearing properties. Plate, all data for e/d ratio of 2.0, where e is edge distance and d is pin diameter. T761 temper: bearing strength, 990 MPa (144 ksi); bearing yield strength, 730 MPa (106 ksi). T7351 temper: bearing strength, 875 MPa (127 ksi); bearing yield strength, 640 MPa (93 ksi). T7651 temper: bearing strength, 925 MPa (134 ksi); bearing yield strength, 655 MPa (95 ksi)

Poisson's ratio. 0.33

Elastic modulus. Tension, 70 GPa (10.2×10^6 psi); shear, 27 GPa (3.9×10^6 psi); compression, 73 GPa (10.6×10^6 psi)

Fatigue strength. At 10^7 cycles in axial fatigue tests of smooth specimens from T7351 plate. Longitudinal or transverse orientation: 205 to 235 MPa (30 to 34 ksi) for $R = 0.0$. Transverse orientation: 315 MPa (46 ksi) for $R = +0.5$; 165 MPa for $R = -1.0$

Plane-strain fracture toughness. See Table 116.

Table 116 Typical fracture-toughness values for alloy 7475

Mass Characteristics

Density. 2.80 g/cm^3 (0.101 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 635 °C (1175 °F)

Incipient melting temperature. 538 °C (1000 °F) for homogenized (solution heat treated) wrought material

Eutectic temperature. 477 °C (890 °F) for as-cast or inhomogeneous wrought material that has not been solution heat treated

Coefficient of thermal expansion. Linear:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
-50 to 20	-58 to 68	21.6	12.0
20 to 100	68 to 212	23.4	13.0
20 to 200	68 to 392	24.3	13.5

Fabrication Characteristics

Annealing temperature. 415 °C (775 °F)

Solution temperature. 515 °C (960 °F); must be preceded by soak at 465 to 477 °C (870 to 890 °F)

Aging temperature. 120 to 175 °C (250 to 350 °F)

Aluminum Foundry Products

Revised by A. Kearney, Avery Kearney & Company; Elwin L. Rooy, Aluminum Company of America

Introduction

ALUMINUM CASTING ALLOYS are the most versatile of all common foundry alloys and generally have the highest castability ratings. As casting materials, aluminum alloys have the following favorable characteristics:

- Good fluidity for filling thin sections
- Low melting point relative to those required for many other metals
- Rapid heat transfer from the molten aluminum to the mold, providing shorter casting cycles
- Hydrogen is the only gas with appreciable solubility in aluminum and its alloys, and hydrogen solubility in aluminum can be readily controlled by processing methods
- Many aluminum alloys are relatively free from hot-short cracking and tearing tendencies
- Chemical stability
- Good as-cast surface finish with lustrous surfaces and little or no blemishes

Aluminum alloy castings are routinely produced by pressure-die, permanent-mold, green-and dry-sand, investment, and plaster casting. Aluminum alloys are also readily cast with vacuum, low-pressure, centrifugal, and pattern-related processes such as lost foam. Total shipments of aluminum foundry products (all types of castings exclusive of ingot) in the United States for 1988 were about 10^6 Mg(10^6 tons), of which about 68% was accounted for by die castings (see the shipment statistics in the article "Introduction to Aluminum and Aluminum Alloys" in this Volume).

Aluminum Foundry Products

Revised by A. Kearney, Avery Kearney & Company; Elwin L. Rooy, Aluminum Company of America

Alloy Systems

Aluminum casting alloys are based on the same alloy systems as those of wrought aluminum alloys, are strengthened by the same mechanisms (with the exception of strain hardening), and are similarly classified into non-heat-treatable and heat-treatable types. The major difference is that the casting alloys used in the greatest volumes contain alloying additions of silicon far in excess of that found (or used) in most wrought alloys. Aluminum casting alloys must contain, in addition to strengthening elements, sufficient amounts of eutectic-forming elements (usually silicon) in order to have adequate fluidity to feed the shrinkage that occurs in all but the simplest castings.

The phase behavior of aluminum-silicon compositions (Fig. 1) provides a simple eutectic-forming system, which makes possible the commercial viability of most high-volume aluminum casting. Silicon contents, ranging from about 4% to the eutectic level of about 12% (Fig. 1), reduce scrap losses, permit production of much more intricate designs with greater variations in section thickness, and yield castings with higher surface and internal quality. These benefits derive from the effects of silicon in increasing fluidity, reducing cracking, and improving feeding to minimize shrinkage porosity.

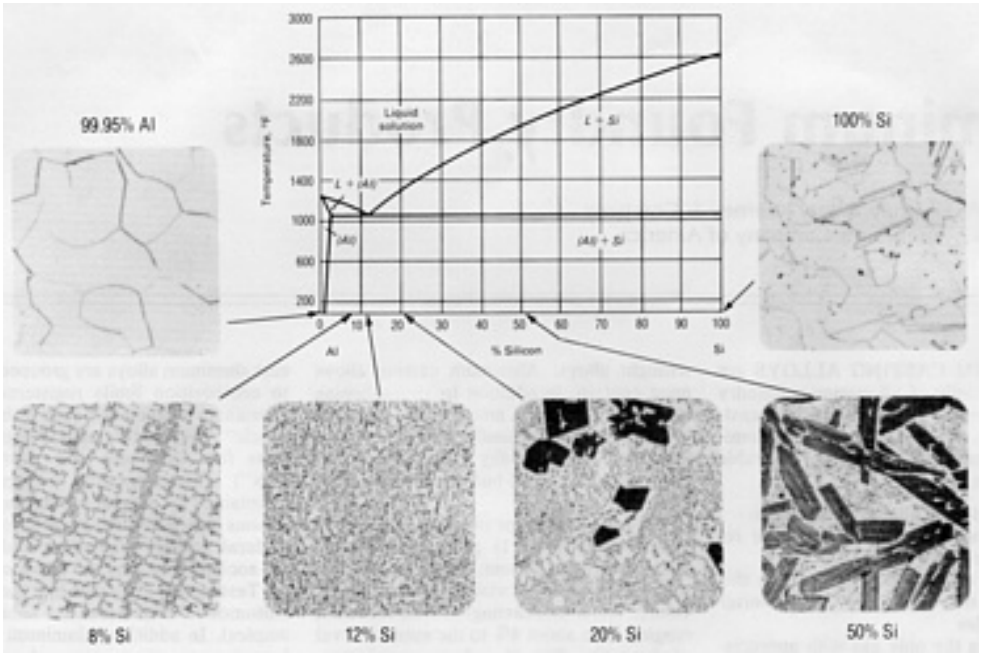

Fig. 1 Aluminum-silicon phase diagram and cast microstructures of pure components and of alloys of various compositions. Alloys with less than 12% Si are referred to as hypoeutectic, those with close to 12% Si as eutectic, and those with over 12% Si as hypereutectic.

The required amounts of eutectic formers depend in part on the casting process. Alloys for sand casting generally are lower in eutectics than those for casting in metal molds because the sand molds can tolerate a degree of hot shortness that would lead to extensive cracking in nonyielding metal molds. Resistance to cracking during casting is favored by a small range of solidification temperature, which drops from about 78 °C (140 °F) at 1% Si to zero at about 12% Si. Good feeding characteristics to minimize shrinkage porosity are benefited by a profile of volume fraction solidified versus temperature that is weighted toward the lower portion of the temperature range--that is, toward increased eutectic concentration.

In the binary aluminum-silicon system, under the nonequilibrium conditions of casting, the volume fraction of eutectic increases linearly from about 0 to 1 as silicon content increases from 1 to 12%.

Alloy Groupings and Designations

Although the systems used to identify and group aluminum casting alloys are not internationally standardized, each nation (and in many cases individual firms) has developed its own alloy nomenclature. In the United States and North America, for example, cast aluminum alloys are grouped according to composition limits registered with the Aluminum Association (see Table 3 in the article "Alloy and Temper Designation Systems for Aluminum and Aluminum Alloys"). Comprehensive listings are also maintained by general procurement specifications issued through government agencies (federal, military, and so on) and by technical societies such as the American Society for Testing and Materials and the Society of Automotive Engineers (see Table 1 for examples). In addition, aluminum casting alloys are sometimes grouped according to their quality level or intended end-use application (see the section "Selection of Casting Alloys"). Of these various methods, the grouping of aluminum casting alloys in terms of chemical compositions is discussed below.

Table 1 Cross-reference chart of frequently used specifications for aluminum alloy sand and permanent mold (PM) castings

(a) Former designations. ASTM adopted the Aluminum Association designation system in 1974.

(b) Former designations used in SAE specifications J452 and/or J453. In 1990, SAE adopted the ANSI/Aluminum Association numbering system for alloys. SAE J453-1986 has also superceded SAE J452.

(c) Designation in MIL-21180c.

(d) Alloy 356.0 is specified in AMS 4217, 4260, 4261, 4284, 4285, and 4286.

(e) Alloy 512.0 is no longer active; it is included for reference purpose only.

The Aluminum Association designation system attempts alloy family recognition by the following scheme:

- 1*xx.x:* Controlled unalloyed compositions
- 2*xx.x:* Aluminum alloys containing copper as the major alloying element
- 3*xx.x:* Aluminum-silicon alloys are also containing magnesium and/or copper
- 4*xx.x:* Binary aluminum-silicon alloys
- 5*xx.x:* Aluminum alloys containing magnesium as the major alloying element
- 6*xx.x;* Currently unused
- 7*xx.x:* Aluminum alloys containing zinc as the major alloying element, usually also containing additions of either copper, magnesium, chromium, manganese, or combinations of these elements
- 8*xx.x* Aluminum alloys containing tin as the major alloying element
- 9*xx.x* Currently unused

Designations in the form *xxx*.1 and *xxx*.2 include the composition of specific alloys in remelt ingot form suitable for foundry use. Designations in the form *xxx*.0 in all cases define composition limits applicable to castings. Further variations in specified compositions are denoted by prefix letters used primarily to define differences in impurity limits. Accordingly, one of the most common gravity cast alloys, 356, has variations A356, B356, and C356; each of these alloys has identical major alloy contents but has decreasing specification limits applicable to impurities, especially iron content.

Composition limits of casting alloys registered with the Aluminum Association are given in Table 3 in the article "Alloy and Temper Designation Systems for Aluminum and Aluminum Alloys."

In designations of the 1*xx.x* type, the second and third digits indicate minimum aluminum content (99.00% or greater); these digits are the same as the two to the right of the decimal point in the minimum aluminum percentage expressed to the nearest 0.01%. The fourth digit in 1*xx.x* designations, which is to the right of the decimal point, indicates product form: 0 denotes castings (such as electric motor rotors), and 1 denotes ingot.

In 2*xx.x* through 8*xx.x* designations for aluminum alloys, the second and third digits have no numerical significance but only identify the various alloys in the group. The digit to the right of the decimal point indicates product form: 0 denotes castings, 1 denotes standard ingot, and 2 denotes ingot having composition ranges narrower than but within those of standard ingot. Alloy modifications, as previously mentioned, are identified by a capital letter preceding the numerical designation.

Alloying-element and impurity limits for ingot are the same as those for castings of the same alloy except that, when the ingot is remelted for making castings, iron and zinc contents tend to increase and magnesium content tends to decrease.

General Composition Groupings. Although the nomenclature and designations for various casting alloys are standardized in North America, many important alloys have been developed for engineered casting production worldwide. For the most part, each nation (and in many cases the individual firm) has developed its own alloy nomenclature. Excellent references are available that correlate, cross reference, or otherwise define significant compositions in international use (Ref 1, 2).

Although a large number of aluminum alloys has been developed for casting, there are six basic types:

- Aluminum-copper
- Aluminum-copper-silicon
- Aluminum-silicon
- Aluminum-magnesium
- Aluminum-zinc-magnesium
- Aluminum-tin

Aluminum-copper alloys that contain 4 to 5% Cu, with the usual impurities iron and silicon and sometimes with small amounts of magnesium, are heat treatable and can reach quite high strengths and ductilities, especially if prepared from ingot containing less than 0.15% Fe. The aluminum-copper alloys are single-phase alloys. Unlike the silicon alloys, there is no highly fluid second phase available at the late stages of solidification. When available, a second phase will aid the required feeding of shrinkage areas and will help compensate for solidification stresses.

When these alloys, and other single-phase alloys, are cast using permanent mold or other rigid mold casting methods, special techniques are required to relieve solidification stresses. Careful techniques are also usually needed to promote the progress of the metal solidification from the remote areas of the casting to the hotter and more liquid casting areas, to the risers, and then to the riser feeders. When these necessary and more exacting casting techniques are used, the aluminum-copper alloys can and have been successfully used to produce high-strength and high-ductility castings. More exacting casting techniques are also helpful and required when casting other single-phase aluminum casting alloys or alloy systems.

In terms of alloy additions, manganese in small amounts may be added, mainly to combine with the iron and silicon and reduce the embrittling effect of essentially insoluble phases. However, these alloys demonstrate poor castability and require more carefully designed gating and more extensive risering if sound castings are to be obtained. Such alloys are used mainly in sand casting; when they are cast in metal molds, silicon must be added to increase fluidity and curtail hot shortness, and this addition of silicon substantially reduces ductility.

Al-Cu alloys with somewhat higher copper contents (7 to 8%), formerly the most commonly used aluminum casting alloys, have steadily been replaced by Al-Cu-Si alloys and today are used to a very limited extent. The best attribute of higher-copper Al-Cu alloys is their insensitivity to impurities. However, these alloys display very low strength and only fair castability.

Also in limited use are Al-Cu alloys that contain 9 to 11% Cu, whose high-temperature strength and wear resistance are attractive for use in aircraft cylinder heads and in automotive (diesel) pistons and cylinder blocks.

Very good high-temperature strength is an attribute of alloys containing copper, nickel, and magnesium, sometimes with iron in place of part of the nickel.

Aluminum-Copper-Silicon Alloys. The most widely used aluminum casting alloys are those that contain silicon and copper. The amounts of both additions vary widely, so that the copper predominates in some alloys and the silicon in others. In these alloys, the copper contributes to strength, and the silicon improves castability and reduces hot shortness; thus, the higher-silicon alloys normally are used for more complex castings and for permanent mold and die casting processes, which often require the use of more exacting casting techniques to avoid problems with hot-short alloys.

Al-Cu-Si alloys with more than 3 to 4% Cu are heat treatable, but usually heat treatment is used only with those alloys that also contain magnesium, which enhances their response to heat treatment. High-silicon alloys (>10% Si) have low thermal expansion, an advantage in some high-temperature operations. When silicon content exceeds 12 to 13% (silicon contents as high as 22% are typical), primary silicon crystals are present, and if properly distributed, impart excellent wear resistance. Automotive engine blocks and pistons are major uses of these hypereutectic alloys.

Aluminum-silicon alloys that do not contain copper additions are used when good castability and good corrosion resistance are needed. Metallographic structures of the pure components and of several intermediate compositions are shown in Fig. 1. The intermediate compositions are mixtures of aluminum containing about 1% Si in solid solution as the continuous

phase, with particles of essentially pure silicon. Alloys with less than 12% Si are referred to as hypoeutectic, those with close to 12% Si as eutectic, and those with over 12% Si as hypereutectic.

If high strength and hardness are needed, magnesium additions make these alloys heat treatable. Alloys with silicon contents as low as 2% have been used for casting, but silicon content usually is between 5 and 13%. Strength and ductility of these alloys, especially those with higher silicon, can be substantially improved by modification of the Al-Si eutectic. Modification of hypoeutectic alloys (<12% Si) is particularly advantageous in sand castings and can be effectively achieved through the addition of a controlled amount of sodium or strontium, which refines the eutectic phase. Calcium and antimony additions are also used. Pseudomodification, in which the fineness of the eutectic but not the structure is affected, may be achieved by control of solidification rates.

In hypereutectic Al-Si alloys, refinement of the proeutectic silicon phase by phosphorus additions is essential for casting and product performance.

Aluminum-magnesium casting alloys are essentially single-phase binary alloys with moderate-to-high strength and toughness properties. High corrosion resistance, especially to seawater and marine atmospheres, is the primary advantage of castings made of Al-Mg alloys. Best corrosion resistance requires low impurity content (both solid and gaseous), and thus alloys must be prepared from high-quality metals and handled with great care in the foundry. These alloys are suitable for welded assemblies and are often used in architectural and other decorative or building needs. Aluminum-magnesium alloys also have good machinability and an attractive appearance when anodized. In comparison to the aluminum-silicon alloys, all the aluminum-magnesium alloys require more care in gating and greater temperature gradients to produce sound castings. This often means more chilling and larger risers. Also, careful melting and pouring practices are needed to compensate for the greater oxidizing tendency of these alloys when molten. This care is also needed because many of the applications of these alloys require polishing and/or fine surface finishing, where defects caused by oxide inclusions are particularly undesirable. The relatively poor castability of Al-Mg alloys and the tendency of the magnesium to oxidized increase handling difficulties, and therefore, cost.

Aluminum-Zinc-magnesium alloys naturally age, achieving full strength by 20 to 30 days at room temperature after casting. This strengthening process can be accelerated by artificial aging. The high-temperature solution heat treatment and drastic quenching required by other alloys (Al-Cu and Al-Si-Mg alloys, for example) are not necessary for optimum properties in most Al-Zn-Mg alloy castings. However, microsegregation of Mg-Zn phases can occur in these alloys, which reverses the accepted rule that faster solidification results in higher as-cast properties. When it is found in an Al-Zn-Mg alloy casting that the strength of the thin or highly chilled sections are lower than the thick or slowly cooled sections, the weaker sections can be strengthened to the required level by solution heat treatment and quenching, followed by natural or artificial (furnace) aging.

These alloys have moderate to good tensile properties in the as-cast condition. With annealing, good dimensional stability in use is developed. The eutectic melting points of alloys of this group are high, an advantage in castings that are to be assembled by brazing. The alloys have good machinability (and resistance to general) corrosion, despite some susceptibility to stress corrosion). They are not generally recommended for service at elevated temperatures. The tensile properties of these alloys develop at room temperatures during the first few weeks after casting due to precipitation hardening. This process continues thereafter at a progressively slower rate. Heat treatments of the T6 and T7 type may be applied to the 707.0, 771.0, and 772.0 alloys.

Castability of Al-Zn-Mg alloys is poor, and careful control of solidification conditions is required to produce sound, defect-free castings. Moderate to steep temperature gradients are required to assure adequate feeding to prevent shrinkage defects. Hot tear cracking where resistance to contraction during solidification and cooling is resisted. However, good foundry techniques and control have enabled well-qualified sand foundries to produce relatively intricate castings. Permanent mold castings, except for relatively simple designs, can be difficult.

Aluminum-tin alloys that contain about 6% Sn (and small amounts of copper and nickel for strengthening) are used for cast bearings because of the excellent lubricity imparted by tin. These tin-containing alloys were developed for bearing applications (in which load-carrying capacity, fatigue strength, and resistance, to corrosion by internal-combustion lubricating oil are important criteria). Bearings of aluminum-tin alloys are superior overall to bearings made using most other materials.

Aluminum-tin casting Alloys 850.0, 851.0, and 852.0 can be cast in sand or permanent molds. However, 850.0 (6.3Sn-1 Cu-1 Ni) and 852.0 (6.3Sn-2 Cu-1.2 Ni-0.8Mg) usually are cast in permanent molds. Major applications are for

connecting rods and crankcase bearings for diesel engines. Sand cast bearings, such as large rolling mill bearings, usually are made of alloy 851.0 (6.3Sn-2.5 Si-1Cu-0.5Ni).

Bearing performance of Al-Sn alloys is strongly affected by casting method. Fine interdendritic distribution of tin, which is necessary for optimum bearing properties, requires small interdendritic spacing, and small spacing is obtained only with casting methods in which cooling is rapid.

From a foundry standpoint, the aluminum-tin alloy system is unique. In the mold, the solidification starts at about 650 °C (1200 °F), and the tin constituents of the alloy are liquid until 229 °C (444 °F). This extremely large solidification range presents unique problems. Rapid solidification rates are recommended to avoid excessive macrosegregation.

Some 850.0 T5 castings are cold worked by reducing the axial dimension 4% (T101 temper). This provides a substantial increase in the compressive yield strength.

Aluminum-lithium casting alloys may offer the same benefits as their wrought counterparts but have not been developed or commercialized as have the wrought aluminum-lithium alloys. (See the article "Aluminum-Lithium Alloys" in this Volume.) The wrought and cast aluminum-lithium alloys consist of aluminum-copper alloys with lithium additions to reduce weight and improve strength.

The behavior of both cast and wrought Al-Li alloys differs from conventional aluminum alloys in terms of fracture mechanisms and temperature effects on mechanical properties. Unlike conventional aluminum alloys, the toughness of Al-Li alloys does not increase with increasing aging temperature beyond the point of overaging (that is, the point required for peak strength). The benefits of reduced density and improved modulus of elasticity are the main incentives in the development of Al-Li alloys.

Aluminum-Base Metal-Matrix Composite (MMC) for casting. Although aluminum-ceramic composites offer exceptional specific stiffness (elastic modulus-to-weight ratio), the initial development (prior to 1986) of aluminum-base MMC materials required energy- or labor-intensive methods, such as powder metallurgy, thermal spray, diffusion bonding, and high-pressure squeeze casting. None of the composites produced from these methods could be remelted and shape cast, and each proved to be prohibitively expensive for most applications, even in the aerospace/defense sector.

An ingot-metallurgical method for producing a castable aluminum-base MMC material with the trade name of Duralcan was introduced in 1986. The product consists, in foundry ingot form, of foundry alloys to which 10, 15, or 20 vol% of particulate silicon carbide (SiC) had been added. The most attractive feature of this ingot-metallurgical product is its low cost, especially at industrial production levels, and its ability to be remelted without an impairment of properties. The Al-SiC composite foundry ingot can be remelted and shape cast easily using standard aluminum foundry practices and equipment. The casting methods successfully demonstrated to date have been sand, permanent mold, low-pressure permanent mold, high-pressure die casting, and investment casting, both shell and plaster. Additional information on castable aluminum-base MMC materials is given in the section "Discontinuous Aluminum MMC" in the article "Metal-Matrix Composites" in this Volume.

Selection of Casting Alloys

The major factors that influence alloy selection for casting applications include casting process to be used, casting design, required properties, and economic (and availability) considerations. These five factors consist of the following characteristics of an alloy:

- *Casting process considerations:* fluidity, resistance to hot tearing, solidification range
- *Casting design considerations:* solidification range, resistance to hot tearing, fluidity, die soldering (die casting)
- *Mechanical-property requirements:* strength and ductility, heat treatability, hardness
- *Service requirements:* pressure tightness characteristic, corrosion resistance, surface treatments, dimensional stability, thermal stability
- *Economics:* machinability, weldability, ingot and melting costs, heat treatment

Several of these characteristics for various alloys are listed in Tables 2 and 3. Table 2 gives the solidification range and thermal properties, while Table 3 ranks various alloys in terms of castability, corrosion resistance, machinability, and weldability. Note that the rankings in Table 3 can vary with the casting process. Each casting process may also require specific metal characteristics. For example, die and permanent mold casting generally require alloys with good fluidity and resistance to hot tearing, whereas these properties are less critical in sand, plaster, and investment casting, where molds and cores offer less resistance to shrinkage.

(a) Ability of alloy to withstand stresses from contraction while cooling through hot short or brittle temperature range.

(b) Ability of liquid alloy to flow readily in mold and to fill thin sections.

(c) Decrease in volume accompanying freezing of alloy and a measure of amount of compensating feed metal required in form of risers.

(d) Based on resistance of alloy in standard salt spray test.

(e) Composite rating based on ease of cutting, chip characteristics, quality of finish, and tool life.

(f) Based on ability of material to be fusion welded with filler rod of same alloy

Also note that Table 2 groups aluminum casting alloys into the following nine categories:

- Rotor alloys
- Commercial Duralumin alloys
- Premium casting alloys
- Piston and elevated-temperature alloys
- Standard, general-purpose alloys
- Die castings
- Magnesium alloys (see the earlier section "General Composition Groupings" in this article)
- Aluminum-zinc-magnesium alloys (see the section "General Composition Groupings")
- Bearing alloys

This grouping of alloys is useful in the selection of alloys because many foundries are dedicated to a particular type of casting alloy. Each group, with the exception of the magnesium and the Al-Zn-Mg alloy groups, is discussed below.

Rotor Castings. Most cast aluminum motor rotors are produced in the carefully controlled pure-alloy conditions 100.0, 150.0, and 170.0 (99.0, 99.5, and 99.7% Al, respectively). Impurities in these alloys are controlled to minimize variations in electrical performance based on conductivity and to minimize the occurrence of microshrinkage and cracks during casting. Minimum and typical conductivities for each alloy grade are:

Alloy	Minimum conductivity, %IACS	Typical conductivity, %IACS
100.1	54	56
150.1	57	59
170.1	59	60

(a) IACS, International Copper Annealed Standard

Rotor alloy 100.0 contains a significantly larger amount of iron and other impurities, and this generally improves castability. With higher iron content crack resistance is improved, and a lower tendency toward shrinkage formation will be observed. This alloy is recommended when the maximum dimension of the part is greater than 125 mm (5 in.). For the same reasons, Alloy 150.0 is preferred over 170.0 in casting performance.

For motor rotors requiring high resistivity (for example, motors with high starting torque) the more highly alloyed die casting compositions are commonly used. The most popular are Alloys 443.2 and A380.2. By choosing alloys such as these, conductivities from 25 to 35% IACS can be obtained; in fact, highly experimental alloys with even higher resistivities have been developed for motor rotor applications.

Although gross casting defects may adversely affect electrical performance, the conductivity of alloys employed in rotor manufacture is more exclusively controlled by composition. Table 4 lists the effects of the various elements in and out of solution on the resistivity of aluminum. Simple calculation using these values accurately predicts total resistivity and its reciprocal conductivity for any composition. A more general and easy-to-use formula for conductivity that offers sufficient accuracy for most purposes is:

$$\text{Conductivity, \%IACS} = 63.50 - 6.9x - 83y$$

where 63.5% is the conductivity of very pure aluminum in %IACS, x = iron + silicon (in wt%), and y = titanium + vanadium + manganese + chromium (in wt%).

Table 4 Effect of elements in and out of solid solution on the resistivity of aluminum

Element	Maximum solubility in Al, %	Average increase[a] in resistivity per wt%, microhm-cm	
		In solution	Out of solution[b]
Chromium	0.77	4.00	0.18
Copper	5.65	0.344	0.030
Iron	0.052	2.56	0.058
Lithium	4.0	3.31	0.68
Magnesium	14.9	0.54[c]	0.22[c]
Manganese	1.82	2.94	0.34

Nickel	0.05	0.81	0.061
Silicon	1.65	1.02	0.088
Titanium	1.0	2.88	0.12
Vanadium	0.5	3.58	0.28
Zinc	82.8	0.094[(d)]	0.023[(d)]
Zirconium	0.28	1.74	0.044

(a) Add above increase to the base resistivity for high-purity aluminum, 2.65 microhm-cm at 20 °C (68 °F) or 2.71 microhm-cm at 25 °C (77 °F).

(b) Limited to about twice the concentration given for the maximum solid solubility, except as noted.

(c) Limited to approximately 10%.

(d) Limited to approximately 20%

References to specific composition limits and manufacturing techniques for rotor alloys show the use of composition controls that reflect electrical considerations. The peritectic elements are limited because their presence is harmful to electrical conductivity. The prealloyed ingots produced to these specifications control conductivity by making boron additions, which form complex precipitates with these elements before casting. In addition the iron and silicon contents are subject to control with the objective of promoting the alpha Al-Fe-si phase intermetallics least harmful to castability. Ignoring these important relationships results in variable electrical performance, and of at least equal importance, variable casting results.

Commercial Duralumin Alloys. These alloys were first produced and were named by Durener Metallwerke Aktien Gesellschaft in the early 1900s. They were the first heat-treatable aluminum alloys.

The Duralumin alloys have been used extensively as cast and wrought products where high strength and toughness are required. Being essentially a single-phase alloy, improved ductility at higher strengths is inherent as compared to the two-phase silicon alloys. However, this difference also makes these alloys more difficult to cast.

After World War I, the European aluminum casting community developed AU5GT (204 type) and similar Al-Cu-Mg alloys. In the United States, alloys 195 and B195 of the Al-Cu-Si composition were popularized. Between World Wars I and II, and in both communities, these alloys served well in the special situations in which strength and toughness were required. This came at the expense of the extra production costs required because of the poorer castability.

Since World War II, the higher-purity aluminum available from the smelters has enabled the foundryman to make substantial improvements in the mechanical properties of highly castable Al-Si, Al-Si-Cu, and Al-Si-Mg alloys. As a result, the use of the Duralumin alloys has dramatically decreased.

The more recently developed Al-Cu-Mg alloys and applications include many that emphasize the unusual strength and toughness achievable with impurity controls. New developments in foundry equipment and control techniques also have helped some foundries to solve the castability problems.

Premium-quality castings provide higher levels of quality and reliability than are found in conventionally produced parts. These castings may display optimum properties in one or more of the following characteristics: mechanical properties (determined by test coupons machined from representative parts), soundness (determined radiographically), dimensional accuracy, and finish. However, castings of this classification are notable primarily for the mechanical property attainment that reflects extreme soundness, fine dendrite-arm spacing, and well-refined grain structure. These technical objectives require the use of chemical compositions competent to display the premium engineering properties. Alloys considered to be premium engineered compositions appear in separately negotiated specifications or in those such as military specification MIL-A-21180, which is extensively used in the United States for premium casting procurement. Mechanical properties of premium aluminum castings are given in the section "Properties of Aluminum Casting Alloys" in this article.

Alloys considered premium by definition and specification are A201.0, A206.0, 224.0, 249.0, 354.0, A356.0 (D356.0), A357.0 (D357.0), and 358.0. All alloys employed in premium casting engineering work are characterized by optimum concentrations of hardening elements and restrictively controlled impurities. Although any alloy can be produced in cast form with properties and soundness conforming to a general description of premium values relative to corresponding commercial limits, only those alloys demonstrating yield strength, tensile strength, and especially elongation in a premium range belong in this grouping. They fall into two categories: high-strength aluminum-silicon compositions, and those alloys of the 2*xx* series, which by restricting impurity element concentrations provide outstanding ductility, toughness, and tensile properties with notably poorer castability.

In all premium casting alloys, impurities are strictly limited for the purposes of improving ductility. In aluminum-silicon alloys, this translates to control iron at or below 0.01% Fe with measurable advantages to the range of 0.03 to 0.05%, the practical limit of commercial smelting capability.

Beryllium is present in A357 and 158 alloys, not to inhibit oxidation (although that is a corollary benefit), but to alter the form of the insoluble phase to a more nodular form less detrimental to ductility.

The development of hot isostatic pressing is pertinent to the broad range of premium castings but is especially relevant for the more difficult-to-cast aluminum-copper series.

Piston and Other Elevated-Temperature Alloys. The universal acceptance of aluminum pistons by all gasoline engine manufacturers in the United States can be attributed to their light weight and high thermal conductivity. The effect of the lower inertia of the aluminum pistons on the bearing loading permits higher engine speeds and reduced crankshaft counterweighting.

Aluminum automotive pistons generally are permanent mold castings. This design usually is superior in economy and design flexibility. The alloy most commonly used for passenger car pistons, 332.0-T5, has a good combination of foundry, mechanical, and physical characteristics, including low thermal expansion. Heat treatment improves hardness for improved machinability and eliminates any permanent changes in dimensions from residual growth due to aging at operating temperatures.

Piston alloys for heavy-duty engines include the low-expansion alloys 336.0-T551 (A132-T551) and 332.0-T5 (F132-T5). Alloy 242-T571 (142-T571) is also used in some heavy-duty pistons because of its higher thermal conductivity and superior properties at elevated temperatures.

Other applications of aluminum alloys for elevated-temperature use include air-cooled cylinder heads for airplanes and motorcycles. The 10% Cu Alloy 222.0-T61 was used extensively for this purpose prior to the 1940s but has been replaced by the 242.0 and 243.0 compositions because of their better properties at elevated temperatures.

For use at moderate elevated temperatures (up to 175 °C, or 350 °F), Alloys 355 and C355 have been extensively used. These applications include aircraft motor and gear housings. Alloy A201.0 and the A206.0 type alloys have also been used in this temperature range when the combination of high strength at room temperatures and elevated temperatures is required.

Standard General-Purpose Aluminum Casting Alloys. Alloys with silicon as the major alloying constituent are by far the most important commercial casting alloys, primarily because of their superior casting characteristics. Binary aluminum-silicon alloys (443.0, 444.0, 413.0, and A413.0) offer further advantages of high resistance to corrosion, good weldability, and low specific gravity. Although castings of these alloys are somewhat difficult to machine, larger quantities are machined successfully with sintered carbide tools and flood application of lubricant. Application areas are:

- *Alloy 443* (Si at 7%) is used with all casting processes for parts where high strength is less important than good ductility, resistance to corrosion, and pressure tightness
- *Permanent mold Alloys 444 and A444* (Si at 7%) have especially high ductility and are used where impact resistance is a primary consideration (for example, highway bridge-rail support castings)
- *Alloys 413.0 and A413.0* (Si at 12%) are close to the eutectic composition, and as a result, have very high fluidity. They are useful in die casting and where cast-in lettering or other high-definition casting surfaces are required

In the silicon-copper alloys (213.0, 308.0, 319.0, and 333.0), the silicon provides good casting characteristics, and the copper imparts moderately high strength and improved machinability with reduced ductility and lower resistance to corrosion. The silicon range is 3 to 10.5%, and the copper content is 2 to 4.5%. These and similar general-purpose alloys are used mainly in the F temper. The T5 temper can be added to some of these alloys to improve hardness and machinability.

Alloy 356.0 (7 Si, 0.3 Mg) has excellent casting characteristics and resistance to corrosion. This justifies its use in large quantities for sand and permanent mold castings. Several heat treatments are used and provide the various combinations

of tensile and physical properties that make it attractive for many applications. This includes many parts in both the auto and aerospace industries. The companion alloy of 356.0 with lower iron content affords higher tensile properties in the premium-quality sand and permanent mold castings. Even higher tensile properties are obtained using this premium casting process using 357.0, A357.0, 358.0, and 359.0 alloys. The high properties of these alloys, attained by T6-type heat treatments, are of special interest to aerospace and military applications.

The 355.0 type alloys, or Al-Si-Mg-Cu alloys, offer greater response to the heat treatment because of the copper addition. This gives the higher strengths with some sacrifice in ductility and resistance to corrosion. Representative sand and permanent mold alloys include 355.0 (5 Si, 1.3 Cu, 0.4 Mg, 0.4 Mn) and 328.0 (8 Si, 1.5 Cu, 0.4 Mg, 0.4 Mn). Some applications include cylinder blocks for internal combustion engines, jet engine compressor cases, and accessory housings.

Alloy C355.0 with low iron is a higher-tensile version of 355, for heat-treated, premium-quality, sand, and permanent mold castings. Some of the applications include tank engine cooling fans, high-speed rotating parts such as impellers. When the premium-strength casting processes are used, even higher tensile properties can be obtained with heat-treated Alloy 354.0 (9 Si, 1.8 Cu, 0.5 Mg). This is also of interest in aerospace applications.

The 390.0 (17 Si, 4.5 Cu, 0.5 Mg) type alloys have enjoyed much growth in recent years. These alloys have high wear resistance and a low thermal expansion coefficient but somewhat poorer casting and machining characteristics than the other alloys in this group. B390.0 is low-iron version of 390.0 that can be used to advantage for sand and permanent mold casting. Some uses and applications include auto engine cylinder blocks, pistons, and so forth.

Die Casting Alloys. In terms of product tonnage, the use of aluminum alloys for die casting is almost twice as large as the usage of aluminum alloys in all other casting methods combined. In addition, alloys of aluminum are used in die casting more extensively than for any other base metal. Aluminum die castings usually are not heat treated, but occasionally are given dimensional and metallurgical stabilization treatments (variations of aging and annealing processes).

Compositions. The highly castable Al-Si family of alloys is the most important group of alloys for die casting. Of these, alloy 380.0 and its modifications constitute about 85% of aluminum die cast production. The 380.0 family of alloys provides a good combination of cost, strength, and corrosion resistance, together with the high fluidity and freedom from hot shortness that are required for ease of casting. Where better corrosion resistance is required, alloys lower in copper, such as 360.0 and 413.0, must be used. Rankings of these alloys in terms of die soldering and die filling capacity are given in Table 5. The hypereutectic aluminum-silicon alloy 390.0 type has found many useful applications in recent years. In heavy-wear uses, the increased hardness has given it a substantial advantage over normal 380.0 alloys (without any significant problems related to castability). Hypereutectic aluminum-silicon alloys are growing in importance as their valuable characteristics and excellent die casting properties are exploited in automotive and other applications.

Table 5 Characteristics of aluminum die casting alloys

See Table 3 for other characteristics.

Alloy	Resistance to die soldering[(a)]	Die filling capacity
360.0	2	3
A360.0	2	3
380.0	1	2
A380.0	1	2
383.0	2	1

384.0	2	1
413.0	1	1
A413.0	1	1
C443.0	4	4
518.0	5	5

(a) Ranking from ASTM B 85. Relative rating of die casting alloys from 1 to 5; 1 is the highest or best possible rating. A rating of 5 in one or more categories does not rule an alloy out of commercial use if other attributes are favorable; however, ratings of 5 may present manufacturing difficulties

Magnesium content is usually controlled at low levels to minimize oxidation and the generation of oxides in the casting process. Nevertheless, alloys containing appreciable magnesium concentrations are routinely produced. Alloy 518.0 for example, is occasionally specified when the highest corrosion resistance is required. This alloy, however, has low fluidity and some tendency to hot shortness. It is difficult to cast, which is reflected in higher costs per casting.

Iron content of 0.7% or greater is preferred in most die casting operations to maximize elevated-temperature strength, to facilitate ejection, and to minimize soldering to the die face. Iron content is usually 1 ± 0.3%. Improved ductility through reduced iron content has been an incentive resulting in widespread efforts to develop a tolerance for iron as low as approximately 0.25%. These efforts focus on process refinements and improved die lubrication.

Additions of zinc are sometimes used to enhance the fluidity of 380.0 and at times, other die casting alloys.

Aluminum-base bearing alloys are primarily alloyed with tin. These alloys are discussed in the section "Aluminum-Tin Alloys" in this article. Aluminum-tin bearing alloys are also discussed in the article "Tin and Tin Alloys" in this Volume.

Effects of Alloying

Antimony. At concentration levels equal to or greater than 0.05%, antimony refines eutectic aluminum-silicon phase to lamellar form in hypoeutectic compositions. The effectiveness of antimony in altering the eutectic structure depends on an absence of phosphorus and on an adequately rapid rate of solidifacation. Antimony also reacts with either sodium or strontium to form coarse intermetallics with adverse effects on castability and eutectic structure.

Antimony is classified as a heavy metal with potential toxicity and hygiene implications, especially as associated with the possibility of stibine gas formation and the effects of human exposure to other antimony compounds. In cases of direct exposure, OSHA Safety and Health Standards 2206 specifies the following 8-h weighted average exposure limits for antimony and other selected metals:

- Antimony, 0.5 mg/m^3
- Chromium, 0.5 mg/m^3
- Copper, 0.1 mg/m^3
- Lead, 0.2 mg/m^3
- Manganese, 0.1 mg/m^3
- Nickel, 1.0 mg/m^3
- Silver, 0.01 mg/m^3
- Zinc, 5.0 mg/m^3
- Beryllium, 2.0 $\mu g/m^3$

- Cadmium, 0.2 mg/m^3

As an additive for aluminum alloys, there is no indication of danger of antimony in aluminum alloys, particularly at the 0.08 to 0.15% levels of antimony in alloys that have been produced for years.

Beryllium additions of as low as few parts per million may be effective in reducing oxidation losses and associated inclusions in magnesium-containing compositions. Studies have shown that proportionally increased beryllium concentrations are required for oxidation suppression as magnesium content increases.

At higher concentrations (>0.04%), beryllium affects the form and composition of iron-containing intermetallics, markedly improving strength and ductility. In addition to changing beneficially the morphology of the insoluble phase, beryllium changes its composition, rejecting magnesium from the Al-Fe-Si complex and thus permitting its full use for hardening purposes.

Beryllium-containing compounds are, however, numbered among the known carcinogens that require specific precautions in the melting, molten metal handling, dross handling and disposition, and welding of alloys. Standard define the maximum beryllium in welding rod and weld base metal as 0.008 and 0.010%, respectively.

Bismuth improves the machinability of cast aluminum alloys at concentrations greater than 0.1%.

Boron combines with other metals to form borides, such as Al_2 and TiB_2. Titanium boride forms stable nucleation sites for interaction with active grain-refining phases such as $TiAl_3$ in molten aluminum.

Metallic borides reduce tool life in machining operations, and in coarse particle form they consist of objectionable inclusions with detrimental effects on mechanical properties and ductility. At high boron concentrations, borides contribute to furnace sludging, particle agglomeration, and increased risk of casting inclusions. However, boron treatment of aluminum-containing peritectic elements is practiced to improve purity and electrical conductivity in rotor casting. High rotor alloy grades may specify boron to exceed titanium and vanadium contents to ensure either the complexing or precipitation of these elements for improved electrical performance (see the section "Rotor Castings" in this article).

Cadmium in concentrations exceeding 0.1% improves machinability. Precautions that acknowledge volatilization at 767 °C (1413 °F) are essential.

Calcium is a weak aluminum-silicon eutectic modifier. It increases hydrogen solubility and is often responsible for casting porosity at trace concentration levels. Calcium concentrations greater than approximately 0.005% also adversely affect ductility in aluminum-magnesium alloys.

Chromium additions are commonly made in low concentrations to room-temperature aging and thermally unstable compositions in which germination and grain growth are know to occur. Chromium typically forms the compound $CrAl_7$, which displays extremely limited solid-state solubility and is therefore useful in suppressing grain growth tendencies. Sludge that contains iron, manganese, and chromium is sometimes encountered in die casting compositions, but it is rarely encountered in gravity casting alloys. Chromium improves corrosion resistance in certain alloys and increase quench sensitivity at higher concentrations.

Copper. The first and most widely used aluminum alloys were those containing 4 to 10% Cu. Copper substantially improves strength and hardness in the as-cast and heat-treated conditions. Alloys containing 4 to 6% Cu respond most strongly to thermal treatment. Copper generally reduces resistance to general corrosion, and in specific compositions and material conditions, stress-corrosion susceptibility. Additions of copper also reduce hot tear resistance and decrease castability.

Iron improves hot tear resistance and decreases the tendency for die sticking or soldering in die casting. Increases in iron content are, however, accompanied by substantially decreased ductility. Iron reacts to form a myriad of insoluble phases in aluminum alloy melts, the most common of which are $FeAl_3$, $FeMnAl_6$, and αAlFeSi. These essentially insoluble phases are responsible for improvements in strength, especially at elevated temperature. As the fraction of insoluble phase increases with increased iron content, casting considerations such as flowability and feeding characteristics are adversely affected. Iron participates in the formation of sludging phases with manganese, chromium, and other elements.

Lead is commonly used in aluminum casting alloys at greater than 0.1% for improved machinability.

Magnesium is the basis for strength and hardness development in heat-treated Al-Si alloys and is commonly used in more complex Al-Si alloys containing copper, nickel, and other elements for the same purpose. The hardening-phase Mg_2Si displays a useful solubility limit corresponding to approximately 0.70% Mg, beyond which either no further strengthening occurs or matrix softening takes place. Common premium-strength compositions in the Al-Si family employ magnesium in the range of 0.40 to 0.070% (see the section "Premium-Quality Castings" in this article).

Binary Al-Mg alloys are widely used in applications requiring a bright surface finish and corrosion resistance, as well as attractive combinations of strength and ductility. Common compositions range from 4 to 10% Mg, and compositions containing more than 7% Mg are heat treatable. Instability and room-temperature aging characteristics at higher magnesium concentrations encourage heat treatment.

Manganese is normally considered an impurity in casting compositions and is controlled to low levels in most gravity cast compositions. Manganese is an important alloying element in wrought compositions through which secondary foundry compositions may contain higher manganese levels. In the absence of work hardening, manganese offers no significant benefits in cast aluminum alloys. Some evidence exists, however, that a high-volume fraction of $MnAl_6$ in alloys containing more than 0.5% Mn may beneficially influence internal casting soundness. Manganese can also be employed to alter response in chemical finishing and anodizing.

Mercury. Compositions containing mercury were developed as sacrificial anode materials for cathodic protection systems, especially in marine environments. The use of these optimally electronegative alloys, which did not passivate in seawater, was severely restricted for environmental reasons.

Nickel is usually employed with copper to enhance elevated-temperature properties. It also reduces the coefficient of thermal expansion.

Phosphorus. In AlP_3 form, phosphorus nucleates and refines primary silicon-phase formation in hypereutectic Al-Si alloys. At parts per million concentrations, phosphorus coarsens the eutectic structure in hypoeutectic Al-Si alloys. Phosphorus diminishes the effectiveness of the common eutectic modifiers sodium and strontium.

Silicon. The outstanding effect of silicon in aluminum alloys is the improvement of casting characteristics. Additions of silicon to pure aluminum dramatically improve fluidity, hot tear resistance, and feeding characteristics. The most prominently used compositions in all casting processes are those of the aluminum-silicon family. Commercial alloys span the hypoeutectic and hypereutectic ranges up to about 25% Si.

In general, an optimum range of silicon content can be assigned to casting processes. For slow cooling-rate processes (such as plaster, investment, and sand), the range is 5 to 7%, for permanent mold 7 to 9%, and for die casting 8 to 12%. The bases for these recommendations are the relationship between cooling rate and fluidity and the effect of percentage of eutectic on feeding. Silicon additions are also accompanied by a reduction in specific gravity and coefficient of thermal expansion.

Silver is used in only a limited range of aluminum-copper premium-strength alloys at concentrations of 0.5 to 1.0%. Silver contributes to precipitation hardening and stress-corrosion resistance.

Sodium modifies the aluminum-silicon eutectic. Its presence is embrittling in aluminum-magnesium alloys. Sodium interacts with phosphorus to reduce its effectiveness in modifying the eutectic and that of phosphorus in the refinement of the primary silicon phase.

Strontium is used to modify the aluminum-silicon eutectic. Effective modification can be achieved at very low addition levels, but a range of recovered strontium of 0.008 to 0.04% is commonly used. Higher addition levels are associated with casting porosity, especially in processes or in thick-section parts in which solidification occurs more slowly. Degassing efficiency may also be adversely affected at higher strontium levels.

Tin is effective in improving antifriction characteristics ad is therefore useful in bearing applications. Casting alloys may contain up to 25% Sn. Additions can also be made to improve machinability. Tin may influence precipitation-hardening response in some alloy systems.

Titanium is extensively used to refine the grain structure of aluminum casting alloys, often in combination with smaller amounts of boron. Titanium in excess of the stoichiometry of TiB_2 is necessary for effective grain refinement. Titanium is often employed at concentrations greater than those required for grain refinement to reduce cracking tendencies in hot-short compositions.

Zinc. No significant technical benefits are obtained by the addition of zinc to aluminum.Accompanied by the addition of copper and/or magnesium, however, zinc results in attractive heat-treatable or naturally aging compositions. A number of such compositions are in common use. Zinc is also commonly found in secondary gravity and die casting compositions. In these secondary alloys, tolerance for up to 3% zinc allows the use of lower grade scrap aluminum to make these alloys and thus lowers cost.

Structure Control

The microstructural features that most strongly affect mechanical properties are:

- Grain size and shape
- Dendrite-arm spacing
- Size and distribution of second-phase particles and inclusions

Some of these microstructural features, such as grain size and dendrite-arm spacing, are primarily controlled by cooling and solidification rates. Figure 2, for example, shows the variation in microstructures and mechanical properties resulting from the different solidification rates associated with different casting processes.

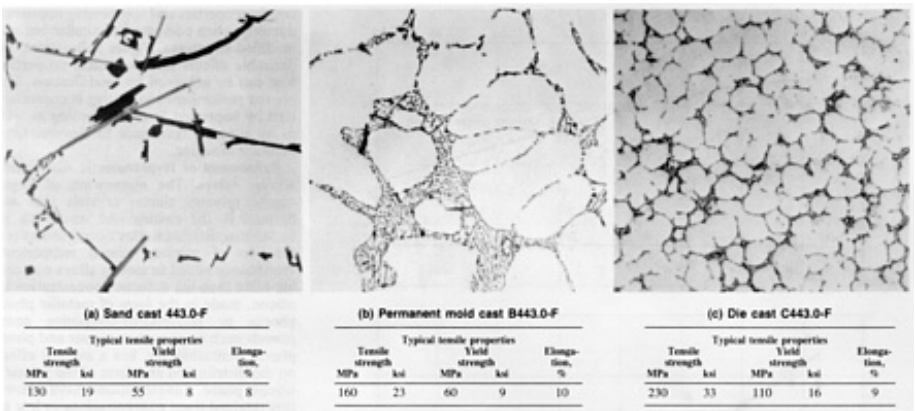

Fig. 2 Aluminum, 5% Si alloy microstructures resulting from different solidification rates characteristic of different casting processes. Dendrite cell size and constituent particle size decrease with increasing cooling rate, from sand cast to permanent mold cast to die cast. Etchant, 0.5% hydrofluoric acid. 500×

Like grain size and interdendritic spacing, the finer the dispersion of inclusions and second-phase particles, the better the properties of the casting. Fine dispersion requires small particles; large masses of oxides or intermetallic compounds produce excessive brittleness. Controlling size and shape of microconstituents can be done to some extent by controlling composition, but is accomplished more efficiently by minimizing the period of time during which microconstituents can

grow. Like minimizing grain size and interdendritic spacing, minimizing time for growth for microconstituents calls for rapid cooling. Thus, it is evident that high cooling rate is of paramount importance in obtaining good casting quality.

Microstructural features such as the size and distribution of primary and intermetallic phase are considerably more complex to control by chemistry. However, chemistry control (particularly control of impurity element concentrations), control of element ratios based on the stoichiometry of intermetallic phases, and control of solidification conditions to ensure uniform size and distribution of intermetallics are all useful. The use of modifiers and refiners to influence eutectic and hypereutectic structures in aluminum-silicon alloys is also an example of the manner in which microstructures and macrostructures can be optimized in foundry operations.

Dendrite-Arm Spacing. In all commercial processes, solidification takes place through the formation of dendrites in the liquid solution. The cells contained within the dendrite structure correspond to the dimensions separating the arms of primary dendrites and are controlled for a given composition primarily by solidification rate. Another factor that may affect interdendritic spacing is the presence of second-phase particles and oxide or gas inclusions. During freezing, inclusions and second-phase particles can segregate to the spaces between dendrite arms and thus increase the spacing.

The farther apart the dendrite arms are, the coarser the distribution of microconstituents and the more pronounced their adverse effects on properties. Thus, small interdendritic spacing is necessary for high casting quality. Figure 3, for example, illustrates the improvement in mechanical properties achievable by the change in dendrite formation controlled by solidification rate. Although several factors affect spacing to some extent, the only efficient way of ensuring fine spacing is use of rapid cooling.

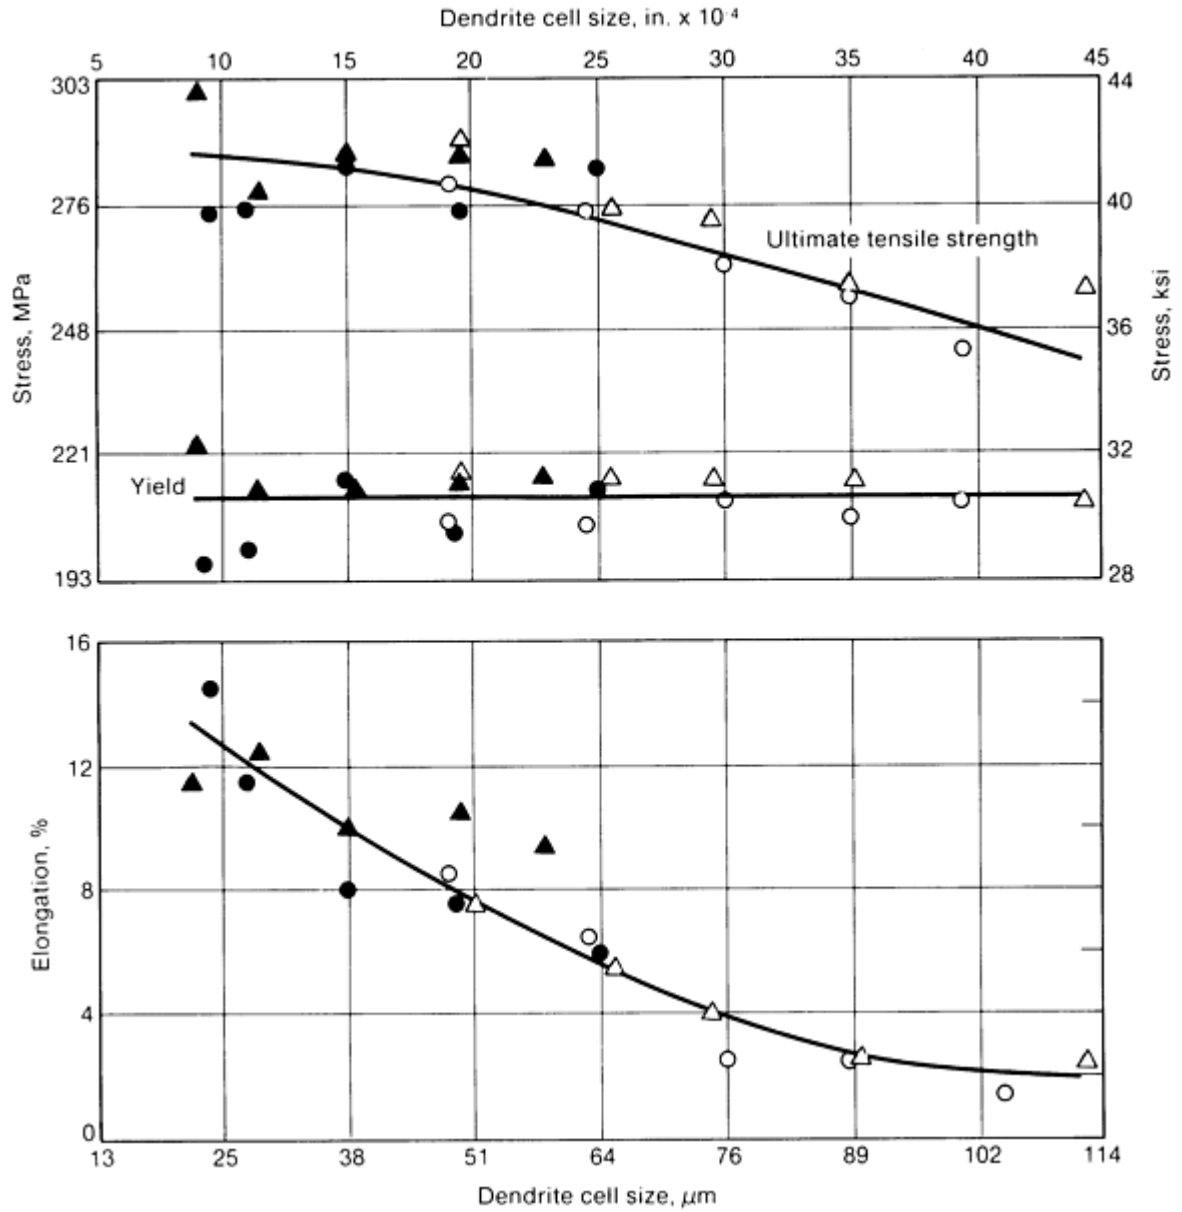

Fig. 3 Tensile properties versus dendrite cell size for four heats of aluminum alloy A356-T62 plaster cast plates

In premium engineered castings and in many other casting applications, careful attention is given to obtaining solidification rates corresponding to optimum mechanical property development. Solidification rate affects more than dendrite cell size, but dendrite cell size measurements are becoming increasingly important.

Grain Refinement. A fine, equiaxed grain structure is normally desired in aluminum castings, because castings with fine, equiaxed grains offer the best combination of strength and ductility. The type and size of grains formed are determined by alloy composition, solidification rate, and the addition of master alloys (grain refiners) containing intermetallic phase particles, which provide sites for heterogeneous grain nucleation.

Grain size is refined by increasing the solidification rate but is also dependent on the presence of grain-refining elements (principally titanium boron) in the alloy. To some extent, size and shape of grains can be controlled by addition of grain refiners, but use of low pouring temperatures and high cooling rates are the preferred methods.

All aluminum alloys can be made to solidify with a fully equiaxed, fine grain structure through the use of suitable grain-refining additions. The most widely used grain refiners are master alloys of titanium, or of titanium and boron, in aluminum. Aluminum-titanium refiners generally contain from 3 to 10% Ti. the same range of titanium concentrations is

used in Al-Ti-B refiners with boron contents from 0.2 to 1% and titanium-to-boron ratios ranging from about 5 to 50. Although grain refiners of these types can be considered conventional hardeners or master alloys, they differs from master alloys added to the melt for alloying purposes alone. To be effective, grain refiners must introduce controlled, predictable, and operative quantities of aluminides (and borides) in the correct form, size, and distribution for grain nucleation. Wrought refiner in rod form, developed for the continuous treatment of aluminum in primary operations, is available in sheared lengths for foundry use. The same grain-refining compositions are furnished in waffle form. In addition to grain-refining master alloys, salts, (usually in compacted form) that react with molten aluminum to form combinations of $TiAl_3$and $TiB_2$are also available.

Modification of hypoeutectic aluminum-silicon alloys involves the improvement of properties by inducing structural modification of the normally occurring eutectic. Modification is achieved by the addition of certain elements such as calcium, sodium, strontium, and antimony. It is also understood that increased solidification is useful in achieving modified structures.

In general, the greatest benefits are achieved in alloys containing from 5% Si to the eutectic concentration. The addition of modifying elements (such as calcium, sodium, strontium, and antimony) to these hypoeutectic aluminum-silicon alloys results in a finer lamellar or fibrous eutectic network (Fig. 4). Although there is no agreement on the mechanisms involved, the most popular explanations suggest that modifying additions suppress the growth of silicon crystal within the eutectic, providing a finer distribution of lamellae relative to the growth of the eutectic. It has also been well established that phosphorus interferes with the modification mechanism. Phosphorus reacts with sodium and probably with strontium and calcium to form phosphides that nullify the intended modification additions. It is therefore desirable to use low-phosphorus metal when modification is a process objective and to make larger modifier additions to compensate for phosphorus-related losses.

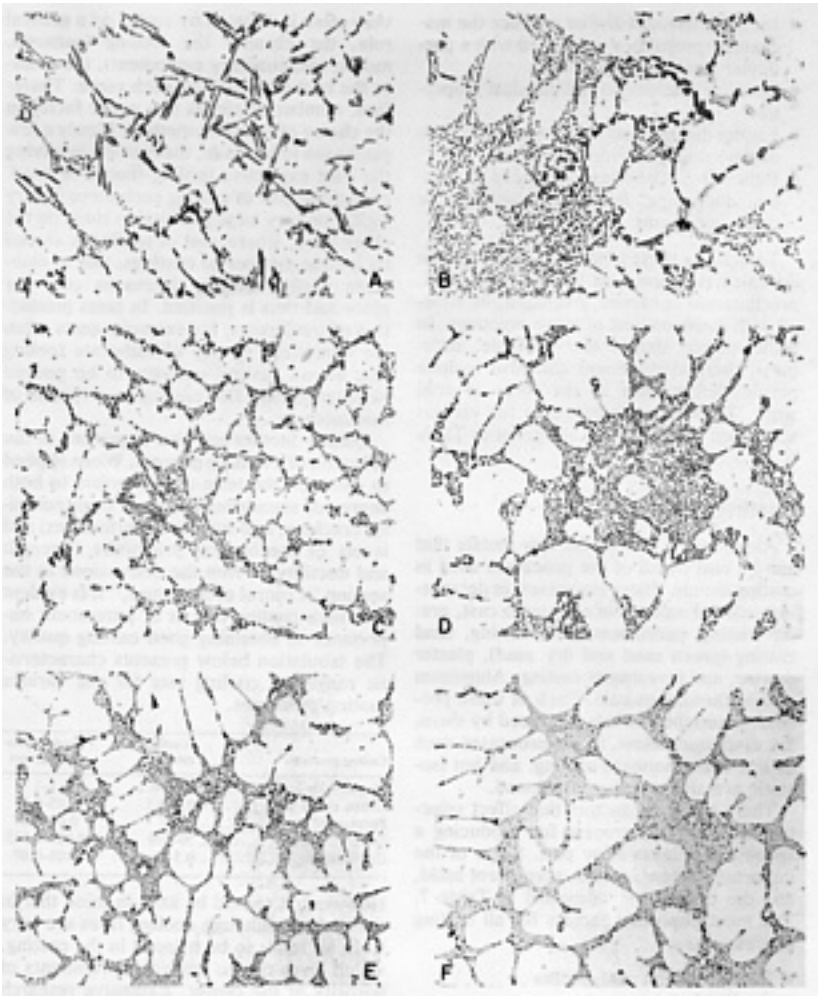

Fig. 4 Varying degrees of aluminum-silicon eutectic modification ranging from unmodified (A) to well modified (F). These are as-cast structures before any solution heat treatment.

Effects of Modification. Typically, modified structures display somewhat higher tensile properties and appreciably improved ductility when compared to similar but unmodified structures. Figure 5 illustrates the desirable effects on mechanical properties that can be achieved by modification. Improved performance in casting is characterized by improved flow and feeding as well as by superior resistance to elevated-temperature cracking.

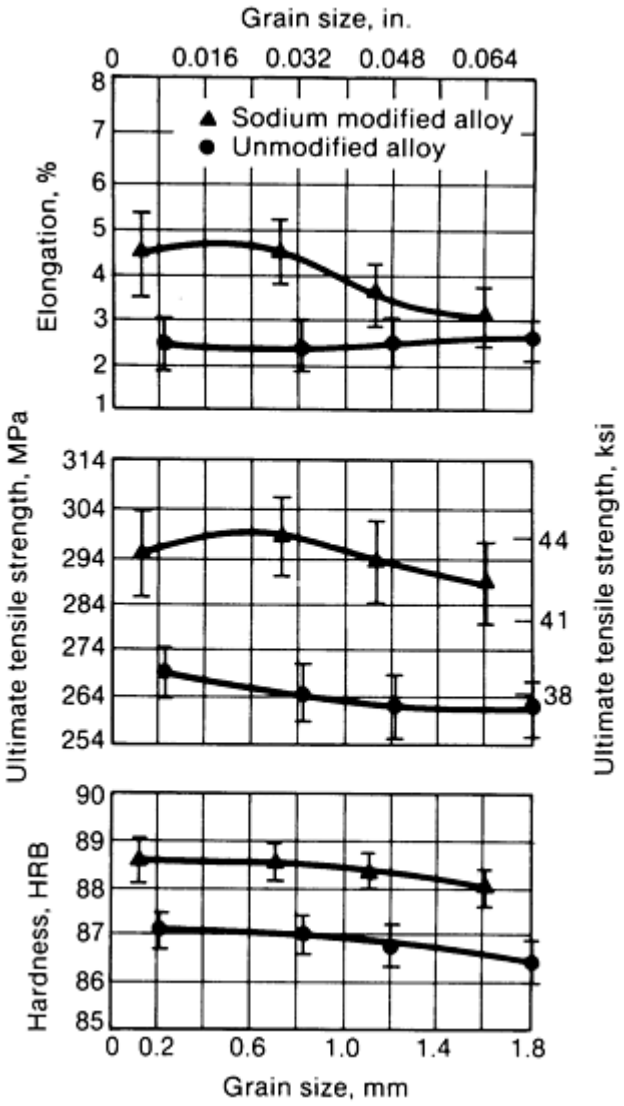

Fig. 5 Mechanical properties of as-cast A356 alloy tensile specimens as a function of modification and grain-size

Refinement of Hypereutectic Aluminum Silicon Alloys. The elimination of large, coarse primary silicon crystals that are harmful in the casting and machining of hypereutectic silicon alloy compositions is a function of primary silicon refinement. Phosphorus added to molten alloys containing more than the eutectic concentration of silicon, made in the form of metallic phosphorus or phosphorus-containing compounds such as phosphor-copper and phosphorus pentachloride, has a marked effect on the distribution and form of the primary silicon phase. Investigations have shown that retained trace concentrations as low as 0.0015 through 0.03% P are effective in achieving the refined structure. Disagreements on recommended phosphorus ranges and addition rates have been caused by the extreme difficulty of accurately sampling and analyzing for phosphorus. More recent developments employing vacuum stage spectrographic or quantometric analysis now provide rapid and accurate phosphorus measurements.

Following melt treatment by phosphorus-containing compounds, refinement can be expected to be less transient than the effects of conventional modifiers on hypoeutectic modification. Furthermore, the solidification phosphorus-treated melts, cooling to room temperature, reheating, remelting, and resampling in repetitive tests have shown that refinement is not lost; however, primary silicon particle size increases gradually, responding to a loss in phosphorus concentration. Common degassing methods accelerate phosphorus loss, especially when chlorine or freon is used. In fact, brief inert gas fluxing is frequently employed to reactive aluminum phosphide nuclei, presumably by resuspension.

Practices that are recommended for melt refinement are as follows:

- Melting and holding temperature should be held to a minimum
- The alloy should be thoroughly chlorine or freon fluxed before refining to remove phosphorus-scavenging impurities such as calcium and sodium
- Brief fluxing after the addition of phosphorus is recommended to remove the hydrogen introduced during the addition and to distribute the aluminum phosphide nuclei uniformly in the melt

Hydrogen Porosity. In general, two types of porosity may occur in cast aluminum: gas porosity and shrinkage porosity. Gas porosity, which generally us fairly spherical in shape, results either from precipitation of hydrogen during solidification (because the solubility of this gas is much higher in the molten metal than in the solid metal) or from occlusion of gas bubbles during the high-velocity injection of molten metal in die casting.

Two types or forms of hydrogen porosity may occur in cast aluminum when the precipitation of molecular hydrogen during the cooling and solidification of molten aluminum results in the formation of primary and/or secondary voids. Of

greater importance is interdendritic porosity, which is encountered when hydrogen contents are sufficiently high that hydrogen rejected at the solidification front results in solution pressures above atmospheric. Secondary (micron-size) porosity occurs when dissolved hydrogen contents are low, and void formation is characteristically subcritical.

Finely distributed hydrogen porosity may not always be undesirable. Hydrogen precipitation may alter the form and distribution of shrinkage porosity in poorly fed parts or part sections. Shrinkage is generally more harmful to casting properties. In isolated cases, hydrogen may actually be intentionally introduced and controlled in specific concentrations compatible with the application requirements of the casting in order to promote superficial soundness.

Nevertheless, hydrogen porosity adversely affects mechanical properties in a manner that varies with the alloy. Figure 6 shows the relationship between actual hydrogen content and observed porosity. Figure 7 defines the effect of porosity on the ultimate tensile strength of selected compositions.

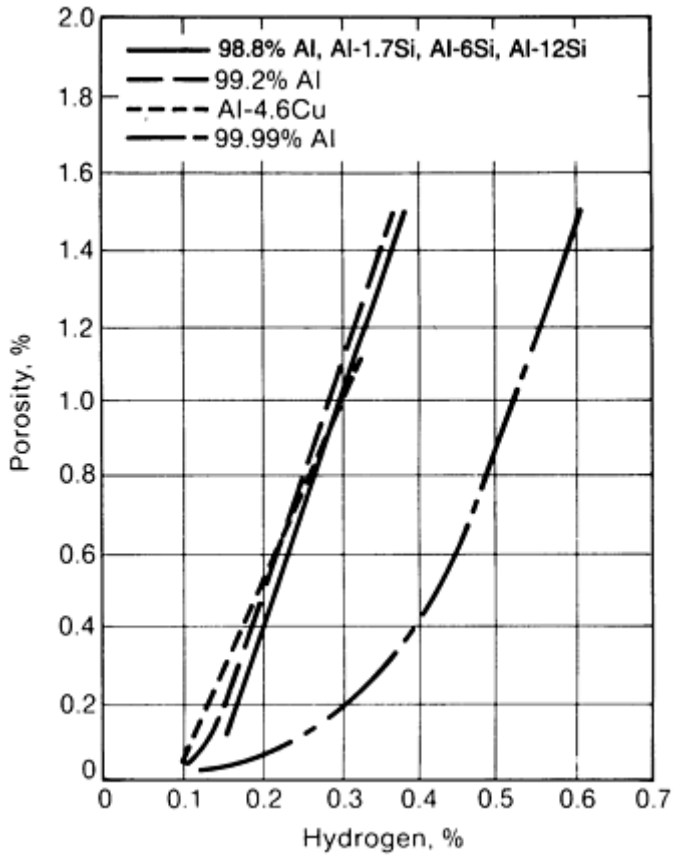

Fig. 6 Porosity as a function of hydrogen content in sand-cast aluminum and aluminum alloy bars

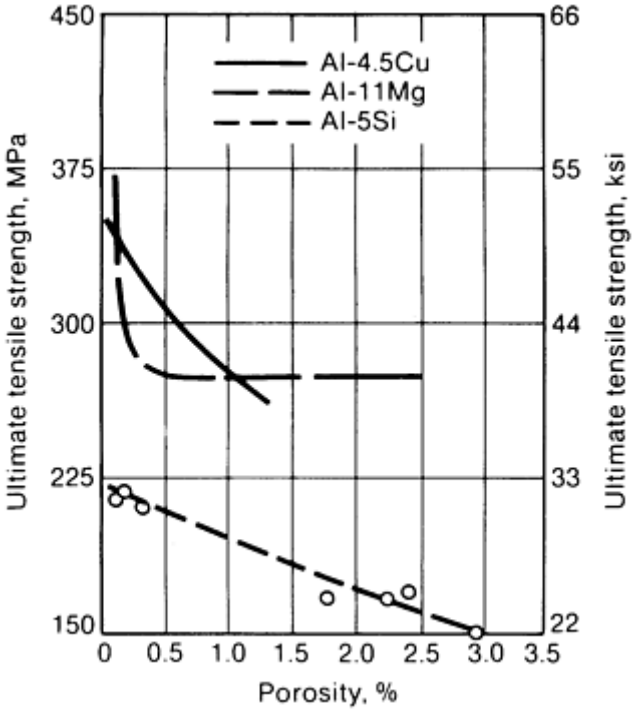

Fig. 7 Ultimate tensile strength versus hydrogen porosity for sand-cast bars of three aluminum alloys. The difference in tensile strength among the three alloys may be a function of heat treatment. The Al-11Mg alloy is typically used in the T4 temper (high toughness and ductility), while the other alloys are typically in the T6 condition (highest strength with acceptable ductility).

It is often assumed that hydrogen may be desirable or tolerable in pressure-tight applications. The assumption is that hydrogen porosity is always present in the cast structure as integrally enclosed rounded voids. In fact, hydrogen porosity may occur as rounded of elongated voids and in the presence of shrinkage may decrease rather than increase resistance to pressure leakage.

Shrinkage Porosity. The other source of porosity is the liquid-to-solid shrinkage that frequently takes the form of interdendritically distributed voids. These voids may be enlarged by hydrogen, and because larger dendrites result from slower solidification, the size of such porosity also increases as solidification rate decreases. It is not possible to establish inherent ratings with respect to anticipated porosity because castings made by any process can vary substantially in soundness--from nearly completely sound to very unsound--depending on casting size and design as well as on foundry techniques.

Heat Treatment. The metallurgy of aluminum and its alloys fortunately offers a wide range of opportunities for employing thermal treatment practices to obtain desirable combinations of mechanical and physical properties. Through alloying and temper selection, it is possible to achieve an impressive array of features that are largely responsible for the current use of aluminum alloy castings in virtually every field of application. Although the term heat treatment is often used to describe the procedures required to achieve maximum strength in any suitable composition through the sequence of solution heat treatment, quenching, and precipitation hardening, in its broadest meaning heat treatment comprises all thermal practices intended to modify the metallurgical structure of products in such a way that physical and mechanical characteristics are controllably altered to meet specific engineering criteria. In all cases, one or more of the following objectives form the basis for temper selection:

- Increase hardness for improved machinability
- Increase strength and/or produce the mechanical properties associated with a particular material condition
- Stabilize mechanical and physical properties
- Ensure dimensional stability as a function of time under service conditions
- Relieve residual stresses induced by casting, quenching, machining, welding, or other operations

To achieve these objectives, parts can be annealed, solution heat treated, quenched, precipitation hardened, overaged, or treated with combinations of these practices. In some simple shapes (for example, bearings), thermal treatment can also include plastic deformation in the form of cold work. Typical heat treatments for various aluminum casting alloys are given in Table 6.

Table 6 Typical heat treatments for aluminum alloy sand and permanent mold castings

(a) S, sand; P, permanent mold.

(b) Unless otherwise indicated, solution treating is followed by quenching in water at 65-100 °C (150-212 °F).

(c) Except where ranges are given, listed temperatures are ±6 °C or ±10 °F.

(d) Casting wall thickness, solidification rate, and grain refinement affect the solution heat-treatment cycle in alloys 201.0, 204.0, and 206.0, and care must be taken in approaching the final solution temperature. Too rapid an approach can result in the occurrence of incipient melting.

(e) For castings with thick or other slowly solidified sections, a pre-solution heat treatment ranging from about 490 to 515 °C (910 to 960 °F) may be needed to avoid too rapid a temperature rise to the solution temperature and the melting of $CuAl_2$.

(f) Temper T43 for 201.0 was developed for improved impact resistance with some decrease in other mechanical properties. Typical Charpy value is 20J (15 ft · lb).

(g) The French precipitation treatment technology for the heat treatment of 204.0 alloy requires 12 h at temperature. The aging temperatures of 140, 160, or 180 °C (285, 320, or 355 °F), are selected to meet the required combination of properties.

(h) Stress relieve for dimensional stability as follows: hold 5 h at 413 ± 14 °C (775 ± 25 °F); furnace cool to 345 °C (650 °F) over a period of 2 h or more: furnace cool to 230 °C (450 °F) over a period of not more than $\frac{1}{2}$ h; furnace cool to 120 °C (250 °F) over a period of approximately 2 h; cool to room temperature in still air outside the furnace.

(i) No quench required; cool in still air outside furnace.

(j) Air-blast quench from solution-treating temperature.

(k) Casting process varies (sand, permanent mold, or composite) depending on desired mechanical properties.

(l) Solution heat treat as indicated, then artificially age by heating uniformly at the temperature and for the time necessary to develop the desired mechanical properties.

(m) Quench in water at 65-100 °C (150-212 °F) for 10-20 s only.

(n) Cool to room temperature in still air outside the furnace.

Casting Processes

Aluminum is one of the few metals that can be cast by all of the processes used in casting metals. These processes, in decreasing order of amount of aluminum cast, are: die casting, permanent mold casting, sand casting (green sand and dry sand), plaster casting, and investment casting. Aluminum also in continuous cast. Each of these processes, and the castings produced by them, are discussed below. Other processes such as lost foam, squeeze casting, and hot isostatic pressing are also mentioned.

There are many factors that affect selection of a casting process for producing a specific aluminum alloy part. Some of the important factors in sand, permanent mold, and die casting are discussed in Table 7. The most important factors for all casting processes are:

- Feasibility and cost factors
- Quality factors

In terms of feasibility, many aluminum alloy castings can be produced by any of the available methods. For a considerable number of castings, however, dimensions or design features automatically determine the best casting method. Because metal molds weigh from 10 to 100 times as much as the castings they are used in producing, most very large cast products are made as sand castings rather than as die or permanent mold castings. Small castings usually are made with metal molds to ensure dimensional accuracy. Some parts can be produced much more easily if cast in two or more separate sections and bolted or welded together. Complex parts with many undercuts can be made easily by sand, plaster, or investment casting, but may be practically impossible to cast in metal molds even if sand cores are used.

Table 7 Factors affecting selection of casting process for aluminum alloys

Factor	**Casting process**		
	Sand casting	**Permanent mold casting**	**Die casting**
Cost of equipment	Lowest cost if only a few items required	Less than die casting	Highest
Casting rate	Lowest rate	11 kg/h (25 lb/h) common; higher rates possible	4.5 kg/h (10 lb/h) common; 45 kg/h (100 lb/h) possible
Size of casting	Largest of any casting method	Limited by size of machine	Limited by size of machine
External and internal shape	Best suited for complex shapes where coring required	Simple sand cores can be used, but more difficult to insert than in sand castings	Cores must be able to be pulled because they are metal; undercuts can be formed only by collapsing cores or loose pieces
Minimum wall thickness	3.0-5.0 mm (0.125-0.200 in.) required; 4.0 mm (0.150 in.) normal	3.0-5.0 mm (0.125-0.200 in.) required; 3.5 mm (0.140 in.) normal	1.0-2.5 mm (0.100-0.040 in.); depends on casting size
Type of cores	Complex baked sand cores can be used	Reuseable cores can be made of steel, or nonreuseable baked cores can be used	Steel cores; must be simple and straight so they can be pulled
Tolerance obtainable	Poorest; best linear tolerance is 300 mm/m (300 mils/in.)	Best linear tolerance is 10 mm/m (10 mils/in.)	Best linear tolerance is 4 mm/m (4 mils/in.)
Surface finish	6.5-12.5 μm (250-500) μin.)	4.0-10 μm (150-400 μin.)	1.5 μm (50 μin.); best finish of the three casting processes
Gas porosity	Lowest porosity possible with good technique	Best pressure tightness; low porosity possible with good	Porosity may be present

		technique	
Cooling rate	0.1-0.5 °C/s (0.2-0.9 °F/s)	0.3-1.0 °C/s (0.5-1.8 °F/s)	50-500 °C/s (90-900 °F/s)
Grain size	Coarse	Fine	Very fine on surface
Strength	Lowest	Excellent	Highest, usually used in the as-cast condition
Fatigue properties	Good	Good	Excellent
Wear resistance	Good	Good	Excellent
Overall quality	Depends on foundry technique	Highest quality	Tolerance and repeatability very good
Remarks	Very versatile as to size, shape, internal configurations	. . .	Excellent for fast production rates

When two or more casting methods are feasible for a given part, the method used very often is dictated by costs. As a general rule, the cheaper the tooling (patterns, molds, and auxiliary equipment), the greater the cost of producing each piece. Therefore, number of pieces is a major factor in the choice of a casting method. if only a few pieces are to be made, the method involving the least expensive tooling should be used, even if the cost of casting each piece is very high. For very large production runs, on the other hand, where cost of tooling is shared by a large number of castings, use of elaborate tooling usually decreases cost per piece and thus is justified. In mass production of small parts, for example, costs often are minimized by use of elaborate tooling that alloys several castings to be poured simultaneously. Die castings are typical of this category.

Quality factors are also important in the selection of a casting process. When applied to castings, the term quality refers to both degree of soundness (freedom from porosity, cracking, and surface imperfections) and levels of mechanical properties (strength and ductility). From the discussions in the section "Structure Control," it is evident that high cooling rate is of paramount importance in obtaining good casting quality. The tabulation below presents characteristics ranges of cooling rate for the various casting processes.

Casting processes	**Cooling rate, °C/s**	**Dendrite-arm spacing, mm**
Plaster, dry sand	0.05-0.2	0.1-1
Green sand, shell	0.1-0.5	0.05-0.5
Permanent mold	0.3-1	0.03-0.07
Die	50-500	0.005-0.015
Continuous	0.5-2	0.03-0.07

owever, it should be kept in mind that in die casting, although cooling rates are very high, air tends to be trapped in the casting, which gives rise to appreciable amounts of porosity at the center. Extensive research has been conducted to find ways of reducing such porosity; however, it is difficult if not impossible to eliminate completely, and die castings often are lower in strength than low-pressure or gravity-fed permanent mold castings, which are more sound in spite of slower cooling.

Die Casting. Alloys of aluminum are used in die casting more extensively than alloys of any other base metal. In the United States alone, about 2.5 billion dollars worth of aluminum alloy die castings is produced each year. The die casting process consumes almost twice as much tonnage of aluminum alloys as all other casting processes combined.

Die casting is especially suited to production of large quantities of relatively small parts. Aluminum die castings weighing up to about 5 kg (10 lb) are common, but castings weighing as much as 50 kg (100 lb) are produced when the high tooling and casting-machine costs are justified.Typical applications of die cast aluminum alloys include:

Alloy 380.0	Lawnmower housings, gear cases, cylinder heads for air-cooled engines
Alloy A380.0	Streetlamp housings, typewriter frames, dental equipment
Alloy 360.0	Frying skillets, cover plates, instrument cases, parts requiring corrosion resistance
Alloy 413.0	Outboard motor parts such as pistons, connecting rods, and housings
Alloy 518.0	Escalator parts, conveyor components, aircraft and marine hardware and fittings

With die casting, it is possible to maintain close tolerances and produce good surface finishes; aluminum alloys can be die cast to basic linear tolerances of ±4 mm/m (±4 mils/in.) and commonly have finishes as fine as 1.3 μm (50 μin.). Die castings are best designed with uniform wall thickness; minimum practical wall thickness for aluminum alloy die castings is dependent on casting size. Small parts are cast as thin as 1.0 mm (0.040 in.). Cores, which are made of metal, are restricted to simple shapes that permit straight-line removal.

Die castings are made by injection of molten metal into metal molds under substantial pressure. Rapid injection (due to the high pressure) and rapid solidification under high pressure (due to the use of bare metal molds) combine to produce a dense, fine-grain surface structure, which results in excellent wear and fatigue properties. Air entrapment and shrinkage, however, may result in porosity, and machine cuts should be limited to 1.0 mm (0.040 in.) to avoid exposing it. Mold coatings are not practical in die casting, which is done at pressures of 2 MPa (300 psi), or higher, because the violence of the rapid injection of molten metal would remove the coating (production of thin-section die castings may involve cavity fill times as brief as 20 ms).

Aluminum alloy die castings usually are not heat treated but occasionally are given dimensional and metallurgical stabilization treatments.

Die castings are not easily welded or heat treated because of entrapped gases. Special techniques and care in production are required for pressure-tight parts. The selection of an alloy with a narrow freezing range also is helpful. The use of vacuum for cavity venting is practiced in some die casting foundries for production of parts for some special applications. In the "pure free" process, the die cavity is purged with oxygen before injection. The entrapped oxygen reacts with the molten aluminum to form oxide particles rather than gas pores.

Approximately 85% of aluminum alloy die castings are produced in aluminum-silicon-copper alloys (alloy 380.0 and its several modifications). This family of alloys provides a good combination of cost, strength, and corrosion resistance,

together with the high fluidity and freedom from hot shortness that are required for ease of casting. Where better corrosion resistance is required, alloys lower in copper, such as 360.0 and 413.0, must be used.

Alloy 518.0 is occasionally specified when highest corrosion resistance is required. This alloy, however, has low fluidity and some tendency to hot shortness. It is difficult to cast, which is reflected in higher cost per casting.

The physical and mechanical properties of the most commonly used aluminum die casting alloys are given in the section "Properties of Aluminum Casting Alloys" in this article. Other characteristics of aluminum die casting alloys are presented in Tables 3 and 5. Final selection of an aluminum alloy for a specific application can best be established by consultation with die casting suppliers.

Permanent mold (gravity die) casting, like die casting, is suited to high-volume production. Permanent mold castings typically are larger than die castings. Maximum weight of permanent mold castings usually is about 10 kg (25 lb), but much larger castings sometimes are made when costs of tooling and casting equipment are justified by the quality required for the casting.

Surface finish of permanent mold castings depends on whether or not a mold wash is used; generally, finishes range from 3.8 to 10 μm (150 to 400 μin.). Basic linear tolerances of about ±10 mm/m (±0.10 in./in.), and minimum wall thicknesses of about 3.6 mm (0.140 in.), are typical. Tooling costs are high, but lower than those for die casting. Because sand cores can be used, internal cavities can be fairly complex. (When sand cores are used, the process usually is referred to as semipermanent mold casting.)

Permanent mold castings are gravity-fed and pouring rate is relatively low, but the metal mold produces rapid solidification. Permanent mold castings exhibit excellent mechanical properties. Castings are generally sound, provided that the alloys used exhibit good fluidity and resistance to hot tearing.

Mechanical properties of permanent mold castings can be further improved by heat treatment. If maximum properties are required, the heat treatment consists of a solution treatment at high temperature followed by a quench (usually in hot water) and then natural or artificial aging. For small castings in which the cooling rate in the mold is very rapid or for less critical parts, the solution treatment and quench may be eliminated and the fast cooling in the mold relied on the retain in solution the compounds that will produce age hardening.

In low-pressure casting (also called low-pressure die casting or pressure permanent mold casting), molten metal is injected into the metal molds at pressures of 170 kPa (25 psi) or less. Gating systems are used to introduce this metal into the mold inlet at the bottom of the mold so as to aid smooth and nonturbulent flow of the molten metal into the casting cavity. Filling of the mold and control of solidification are aided by application of refractory mold coating to selected areas of the die cavity, which slows down cooling in those areas. Thinner walls can be cast by low-pressure casting than by regular permanent mold casting. Low-pressure casting also has the economic advantage in that it can be highly automated.

Some common aluminum permanent mold casting alloys, and typical products cast from them, are presented below.

Alloy 366.0	Automotive pistons
Alloys 355.0, C355.0, A357.0	Timing gears, impellers, compressors, and aircraft and missile components requiring high strength
Alloys 356.0, A356.0	Machine tool parts, aircraft wheels, pump parts, marine hardware, valve bodies
Alloy B443.0	Carburetor bodies, waffle irons

Alloy 513.0	Ornamental hardware and architectural fittings

Other aluminum alloys commonly used for permanent mold castings include 296.0, 319.0, and 333.0.

Sand casting, which in a general sense involves the forming of a casting mold with sand, includes conventional sand casting and evaporative pattern (lost-foam) casting. This section focuses on conventional sand casting, which uses bonded sand molds. Evaporative pattern casting, which uses unbonded sand molds, is discussed in the next section.

In conventional sand casting, the mold is formed around a pattern by ramming sand, mixed with the proper bonding agent, onto the pattern. Then the pattern is removed, leaving a cavity in the shape of the casting to be made. If the casting is to have internal cavities or undercuts, sand cores are used to make them. Molten metal is poured into the mold, and after it has solidified the mold is broken to remove the casting. In making molds and cores, various agents can be used for bonding the sand. The agent most often used is a mixture of clay and water. (Sand bonded with clay and water is called green sand). Sand bonded with oils or resins, which is very strong after baking, is used mostly for cores. Water glass (sodium silicate) hardened with CO_2 is used extensively as a bonding agent for both molds and cores.

The main advantages of sand casting are versatility (a wide variety of alloys, shapes, and sizes can be sand cast) and low cost of minimum equipment when a small number of castings is to be made. Among its disadvantages are low dimensional accuracy and poor surface finish; basic linear tolerances of ±30 mm/m (±0.030 in./in.) and surface finishes of 7 to 13 μm, or 250 to 500 μin., as well as low strength as a result of slow cooling, are typical for aluminum sand castings. Use of dry sands bonded with resins or water glass results in better surface finishes and dimensional accuracy, but with a corresponding decrease in cooling rate.

Casting quality is determined to a large extent by foundry technique. Proper metal-handling and gating practice is necessary for obtaining sound castings. Complex castings with varying wall thickness will be sound only if proper techniques are used. A minimum wall thickness of 4 mm (0.15 in.) normally is required for aluminum sand castings.

Typical products made from some common aluminum sand casting alloys include:

Alloy C355.0	Air-compressor fittings, crankcases, gear housings
Alloy A356.0	Automobile transmission cases, oil pans, and rear-axle housings
Alloy 357.0	Pump bodies, cylinder blocks for water-cooled engines
Alloy 443.0	Pipe fittings, cooking utensils, ornamental fittings, marine fittings
Alloy 520.0	Aircraft fittings, truck and bus frame components, levers, brackets
Alloy 713.0	General-purpose casting alloy for applications that require strength without heat treatment or that involve brazing

Other aluminum alloys commonly used for sand castings include 319.0, 355.0, 356.0, 514.0, and 535.0.

Evaporative (lost-foam) pattern casting (EPC) is a sand casting process that uses an unbonded sand mold with an expendable polystyrene pattern placed inside of the mold. This process in somewhat similar to investment casting in that an expendable material can be used to form relatively intricate patterns in a surrounding mold material. Unlike investment

casting, however, evaporative pattern casting (EPC) involves a polystyrene foam pattern that vaporizes during the pouring of molten metal into a surrounding mold unbonded sand. With investment casting, a wax or plastic pattern is encased in a ceramic mold and removed by heat prior to the filling of the mold with molten metal.

The EPC process (also known as lost foam or evaporative foam casting) originated in 1958 when H.F. Shroyer was granted a patent (2,830,343) for a cavityless casting method using a polystyrene foam pattern embedded in traditional green sand. A polystyrene foam pattern left in the sand mold is decomposed by the molten metal, thus replacing the foam pattern and duplicating all of the features of the pattern. Early use of the process was limited to one-of-a-kind rough castings because the foam material was coarse and hand fabricated and because the packed green sand mold would not allow the gases from the decomposing foam pattern to escape rapidly from the mold (the trapped gases usually resulted in porous castings). Later, in 1964, T.R. Smith was granted a patent (3,157,924) for the utilization of loose, unbonded sand as a casting medium. With this important breakthrough, the EPC became an emerging subject of investigation in automotive company research facilities. Use of the process has been increasing rapidly and many casting facilities are now dedicated to the EPC process.

The major difference between sand castings and castings made by the EPC process is in subsequent machining and cleaning operations. The castings in the EPC process are consistently poured at closer tolerances with less stock for grinding and finishing. Dimensional variability associated with core setting, mating of cope, and drag are eliminated.

The use of untreated, unbonded sand makes the sand system economical and easy to manage. Casting cleaning is also greatly reduced and (except for removal of the wash coating) is sometimes eliminated because of the absence of flash, sand, and resin.

Casting yield can be considerably increased by pouring into a three-dimensional flask with the castings gated to a center sprue. An EPC casting facility also has the ability to produce a variety of castings in a continuous and timely manner. Foundries with EPC can pour diverse metals with very few changeover problems, and this adds to the versatility of the foundry.

Further benefits of the EPC process result from the freedom in part design offered by the process. Assembled patterns can be used to make castings that cannot be produced by any other high-production process. Part-development costs can be reduced because of the ability to prototype with the foam. Product and process development can be kept in-house.

The major concern in the EPC process is shrinkage of the foam pattern. The major difference between traditional methods of foundry tooling and evaporative pattern tooling is the continual heating and cooling of the tool and the subsequent stresses and geometrical considerations that this condition implies.

Shell Mold Casting. In shell mold casting, the molten metal is poured into a shell of resin-bonded sand only 10 to 20 mm (0.4 to 0.8 in.) thick--much thinner than the massive molds commonly used in sand foundries. Shell mold castings surpass ordinary sand castings in surface finish and dimensional accuracy and cool at slightly higher rates; however, equipment and production costs are higher, and size and complexity of castings that can be produced are limited.

Plaster Casting. In this method, either a permeable (aerated) or impermeable plaster is used for the mold. The plaster in slurry form is poured around a pattern, the pattern is removed and the plaster mold is baked before the casting is poured. The high insulating value of the plaster allows castings with thin walls to be poured. Minimum wall thickness of aluminum plaster castings typically is 1.5 mm (0.060 in.). Plaster molds have high reproducibility, permitting castings to be made with fine details and close tolerances; basic linear tolerances of ±5 mm/m (±0.005 in./in.) are typical for aluminum castings. Surface finish of plaster castings also is very good; aluminum castings attain finishes 1.3 to 3.2 μm (50 to 125 μin.). For castings of certain complex shapes, such as some precision impellers and electronic parts, mold patterns made of rubber are used because their flexibility makes them easier to withdraw from the molds than rigid patterns.

Mechanical properties and casting quality depend on alloy composition and foundry technique. Slow cooling due to the highly insulating nature of plaster molds tends to magnify solidification-related problems, and thus solidification must be controlled carefully to obtain good mechanical properties.

Plaster casting is sometimes used to make prototype parts before proceeding to make tooling for production die casting of the part.

Cost of basic equipment for plaster casting is low; however, because plaster molding is lower than sand molding, cost of operation is high. Aluminum alloys commonly used for plaster casting are 295.0, 355.0, C355.0, 356.0, and A356.0.

Investment casting of aluminum most commonly employs plaster molds and expendable patterns of wax or other fusible materials. A plaster slurry is "invested" around patterns for several castings, and the patterns are melted out as the plaster is baked.

Investment casting produces precision parts; aluminum castings can have walls as thin as 0.40 to 0.75 mm (0.015 to 0.030 in.), basic linear tolerances as narrow as ±5 mm/m (±5 mils/in.) and surface finishes of 1.5 to 2.3 μm (60 to 90 μin.). Some internal porosity usually is present, and it is recommended that machining be limited to avoid exposing it. However, investment molding is often used to produce large quantities of intricately shaped parts requiring no further machining so internal porosity seldom is a problem. Because of porosity and slow solidification, mechanical properties are low.

Investment castings usually are small, and thus gating techniques are limited. Christmas-tree gating systems often are employed to produce many parts per mold. Investment casting is especially suited to production of jewelry and parts for precision instruments. Recent strong interest by the aerospace industry in the investment casting process has resulted in limited use of improved technology to produce premium quality castings. The "near-net-shape" requirements of aerospace parts are often attainable using the investment casting techniques. Combining this accurate dimensional control with the high and carefully controlled mechanical properties can, at times, justify casting costs and prices normally not considered practical.

Aluminum alloys commonly used for investment castings are 208.0, 295.0, 308.0, 355.0, 356.0, 443.0, 514.0, and 712.0.

Centrifugal Casting. Centrifuging is another method of forcing metal into a mold. Steel, baked sand, plaster, cast iron, or graphite molds and cores are used for centrifugal casting of aluminum. Metal dies or molds provide rapid chilling, resulting in a level of soundness and mechanical properties comparable or superior to that of gravity-poured permanent mold castings. Baked sand and plaster molds are commonly used for centrifuge casting because multiple mold cavities can be arranged readily around a central pouring sprue. Graphite has two major advantages as a mold material: its high heat conductivity provides rapid chilling of the cast metal, and its low specific gravity, compared to ferrous mold materials, reduces the power required to attain the desired speeds.

Centrifugal casting has the advantage over other casting processes in that, if molds are properly designed, inclusions such as gases or oxides tend to be forced into the gates, and thus castings have properties that closely match those of wrought products. Limitations on shape and size are severe, and cost of castings is very high.

Wheels, wheel hubs, and papermaking or printing rolls are examples of aluminum parts produced by centrifugal casting. Aluminum alloys suitable for permanent mold, sand, or plaster casting can be cast centrifugally.

Continuous Casting. Long shapes of simple cross section (such as round, square, and hexagonal rods) can be produced by continuous casting, which is done in a short, bottomless, water-cooled metal mold. The casting is continuously withdrawn from the bottom of the mold; because the mold is water cooled, cooling rate is very high. As a result of continuous feeding, castings generally are free of porosity. In most instances, however, the same product can be made by extrusion at approximately the same cost and with better properties, and thus use of continuous casting is limited. The largest application of continuous casting is production of ingot for rolling, extrusion, or forging.

Composite-Mold Casting. Many of the molding methods described above can be combined to obtain greater flexibility in casting. Thus, dry sand cores often are used in green sand molds, and metal chills can be used in sand molds to accelerate local cooling. Semipermanent molds, which comprise metal molds and sand cores, take advantage of the better properties obtainable with metal molds and the greater flexibility in shape of internal cavities that results from use of cores that can be extracted piecemeal.

Hot isostatic pressing of aluminum castings reduces porosity and can thus decrease the scatter in mechanical properties. The method also makes possible the salvaging of castings that have been scrapped for reasons of internal porosity, thereby achieving improved foundry recovery. This advantage is of more significant importance in the manufacture of castings subject to radiographic inspection when required levels of soundness are not achieved in the casting process. The development of hot isostatic pressing is pertinent to the broad range of premium castings, but is especially relevant for the more difficult-to-cast aluminum-copper series.

Hybrid Permanent Mold Processes. Although die casting, centrifugal casting, and gravity die casting constitute, on a volume basis, the major permanent mold processes, there are also some hybrid processes that use permanent molds. This includes squeeze casting and semisolid metal processing.

Squeeze casting, also known as liquid-metal forging, is a process by which molten metal solidifies under pressure within closed dies positioned between the plates of a hydraulic press. The applied pressure and the instant contact of the molten metal with the die surface produces a rapid heat transfer condition that yields a pore-free fine-grain casting with excellent mechanical properties (Table 8). The squeeze casting process is easily automated to produce near-net to net-shape high-quality components.

Table 8 Effect of squeeze casting on tensile properties

Alloy	Process	Tensile strength		Yield strength		Elongation, %
		MPa	ksi	MPa	ksi	
356-T6 aluminum	Squeeze casting	309	44.8	265	38.5	3
	Permanent mold	262	38.0	186	27.0	5
	Sand casting	172	25.0	138	20.0	2
535 aluminum (quenched)	Squeeze casting	312	45.2	152	22.1	34.2
	Permanent mold	194	28.2	128	18.6	7
6061-T6 aluminum	Squeeze casting	292	42.3	268	38.8	10
	Forging	262	38.0	241	35.0	10
A356 T4 aluminum	Squeeze casting	265	38.4	179	25.9	20
A206 T4 aluminum	Squeeze casting	390	56.5	236	34.2	24
CDA 377 forging brass	Squeeze casting	379	55.0	193	28.0	32.0
	Extrusion	379	55.0	145	21.0	48.0
CDA 624 aluminum bronze	Squeeze casting	783	113.5	365	53.0	13.5
	Forging	703	102.0	345	50.0	15.0
CDA 925 leaded tin bronze	Squeeze casting	382	55.4	245	35.6	19.2

	Sand casting	306	44.4	182	26.4	16.5
Type 357 (annealed)	Squeeze casting	614	89.0	303	44.0	46
	Sand casting	400	58.0	241	35.0	20
	Extrusion	621	90.0	241	35.0	50
Type 321 (heat treated)	Squeeze casting	1063	154.2	889	129.0	15
	Forging	1077	156.2	783	113.6	7

Squeeze casting has been successfully applied to a variety of ferrous and nonferrous alloys in traditionally cast and wrought compositions. Applications of squeeze-cast aluminum alloys include pistons for engines, disk brakes, automotive wheels, truck hubs, barrel heads, and hubbed flanges. Squeeze casting is simple and economical, efficient in its use of raw material, and has excellent potential for automated operation at high rates of production. The process generates the highest mechanical properties attainable in a cast product. The microstructural refinement and integrity of squeeze-cast products are desirable for many critical applications.

Semisolid-Metal Processing. Semisolid metalworking, also known as semisolid forming, is a hybrid manufacturing method that incorporates elements of both casting and forging. It involves a two-step process for the near-net shape forming of metal parts using a semisolid raw material that incorporates a unique nondendritic microstructure (Fig. 8).

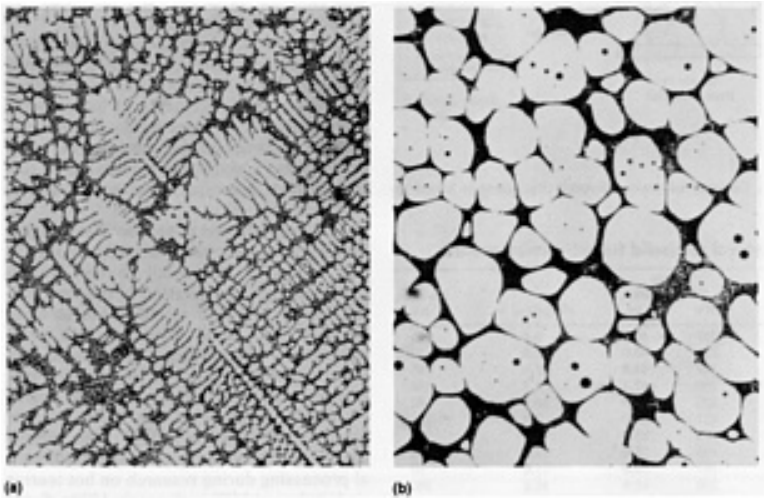

Fig. 8 Comparison of aluminum alloy 357 (Al-7Si-0.5Mg). (a) A dendritic microstructure from conventional casting. (b) A nondendritic microstructure formed during rheocasting or thixocasting. Both 200×

The basic process semisolid-metal processing is shown schematically in Fig. 9. The key (and first step) to the process involves vigorous agitation of the melt during earlier stages of solidification so as to break up the solid dendrites into small spherulites. There are two general approaches to this process: rheocasting and thixocasting. Rheocasting is a term coined by the researchers at the Massachusetts Institute of Technology (MIT) who initially discovered the techniques of semisolid-metal processing during research on hot tearing undertaken at MIT in the early 1970s. Seeking to understand the magnitude of the forces involved in deforming and fragmenting dendritic growth structures, MIT researchers constructed a high-temperature viscometer. They poured molten lead-tin alloys into the annular space created by two concentric cylinders and measured the forces transmitted through the freezing alloy when the outer cylinder was rotated. During the course of these experiments, it was discovered that when the outer cylinder was continuously rotated, the semisolid alloy exhibited remarkably low shear strength even at relatively high fractions solidified. This unique property was attributed to a novel nondendritic (that is, spheroidal) microstructure.

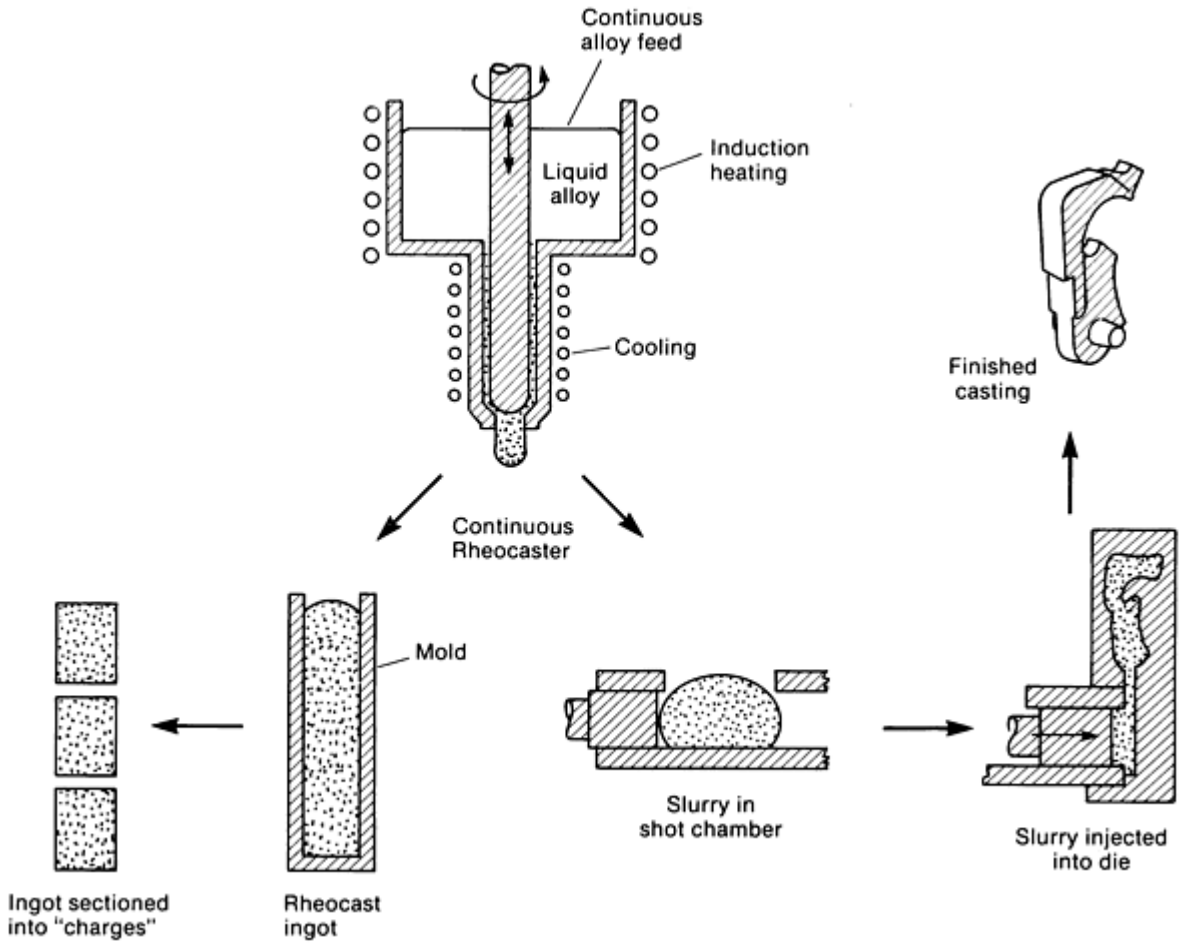

Fig. 9 Semisolid-metal processing with a rheocaster. Commercial semisolid-metal processing is based on thixocasting.

As these ideas unfolded, research into the nature of semisolid alloys progressed, and it became apparent that bars could be cast from semisolid fluids possessing the rheocast nondendritic microstructure. The final freezing of these bars captures this microstructure.The bars then represented a raw material that could be heated at a later time or a remote location to the semisolid temperature range to reclaim the special rheological characteristics. This process, using semisolid alloys heated from specially cast bars, was termed thixocasting (Ref 3). This distinguished it from rheocasting, which has come to be known as the process used for producing semisolid structures and/or forming parts from slurry without an intermediate freezing step.

A number of alternative approaches to the production of the semisolid raw material have been developed. Although several of these techniques build upon the mechanical agitation approach (Ref 4, 5), others utilize a passive stirring technique for stimulating turbulent flow through cooling channels (Ref 6, 7). At least one approach uses isothermal holding to induce particle coarsening. Most of these alternatives appear to be confined to the laboratory, although one or two have been demonstrated at a pilot production level. To date, none has shown economic viability.

There have been several attempts in the United States and abroad to commercialize rheocasting, but none of these ventures is known to have been commercially successful (Ref 4, 8). On the other hand, semisolid forging, which exploits the manufacturing advantages of thixotropic semisolid alloy bars, began commercial production in 1981 and is now a rapidly expanding commercial process. The production of raw material has been brought to full commercial realization, and the use of semisolid forged parts is broadening in the aerospace, automotive, military, and industrial sectors.

The advantages of semisolid forging have enabled it to compete effectively with a variety of conventional processes in a number of different applications. Semisolid forged parts have replaced conventional forgings, permanent mold and investment castings, impact extrusions, machined extrusion profiles, parts produced on screw machines, and in unusual circumstances, die castings and stampings. Applications include automobile wheels, master brake cylinders, antilock

brake valves, disk brake calipers, power steering pump housings, power steering pinion valve housings, engine pistons, compressor housings, steering column mechanical components, airbag containment housings, power brake proportioning valves, electrical connectors, and various covers and housings that require leak-tight integrity. Table 9 lists mechanical properties of selected aluminum alloys used in these components.

Table 9 Tensile properties and hardness of typical semisolid forged aluminum parts

Aluminum alloy	Temper	Ultimate tensile strength		Tensile yield strength		Elongation, %	Hardness, HB
		MPa	ksi	MPa	ksi		
206	T7	386	56.0	317	46.0	6.0	103
2017	T4	386	56.0	276	40.0	8.8	89
2219	T8	352	51.0	310	45.0	5.0	89
6061	T6	330	47.8	290	42.1	8.2	104
6262	T6	365	52.9	330	47.9	10.0	82
7075	T6	496	72.0	421	61.0	7.0	135
356	T5	234	34.0	172	25.0	11.0	89
356	T6	296	43.0	193	28.0	12.0	90
357	T5	296	43.0	207	30.0	11.0	90

There are several potential advantages of semisolid alloys. First, and particularly significant for higher-melting alloys, semisolid metalworking afforded lower operating temperatures and reduced metal heat content (reduced enthalpy of fusion). Second, the viscous flow behavior could provide for a more laminar cavity fill than could generally be achieved with liquid alloys. This could lead to reduced gas entrainment. Third, solidification shrinkage would be reduced in direct proportion to the fraction solidified within the semisolid metalworking alloy, which should reduce both shrinkage porosity and the tendency toward hot tearing. In addition, the viscous nature of semisolid alloys provides a natural environment for the incorporation of third-phase particles in the preparation of particulate-reinforced metal-matrix composites. The semisolid state also allows greater use of automation in material handling.

Example 1: Comparison of Semisolid Forging and Permanent Mold Casting in the Production of Aluminum Automobile Wheels.

Aluminum automobile wheels have been produced by permanent mold casting (gravity and low pressure), squeeze casting, and fabrications of castings or stampings welded to rolled rims. Semisolid forging is a more recent process. Table 10 compares the characteristics of aluminum automobile wheels produced by semisolid forging and permanent mold casting. In addition to an economic advantage, semisolid forging offers other advantages that are discussed below.

Table 10 Comparison of semisolid forging and permanent mold casting for the production of aluminum automobile wheels

See Example 1.

Process	Characteristic											
	Weight direct from die or mold		Finished part weight		Production rate per die or mold, pieces per h	Aluminum alloy	Heat treatment	Ultimate tensile strength		Yield strength		Elongation, %
	kg	lb	kg	lb				MPa	ksi	MPa	ksi	
Semisolid forging	7.5	16.5	6.1	13.5	90	357	T5	290	42	214	31	10
Permanent mold	11.1	24.5	8.6	19.0	12	356	T6	221	32	152	22	8

Lighte Weight. The ability to form thinner sections without heavy ribs to aid in filling the cavity allows a wheel to be semisolid formed nearer to net size with light ribs on the brake side. This results in a finished wheel that is up to 30% lighter than a cast wheel of the same style.

Consistent Quality. The forging process employs a high-quality, specially prepared (magnetohydrodynamic casting) billet with an engineered metallurgical structure, closely controlled chemistry, and consistent casting variables, supplying an extremely consistent raw material with complete traceability. The wheel-forming process is computer controlled and automated with precise control of the heating and forging process variables, making the entire process adaptable to statistical process control.

Structure and Properties. The semisolid forged wheel is fine grained, dense structured, and formed to close tolerances in precision tooling in which the temperature is controlled to provide consistent forging conditions. This provides consistency in part dimensions and metallurgical properties. Forging in the semisolid state avoids the entrapment of air or mold gas, and the high fraction of solid material, together with the high pressure after forming, reduces the microporosity due to liquid/solid shrinkage. Unlike conventional forgings, the wheel properties are isotropic, reflecting the nondendritic structure of the high-performance aluminum alloy 357 used in the billet.

Design Versatility. The ability to form thin sections (roughly one-quarter to one-half the thickness of casting) permits not only a reduction in the weight of the wheel, but also allows the designer to style the wheel with thinner ribs/spokes and finer detail. Forming in the semisolid state under very high final pressure provides part surfaces and details that reflect the die surfaces. Therefore, the designer has a selection of surface conditions to enhance the style and can obtain exact replication of the fine detail designed in the die.

Properties of Aluminum Casting Alloys

Although the physical and mechanical properties of aluminum casting alloys are well documented, the data given in this section should only be used for alloy comparison and not for design purposes. Properties for design must be obtained from pertinent specifications or design standards or by negotiation with the producer. Additional information on properties is also available in the "Selected References" listed at the end of this article and in the next article "Properties of Cast Aluminum Alloys" in this Volume.

Physical Properties

Table 2 gives typical values for some of the important physical properties of various aluminum casting alloys, which are grouped into the nine alloy categories mentioned earlier in the section "Selection of Casting Alloys." The effects of alloying elements on electrical conductivity and thermal expansion is shown in Table 4 and Fig. 10, respectively. Other important physical properties related to castability are fluidity and shrinkage.

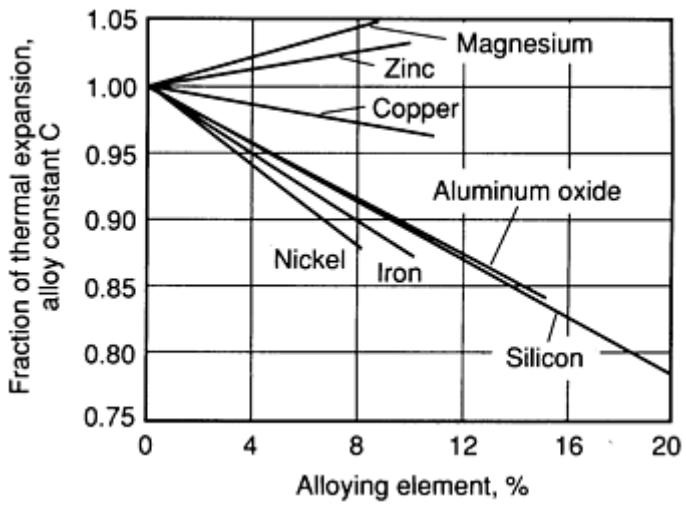

Fig. 10 Effects of alloying elements in the thermal expansion of aluminum. Fraction is based on a value of 1.00 for 99.996 Al. Source: L.A. Willey, Alcoa

Factors Affecting Fluidity. Fluidity depends on two major factors: the intrinsic fluid properties of the molten metal, and casting conditions. The properties usually thought to influence fluidity are viscosity, surface tension, the character of the surface oxide film, inclusion content, and manner in which the particular alloy solidifies.

Casting conditions that influence fluidity include part configuration; physical measures of the fluid dynamics of the system such as liquidstatic pressure drops, casting head, and velocities; mold material; mold surface characteristics; heat flux; rate of pouring; and degree of superheat.

Viscosity. The measured viscosities of molten aluminum alloys are quite low and fall within a relatively narrow range. Kinematic viscosity (viscosity/specific gravity) is less than that of water. It is evident on this basis that viscosity is not strongly influential in determining casting behavior and therefore is an unlikely source of variability in casting results.

Surface Tension and Oxide Film. A high surface tension has the effect of increasing the pressure required for liquid metal flow. A number of elements influence surface tension, primarily through their effects on the surface tension of the oxide. Figure 11 illustrates the effect of selected elements on surface tension. In aluminum alloys, the true effect of surface tension is overpowered by the influence of surface oxide film characteristics. The oxide film on pure aluminum, for example, triples apparent surface tension.

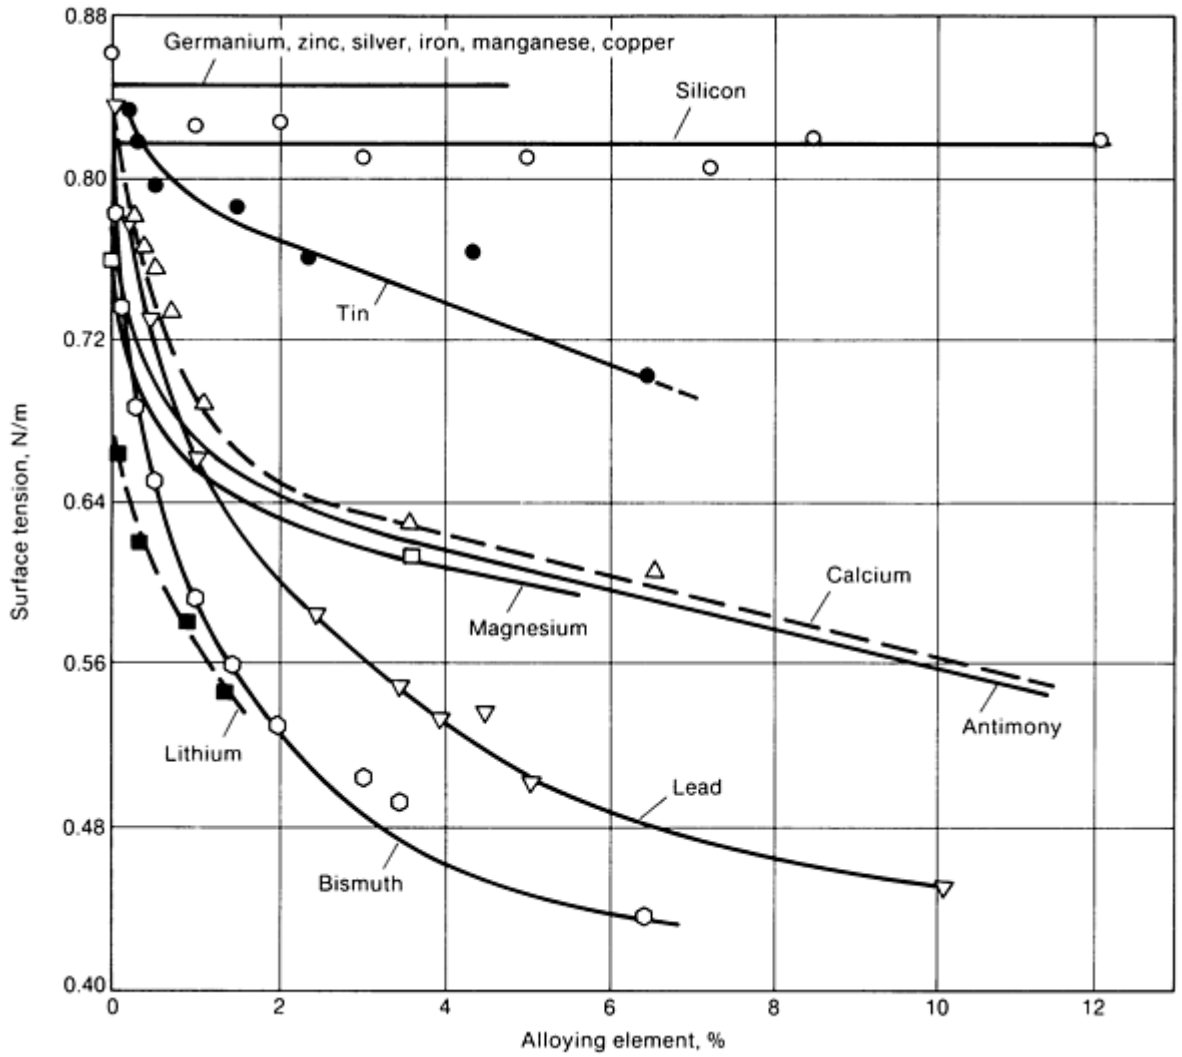

Fig. 11 Effect of various elements on surface tension of 99.99% Al in argon at 700 to 740 °C (1290 to 1365 °F)

Inclusions in the form of suspended insoluble nonmetallic particles dramatically reduce the fluidity of molten aluminum.

Solidification. It has been shown that fluidity is inversely proportional to freezing range (that is, fluidity is highest for pure metals and eutectics, and lowest for solid-solution alloys). The manner in which solidification occurs may also influence fluidity.

Shrinkage. For most metals, the transformation from the liquid to the solid state is accompanied by a decrease in volume. In aluminum alloys, volumetric solidification shrinkage can range from 3.5 to 8.5%. The tendency for formation of shrinkage porosity is related to both the liquid/solid volume fraction and the solidification temperature range of the alloy. Riser requirements relative to the casting weight can be expected to increase with increasing solidification temperature range. Requirements for the establishment of more severe thermal gradients, such as by the use of chills or antichills, also increase.

Mechanical Properties

Typical mechanical properties of various aluminum casting alloys are given in Tables 11, 12, and 13. These typical values should be used only for assessing the suitability of an alloy for a particular application, and not for design purposes. Design-stress values are significantly below typical properties as discussed in the section on "Mechanical Test Methods" later in this article. Actual design strength depends on several factors, including:

- Section size
- Expected degree of porosity
- Presence of sharp corners
- Probability of cyclic loading in service

(a) 10 mm (0.4 in.) ball with 500 kgf (1100 lbf) load.

(b) Rotating beam test at 5×10^8 cycles.

(c) Typical values of premium-quality casting are the same regardless of class or the area from which the specimen is cut; see Table 14 for minimum values.

(d) Fatigue strength for 10^6 cycles

Minimum mechanical property limits are usually defined by the terms of general procurement specifications, such as those developed by government agencies and technical societies. These documents often specify testing frequency, tensile bar type and design, lot definitions, testing procedures, and the limits applicable to test results. By references to general process specifications, these documents also invoke standards and limits for many additional supplier obligations, such as specific practices and controls in melt preparation, heat treatment, radiographic and liquid penetrant inspection, and test procedures and interpretation. Tables 11 and 14 include minimum tensile properties of various casting alloys.

Table 14 Minimum tensile properties of premium-quality aluminum alloy castings

These mechanical property values are attainable in favorable casting configurations and must be negotiated with the foundry for the particular configuration desired.

(a) Values from specification MIL-A-21180

Mechanical Test Methods. Typical and minimum mechanical-property values commonly reported for castings of particular aluminum alloys are determined using separately cast test bars that are $\frac{1}{2}$ in. diameter (for sand and permanent mold castings) or $\frac{1}{4}$ in. diameter (for die castings). As such, these values represent properties of sound castings, 13 or 6 mm ($\frac{1}{2}$ or $\frac{1}{4}$ in.) in section thickness, made using normal casting practice; they do not represent properties in all sections and locations of full-size production castings. Typical and minimum properties of test bars, however, are useful in determining relative strengths of the various alloy/temper combinations. Minimum properties--those values listed in applicable specifications--apply, except where otherwise noted, only to separate cast test bars. These values, unlike minimum values based on bars cut from production castings, are not usable as design limits for production castings. However, they can be useful in quality assurance. Actual mechanical properties, whether of separately cast test bars or of full-size castings, are dependent on two main factors:

- Alloy composition and heat treatment
- Solidification pattern and casting soundness

Some specifications for sand, permanent mold, plaster, and investment castings have defined the correlation between test results from specimens cut from the casting and separately cast specimens. A frequent error is the assumption that test values determined from these sources should agree. Rather, the properties of separately cast specimens should be expected to be superior to those of specimens machined from the casting. In the absence of more specific guidelines, one rule of thumb defines the average tensile and yield strengths of machined specimens as not less than 75% of the minimum requirements for separately cast specimens, and elongation as not less than 25% of the minimum requirement. These relations may be useful in establishing the commercial acceptability of parts in dispute.

Test Specimens. Accurate determination of mechanical properties of aluminum alloy castings (or of castings of any other metal) requires proper selection of test specimens. For most wrought products, a small piece of the material often is

considered typical of the rest, and mechanical properties determined from that small piece also are considered typical. Properties of castings, however, vary substantially from one area of a given casting to another, and may vary from casting to casting in a given heat.

If castings are small, one from each batch can be sacrificed and cut into test bars. If castings are too large to be economically sacrificed, test bars can be molded as an integral part of each casting, or can be cast in a separate mold.

Usually, test bars are cast in a separate mold. When this is done, care must be taken to ensure that the metal poured into the test-bar mold is representative of the metal in the castings that the test bars are supposed to represent. in addition, differences in pouring temperature and cooling rate, which can make the properties of separately cast test bars different from those of production castings, must be avoided.

For highly stressed castings, integrally cast test bars are preferable to separately cast bars. When integrally cast bars are selected, however, gating and risering must be designed carefully to ensure that test bars and castings have equivalent microstructure and integrity. Also, if there are substantial differences between test-bar diameter and wall thickness in critical areas of the casting, use of integrally cast test panels equal in thickness to those critical areas, instead of standard test bars, should be considered.

ASTM E8 defines the test bars suitable for evaluation of aluminum castings. The use of test bars cut from die castings is not recommended; simulated service (proof) testing is considered more appropriate.

Chemical Composition and Heat Treatment. Mechanical properties of castings depend not only on choice of alloy but also depend somewhat on other considerations linked with the alloy. Variations in chemical composition, even within specified limits, can have measurable effects. Metallurgical considerations such as coring, phase segregation, and modification also can alter properties. Modification is commonly used for those aluminum alloys with 5% or more silicon.

In hypoeutectic Al-Si alloys, the coarse silicon eutectic has been refined and dispersed by modification. The modified structure increases both ductility and mechanical strength. Modification is accomplished by addition of small amounts (0.02%) of sodium or strontium. Making those additions often introduces gas into the melt. Their use, therefore, must be weighed against applicable radiographic specifications. In the hypereutectic aluminum-silicon alloys (silicon greater than 11.7%), refinement of primary silicon in sand and permanent mold castings is accomplished by adding 0.05% P. (Phosphorus modification is required in only those die castings that have thick walls.) In these alloys, the phosphorus addition provides moderate improvements in strength and machinability.

Where heat treatment is required, choice of temper affects properties. Heat treating variables such as solution time and temperature, temperature of quenching medium, and quench delay also can alter properties.

Casting variables also contribute to mechanical-property variations. The differences between typical test-bar properties and mechanical properties of full-size castings result from differences in soundness and solidification characteristics. Casting soundness depends on the amount of porosity or other imperfections present in the casting. The presence of dross, shrinkage porosity, and gas porosity will all decrease properties. Dross inclusions and gas porosity are minimized by proper melting and pouring techniques.

Properties of production castings vary depending on two aspects of the solidification characteristics in each section of the casting--solidification rate and location and form of shrinkage. Shrinkage results when supply of molten metal is not adequate throughout solidification. Shrinkage may be apparent as sponge shrinkage, centerline shrinkage, shrinkage porosity, or a large shrinkage cavity. Shrinkage, however, can be controlled by proper use of directional solidification.

Directional solidification in a casting section is accomplished by starting solidification at a selected point and allowing it to progress toward a riser. If solidification also starts at a second point (such as a thinner region), then shrinkage between these two points results, as illustrated in Fig. 12. In designing a gating system for a casting, each section is examined in an attempt to establish directional solidification by proper use of chills, risers, and insulating materials. Casting design also is very important in ensuring that the necessary thermal gradients are established.

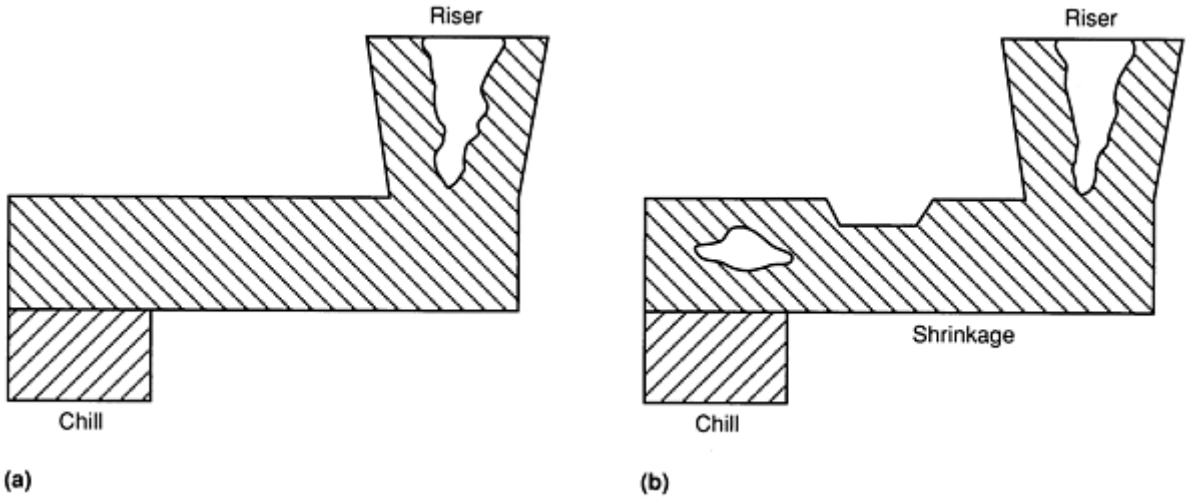

Fig. 12 Effect of gating system on formation of shrinkage cavities. Solidification starts at the chill and progresses toward the riser. In (a), molten metal can easily feed from the riser into the entire length of the casting. In (b), the narrow portion of the casting can freeze shut before solidification of the left portion of the casting is completed, and thus the riser can no longer feed that portion and a shrinkage cavity develops.

When the solidification characteristics of the entire casting are examined, solidification may be faster in some areas of the casting than in others; for example, the rate will be faster at a chilled area than at a riser area. The solidification rate of a casting section can be determined using a metallographic technique that measures dendrite-arm spacing. High solidification rates produce relatively small dendrite-arm spacing.

As explained in the section "Structure Control" in this article, casting processes all are characterized by solidification mode. In die casting, metal is rapidly injected and thus is subject to high chill rates. This results in rapid solidification and a fine metallographic structure at the surface. The fast chill rate and rapid rejection, however, usually result in centerline shrinkage. It has generally been impractical to achieve directional solidification in die castings to overcome this centerline shrinkage. In permanent mold casting chill rate also is high, but slower pouring allows longer feed times and more sound castings; design is very important in ensuring the proper solidification pattern. Because of high solidification rates, the properties of die and permanent mold castings are relatively insensitive to casting variables.

Due to relatively long solidification times, properties of sand and plaster castings are very sensitive to variations in casting technique; chills, risers, and gates significantly affect properties. Plaster molds, with their insulating properties, keep solidification rate low and consequently produce castings with relatively low properties.

The fatigue strength of castings is normally lower than that of wrought materials when the specimens are smooth. However, because castings are less notch sensitive than wrought products, castings may be beneficial in applications with multidirectional loading and/or notch susceptibility. Table 12 gives typical fatigue-strength limits of various casting alloys.

Premium (high-strength, high-toughness) castings combine a number of conventional casting procedures in a selective manner to provide premium strength, soundness, dimensional tolerances, surface finish, or a combination of these characteristics. As a result, premium engineered castings typically have somewhat higher fatigue resistance than conventional castings. Table 13 gives fatigue limits on various premium castings. Figure 13 compares premium castings and wrought plate in terms of notch-yield ratio and propagation energy values.

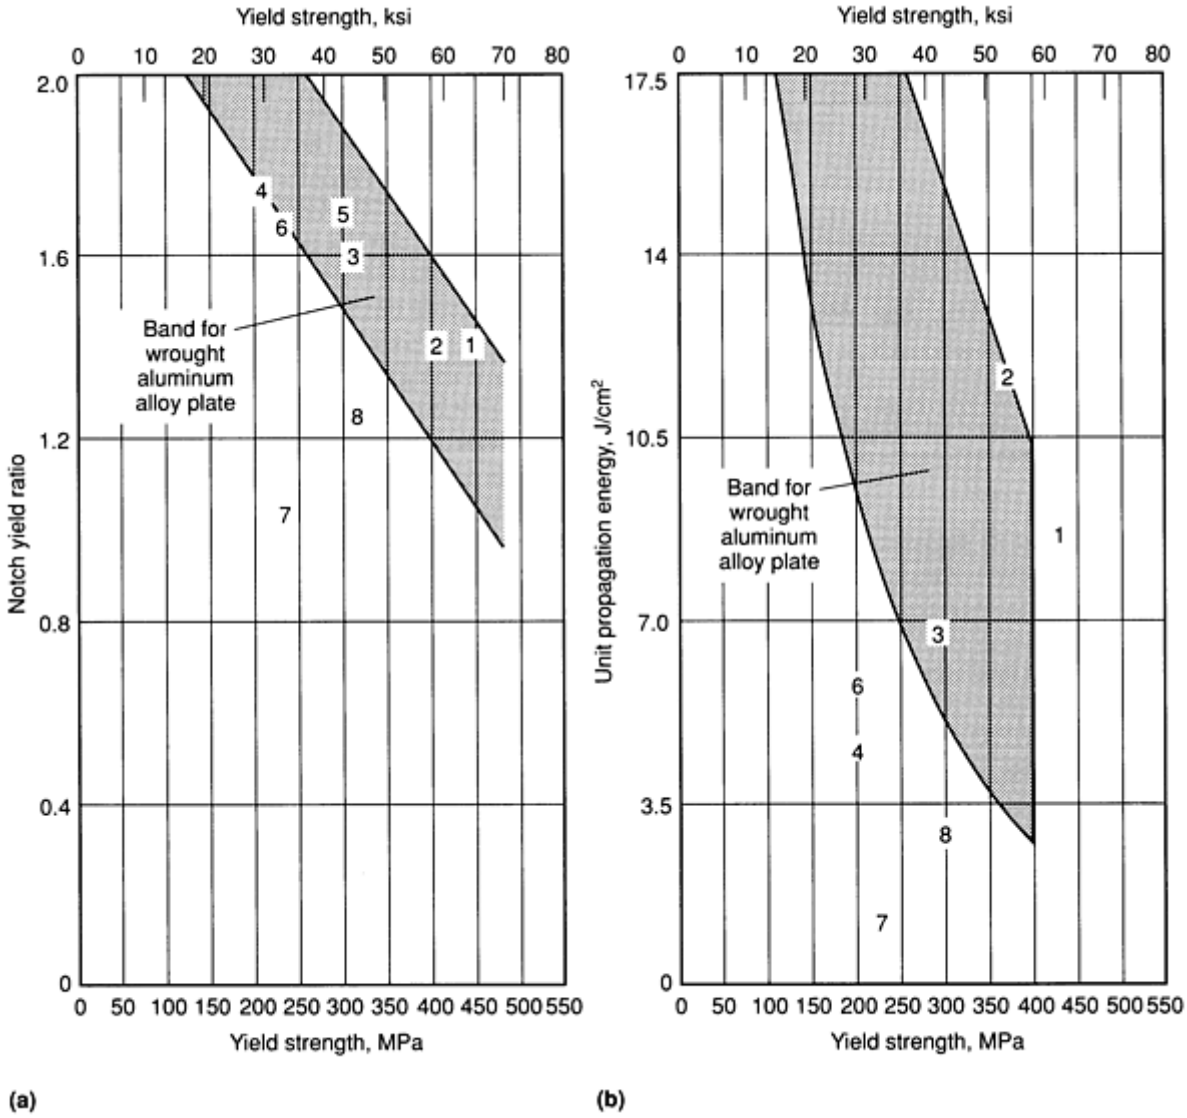

Fig. 13 Comparison of (a) notch yield ratio and (b) unit propagation energy versus yield strength for various aluminum alloy premium-quality castings and wrought aluminum alloy plate. 1, XA201.0-T7; 2, 249.0-T7; 3, 224.0-T7; 4, C355.0-T6; 5, 354.0-T6; 6, A356.0-T6; 7, 356.0-T6; 8, A357.0-T6

The production of premium-quality castings is an example of understanding and using the solidification process to good advantage. In production of premium-quality castings, composite molds combining several mold materials are used to take advantage of the special properties of each casting process. High mechanical properties in designated areas are obtained by use of special chills. Plaster sections and risers may be used to extend the feeding range of the casting.

Premium-quality castings are made to the tight radiographic and mechanical specifications required for aerospace and other critical applications. Basic linear tolerances of ±15 mm/m (±15 mils/in.) are possible with aluminum alloy castings, depending on mold material, equipment, and available fixtures, and minimum wall thickness of 3.8 mm (0.150 in.) is typical. Aluminum alloys commonly poured as premium-quality castings include C355.0, A356.0, and A357.

Table 14 gives mechanical property limits normally applied to premium engineered castings. It must be emphasized that the negotiation of limits for specific parts is usual practice, with higher as well as lower specific limits based on part design needs and foundry capabilities. Properties of the premium casting alloys at elevated temperatures are shown in Fig. 14, 15, and 16.

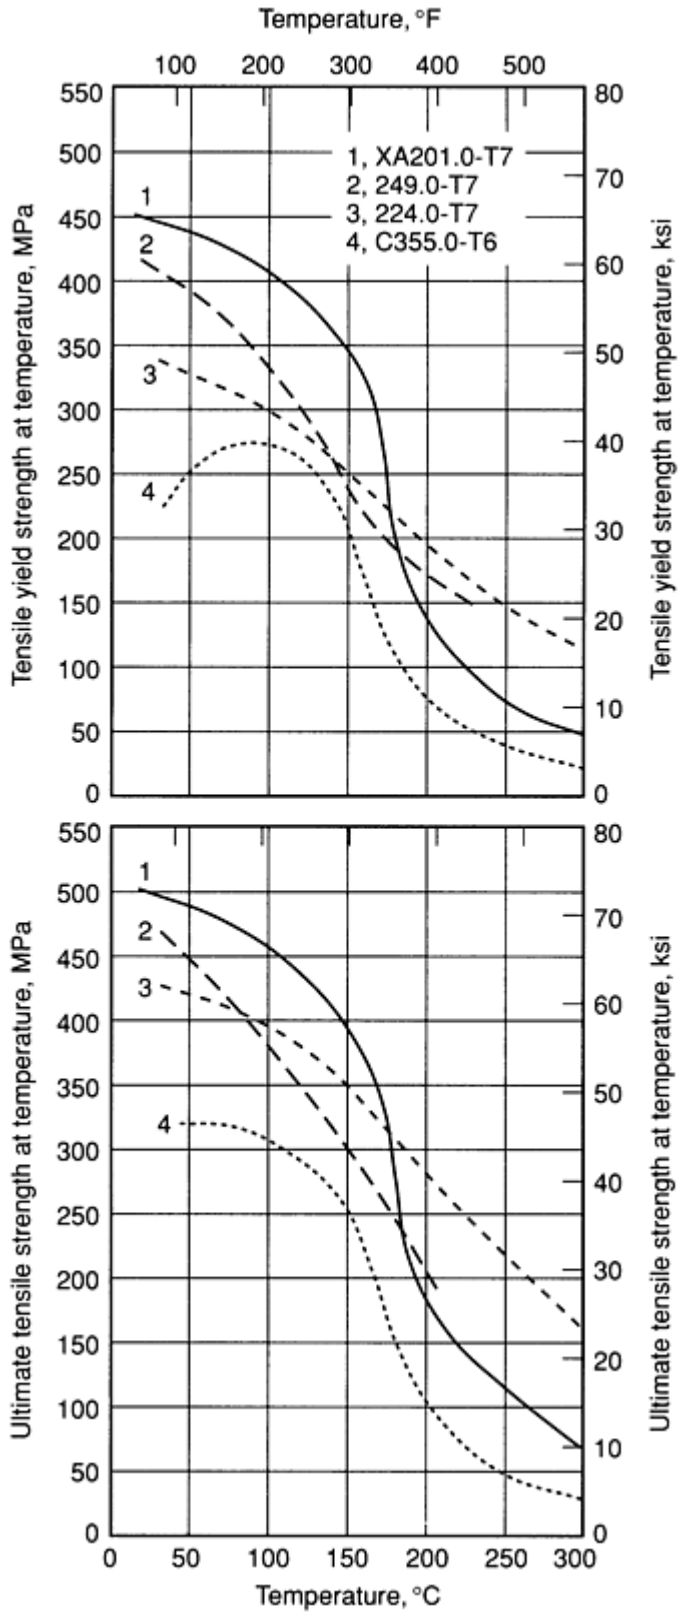

Fig. 14 Elevated-temperature tensile strengths of various premium casting alloys suggested for elevated-temperature service. Duration of temperature exposure was 10,000 h.

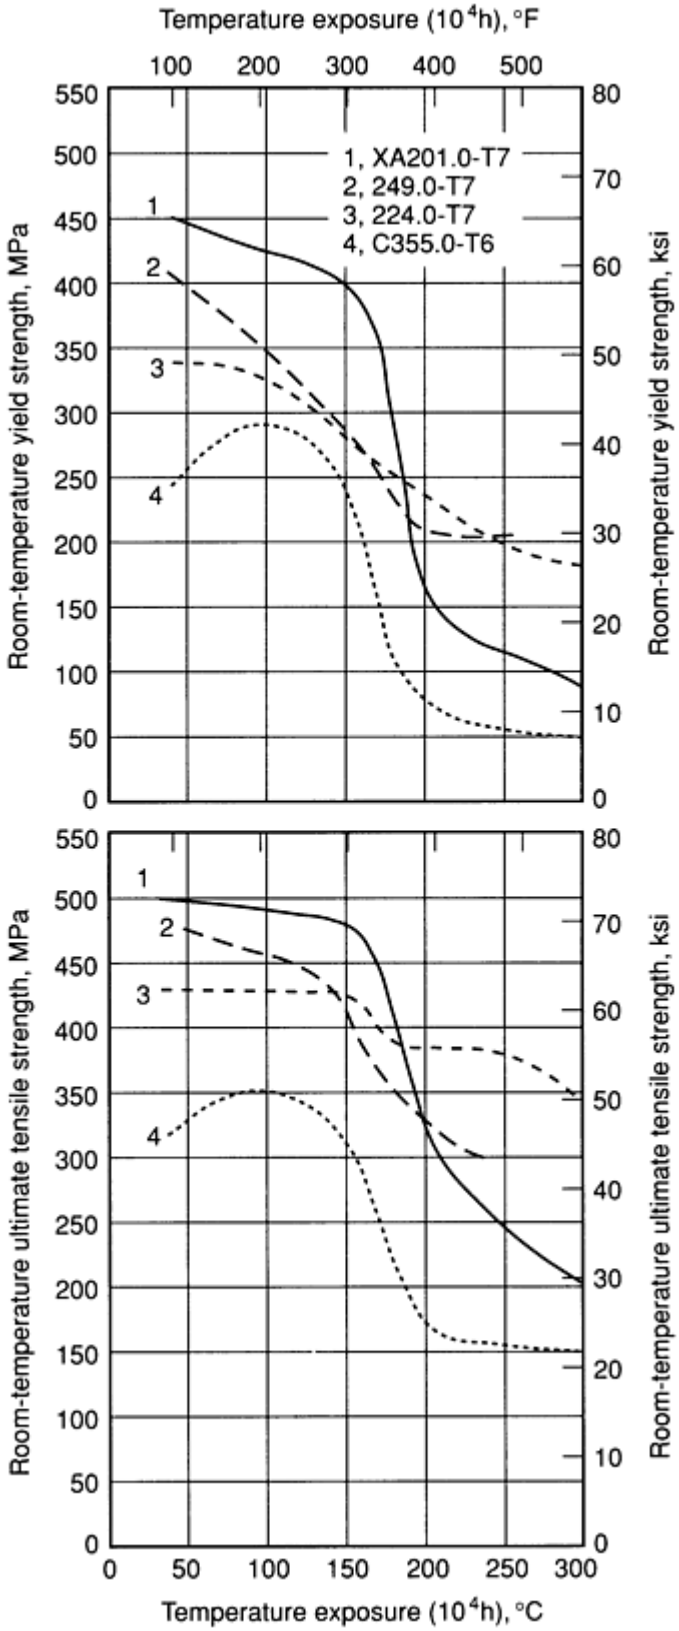

Fig. 15 Room-temperature tensile strengths of various aluminum alloy premium-quality castings after 10,000-h temperature exposure

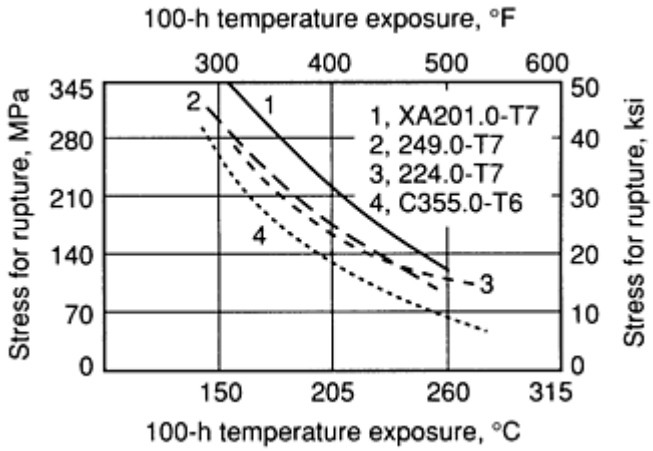

Fig. 16 100-h stress rupture of premium-quality aluminum alloy castings for elevated-temperature service

Other Engineering Characteristics

The modulus of elasticity of cast aluminum alloys varies somewhat with alloy contents, but 71 GPa (10.3×10^6 psi) is an appropriate average value for most design considerations.

Poisson's Ratio. The ratio of transverse contraction to the longitudinal elongation of a strain specimen is about 0.33 for aluminum casting alloys.

Corrosion Resistance. Aluminum and aluminum alloys have a highly protective, tightly adherent, invisible oxide film on its surface. Because of this film there is an inherent ability to resist corrosion. When this film is broken in most environments, it begins to reform immediately, the protective cover is restored, and deterioration by corrosion is resisted. Resistance to corrosion is greatly dependent on alloy content and its effect on the oxide film. For example, copper additions lower corrosion resistance, whereas silicon and magnesium enhance corrosion resistance. The most widely used test for corrosion resistance is the standard salt spray test. Relative rankings are given in Table 3.

Machinability. Aluminum exhibits better machinability than most metals and alloys. Its high thermal conductivity fosters long tool life by quickly diffusing heat away from the cutting tool. The typically low cutting forces permit the use of almost limitless machining speeds. In most cases the surface quality is exceptional. The casting alloys containing silicon (3*xx*.0 and 4*xx*.0 series) are less of a problem with regard to large chips because the cast structure is less homogeneous than wrought products. The grain-boundary segregation and second-phase silicon constituent aid chip breakage. To overcome problems with long chips of the single-phase alloys (2*xx*.0, 5*xx*.0, 7*xx*.0, and 8*xx*.0 series), the cutting tools are often ground or fitted with chip breakers. The main problem in machining aluminum is the tendency to form long continuous chips.

Coarse grain and large silicon constituent size in a casting can detract from the machinability because they accelerate tool wear. In the same manner alloys containing high contents of Fe, Mn, Cr, B, or Ti tend to form very hard second phases and may also cause excessive tool wear.

Alloys that contain small amounts of the low-melting-point metals like Sn, Pb, and Bi may exhibit free-machining characteristics.

Weldability. The weldability ratings given in Table 2 are based on the ability to be fusion welded with filler metal of the same alloy. This relates to the salvage problem of surface and dimensional defects and surface irregularities. The inert gas-shielded arc welding processes are normally used in preference to salt fluxes or flux-coated filler rods. The welding techniques used on casting are similar to those used on wrought products. However, special consideration must be made for the thicker as-cast surface aluminum oxide film and the gas porosity content of the castings. During welding this gas expands and "bubbles" up through the weld pool, causing defects in the weld. From this one must recognize that the quality of the weld is closely related to the casting quality or soundness in the area of the weld.

The large amount of oxides and porosity usually found in commercial die castings makes welding of these castings impractical in most cases. Recent quality-enhancing die casting techniques have, in a few cases, overcome this limitation.

Welding of castings to extrusions or other wrought aluminum products is often done. This part-assembly technique has been useful in many applications. Here the techniques normally used for welding wrought products apply, keeping in mind the effects of casting discontinuities on the weld quality.

Commercial Names

Trade name. KO-1

Specifications

Former ASTM. CQ 51A

SAE. 382

UNS number. A02010

AMS. 4228 and 4229

Chemical Composition

Composition limits. 4.0 to 5.2 Cu, 0.15 to 0.55 Mg, 0.20 to 0.50 Mn, 0.10 Si max, 0.15 Fe max, 0.15 to 0.35 Ti, 0.40 to 1.0 Ag, 0.05 other (each) max, 0.10 others (total) max, bal Al

Consequence of exceeding impurity limits. High iron or silicon decreases tensile properties.

Applications

Typical uses. Sand castings, permanent mold and investment castings. Structural casting members, aerospace housings, electrical transmission line fittings, insulator caps, truck and trailer castings, other applications requiring highest tensile and yield strengths with moderate elongation. Gasoline engine cylinder heads and pistons, turbine and supercharger impellers, rocker arms, connecting rods, missile fins, other applications where strength at elevated temperatures is important. Structural gear housings, aircraft landing gear castings, ordnance castings, pump housings, other applications where high strength and high energy-absorption capacity are required

Precautions in use. 201.0 castings should be specified in the T7 temper wherever resistance to stress-corrosion cracking is an important consideration (exceeds requirement of 60 days alternate immersion exposure--10 min/h to 3.5% NaCl and stressed to 75% of yield strength). T6 temper unsuitable for such applications

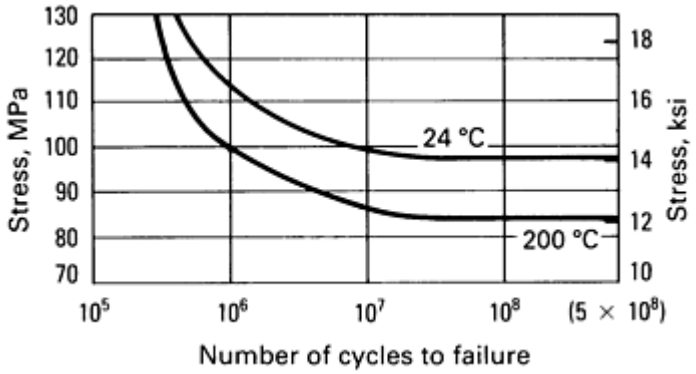

Fig. 1 *S-N* fatigue curves for alloy 201-0.T7 at 24 °C (75 °F) and 200 °C (400 °F). Curves are from R.R. Moore smooth specimens with completely reversed bending.

Shear strength. Typical values of 290 ± 30 MPa (42 ± 4 ksi)

Mass Characteristics

Density. 2.80 g/cm^3 (0.101 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 650 °C (1200 °F)

Solidus temperature. 535 °C (995 °F)

Coefficient of linear thermal expansion. T6 and T7 conditions:

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
20-100	68-212	19.3	10.7
20-200	68-392	22.7	12.6
20-300	68-572	24.7	13.7

Specific heat. 920 J/kg · K (0.22 Btu/lb · °F) at 100 °C (212 °F)

Latent heat of fusion. 389 kJ/kg (167 Btu/lb)

Thermal conductivity. 121 W/m · K (70 Btu/ft · h · °F) at 25 °C (77 °F)

Electrical Properties

Electrical conductivity. Volumetric, T6 condition: 27 to 32% IACS at 20 °C (68 °F)

Electrical resistivity. T6 condition: 54 to 64 nΩ · m at 20 °C (68 °F)

Electrolytic solution potential. Versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter: as-cast, -0.70 V; T4 condition, -0.59 V; T6 condition, -0.68 V; T7 condition, -0.73 V

Fabrication Characteristics

Solution temperature. See Table 4.

Table 4 Heat treatment practice for alloys 201.0 and 206.0

Temper designation	Solution treatment	Aging treatment
T4	510-515 °C (950-960 °F) for 2 h followed by 525-530 °C (980-990 °F)[(a)] for 14-20 h[(b)] and a water quench[(c)]	None
T6	Same as T4	Room temperature for 12-24 h, or 150 -155 °C (305-315 °F) for 20 h
T7	Same as T4	Room temperature for 12-24 h, or 185-190 °C (365-375 °F) for 5 h

T43[d]	525 °C (980 °F) for 20 h and water quenched[c]	24 h at room temperature plus $\frac{1}{2}$ to 1 h at 160 °C (320 °F)

(a) Careful composition and temperature control must be maintained during solution heat treatment in order to attain both adequate solution and to prevent incipient melting.

(b) Soaking time periods required for average sand castings after load has reached specified temperature. Time changes may be required. Permanent mold and thin wall castings, in general, take less time.

(c) At 65 to 100 °C (150 to 212 °F).

(d) Temper T43 developed for alloy 201.0 for improved impact resistance with some decrease in other properties

Aging temperature. See Table 4.

Castability. Resistance to both hot cracking and solidification shrinkage is only rated fair for this alloy. Pressure tightness is rated good. Successful production of high-quality castings requires close control of alloy composition, grain refining, melt temperature, fluxing, and heat-treating practices. Melt temperature should not exceed 790 °C (1450 °F).

Machinability. Rating is excellent. Moderate to fast speeds and feeds are recommended.

Weldability. Very good results can be obtained when joining castings of alloy 201.0 to components of similar composition, using arc or resistance welding methods. Weld repair methods are not simple and require close control of the temperature of the casting during welding to prevent hot tearing and solidification cracking.

Finishing. Electroplating imparts an excellent finish to this alloy. Mechanical polishing also gives excellent results. Anodizing produces very good appearance and good protection.

204.0
4.6Cu-0.25Mg-0.17Fe-0.17Ti

Commercial Name

A-U5GT (Pechiney)

ELT-204 (French AFNOR)

Applications

Typical uses. Extensively used in France for high-performance sand and permanent mold castings

Permanent mold. Break calipers in Bendix brakes for European cars 1958 through early 1980s (many million castings produced and used without problems)

Sand and permanent mold. Light- and heavy-duty impellers, structural parts for aerospace and auto industry. Ordinance parts for tanks, off-the-highway trucks and other equipment, light-weight, high-strength hand tools, light-weight power-train castings in auto and truck industry

Mechanical Properties

Tensile properties. See Table 5 and Fig. 2.

Table 5 Tensile properties and heat treatment of alloy 204.0

Condition	Precipitation treatment[(a)]	Hardness, HB	Mean property values and estimated standard deviation				
			Tensile strength		0.2% yield strength		Elongation in 50 mm (2 in.), %
			MPa	ksi	MPa	ksi	
Permanent molds

Y33 (T6)	12 h at 140 °C (285 °F)	105	395 ± 10	57 ± 1.5	230 ± 10	33 ± 1.5	20 ± 2
	12 h at 160 °C (320 °F)	115	405 ± 20	59 ± 3	290 ± 20	42 ± 3	16 ± 1
	12 h at 180 °C (355 °F)	125	420 ± 20	61 ± 3	380 ± 20	55 ± 3	8 ± 1
Sand castings							
Y24 (T4)	At least 5 days at 20 °C (68 °F)	110	400 ± 10	58 ± 1.5	265 ± 10	38.5 ± 1.5	14 ± 1
Y23 (T6)	12 h at 140 °C (285 °F)	105	395 ± 10	57 ± 1.5	250 ± 10	36 ± 1.5	13.5 ± 1
	12 h at 160 °C (320 °F)	115	400 ± 10	58 ± 1.5	300 ± 20	43.5 ± 3	9 ± 1

(a) Precipitation treatment preceded by a solution treatment of 12 h at 530 °C (985 °F) and a water quench

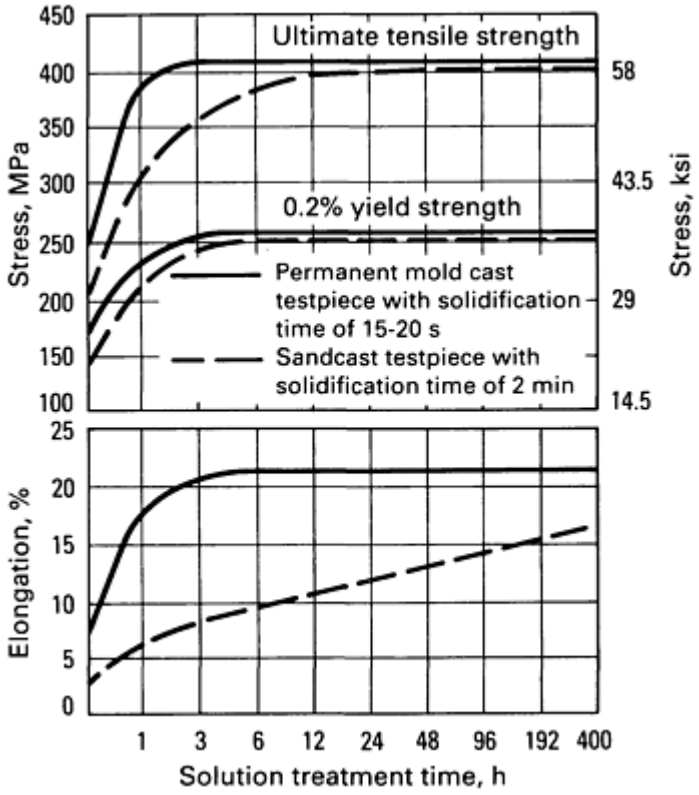

Fig. 2 Effect of solution treatment time on tensile properties of alloy 204.0. An AFNOR testpiece was cast in a permanent mold (solidification time 15 to 20 s). An Aluminum Pechiney testpiece was cast in sand (solidification time 2 min). Solution treatment at 530 °C (985 °F) followed by cold water quench and natural aging

The effects of solution treatment time depend to a considerable extent on the rate of solidification of the casting. A casting that has solidified rapidly permits a short solution treatment, whereas one that has solidified slowly requires a longer solution treatment time. The graphs in Fig. 2 compare mechanical property test results or permanent mold test specimens with sand cast test specimens as related to the solidification rate. Note the much longer times at the solution time required for the slowly solidified sand cast bars as compared with the rapidly solidified permanent mold test pieces. This difference is most pronounced in 204.0-type alloys (Fig. 2). However, some degree of these solution heat-treatment effects on mechanical properties occurs in all aluminum casting alloys.

206.0, A206.0
4.5Cu-0.30Mn-0.25Mg-0.22Ti

Specifications

AMS. 4235, 4236, 4237

Chemical Composition

Composition limits. 4.2 to 5.0 Cu, 0.15 to 0.35 Mg, 0.20 to 0.50 Mn, 0.10 Si max, 0.15 Fe max, 0.10 Zn max, 0.15 to 0.30 Ti, 0.05 Ni max, 0.05 Sn max, 0.05 other (each) max, 0.15 others (total) max, bal Al. A206.0: 4.2 to 5.0 Cu, 0.15 to 0.35 Mg, 0.20 to 0.50 Mn, 0.05 Si max, 0.10 Fe max, 0.10 Zn max, 0.15 to 0.30 Ti, 0.05 Ni max, 0.05 Sn max, 0.05 other (each) max, 0.15 others (total) max, bal Al

Applications

Typical uses. Structural castings in heat-treated temper for automotive, aerospace, and other applications where high tensile and yield strength and moderate elongation are needed. Gear housings, truck spring hanger castings, and other applications where high fracture toughness is required. Cylinder heads for gasoline and diesel motors, turbine and supercharger impellers, other applications where high strength at elevated temperatures and special aging treatment are required

Precautions in use. Subject to corrosion problems due to copper content of alloy. T4 and T7 heat treatments qualify and meet federal test requirements for stress-corrosion cracking. T6 temper should not be used where stress-corrosion cracking could be a problem.

Mechanical Properties

Tensile properties. Separately cast test bars. Tensile strength and yield strength, see Table 6 and Fig. 3. Elongation in 50 mm or 2 in. (typical for A206.0-T7): 11.7% at room temperature, 14.0% at 120 °C (250 °F), 17.7% at 175 °C (350 °F). Reduction in area (typical for A206.0-T7): 26.0% at room temperature, 40.4% at 120 °C (250 °F), 53.7% at 175 °C (350 °F)

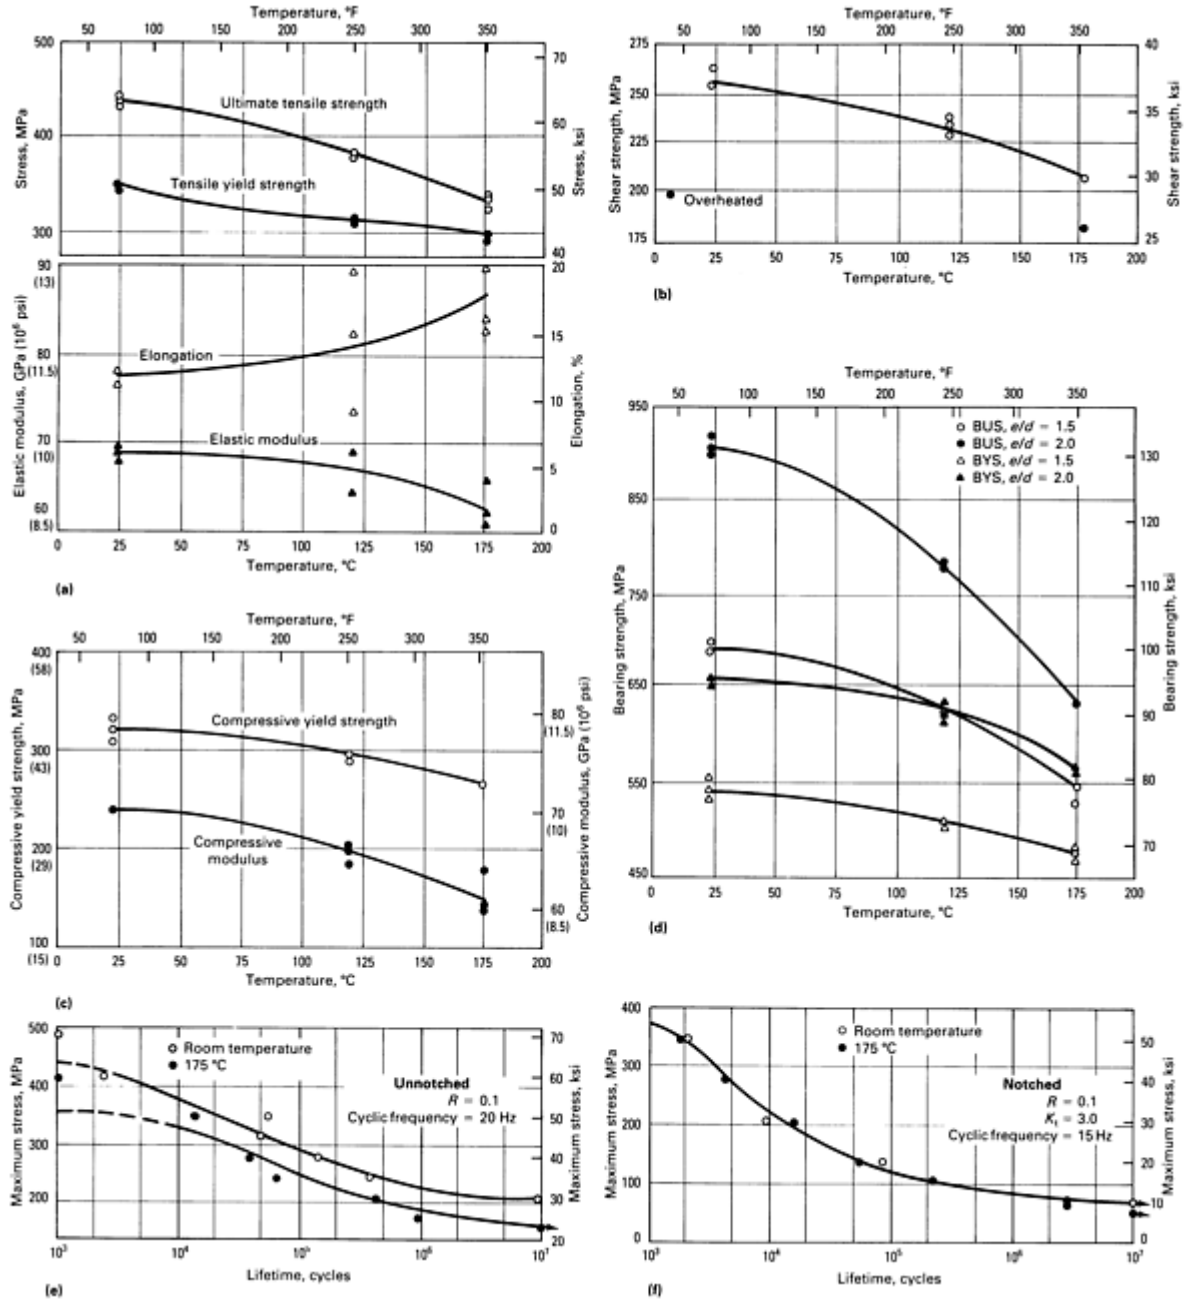

Fig. 3 Effect of temperature on the strength of A206.0-T7. (a) Tensile properties. (b) Shear strength. (c) Compressive properties. (d) Bearing strengths. (e) Unnotched fatigue limits. (f)Notched fatigue limits

Shear strength. See Table 6 and Fig. 3.

Compressive strength. See Table 6 and Fig. 3.

Bearing properties. See Table 6 and Fig. 3.

Hardness. T4 temper, 118 HV; T7 temper 137 HV

Poisson's ratio. 0.33 at 20 °C (68 °F)

Elastic modulus. Tension: 70 GPa (10.2×10^6 psi) at room temperature, 69 GPa (10.0×10^6 psi) at 120 °C (250 °F), 65 GPa (9.4×10^6 psi) at 175 °C (350 °F). See also Fig. 3.

Impact strength. Charpy V-notch, 9.5 J (7.0 ft · lbf) at 20 °C (68 ° F)

Fatigue strength. See Table 6 and Fig. 3.

Plane-strain fracture toughness. 43 MPa $\sqrt{m}$ (39 ksi $\sqrt{in}$) for A206.0-T7 (not a true K_{Ic} value per ASTM E399). See also Fig. 4.

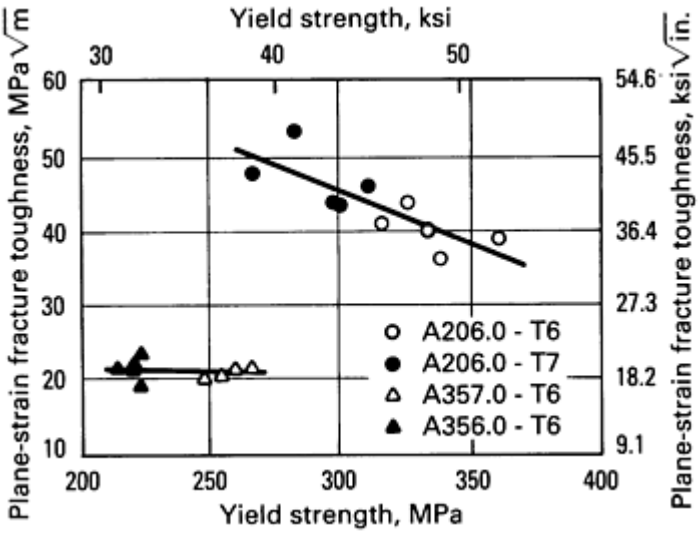

Fig. 4 Variation in plain strain-fracture toughness with yield strength of alloys A206.0, A357.0, and A356.0

Mass Characteristics

Density. 2.80 g/cm^3 (0.101 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 650 °C (1202 °F)

Solidus temperature. 570 °C (1058 °F)

Incipient melting temperature. 542 °C (1008 °F)

Coefficient of linear thermal expansion. 19.3 μm/m · K (10.7 μin./in · °F) at 20 to 100 °C (68 to 212 °F)

Specific heat. 920 J/kg · K (0.22 Btu/lb · °F) at 100 °C (212 °F)

Thermal conductivity. 121 W/m · K (70.1 Btu/ft · h · °F)

Electrical Properties

Electrical resistivity. At 20 °C (68 °F): T6 temper, 54 to 64 nΩ · m; T7 temper, 50 to 54 nΩ · m

Chemical Properties

General corrosion behavior. Comparable to other wrought or cast aluminum alloys containing equivalent amounts of copper

Fabrication Characteristics

Weldability. Fair repair welding characteristics

Solution temperature. See Table 4.

Aging temperature. See Table 4 or the following:

- T7 temper, 200 °C (390 °F), hold at temperature for 8 h
- T6 temper, 155 °C (310 °F), hold at temperature for 8 h
- T4 temper, room temperature

208.0
4Cu-3Si

Commercial Names

Former designation. 108

Specifications

Former SAE. 380

Former ASTM. CS43A

UNS number. A 02080

Government. QQ-A-601, class 8

Chemical Composition

Composition limits. 3.5 to 4.5 Cu, 0.10 Mg max, 0.5 Mn max, 2.5 to 3.5 Si, 1.2 Fe max, 1.0 Zn max, 0.35 Ni max, 0.25 Ti max, 0.50 others (total) max, bal Al

Consequence of exceeding impurity limits. High iron decreases mechanical properties, especially ductility. Zinc or tin decreases mechanical properties. Magnesium reduces ductility.

Applications

Typical uses.

Manifolds, valve bodies, and similar castings requiring pressure tightness. Other applications where good casting characteristics, good weldability, pressure tightness, and moderate strength are required

Mechanical Properties

Tensile properties. Typical for separately cast test bars. F temper: tensile strength, 145 MPa (21 ksi); yield strength, 95 MPa (14 ksi); elongation, in 50 mm or 2 in., 2.5%

Shear strength. 115 MPa (17 ksi)

Compressive yield strength. 105 MPa (15 ksi)

Hardness. 55 HB (500 kg load, 10 mm ball)

Poisson's ratio. 0.33

Elastic modulus. Tension, 71 GPa (10.3×10^6 psi); shear, 26.5 GPa (3.85×10^6 psi)

Fatigue strength. 76 MPa (11 ksi) at 5×10^8 cycles (R.R. Moore type test)

Mass Characteristics

Density. 2.79 g/cm^3 (0.101 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 625 °C (1160 °F)

Solidus temperature. 520 °C (970 °F)

Coefficient of linear thermal expansion.

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
20-100	68-212	22.0	12.2
20-200	68-392	23.0	12.7
20-300	68-572	24.0	13.3

Specific heat. 963 J/kg · K (0.230 Btu/lb · °F) at 100 °C (212 °F)

Latent heat of fusion. 389 kJ/kg (167 Btu/lb)

Thermal conductivity. At 25 °C (77 °F): as-cast, 121 W/m · K (70 Btu/ft · h · F); annealed, 146 W/m · K (84.4 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F): as-cast, 31% IACS; annealed, 38% IACS

Electrical resistivity. At 20 °C (68 °F): as-cast, 55.6 nΩ · m; annealed, 45.4 nΩ · m

Electrolytic solution potential. -0.77 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Melting temperature. 675 to 815 °C (1250 to 1500 °F)

Casting temperature. 675 to 790 °C (1250 to 1450 °F)

Joining. Rivet compositions: 2117-T4, 2017-T4. Soft solder with Alcoa No. 802; no flux. Rub-tin with Alcoa No. 33 flux: flame either reducing oxyacetylene or reducing oxyhydrogen. Metal-arc weld with 4043 alloy: Alcoa No. 27 flux. Carbon-arc weld with 4043 alloy: Alcoa No. 24 flux (automatic), Alcoa No. 27 flux (manual). Tungsten-arc argon-atmosphere weld with 4043 alloy: no flux. Resistance welding: spot, seam, and flash methods

Aging temperature. T55 temper: 150 to 160 °C (300 to 320 °F) for 16 h

(a) In 50 mm or 2 in.

Shear strength. T4 temper: 180 MPa (26 ksi). T6 temper: 205 MPa (30 ksi). T62 temper: 230 MPa (33 ksi)

Compressive yield strength. T4 temper: 115 MPa (17 ksi); T6 temper: 170 MPa (25 ksi); T62 temper: 235 MPa (34 ksi)

Hardness. T4 temper, 60 HB; T6 temper, 75 HB; T62 temper, 90 HB (500 kg load, 10 mm ball)

Poisson's ratio. 0.33

Elastic modulus. Tension, 70 GPa (10.0×10^6 psi); shear, 25.9 GPa (3.75×10^6 psi)

Fatigue strength. At 5×10^8 cycles: T4 temper, 48 MPa (7 ksi); T6 temper, 52 MPa (7.5 ksi); T62 temper, 55 MPa (8.0 ksi) (R.R. Moore type test)

Mass Characteristics

Density. 2.823 g/cm^3 (0.102 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 645 °C (1190 °F)

Solidus temperature. 520 °C (970 °F)

Coefficient of linear thermal expansion.

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
20-100	68-212	23.0	12.8
20-200	68-392	24.0	13.3
20-300	68-572	25.0	13.9

Specific heat. 963 J/kg · K (0.230 Btu/lb · °F at 100 °C (212 °F)

Latent heat of fusion. 389 kJ/kg (167 Btu/lb)

Thermal conductivity. T4 and T62 tempers: 138 W/m · K (79.8 Btu/ft · h · °F) at 25 °C (77 °F)

Electrical Properties

Electrical conductivity. Volumetric: T4 temper, 35% IACS; T62 temper, 37% IACS

Electrical resistivity. T4 and T6 tempers: 49.3 nΩ · m at 20 °C (68 °F)

Electrolytic solution potential. Versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter: T4 temper, -0.70 V; T6 temper, -0.71 V; T62 temper, -0.73 V

Fabrication Characteristics

Melting temperature. 675 to 815 °C (1250 to 1500 °F)

Casting temperature. 675 to 790 °C (1250 to 1450 °F)

Solution temperature. 515 to 520 °C (955 to 965 °F); hold at temperature for 12 h; cool in water at 65 to 100 °C (150 to 212 °F)

Aging temperature. 150 to 155 °C (305 to 315 °F). To obtain T6 temper from solution heat-treated material, hold at temperature for 3 to 5 h; for T62 temper, hold at temperature for 12 to 16 h.

Joining. Rivet compositions: 2117-T4, 2017-T4. Soft solder with Alcoa No. 802; no flux. Rub-tin with Alcoa No. 802. Atomic-hydrogen weld with 4043 alloy; Alcoa No. 22 flux. Oxyacetylene weld with 4043 alloy; Alcoa No. 22 flux; flame neutral. Metal-arc weld with 4043 alloy; Alcoa No. 27 flux. Carbon-arc weld with 4043 alloy; Alcoa No. 24 flux (automatic), Alcoa No. 27 flux (manual). Tungsten-arc argon-atmosphere weld with 4043 alloy; no flux. Resistance welding: spot, seam, and flash methods

296.0
4.5Cu-2.5Si

Commercial Names

Former designations. B 295.0, B 195

Specifications

AMS. 4282, 4283

SAE. 380

UNS number. A-22950

Government. QQ-A-596, class 4

Chemical Composition

Composition limits. 4.0 to 5.0 Cu, 0.05 Mg max, 0.35 Mn max, 2.0 to 3.0 Si, 1.2 Fe max, 0.50 Zn max, 0.25 Ti max, 0.35 Ni max, 0.35 others (total) max, bal Al

Consequence of exceeding impurity limits. High iron decreases tensile properties, especially ductility. Zinc or tin decreases tensile properties. Manganese or magnesium reduces ductility.

Applications

Typical uses. Aircraft fittings, aircraft gun control parts, aircraft wheels, railroad car seat frames, compressor connecting rods, full pump bodies, other applications requiring a combination of high-tensile properties and good machinability

Mechanical Properties

Tensile properties. Typical for separately cast test bars. Tensile strength: T4 temper, 255 MPa (37 ksi); T6 temper, 275 MPa (40 ksi); T7 temper, 270 MPa (39 ksi). Yield strength: T4 temper, 130 MPa (19 ksi), T6 temper, 180 MPa (26 ksi); T7 temper, 140 MPa (20 ksi). Elongation, in 50 mm or 2 in.: T4 temper, 9%; T6 temper, 5%; T7 temper, 4.5%. Strengths and elongations remain unchanged or improve at low temperatures. See also Table 12.

Table 12 Typical tensile properties of separately permanent mold cast test bars of alloy 296.0 at elevated temperature

Temperature		Tensile strength		Yield strength		Elongation[(a)], %
°C	°F	MPa	ksi	MPa	ksi	
T4 temper						
24	75	255	37	130	19	9
150	300	200	29	160	23	5
205	400	115	17	75	11	15

260	500	50	7	30	4	25
315	600	25	3.5	15	2.5	75
T6 temper						
24	75	275	40	180	26	5
150	300	200	29	160	23	5
205	400	115	17	75	11	15
260	500	50	7	30	4	25
315	600	25	3.5	15	2.5	75

(a) In 50 mm or 2 in.

Shear strength. T4 and T7 tempers, 205 MPa (30 ksi). T6 temper, 220 MPa (32 ksi)

Compressive yield strength. T4 and T7 tempers: 140 MPa (20 ksi); T6 temper: 180 MP (26 ksi)

Hardness. T4 temper: 75 HB; T6 temper: 90 HB; T7 temper: 80 HB (500 kg load, 10 mm ball)

Poisson's ratio. 0.33

Elastic modulus. Tension, 69 GPa (10.0×10^6 psi); shear, 26.2 GPa (3.80×10^6 psi)

Fatigue strength. At 5×10^8 cycles: T4 temper, 65 MPa (9.5 ksi); T6 temper, 70 MPa (10 ksi); T7 temper, 60 MPa (9 ksi) (R.R. Moore type test)

Mass Characteristics

Density. 2.796 g/cm^3 (0.101 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 635 °C (1170 °F)

Solidus temperature. 530 °C (990 °F)

Coefficient of linear thermal expansion.

Specific heat. 963 J/kg · K (0.230 Btu/lb · °F) at 100 °C (212 °F)

Latent heat of fusion. 389 kJ/kg (167 Btu/lb)

Thermal conductivity. T4 and T6 tempers: 130 W/m · K (75 Btu/ft · h · °F)

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
20-100	68-212	22	12.2
20-200	68-392	23	12.7
20-300	68-572	24	13.3

Electrical Properties

Electrical conductivity. Volumetric, T4 and T6 tempers: 33% IACS

Electrical resistivity. T4 and T6 tempers: 52.2 nΩ · m at 20 °C (68 °F)

Electrolytic solution potential. T4 temper: -0.71 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Melting temperature. 675 to 815 °C (1250 to 1500 °F)

Casting temperature. 675 to 815 °C (1250 to 1500 °F)

Solution temperature. 505 to 515 °C (945 to 955 °F); hold at temperature for 8 h; cool in water at 65 to 100 °C (150 to 212 °F)

Aging temperature. To obtain T6 temper from solution heat-treated material, 150 to 155 °C (305 to 315 °F) and hold at temperature 5 to 7 h; for T7 temper (U.S. Patent 1,822,877) 255 to 265 °C (495 to 505 °F) and hold at temperature 4 to6 h

Joining. Same as alloy 295.0

308.0
5.5Si-4.5Cu

Commercial Names

Former designation. A108

Specifications

Former ASTM. SC64A

SAE. 330

UNS number. A03080

Government. QQ-A-596, class 6

Chemical Composition

Composition limits. 4.0 to 5.0 Cu, 0.10 Mg max, 0.50 Mn max, 5.0 to 6.0 Si, 1.0 Fe max, 1.0 Zn max, 0.25 Ti max, 0.50 others (total) max, bal Al

Consequence of exceeding impurity limits. High iron, zinc, or tin decreases mechanical properties. Magnesium decreases ductility.

Applications

Typical uses. Ornamental grills, reflectors, general-purpose castings, and other applications where good casting characteristics, good weldability, pressure tightness, and moderate strength are required

Mechanical Properties

Tensile properties. Typical for separately cast test bars. F temper: tensile strength, 195 MPa (28 ksi); yield strength, 110 MPa (16 ksi); elongation in 50 mm or 2 in., 2.0%

Shear strength. 150 MPa (22 ksi)

Hardness. 70 HB (500 kg load, 10 mm ball)

Poisson's ratio. 0.33

Elastic modulus. Tension, 71 GPa (10.3×10^6 psi); shear, 26.5 GPa (3.85×10^6 psi)

Mass Characteristics

Density. 2.79 g/cm^3 (0.101 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 615 °C (1135 °F)

Solidus temperature. 520 °C (970 °F)

Coefficient of linear thermal expansion.

°C	°F	µm/m · K	µin./in. · °F
20-100	68-212	21.5	11.9
20-200	68-392	22.5	12.5
20-300	68-572	23.0	12.8

Specific heat. 963 J/kg · K (0.230 Btu/lb · °F) at 100 °C (212 °F)

Latent heat of fusion. 389 kJ/kg (167 Btu/lb)

Thermal conductivity. 142 W/m · K (82.2 Btu/ft · h · °F) at 25 °C (77 °F)

Electrical Properties

Electrical conductivity. Volumetric, 37% IACS at 20 °C (68 °F)

Electrical resistivity. 46.6 nΩ · m at 20 °C (68 °F)

Electrolytic solution potential. -0.75 versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Melting temperature. 675 to 815 °C (1250 to 1500 °F)

Casting temperature. 675 to 790 °C (1250 to 1450 °F)

Joining. Rivet compositions: 2117-T4, 2017-T4. Soft solder with Alcoa No. 802. Braze with Alcoa No. 717; Alcoa No. 33 flux; flame either reducing oxyacetylene or reducing oxyhydrogen. Metal-arc weld with 4043 alloy; Alcoa No. 27 flux. Carbon-arc weld with 4043 alloy; Alcoa No. 24 flux (automatic), Alcoa No. 27 flux (manual). Tungsten-arc argon-atmosphere weld with 4043 alloy, no flux. Resistance welding: spot, seam, and flash

319.0
6Si-3.5Cu

Commercial Names

Former designations. 319, Allcast

Specifications

Former ASTM. SC64D

SAE. 326

UNS number. A03190

Foreign. ISO: AlSi6Cu4

Chemical Composition

Composition limits. 3.0 to 4.0 Cu, 0.10 Mg max, 0.50 Mn max, 5.5 to 6.5 Si, 1.0 Fe max, 1.0 Zn max, 0.25 Ti max, 0.35 Ni max, 0.50 others (total) max, bal Al

Consequence of exceeding impurity limits. Mechanical properties are relatively insensitive to impurities.

Applications

Typical uses. Automotive cylinder heads, internal combustion engine crankcases, typewriter frames, piano plates, and other applications where good casting characteristics and weldability, pressure tightness, and moderate strength are required

Mechanical Properties

Tensile properties. See Table 13.

Table 13 Typical mechanical properties for separately cast test bars of alloy 319.0

Temper	Tensile strength[a]		Tensile yield strength[a]		Elongation[a][b], %	Hardness[c], HB	Shear strength		Fatigue strength[d]		Compressive yield strength[a]

Mass Characteristics

Density. 2.71 g/cm^3 (0.098 lb/in.^{3})

Thermal Properties

Coefficient of linear thermal expansion. 20.9 μm/m · K (11.6 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Specific heat. 963 J/kg · K (0.230 Btu/lb · °F) at 100 °C (212 °F)

Thermal conductivity. 128 W/m · K (74 Btu/ft · h · °F)

Fabrication Characteristics

Solution temperature. 525 °C (980 °F); hold at temperature 10 to 12 h; quench in hot water 60 to 80 °C (140 to 176 °F)

Aging temperature. To obtain T61 temper from solution heat-treated material, room temperature for 8 to 16 h; 155 °C (310 °F); hold at temperature for 10 to 12 h

---

355.0, C355.0
5Si-1.3Cu-0.5Mg

Specifications

AMS. 4210, 4212, 4214, 4280, 4281

Former ASTM. 355.0: SC51A. C355.0: SC51B

SAE. 322

UNS number. A03550

Government. 355.0: sand castings, QQ-A-601, class 10; permanent mold castings, QQ-A-596, class 6. C355.0: MIL-A-21180

Foreign. Canada: CSA SC51

Chemical Composition

Composition limits. 355.0: 1.0 to 1.5 Cu, 0.40 to 0.60 Mg, 0.50 Mn max, 4.5 to 5.5 Si, 0.6 Fe max, 0.25 Cr max, 0.35 Zn max, 0.25 Ti max, 0.05 other (each) max, 0.15 others (total) max, bal Al. (If Fe exceeds 0.45, Mn content may not be less than $\frac{1}{2}$ Fe content). C355.0: 1.0 to 1.5 Cu, 0.40 to 0.60 Mg, 0.10 Mn max, 4.5 to 5.5 Si, 0.20 Fe max, 0.10 Zn max, 0.20 Ti max, 0.05 other (each) max, 0.15 others (total) max, bal Al

Consequence of exceeding impurity limits. High iron decreases ductility. Nickel decreases resistance to corrosion. Tin reduces mechanical properties.

Applications

Typical uses. Aircraft supercharger covers, fuel-pump bodies, air-compressor pistons, liquid-cooled cylinder heads, liquid-cooled aircraft engine crankcases, water jackets, and blower housings. Other applications where good castability, weldability, and pressure tightness are required. The presence of copper in 355.0 increases strength but reduces corrosion resistance and ductility.

Mechanical Properties

Tensile properties. See Tables 21, 22, 23, 24, and 25.

Table 21 Minimum mechanical properties for alloy C355.0-T61 castings

Class[a]	Tensile strength		Tensile yield strength[b][c]		Elongation[d], %	Compressive yield strength[e]	
	MPa	ksi	MPa	ksi		MPa	ksi
1	285	41	215	31	3	215	31
2	305	44	230	33	3	230	33
3	345	50	275	40	2	275	40
10	285	41	215	31	3	215	31
11	255	37	205	30	1	205	30

(a) Classes 1, 2, and 3 (levels of properties) obtainable only at designated areas of casting; classes 10, 11, and 12 may be obtained from any location in casting.

(b) Specified in MIL-A-21180. High properties are obtained by advanced foundry techniques and by careful control of trace elements at lower levels than specified for alloy 355.0 castings.

(c) 0.2% offset.

(d) In 4*d*, where *d* is diameter of reduced section of tensile-test specimen.

(e) Design values; not specified

Mass Characteristics

Density. 2.71 g/cm^3 (0.098 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 620 °C (1150 °F)

Solidus temperature. 545 °C (1015 °F)

Coefficient of linear thermal expansion.

Temperature range		Average coefficient	
°C	**°F**	**µm/m · K**	**µin./in. · ° F**
20-100	68-212	22.4	12.4
20-200	68-392	23	12.8
20-300	68-572	24	13.3

Specific heat. 963 J/kg · K (0.230 Btu/lb · °F) at 100 °C (212 °F)

Thermal conductivity. At 25 °C (77 °F):

Temper and form	Conductivity	
	W/m · K	**Btu/ft · h · °F**
T51, sand	167	96
T6, T61, sand	152	88
T7, sand	163	94

Electrical Properties

Electrical conductivity. Volumetric:

Temper and form	Conductivity, % IACS

T51, sand	43
T6, sand	36
T61, sand	39
T7, sand	42
T6, permanent mold	39

Electrical resistivity. AT 20 °C (68 °F):

Temper and form	Resistivity, nΩ · m
T51, sand	40.1
T6, sand	47.9
T61, sand	44.2
T7, sand	41.0
T6, permanent mold	44.2

Electrolytic solution potential. T4 temper, -0.78 V and T6 temper, -0.79 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Melting temperature. 675 to 815 °C (1250 to 1500 °F)

Casting temperature. 675 to 790 °C (1250 to 1450 °F)

Solution temperature. See Table 28.

Table 28 Heat treatments for separately cast test bars of alloy 355.0

Purpose (and resulting temper)	Temperature		Time at temperature, h
	°C	°F	
Sand castings			
Solution	520-530	970-990	12[(a)(b)]
Aging

Permanent mold castings			
Solution	520-530	970-980	8[a][b]
Aging[f]			
T62[d]	170-175	335-345	14-18

(a) Soaking-time periods required for average castings after load has reached specified temperature. Time can be decreased or may have to be increased, depending on experience with particular castings.

(b) Cool in water at 65 to 100 °C (150 to 212 °F).

(c) No solution heat treatment.

(d) Start with solution heat-treated material.

(e) U.S. Patent 1,822,877.

(f) Except for temper listed under this head, temperature values for all tempers are the same as for sand castings.

Aging temperature. See Table 28.

Joining. Same as alloy 514.0

356.0, A356.0
7Si-0.3Mg

Specifications

AMS. 356.0: 4217, 4260, 4261, 4284, 4285, 4286. A356.0: 4218

Former ASTM. 356.0, SG70A; A356.0, SG70B

SAE. 356.0: J452, 323

UNS number. 356.0: A03560. A356.0: A13560

Government. 356.0: QQ-A-601, QQ-A-596. A356.0: MIL-C-21180 (class 12)

Foreign. ISO: AlSi7Mg

Chemical Composition

Composition limits. 356.0: 0.25 Cu max, 0.20 to 0.45 Mg, 0.35 Mn max, 6.5 to 7.5 Si, 0.6 Fe max, 0.35 Zn max, 0.25 Ti max 0.5 other (each) max, 0.15 others (total) max, bal Al. A356.0: 0.20 Cu max, 0.25 to 0.45 Mg, 0.10 Mn max, 6.5 to 7.5 Si, 0.20 Fe max, 0.10 Zn max, 0.20 Ti max, 0.05 other (each) max, 0.15 others (total) max, bal Al

Consequence of exceeding impurity limits. High copper or nickel decreases ductility and resistance to corrosion. High iron decreases strength and ductility.

Applications

Typical uses. 356.0: aircraft pump parts, automotive transmission cases, aircraft fittings and control parts, water-cooled cylinder blocks. Other applications where excellent castability and good weldability, pressure tightness, and good resistance to corrosion are required. A356.0: aircraft structures and engine controls, nuclear energy installations, and other applications where high-strength permanent mold or investment castings are required

Mechanical Properties

Tensile properties. See Tables 29, 30, 31, 32, and 33.

Table 29 Minimum mechanical properties for alloy A356.0-T61 castings

Class[a]	Tensile strength[b]		Tensile yield strength[b][c]		Elongation[d], %	Compressive yield strength[e]	
	MPa	ksi	MPa	ksi		MPa	ksi
1	260	38	195	28	5	195	28

		100	200	29	195	28	185	27	170	25	165	24

Mass Characteristics

Density. 2.685 g/cm^3 (0.097 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 615 °C (1135 °F)

Solidus temperature. 555 °C (1035 °F)

Coefficient of linear thermal expansion.

Temperature range		Average coefficient	
°C	°F	µm/m · K	µin./in. · °F
20-100	68-212	21.5	11.9
20-200	68-392	22.5	12.5
20-300	68-572	23.5	13.1

Specific heat. 963 J/kg · K (0.230 Btu/lb · °F) at 100 °C (212 °F

Latent heat of fusion. 389 kJ/kg

Thermal conductivity. At 25 °C (77 °F):

Temper and form	Conductivity	
	W/m · K	Btu/ft · h · °F
T51, sand	167	96
T6, sand	151	87
T7, sand	155	90

Electrical Properties

Electrical conductivity. Volumetric:

Temper and form	IACS, %
T51, sand	43
T6, sand	39
T7, sand	40
T6, permanent mold	41

Electrical resistivity. At 20 °C (68 °F):

Temper and form	Resistivity, nΩ · m
T51, sand	40.1
T6, sand	44.2

T7, sand	43.1
T6, permanent mold	42.1

Electrolytic solution potential. T6 temper (sand): -0.82 V versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Radiation Effect on Properties

Effect of neutron irradiation. See Table 35.

Table 35 Effect of neutron radiation on tensile properties of alloy A356.0-T61

Fast neutron flux, n/cm^2	Tensile strength		Yield strength		Elongation, %
	MPa	ksi	MPa	ksi	
Control sample	230	33	180	26	4
2.0×10^{19}	255	37	200	29	6
1.2×10^{20}	290	42	230	33	6
5.6×10^{20}	315	46	290	42	6
9.8×10^{20}	375	54	360	52	3

Fabrication Characteristics

Melting temperature. 675 to 815 °C (1250 to 1500 °F)

Casting temperature. 675 to 790 °C (1250 to 1450 °F)

Solution temperature. See Table 36.

Table 36 Heat treatments for separately cast test bars of alloys 356.0 and A356.0

Purpose (and resulting temper)	Temperature		Time at temperature, h
	°C	°F	
Sand castings			

Solution	535-540	995-1005	12[a][b]
Aging			
T51[c]	225-230	435-445	7-9
T6[d]	150-155	305-315	2-5
T7[d][e]	225-230	435-445	7-9
T71[d]	245-250	470-480	2-4
Permanent mold castings			
Solution	535-540	995-1005	8[a][b]
Aging[f]			

(a) Soaking-time periods required for average castings after load has reached specified temperature. Time can be decreased or may have to be increased, depending on experience with particular castings.

(b) Cool in water at 65 to 100 °C (150 to 212 °F).

(c) No solution heat treatment.

(d) Start with solution heat-treated material.

(e) U.S. Patent 1,822,877.

(f) Except for temper listed under this head, temperature values for all tempers are the same as for sand castings.

Aging temperature. See Table 36.

Joining. Same as alloy 514.0

357.0, A357.0
7Si-0.5Mg

Specifications

UNS number. 357.0: A03570. A357.0: A13570

Government. A357.0: MIL-A-21180

Chemical Composition

Composition limits. 357.0: 0.05 Cu max; 0.45 to 0.6 Mg, 0.03 Mn max, 6.5 to 7.5 Si, 0.15 Fe max, 0.05 Zn max, 0.20 Ti max, 0.05 other (each) max, 0.15 others (total) max, bal Al. A357.0: 0.20 Cu max, 0.40 to 0.7 Mg, 0.10 Mn max, 6.5 to 7.5 Si, 0.20 Fe max, 0.10 Zn max, 0.10 to 0.20 Ti, 0.04 to 0.07 Be, 0.05 other (each) max, 0.15 others (total) max, bal Al

Applications

Typical uses. Critical aerospace applications and other uses requiring heat-treatable permanent mold casting that combines ready weldability with high strength and good toughness

Mechanical Properties

Tensile properties. See Tables 37 and 38.

Table 37 Minimum mechanical properties for alloy A357.0 castings

Class[a]	Tensile strength[b]		Tensile yield strength[b][c]		Elongation[b][d], %	Compressive yield strength[e]	
	MPa	ksi	MPa	ksi		MPa	ksi
T61, permanent mold castings

(a) In 4*d*, where *d* is diameter of reduced section of tensile-test specimen

Compressive yield strength. See Table 37.

Hardness. A357.0, T61 temper: 100 HB

Elastic modulus. A357.0: tension, 71.7 GPa (10.4×10^6 psi); shear, 26.8 GPa (3.9×10^6 psi); compression, 72.4 GPa (10.5×10^6 psi)

Fatigue strength. A357.0-T62 (rotating-beam tests):

Number of cycles	Stress	
	MPa	ksi
10^5	255	37
10^6	195	28
10^7	145	21
10^8	115	17
5×10^8	110	16

Mass Characteristics

Density. 2.68 g/cm^3 (0.097 lb/in.^{3})

Thermal Properties

Liquidus temperature. A357.0: 615 °C (1135 °F)

Solidus temperature. 555 °C (1035 °F)

Coefficient of linear thermal expansion. 21.6 μm · K (12.0 μin./in. · °F) at 17 to 100 °C (63 to 212 °F)

Specific heat. 963 J/kg · K (0.230 Btu/lb · °F) at 100 °C (212 °F)

Thermal conductivity. 152 W/m · K (88 Btu/ft · h · °F) at 25 °C (77 °F)

Fabrication Characteristics

Solution temperature. 540 °C (1005 °F); hold at temperature for 8 h; hot water quench

Aging temperature. T6 temper: 170 °C (340 °F); hold at temperature 3 to 5 h

Joining. Because of the beryllium content, care should be taken not to inhale fumes during welding.

359.0
9Si-0.6Mg

Specifications

Former ASTM. SG91A

UNS number. A03590

Government. MIL-A-21180

Chemical Composition

Composition limits. 0.20 Cu max, 0.50 to 0.7 Mg, 0.10 Mn max, 8.5 to 9.5 Si, 0.20 Fe max, 0.10 Zn max, 0.20 Ti max, 0.05 other (each) max, 0.15 others (total) max, bal Al

Applications

Typical uses. A moderately high-strength permanent mold casting alloy having superior casting characteristics

Mechanical Properties

Tensile properties. See Tables 39 and 40.

Table 39 Minimum mechanical properties for alloy 359.0-T61

Class[a]	Tensile strength[b]		Tensile yield strength[b][c]		Elongation[b][d], %	Compressive yield strength[e]

10^7	145	21
10^8	115	17
5×10^8	110	16

Mass Characteristics

Density. 2.685 g/cm^3 (0.097 lb/in.^{3})

Thermal Properties

Liquidus temperature. 615 °C (1135 °F)

Solidus temperature. 555 °C (1035 °F)

Coefficient of linear thermal expansion. 20.9 μm/m · K (11.6 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Specific heat. 963 J/kg · K (0.230 Btu/lb · °F)

Thermal conductivity. 138 W/m · K (80 Btu/ft · h · °F)

Fabrication Characteristics

Solution temperature. 540 °C (1000 °F); hold at temperature 10 to 14 h; hot water quench 60 to 80 °C (140 to 175 °F)

Aging temperature. Room temperature for 8 to 16 h after solution treatment, then 155 °C (310 °F) for 10 to 12 h (T61 temper), or 170 °C (340 °F) for 6 to 10 h (T62 temper)

360.0, A360.0
9.5 Si-0.5Mg

Specifications

AMS. 360.0: 4290F

Former ASTM. 360.0: SG100B. A360.0: SG100A

SAE. A360.0: J452, 309

UNS number. 360.0: A03600. A360.0: A13600

Government. 360.0: QQ-A-591

Chemical Composition

Composition limits. 360.0: 0.6 Cu max, 0.40 to 0.6 Mg, 0.35 Mn max, 9.0 to 10.0 Si, 2.0 Fe max, 0.50 Ni max, 0.50 Zn max, 0.15 Sn max, 0.25 other (total) max, bal Al. A360.0: 0.6 Cu max, 0.40 to 0.6 Mg, 0.35 Mn max, 9.0 to 10.0 Si, 1.3 Fe max, 0.50 Ni max, 0.50 Zn max, 0.15 Sn max, 0.25 other (total) max, bal Al

Consequence of exceeding impurity limits. Increasing copper limits lowers resistance to corrosion; increasing iron lowers ductility. Decreasing silicon reduces castability.

Applications

Typical uses. Die castings requiring improved corrosion resistance compared to 3800. Other applications where excellent castability, pressure tightness, resistance to hot cracking, strength at elevated temperatures, and ability to be electroplated are required. Poor weldability and brazeability. General-purpose casting alloy for such items as cover plates and instrument cases

Mechanical Properties

Tensile properties. Typical for separately cast test bars, as-cast. 360.0: tensile strength, 305 MPa (44 ksi); yield strength, 170 MPa (25 ksi); elongation, 2.5% in 50 mm or 2 in. A360.0: tensile strength, 320 MPa (46 ksi); yield strength, 170 MPa (25 ksi); elongation, 3.5% in 50 mm or 2 in. See also Table 41.

Table 41 Typical tensile properties for separately cast test bars of alloys 360.0-F and A360.0-F at elevated temperature

Temperature		Tensile strength		Yield strength[(a)]		Elongation[(b)], %

UNS number. 380.0: A03800. A380.0: A13800

Government. A380.0: QQ-A-591

Foreign. 380.0: Canada, CSA SC84

Chemical Composition

Composition limits. 380.0: 3.0 to 4.0 Cu, 0.10 Mg max, 0.50 Mn max, 7.5 to 9.5 Si, 2.0 Fe max, 0.50 Ni max, 3.0 Zn max, 0.35 Sn max, 0.50 others (total) max, bal Al. A380.0: 3.0 to 4.0 Cu, 0.10 Mg max, 0.50 Mn max, 7.5 to 9.5 Si, 1.3 Fe max, 0.50 Ni max, 3.0 Zn max, 0.35 Sn max, 0.50 others (total) max, bal Al

Consequence of exceeding impurity limits. Increasing iron will lower ductility. Relatively large quantities of impurities may be present before serious effects are detected.

Applications

Typical uses. Vacuum cleaners, floor polishers, parts for automotive and electrical industries such as motor frames and housings. Most widely used aluminum die casting alloy. Poor weldability and brazeability; fair strength at elevated temperatures

Mechanical Properties

Tensile properties. Typical for separately cast test bars, as-cast. 380.0: tensile strength, 330 MPa (48 ksi); yield strength, 165 MPa (24 ksi); elongation, 3% in 50 mm or 2 in. A380.0: tensile strength, 325 MPa (47 ksi); yield strength, 160 MPa (23 ksi); elongation, 4% in 50 mm or in. See also Tables 42 and 43.

Table 42 Typical tensile properties for separately cast test bars of alloy 380.0-F at elevated temperature

Temperature		Tensile strength		Yield strength		Elongation, %

Fatigue strength. At 5×10^8 cycles, 380.0 and A380.0: 138 MPa (20 ksi) (R.R. Moore type test)

Mass Characteristics

Density. 2.71 g/cm^3 (0.098 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 595 °C (1100 °F)

Solidus temperature. 540 °C (1000 °F)

Coefficient of linear thermal expansion. At 20 to 200 °C (68 to 392 °F). 380.0: 22.0 μm/m · K (12.2 μin./in. · °F). A380.0: 21.8 μm/m · K (12.1 μin./in. · °F)

Specific heat. 963 J/kg · K (0.230 Btu/lb · °F) at 100 °C (212 °F)

Latent heat of fusion. 389 kJ/kg (167 Btu/lb)

Thermal conductivity. 96.2 W/m · K (55.6 Btu/ft · h · °F) at 25 °C (77 °F)

Electrical Properties

Electrical conductivity. Volumetric, 27% IACS at 20 °C (68 °F)

Electrical resistivity. 65 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Melting temperature. 650 to 760 °C (1200 to 1400 °F)

Die casting temperature. 635 to 705 °C (1175 to 1300 °F)

Annealing temperature. For increased ductility, 260 to 370 °C (500 to 700 °F); hold at temperature 4 to 6 h; furnace cool or cool in still air

Stress relief temperature. 175 to 260 °C (350 to 500 °F); hold at temperature 4 to 6 h; cool in still air

Joining. Same as alloy 413.0 and A413.0

383.0
10.5Si-2.5Cu

Specifications

Former ASTM. SC102A

SAE. 383

UNS number. A03830

Chemical Composition

Composition limits. 2.0 to 3.0 Cu, 0.10 Mg max, 0.50 Mn max, 9.5 to 11.5 Si, 1.3 Fe max, 0.30 Ni max, 3.0 Zn max, 0.15 Sn max, 0.50 others (total) max, bal Al

Applications

Typical uses. Applications requiring good die filling capacity, fair pressure tightness, electroplating and machining characteristics, and strength at elevated temperature, poor weldability, and brazeability; anodizing quality is poor

Mechanical Properties

Tensile properties. Typical for separately cast test bars, as-cast; tensile strength, 310MPa (45 ksi); yield strength, 150 MPa (22 ksi); elongation, 3.5% in 50 mm or 2 in.

Hardness. 75 HB (500 kg load, 10 mm ball)

Poisson's ratio. 0.33

Fatigue strength. 145 MPa (21 ksi) at 5×10^8 cycles

Impact strength. Charpy V-notch: 4 J (3 ft · lbf)

Mass Characteristics

Density. 2.74 g/cm^3 (0.099 lb/in.^{3})

Thermal Properties

Liquidus temperature. 580 °C (1080 °F)

Solidus temperature. 515 °C (960 °F)

Coefficient of linear thermal expansion. 21.1 μm/m · K (11.7 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Thermal conductivity. 96.2 W/m · K (55.6 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, 23% IACS at 20 °C (68 °F)

Fabrication Characteristics

Die casting temperature. 615 to 700 °C (1140 to 1290 °F)

Stress relief temperature. 175 to 260 °C (350 to 500 °F); hold at temperature 4 to 6 h; cool in still air

Annealing temperature. For increased ductility, 260 to 370 °C (500 to 700 °F); hold at temperature 4 to 6 h; furnace cool or cool in still air

---

384.0, A384.0
11.2Si-3.8Cu

Specifications

Former ASTM. SC114A

SAE. 303

UNS number. 384.0: A03840. A384.0: A13840

Government. 384.0: QQ-A-591

Chemical Composition

Composition limits. 384.0: 3.0 to 4.5 Cu, 0.10 Mg max, 0.5 Mn max, 10.5 to 12.0 Si, 1.3 Fe max, 0.50 Ni max, 3.0 Zn max, 0.35 Sn max, 0.50 others (total) max, bal Al. A384.0: 3.0 to 4.5 Cu, 0.10 Mg max, 0.50 Mn max, 10.5 to 12.0 Si, 1.3 Fe max, 0.50 Ni max, 1.0 Zn max, 0.35 Sn max, 0.50 other (total) max, bal Al

Consequence of exceeding impurity limits. Generally insensitive to minor variations in composition, but resistance to corrosion is reduced and lowers as copper increases

Applications

Typical uses. Die casting applications where fair pressure tightness and fair strength at elevated temperatures are required. Better die filling than 380.0. Poor weldability and brazeability

Mechanical Properties

Tensile properties. Typical for separately cast test bars, as-cast, 384.0 and A384.0: tensile strength, 330 MPa (48 ksi); yield strength, 165 MPa (24 ksi); elongation, 2.5% in 50 mm or 2 in.

Shear strength. 384.0: 200 MPa (29 ksi)

Hardness. 384.0 and A384.0: 85 HB (500 kg load, 10 mm ball)

Fatigue strength. 384.0 140 MPa (20 ksi)

Mass Characteristics

Density. 384.0: 2.823 g/cm^3 (0.102 lb/in.^{3}). A384.0: 2.768 g/cm^3 (0.100 lb/in.^{3})

Thermal Properties

Liquidus temperature. 580 °C (1080 °F)

Solidus temperature. 515 °C (960 °F)

Coefficient of linear thermal expansion. 384.0: 20.8 μm · K (11.6 μin./in. · °F). A384.0: 20.7 μm · K (11.5 μin./in. · °F)

Thermal conductivity. 384.0: 92 W/m · K (53 Btu/ft · h · °F). A384.0: 96 W/m · K (56 Btu/ft · h · °F).

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F). 384.0: 22% IACS. A384.0: 23% IACS

Fabrication Characteristics

Die casting temperature. 615 to 700 °C (1140 to 1290 °F)

Stress relief temperature. 175 to 260 °C (350 to 500 °F); hold at temperature 4 to 6 h; cool in still air

Annealing temperature. For increased ductility, 260 to 370 °C (500 to 700 °F); hold at temperature 4 to 6 h; furnace cool or cool in still air

---

390.0, A390.0
17.0Si-4.5Cu-0.6Mg

Specifications

UNS number. 390.0 die castings, A03900, A390.0: sand and permanent mold castings, A13900

Chemical Composition

Composition limits. 390.0: 4.0 to 5.0 Cu, 0.45 to 0.65 Mg, 0.10 Mn max, 16.0 to 18.0 Si, 1.3 Fe max, 0.10 Zn max, 0.20 Ti max, 0.10 other (each) max, 0.20 others (total) max, bal Al. A390.0: 4.0 to 5.0 Cu, 0.45 to 0.65 Mg, 0.10 Mn max, 16.0 to 18.0 Si, 0.5 Fe max, 0.10 Zn max, 0.20 Ti max, 0.10 other (each) max, 0.20 others (total) max, bal Al

Applications

Typical uses. Automotive cylinder block, four cycle air-cooled engines, air compressors, Freon compressors, pumps requiring abrasive resistance, pulleys, and brake shoes. Other applications where high wear resistance, low coefficient of thermal expansion, good elevated-temperature strength, and good fluidity are required

Mechanical Properties

Tensile properties. See Tables 44 and 45. Typical elongation. 390.0: die and Acurad castings (F and T5 tempers), 1.0% in 50 mm or 2 in.; Acurad castings (T6 and T7 tempers), <1.0% in 50 mm or 2 in. A390.0: sand castings (all tempers) and permanent mold castings (T6 and T7 tempers), <1.0% in 50 mm or 2 in.; permanent mold castings (F and T5 tempers), 1.0% in 50 mm or 2 in.

Table 44 Typical room-temperature mechanical properties for separately cast test bars of alloys 390.0 and A390.0

Temper	Tensile strength[a]		Yield strength[b]		Hardness[a][c], HB	Fatigue strength[d]	
	MPa	ksi	MPa	ksi		MPa	ksi
A390.0, sand castings							
F, T5	180	26	180	26	100	. . .	. . .

T6	275	40	275	40	140	105	15
T7	250	36	250	36	115	. . .	. . .
A390.0, permanent mold castings							
F, T5	200	29	200	29	110	. . .	. . .
T6	310	45	310	45	145	115	17
T7	260	38	260	38	120	100	14.5
390.0, conventional die castings							
F	280	40.5	240	35	120	140	20
T5	295	43	260	38	125	. . .	. . .
390.0, Acurad castings							
F	205	30	195	28	110	90	13
T5	205	30	200	29	110	95	14
T6	365	53	365	53	150	115	17
T7	275	40	275	40	125	110	16

(a) Tensile properties and hardness are determined from standard cast-to-size tensile specimens 12.7 mm ($\frac{1}{2}$ in.) diameter for sand, permanent mold, and Acurad castings and 6.4 mm ($\frac{1}{4}$ in.) diameter for die castings and tested without machining the surface.

(b) 0.2% offset. For 390.0 and A390.0 castings, yield strength normally equals tensile strength because 0.2% offset is not reached prior to fracture.

(c) 500 kg load; 10 mm ball.

(d) At 5×10^8 cycles; R.R. Moore type test

Table 45 Typical elevated-temperature tensile yield strength for separately cast test bars of alloy 390.0

(a) Based on cast-to-size test specimens tested after 1000 h holding at test temperature

Hardness. See Table 44.

Elastic modulus. Tension, 81.2 GPa (11.8×10^6 psi); compression, 82.8 GPa (12.0×10^6 psi)

Fatigue strength. See Table 44.

Mass Characteristics

Density. 2.73 g/cm^3 (0.099 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 650 °C (1200 °F)

Solidus temperature. 505 °C (945 °F)

Coefficient of linear thermal expansion. 18.0 μm/m · K (10.0 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Thermal conductivity. 134 W/m · K (77.4 Btu/ft · h · °F) at 25 °C (77 °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F). F temper: 27% IACS. T5 temper: 25% IACS

Fabrication Characteristics

Solution temperature. 495 °C (925 °F)

Aging temperature. T5 and T7 tempers: 230 °C (450 °F). T6 temper: 175 °C (350 °F); hold at temperature for 8 h

413.0, A413.0
12Si

Commercial Names

Former designation. 413.0: 13. A413.0: A13

Specifications

Former ASTM. 413.0: S12B. B85 S12A

SAE. A413.0: J453, 305

UNS number. 413.0: A04130. A413.0: A14130

Government. A413.0: QQ-A-591 (class 2)

Foreign. Canada: A413.0, CSA S12P. France: NF A-S13. ISO: AlSi12

Chemical Composition

Composition limits. 413.0: 1.0 Cu max, 0.10 Mg max, 0.35 Mn max, 11.0 to 13.0 Si, 2.0 Fe max, 0.50 Ni max, 0.50 Zn max, 0.15 Sn max, 0.25 others (total) max, bal Al. A413.0: 1.0 Cu max, 0.10 Mg max, 0.35 Mn max, 11.0 to 13.0 Si, 1.3 Fe max, 0.50 Ni max, 0.50 Zn max, 0.15 Sn max, 0.25 others (total) max, bal Al

Consequences of exceeding impurity limits. Content of impurities may be quite high before serious effects are detected. Increasing copper lowers corrosion resistance; increasing iron and magnesium lowers ductility; increasing silicon content may lead to machining problems.

Applications

Typical uses. Miscellaneous thin-walled and intricately designed castings. Other applications where excellent castability, resistance to corrosion, and pressure tightness are required

Mechanical Properties

Tensile properties. Typical for separately cast test bars, as-cast, 413.0: tensile strength, 300 MPa (43 ksi); yield strength, 145 MPa (21 ksi); elongation, 2.5% in 50 mm or 2 in. 413.0: tensile strength, 290 MPa (42 ksi); yield strength, 130 MPa (19 ksi); elongation, 3.5% in 50 mm or 2 in. See also Table 46.

Mass Characteristics

Density. 2.657 g/cm^3 (0.096 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Coefficient of linear thermal expansion.

Temperature range		**Average coefficient**	
°C	**°F**	**µm/m · K**	**µin./in. · °F**
20-100	68-212	20.4	11.3
20-200	68-392	21.4	11.8
20-300	68-572	22.4	12.4

Specific heat. 963 J/kg · K (0.230 Btu/lb · °F)

Latent heat of fusion. 389 kJ/kg (167 Btu/lb)

Thermal conductivity. 121 W/m · K (70 Btu/ft · h · °F) at 25 °C (77 °F)

Electrical Properties

Electrical conductivity. Volumetric, 31% IACS at 20 °C (68 °F)

Electrical resistivity. 55.6 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Melting temperature. 650 to 760 °C (1200 to 1400 °F)

Die casting temperature. 635 to 705 °C (1175 to 1300 °F)

Joining. Rivet compositions: 6053-T4, 6053-T6, 6053-T61. Soft solder: After copper plating, then use methods applicable to copper-base alloys. Resistance welding: flash method

B443.0: 0.15 Cu max, 0.05 Mg max, 0.35 Mn max, 4.5 to 6.0 Si, 0.8 Fe max, 0.35 Zn max, 0.25 Ti max, 0.25 others (total) max, bal Al. C443.0: 0.6 Cu max, 0.10 Mg max, 0.35 Mn max, 4.5 to 6.0 Si, 2.0 Fe max, 0.50 Ni max, 0.50 Zn max, 0.15 Sn max, 0.25 others (total) max, bal Al

Consequence of exceeding impurity limits. For die cast alloy, relatively large quantities of impurities may be present before serious effects are detected. Increasing copper tends to lower resistance to corrosion; increasing iron and magnesium tends to lower ductility. For sand and permanent mold cast alloys, high copper, iron, or nickel decreasing ductility and resistance to corrosion. Increasing magnesium reduces ductility.

Applications

Typical uses. Cooking utensils, food-handling equipment, marine fittings, miscellaneous thin-section castings. Die castings: applications where good pressure tightness, above-average ductility, and excellent resistance to corrosion are

required. Sand and permanent mold castings: applications where very good castability and resistance to corrosion with moderate strength are required

Mechanical Properties

Tensile properties. See Table 47.

Table 47 Typical tensile properties for separately cast test bars of alloys 443.0, 443.0-F, B443.0-F, and C443.0-F

Temperature		Tensile strength		Yield strength[(a)]		Elongation[(b)], %

(b) In 50 mm or 2 in.

Shear strength. F temper: 443.0 (sand castings): 95 MPa (14 ksi). B443.0 (permanent mold castings: 110 MPa (16 ksi). C443.0 (die castings): 145 MPa (21 ksi)

Hardness. F temper: 443.0 (sand castings): 40 HB. B443.0 (permanent mold castings): 45 HB. C443.0 (die castings): 65 HB (500 kg load, 10 mm ball)

Poisson's ratio. 0.33

Elastic modulus. Tension, 71.0 GPa (10.3×10^6 psi); shear, 26.5 GPa (3.85×10^6 psi)

Fatigue strength. F temper, at 5×10^8 cycles. 443.0 (sand castings) and B443.0 (permanent mold castings): 55 MPa (8 ksi). C443.0 (die castings): 115 MPa (17 ksi) (R.R. Moore type test)

Mass Characteristics

Density. 2.69 g/cm^3 (0.097 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 630 °C (1170 °F)

Solidus temperature. 575 °C (1065 °F)

Coefficient of linear thermal expansion.

Temperature range		Average coefficient	
°C	**°F**	**µm/m · K**	**µin./in. · °F**
20-100	68-212	22	12.2
20-200	68-392	23	12.8
20-300	68-572	24	13.3

Specific heat. 963 J/kg · K (0.230 Btu/lb · °F) at 100 °C (212 °F)

Latent heat of fusion. 389 kJ/Kg (167 Btu/lb)

Thermal conductivity. As-cast: 142 W/m · K (82.2 Btu/ft · h · °F). Annealed: 163 W/m · K (94.3 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric at 20 °C (68 °F). As-cast (sand, permanent mold, and die castings): 37% IACS

Electrical resistivity. At 20 °C (68 °F). As-cast (sand, permanent mold, and die castings): 46.6 nΩ · m. Annealed (sand and permanent mold): 41.0 nΩ · m

Electrolytic solution potential. -0.83 V (sand cast) and -0.82 V (permanent mold cast) versus 0.1 *N* calomel electrode in an aqueous solution containing 53 g NaCl plus 3 g H_2O_2 per liter

Fabrication Characteristics

Melting temperature. Die castings: 650 to 760 °C (1200 to 1400 °F). Sand and permanent mold castings: 675 to 815 °C (1250 to 1500 °F)

Casting temperature. Die castings: 635 to 705 °C (1175 to 1300 °F). Sand and permanent mold castings: 675 to 790 °C (1250 to 1450 °F)

Joining. Rivet compositions: 6053-T4, 6053-T6, 6053-T61. Soft solder with copper plate and use methods applicable to copper-base alloys for die castings. Use Alcoa No. 802, no flux or rub-tin with Alcoa No. 802 for sand and permanent mold castings. Sand and permanent mold castings alloys (unless otherwise noted): braze with Alcoa No. 717; Alcoa No. 33 flux, flame either reducing oxyacetylene or reducing oxyhydrogen. Atomic-hydrogen weld with 4043 alloy; Alcoa No. 22 flux. Oxyacetylene weld with 4043 alloy; Alcoa No. 22 flux; neutral flame. Metal-arc weld with 4043 alloy; Alcoa No. 27 flux. Carbon-arc weld with 4043 alloy; Alcoa No. 24 flux (automatic), Alcoa No. 27 flux (manual). Tungsten-arc argon-atmosphere weld with 4043 alloy; no flux. Resistance weld: flash method for die cast alloys; spot, seam, and flash methods for sand and permanent mold cast alloys

Temperature range		Average coefficient	
°C	**°F**	**µm/m · K**	**µin./in. · °F**
-60 to -20	-76 to 68	21.6	12.0
20-100	68-212	23.6	13.1
20-200	68-392	25.6	14.2
20-300	68-572	26.6	14.8

Electrical Properties

Electrical conductivity. Volumetric, 23% IACS at 20 °C (68 °F)

Electrical resistivity. 75 nΩ · m at 20 °C (68 °F)

Chemical Properties

General corrosion behavior. 535.0 has the highest resistance to corrosion of any of the common aluminum casting alloys.

Fabrication Characteristics

Machinability. Superior, can be milled at speeds four times faster than other aluminum casting alloys. High microfinishes can be achieved at high speeds. 535.0 takes a very high mirror polish. Normally this alloy is used for sand and permanent mold castings, but it can also be used for die casting. Where high dimensional tolerance is required, the following procedure should be used; rough machine parts; heat at 200 °C (400 °F) for 14 h; cycle between -73 to 100 °C (100 to 212 °F) five times (30 h/cycle); finish machine; heat 10 h at 200 °C (400 °F); cycle between -73 to 100 °C (-100 to 212 °F) 25 times (30 h/cycle). 535.0 may be stress relieved at approximately 370 °C (700 °F) for 5 h; air cool. Creep resistance at 370 °C (700 °F) is very low, permitting plastic flow under the load of locked-up stresses and resulting in stress-free castings. On air cooling from 370 °C (700 °F), 535.0 will have full hard and physical properties and will be stable. After being stress relieved, most castings from 535.0, A535.0 B535.0 can be rough and finish machined without breaking into the machining sequence.

Weldability. Can be welded any inert gas shielded-arc systems using filler material of 5356 or 535.0 aluminum. Welding fluxes should be avoided if possible. Because of the beryllium content in alloy 535.0, care should be taken not to inhale fumes during welding.

Anodizing. Use sulfuric acid process to produce a pure satin white finish capable of being dyed to brilliant pastel colors.

712.0
5.8Zn-0.6Mg-0.5Cr-0.2Ti

Commercial Names

Former designations. D712.0, D612, 40E

Specifications

Hardness. 70 HB (500 kg load, 10 mm ball)

Poisson's ratio. 0.33

Elastic modulus. Tension, 71 GPa (10.3×10^6 psi); shear, 26.5 GPa (3.85×10^6 psi)

Impact strength. Charpy V-notch: 2.7 to 4.0 J (2 to 3 ft · lbf)

Fatigue strength. 62 MPa (9 ksi) at 5×10^8 cycles (R.R. Moore type test)

Mass Characteristics

Density. 2.81 g/cm^3 (0.101 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 615 °C (1140 °F)

Solidus temperature. 570 °C (1060 °F)

Coefficient of linear thermal expansion. 24.7 μm/m · K (13.7 μin./in. · °F) at 20 to 93 °C (68 to 199 °F)

Specific heat. 963 J/kg · K (0.230 Btu/lb · °F) at 100 °C (212 °F)

Latent heat of fusion. 389 kJ/kg (167 Btu/lb)

Thermal conductivity. 138 W/m · K (79.8 Btu/ft · h · °F) at 25 °C (77 °F)

Electrical Properties

Electrical conductivity. Volumetric, 35% IACS at 20 °C (68 °F)

Electrical resistivity. 49.3 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Melting temperature. F temper: 610 to 650 °C (1130 to 1200 °F)

Aging temperature. T5 temper: room temperature for 21 days or at 157 °C (315 °F) for 6 to 8 h

---

713.0
7.5Zn-0.7Cu-0.35Mg

Commercial Names

Former designation. 613, Tenzaloy

Specifications

Former ASTM. Sand castings, B26 ZC81A. Permanent mold castings, B108 ZC81B

Former SAE. 315

UNS number. A07130

Government. Sand castings, QQ-A-601 (class 22). Permanent mold castings: QQ-A-596 (class 12)

Chemical Composition

Composition limits. 0.40 to 1.0 Cu, 0.20 to 0.50 Mg, 0.6 Mn max, 0.25 Si max, 1.1 Fe max, 0.35 Cr max, 0.15 Ni max, 7.0 to 8.0 Zn, 0.25 Ti max, 0.10 other (each) max, 0.25 others (total) max, bal Al

Applications

Typical uses. Cast aluminum furniture and other very large casting applications that require high strength without heat treatment. 713.0 ages at room temperature to produce mechanical properties equivalent to those of common heat-treated aluminum cast alloys. These properties develop in 10 to 14 days at room temperature or in 12 h at 120 °C (250 °F).

Mechanical Properties

Tensile properties. Typical for T5 temper, aged at room temperature for 21 days or artificially aged at 120 ± 5.5 °C (250 ± 10 °F) for 16 h. Sand casting: tensile strength, 205 MPa (30 ksi); yield strength: 150 MPa (22 ksi); elongation, 4.0% in 50 mm or 2 in. Permanent mold casting: tensile strength, 220 MPa (32 ksi); yield strength: 150 MPa (22 ksi); elongation, 3.0% in 50 mm or 2 in.

Shear strength. 180 MPa (26 ksi)

Compressive yield strength. 170 MPa (25 ksi)

Impact strength. Charpy V-notch: sand castings, 3.4 J (2.5 ft · lbf); permanent mold castings, 4 J (3 ft · lbf). Unnotched: sand castings, 16.3 J (12 ft · lbf); permanent mold castings, 27 J (20 ft · lbf)

Fatigue strength. 60 MPa (9 ksi) at 5×10^8 cycles (R.R. Moore type test)

Mass Characteristics

Density. 2.81 g/cm^3 (0.102 lb/in.^{3})

Thermal Properties

Coefficient of linear thermal expansion. 24.1 μm/m · K (13.4 μin./in. · °F) at 20 to 200 °C (68 to 392 °F)

Thermal conductivity. 140 W/m · K (80 Btu/ft · h · °F) at 25 °C (77 °F)

Electrical Properties

Electrical conductivity. Volumetric, 35% IACS at 20 °C (68 °F)

Chemical Properties

General corrosion behavior. Good resistance to corrosion, equivalent to aluminum-silicon alloys. A typical corrosion test showed no loss in mechanical properties after immersion for 90 days in aerated 3% salt-water solution. Not subject to acceleration of corrosion by stress or to stress-corrosion cracking as determined by the standard test of exposure for 14 days to the corrosive medium while under a continuous load of 75% of yield strength

Fabrication Characteristics

Melting temperature. Approximate, 595 to 640 °C (1100 to 1185 °F)

Machinability. Good machinability and polishing characteristics. Very good dimensional stability. Fully aged material shows a decrease in length of less than 0.1 min/in. of length. If 713.0 is given a stress-relief treatment of 6 h at 450 °C (850 °F) and air cooled, it ages naturally. The resulting product is a stress-free, full-strength casting. This is not possible with any heat-treated aluminum alloy.

Weldability. For high-strength welds, shielded-arc methods can be used with filler alloys 5154 and 5356.

Brazeability. Readily brazed at 540 to 595 °C (1000 to 1100 °F) using any of the common brazing methods

T52	250	36	205	30	1.5	85
T6	290	42	240	35	5.0	90
T71	330	48	310	45	2.0	120

(a) 0.2% offset.

(b) In 50 mm or 2 in.

(c) 500 kg load, 10 mm ball

Compressive properties. Compressive strength, T71 temper, 925 MPa (134 ksi); compressive yield strength, 370 MPa (54 ksi)

Elastic modulus. Tension, 71.0 GPa (10.3×10^6 psi)

Mass Characteristics

Density. 2.823 g/cm^3 (0.102 lb/in.^{3})

Thermal Properties

Liquidus temperature. 645 °C (1190 °F)

Solidus temperature. 605 °C (1120 °F)

Coefficient of linear thermal expansion. 24.7 μm/m · K (13.7 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Thermal conductivity. 138 W/m · K (79.8 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, 27% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 771.0-T5 has good stability and machinability. It can be milled five times faster and hole worked at twice the speed of alloys such as 356.0 and 319.0. It can be finished machined in one clamping operation to flatness tolerance of 0.001 in. This reduces total cost of machining over most casting alloys, which require two clamping operations to obtain this type of flatness tolerance.

Welding. Can be welded by either gas tungsten-arc or gas metal-arc welding using 5356 rod or wire. Special procedure should be followed in welding to ensure good results.

If parts are to be welded, the operation should be made part of the heat-treating cycle. If welding is to be done on T6 or T71 parts, the castings are heated to 580 °C (1080 °F), removed from heat-treating furnace, and welded while hot. The parts are then returned to the furnace and the T6 and T71 heat treatments continued. If the parts are to be used in the T52 or T2 temper, they are heated to 415 °C (775 °F), taken from the furnace, welded hot, then returned to the furnace and the heat treatment continued. Items to be used in the T51 temper are heated to 205 °C (405 °F), taken from the furnace, welded hot ,then returned to the furnace and T51 treatment continued. Repair weld parts should be heated and welded as described above.

The T5 temper should not be welded but can be welded if the procedure for T51 is used.

Heat treatments. See Table 53.

Table 53 Heat treatments for alloy 771.0

Temper	Treatment
T2	Hold at 415 ± 14 °C (775 ± 25 °F) for 5 h; cool outside furnace in still air to room temperature; harden by reheating to 180 ± 3 °C (360 ± 5 °F) for 4 h; cool in air
T5	Hold at 180 ± 3 °C (355 ± 5 °F) for 3 to 5; cool outside furnace in still air to room temperature
T6	Hold at 580 to 594 °C (1080 to 1100 °F) for 6 h; cool outside furnace to room temperature in still air; age by holding for 3 h at 130 °C (265 °F) followed by cooling in still air
T51	Age by holding at 205 °C (405 °F) for 6 h; cool in still air
T52	Hold at 415 °C (775 ± 25 °F) for 5 h; cool from 415 to 345 °C (775 to 650 °F) in 2 h or more; cool from 345 to 230 °C (650 to 450 °F) in not more than $\frac{1}{2}$ h (20 min desirable); cool from 230 to 120 °C (450 to 250 °F) in approximately 2 h; cool from 120 °C (250 °F) to room temperature in still air outside of furnace; harden by reheating to 165 °C (330 °F) for 6 to 16 h and cooling outside of furnace in still air
T71	Hold at 580 to 595 °C (1080 to 1100 °F) for 6 h; cool outside furnace to room temperature in still air; age by holding at 140 °C (285 °F) for 15 h followed by cooling in still air. Similar properties can be obtained by aging at 155 °C (310 °F) for 3 h

Aluminum-Lithium Alloys

Richard S. James, Aluminum Company of America

Introduction

ALUMINUM-LITHIUM ALLOYS have been developed primarily to reduce the weight of aircraft and aerospace structures; more recently, they have been investigated for use in cryogenic applications (for example, liquid oxygen and hydrogen fuel tanks for aerospace vehicles).

The major development work began in the 1970s, when aluminum producers accelerated the development of aluminum-lithium alloys as replacements for conventional airframe alloys. The lower-density aluminum-lithium alloys were expected to reduce the weight and improve the performance of aircraft. The goal was to introduce ingot aluminum-lithium alloys that could be fabricated on the existing equipment of aluminum producers and then used by airframe manufacturers as direct replacements for the conventional aluminum alloys (which typically have constituted 70 to 80% of the weight of current aircraft). The development work led to the introduction of commercial alloys 8090, 2090, and 2091 in the mid-1980s; Weldalite 049 and CP276 were introduced shortly thereafter. These alloys are characterized by the following approximate nominal (wt%) compositions (balance aluminum):

- *Weldalite 049:* 5.4 Cu, 1.3 Li, 0.4 Ag, 0.4 Mg, 0.14 Zr
- *Alloy 2090:* 2.7 Cu, 2.2 Li, 0.12 Zr
- *Alloy 2091:* 2.1 Cu, 2.0 Li, 0.10 Zr
- *Alloy 8090:* 2.45 Li, 0.12 Zr, 1.3 Cu, 0.95 Mg
- *Alloy CP276:* 2.7 Cu, 2.2 Li, 0.5 Mg, 0.12 Zr

Commercial aluminum-lithium alloys are targeted as advanced materials for aerospace technology primarily because of their low density, high specific modulus, and excellent fatigue and cryogenic toughness properties. The superior fatigue crack propagation resistance of aluminum-lithium alloys, in comparison with that of traditional 2*xxx* and 7*xxx* alloys, is primarily due to high levels of crack tip shielding, meandering crack paths, and the resultant roughness-induced crack closure. However, the fact that these alloys derive their superior properties extrinsically from the above mechanisms has certain implications with respect to small-crack and variable-amplitude behavior. For example, aluminum-lithium alloys lose their fatigue advantage over conventional aluminum alloys in compression-dominated variable-amplitude fatigue spectra tests. However, in tension-dominated spectra, aluminum-lithium alloys show greater retardations on the application of single-peak tensile overloads.

The principal disadvantages of peak-strength aluminum-lithium alloys are reduced ductility and fracture toughness in the short-transverse direction, anisotropy of in-plane properties, the need for cold work to attain peak properties, and accelerated fatigue crack extension rates when cracks are microstructurally small (Ref 1). These limitations have precluded the direct substitution of aluminum airframe alloys with aluminum-lithium alloys, although it is possible to group the present aluminum alloys and the current aluminum-lithium alloys in terms of product form and primary design criteria (as is done in Table 1 for present aluminum and aluminum-lithium aerospace alloys). The grouping in (Table 1 indicates that certain aluminum-lithium alloys exhibit more damage tolerance, strength, and corrosion resistance than other aluminum-lithium alloys. While this grouping may not be complete, it does provide a starting guideline when considering potential applications for aluminum-lithium alloys, even though they are generally unsuitable for direct comparison with or replacement of the more commonly used aluminum aerospace alloys included in Table 1.

Table 1 Groupings of selected aerospace alloys and temper conditions according to primary design requirements

The groupings do not imply that aluminum-lithium alloys can be directly substituted for aluminum alloys. See text for discussion.

Physical Metallurgy

In the development of low-density alloys, the simplest approach to reducing the weight of an alloy is to add elements with low atomic weights as alloying elements. In the case of aluminum alloys, lithium and beryllium are the most effective metallic additions for lowering density. Lithium is the lightest metallic element, and each 1% of lithium (up to the 4.2% Li solubility limit) reduces alloy density by about 3% and increases modulus by about 5% (Ref 3, 4). In addition, lithium in small amounts allows the precipitation strengthening of aluminum when a homogeneous distribution of coherent, spherical δ' (Al_3Li) precipitates is formed during heat treatment. Beryllium additions, on the other hand, do not give rise to significant precipitation strengthening in aluminum. The combined density-reducing and precipitation-strengthening characteristics of lithium were the main reasons for its choice as the alloying element for the development of low-density aluminum-base alloys.

Like other age-hardened aluminum alloys, aluminum-lithium alloys achieve precipitation strengthening by thermal aging after a solution heat treatment. The precipitate structure is sensitive to a number of processing variables, including, but not limited to, the quenching rate following the solution heat treatment, the degree of cold deformation prior to aging, and the aging temperature and time. Minor alloying elements can also have a significant effect on the aging process (Fig. 1) by changing the interface energy of the precipitate, by increasing the vacancy concentration, and/or by raising the critical temperature for homogeneous precipitation. In addition, heterogeneous precipitation at interfaces and grain boundaries (which occurs in addition to the homogeneous precipitation of the strengthening phase) can have an adverse effect on

fracture behavior. Depending on the composition and temperature, the relative size and volume fraction of the different precipitates can be systematically varied.

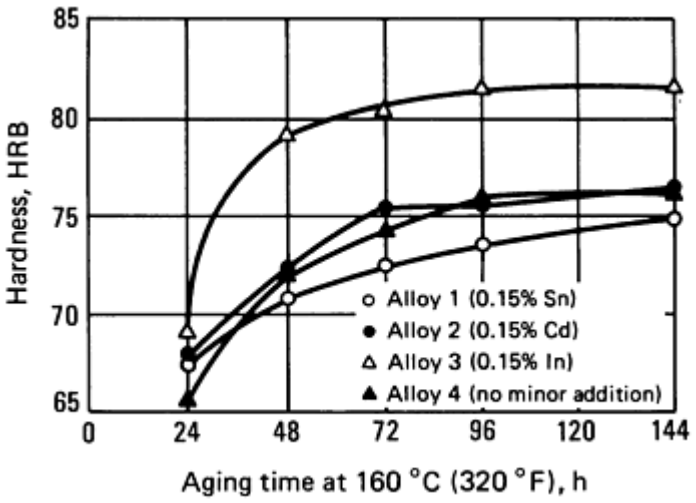

Fig. 1 Effect of minor additions (0.15 wt%) of cadmium, iridium, and tin on the age-hardening response of aluminum-lithium alloy 2090 (2.3 Cu, 2.3 Li, 0.15 Zr)

Al-Li Alloys. The age hardening of aluminum-lithium alloys involves the continuous precipitation of δ' (Al_3Li) from a super-saturated solid solution. The aluminum and lithium in the δ' precipitates are positioned at specific locations. The eight shared corner sites are occupied by lithium, and the six shared faces are occupied by aluminum. This gives rise to the aluminum-lithium composition of δ' precipitates. The geometrical similarity between the lattice of the precipitates and the face-centered cubic lattice of the solid solution facilitates the observed cube/cube orientation dependence (Ref 5, 6, 7). The lattice parameters of the precipitate are closely matched to those of the matrix. Consequently, the microstructure of an aluminum-lithium alloy solution heat treated and aged for short times below the δ' solvus is characterized by a homogeneous distribution of coherent, spherical δ' precipitates.

Aluminum-lithium-base alloys are microstructurally unique. They differ from most of the aluminum alloys in that once the major strengthening precipitate (δ') is homogeneously precipitated, it remains coherent even after extensive aging. In addition, extensive aging at high temperatures (>190 °C, or 375 °F) can result in the precipitation of icosahedral grain-boundary precipitates with five-fold symmetry. Although the quasi-crystalline structure and the composition of these grain boundary precipitates are not yet exactly known, it has been suggested that both the precipitates and the precipitate-free zones (PFZs) near the grain boundaries might play a major role in the fracture process.

The low ductility and toughness of binary aluminum-lithium alloys can be traced, at least in part, to the inhomogeneous nature of their slip, resulting from coherent-particle hardening of spherical δ' precipitates. The presence of equilibrium δ(AlLi) precipitates at grain boundaries can also cause PFZs, which can induce further strain localization and promote intergranular failure. Consequently, for the development of commercial alloys, slip has been homogenized by introducing dispersoids (manganese, zirconium) and semicoherent/incoherent precipitates, such as T_1, (Al_2CuLi), θ' (Al_2Cu), or S (Al_2LiMg), through copper or magnesium additions. Concurrent developments in thermomechanical processing have optimized aluminum-lithium microstructures for the best combinations of strength and toughness. The resulting material tends to be highly textured where zirconium additions are used to inhibit recrystallization. Texture increases the variability of properties with orientation.

Al-Li-*X* Alloys. As mentioned above, various modifications in alloy chemistry and fabrication techniques have been used in an attempt to improve the ductility and toughness of aluminum-lithium alloys while maintaining a high strength. Copper, magnesium, and zirconium solute additions have been shown to have beneficial effects. Magnesium and copper improve the strength of aluminum-lithium alloys through solid-solution and precipitate strengthening, and they can minimize the formation of PFZs near grain boundaries. Zirconium, which forms the cubic Al_3Zr coherent dispersoid, stabilizes the subgrain structure and suppresses recrystallization.

Compared with traditional high-strength aluminum alloys, Al-Li-*X* alloys show 7 to 12% higher stiffness, generally superior fatigue crack propagation resistance, and improved toughness at cryogenic temperatures. On the negative side, however, they can suffer from poor short-transverse properties, and they have been shown to display significantly accelerated fatigue crack extension rates when cracks are microstructurally small (Ref 1).

The creep crack growth rates of Al-Li-*X* alloys may be slower or greater than those of conventional aluminum aerospace alloys, depending on orientation. Figure 2, for example, compares crack growth rates in an extruded Al-Li-Cu-Mg-Zr alloy (Al-Li 8090) with those of other aluminum alloys. Crack growth rates for Al-Li 8090 in the T-L orientation (crack plane and growth direction parallel to the extrusion direction) are on the average much higher than those for aluminum alloys 2219 and 2124. In contrast, the growth rates for Al-Li 8090 in the L-T orientation (crack plane and growth direction parallel to the extrusion direction) are much lower than those for other aluminum alloys.

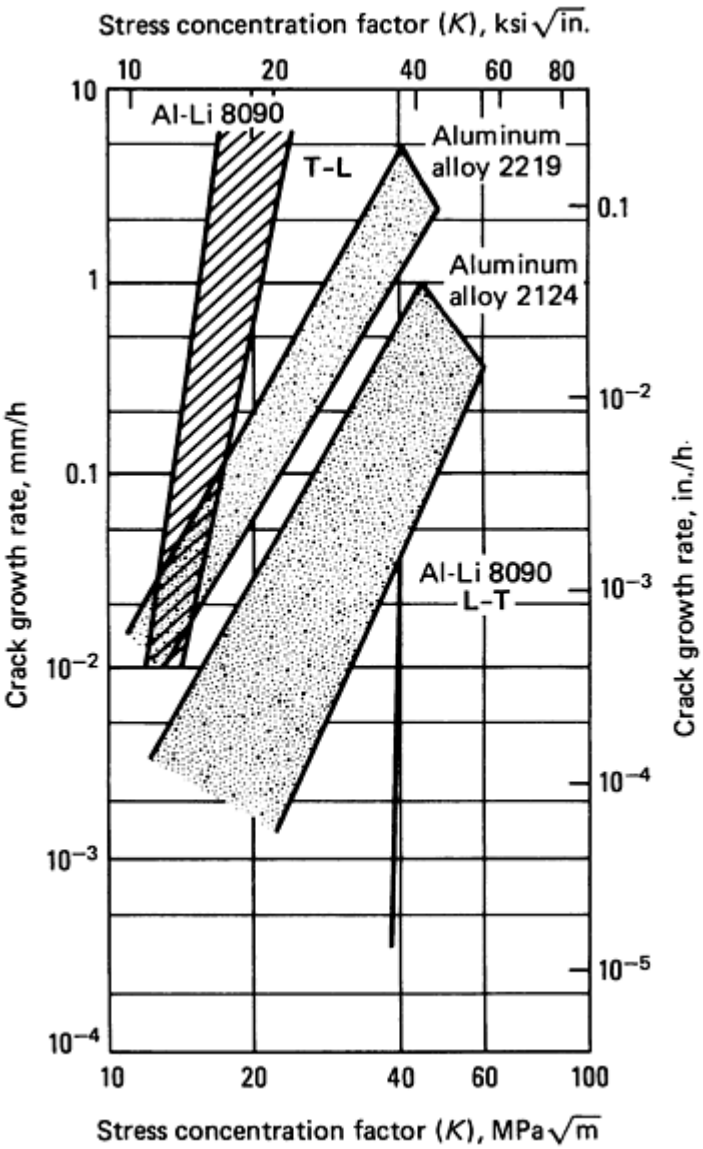

Fig. 2 Comparison of creep crack growth rates for aluminum-lithium alloy extrusions with those for other aluminum alloys. Alloy 8090 contains 2.5% Li, 1.5% Cu, 1.0% Mg, 0.12% Zr, and a balance of aluminum. T-L, crack plane and growth directions parallel to extrusion direction; L-T, crack plane and growth directions perpendicular to extrusion direction. Source: Ref 8

In terms of δ' precipitation, the only effect of magnesium appears to be a reduction in the solubility of lithium. The microstructure of an aluminum-magnesium-lithium alloy in the early stages of aging is similar to that of an aluminum-lithium alloy (Ref 9, 10, 11). Precipitation in the aluminum-copper-lithium system is more complicated than that in either the aluminum-lithium or aluminum-magnesium-lithium systems.

Thermomechanical Effects. In addition to precipitation hardening, aluminum-lithium alloys derive part of their strength from a controlled grain microstructure generated through hot and cold deformation. Alloying additions of ancillary metallic elements such as manganese, chromium, and zirconium are made to control the grain microstructure during thermomechanical operations. Of these elements, zirconium has improved the combination of strength and fracture toughness in aluminum-lithium-base alloys.

Unlike aluminum-zinc-magnesium-base alloys, aluminum-lithium-base alloys gain increased strength and toughness from deformation prior to aging. This unusual phenomenon has given rise to a number of thermomechanical processing steps for aluminum-lithium alloys aimed at optimizing mechanical properties after artificial aging.

Deformation prior to aging also affects the extent of precipitation strengthening. For example, in aluminum-lithium-copper alloys such as alloy 2090, the T_1 (Al_2CuLi) strengthening precipitates have large coherency strains that are minimized when the precipitates are nucleated on dislocations. In fact, it is believed that dislocations are necessary for the nucleation of the T_1 phase. Similar effects also apply to the S' (Al_2LiMg) strengthening precipitate in aluminum-lithium-copper-magnesium alloys such as 8090.

Because of the effect of dislocations on the precipitation strengthening of these alloys, deformation prior to aging is often used to increase the dislocation density and thus the nucleation sites for the strengthening precipitates. This deformation is normally applied by a tensile stress for sheet, plate, and extruded material, and by compression for forgings. The tensile deformation is usually fairly uniform; however, the compression strain may vary considerably from the surface to the centerline of the product. Therefore, it is important to understand the relationship between the magnitude of strain and the aging response of the alloy.

The effect of deformation on the number, density, and volume fraction of T_1 in an aluminum-lithium-copper-zirconium alloy is shown in Fig. 3. Figure 4, which shows the effect of deformation (stretch) on the yield strength of samples aged for various times at 190 °C (375 °F), correlates very well with Fig. 3 on the effect of stretch on the volume fraction of strengthening precipitates. It is well established that the strength of age-hardened aluminum alloys depends on both the size and volume fraction of the strengthening precipitates. This example shows that the aging response is very sensitive to the degree of deformation prior to artificial aging. An important point to note is that an inhomogeneous distribution of strain can have a pronounced effect on the aging response and thus on the local strength in Al-Li-*X* alloys. This effect of strain on aging response diminishes as the amount of work goes beyond 4%. Consequently, when sections are stretched or compressed to develop a T8 temper, large variations in properties may result if the strain is not homogeneous or at least in excess of some minimum value around 4%.

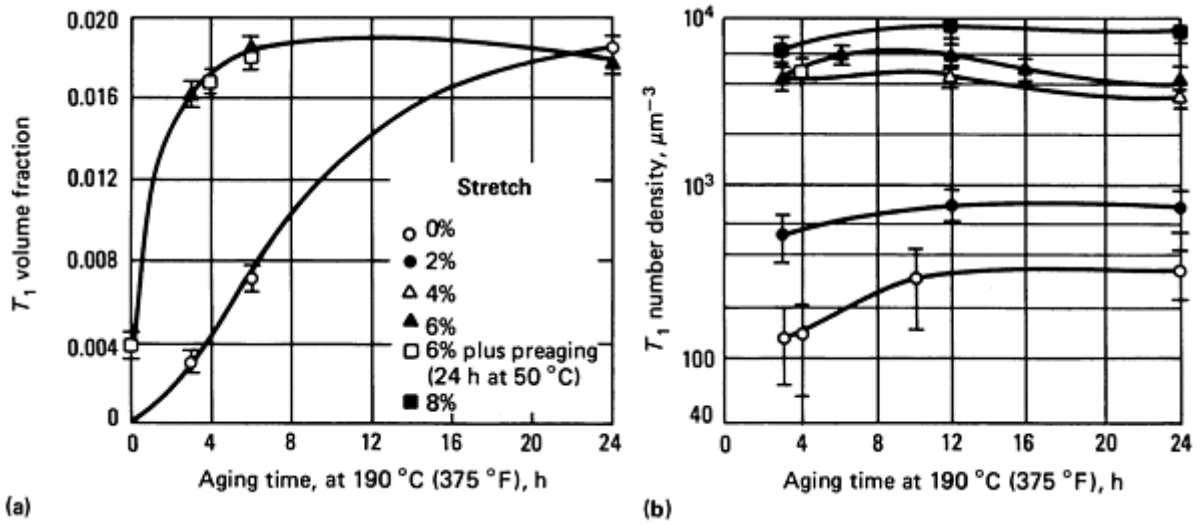

Fig. 3 Effect of prior deformation and aging time on the amount of T_1 precipitates in aluminum-lithium alloy 2090 (2.4% Li, 2.4% Cu, 0.18% Zr, bal aluminum). (a) Volume fraction of T_1. (b) Number density of T_1

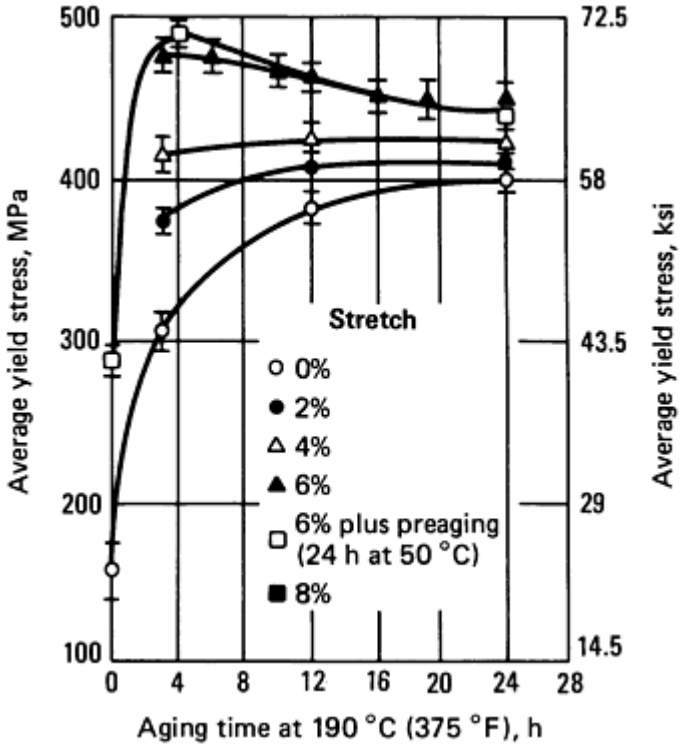

Fig. 4 Average yield stress versus aging time for aluminum-lithium alloy 2090 (2.4% Li, 2.4% Cu, 0.18% Zr, balance aluminum) with various amounts of prior deformation

Alloy Development

The development of aluminum-lithium alloys has spanned over 65 years. Some of the major milestones in the development of these alloys include the introduction of the first aluminum-lithium alloy (Scleron, Al-Zn-Cu-Li) by the Germans in the 1920s (Ref 12), the introduction of alloy 2020 (Al-Cu-Li-Cd) in the late 1950s (Ref 13), and the introduction of alloy 1420 (Al-Mg-Li) in the Soviet Union in the mid-1960s (Ref 14). There were no major commercial applications for Scleron; the only applications for 2020 were the wings and horizontal stabilizers for the RA5C Vigilante aircraft (Ref 15). Alloy 1420, while still being used, has not gained widespread acceptance outside of the Soviet Union. There were a number of reasons for the limited applications for each of these early aluminum-lithium alloys, including shortcomings in properties (primarily fracture toughness) and continuing improvements to existing aluminum alloys.

The development of aluminum-lithium alloys continued into the 1970s; these alloys were intended for use as low-density materials for reducing the weight of aircraft. Studies have shown that reducing the density of structural materials is the most influential factor in reducing aircraft weight (Ref 16) and is more important than increasing the strength, modulus, or damage-tolerant properties of these materials. The goal of aluminum-lithium development work was to introduce ingot metallurgy alloys that could be fabricated on the existing equipment of aluminum producers and then used by airframe manufacturers in the same way the conventional aluminum alloys were used. In addition to the lower material costs of aluminum-lithium alloys relative to composites, it was postulated that these alloys would require no basic changes in airframe production methods. A direct-substitution scenario implied that property equivalence would translate directly into weight savings by the replacement of existing aluminum parts with identical aluminum-lithium parts. This direct substitution has not come to pass; however, the properties of aluminum-lithium alloys have been found to be very attractive in a number of applications, and the alloys that have been developed have proved to be very usable in these cases.

Current Al-Li-*X* Alloys and Their Applications. In the early 1980s, aluminum manufacturers were working on aluminum-lithium alloys that they planned to introduce as direct substitutes for aluminum alloys. This work led to the introduction of commercial alloys 8090, 2090, and 2091 in the mid-1980s, and the introduction of Weldalite 049 and CP276 toward the end of the decade. Properties of these alloys are discussed in the section "Commercial Aluminum-Lithium Alloys" in this article.

At the present time, a number of producers (Table 2) are making aluminum-lithium alloys that are registered and well characterized. However, quite a bit of confusion still exists concerning temper designations, alloys, and supply, and any list of tempers, alloys, and producers is subject to change. Therefore, it is suggested that the reader contact the Aluminum Association and the Aerospace Materials specifications for information about current alloy registration and specification properties.

Table 2 Major producers of aluminum-lithium alloys

Producer	Alloys	Products
Producers with casting facilities		
British Alcan	8090	Sheet, plate, extrusions, forgings
Alcoa	2090, 2091, 8090	Sheet, plate, extrusions, forgings
Pechiney	2091, 8090, CP276	Sheet, plate, extrusions, forgings
Reynolds	Weldalite	Sheet, plate, extrusions, forgings
Producers without casting facilities		
ILM	8090, 2090	Extrusions
Otto Fuchs	8090	Extrusions, forgings
Menziken	8090	Extrusions
VAW	8090	Extrusions
HyDuty	8090	Forgings
Hoogevens	8090	Sheet, plate

Although the direct replacement of conventional aluminum aerospace alloys with aluminum-lithium alloys has not been possible, aluminum-lithium alloys have gained acceptance in a number of aerospace applications for both primary and secondary structures. Table 1 provides a guideline to start with when considering aluminum-lithium alloys for an existing or new design. However, because the properties of aluminum-lithium alloys are unique and because these alloys cannot be directly substituted for existing aluminum aerospace alloys, most applications for aluminum-lithium alloys are found in new programs. These limitations have slowed the market development of these products. In addition, the cost of Al-Li alloys is typically three to five times that of conventional aluminum alloys because of the specialized equipment required for processing and the high cost of lithium; therefore, application of these alloys has been limited to programs where weight reduction is an overriding concern.

Commercial applications in production include aircraft parts such as leading and trailing edges, access covers, seat tracks, and wing skins. Figure 5 shows present and potential uses of aluminum-lithium materials on a generic commercial transport, and thereby serves as a summary of alloys and tempers that are in production or under evaluation. Figure 5 is not intended as a recommendation for the use of aluminum-lithium for specific applications, nor is it a complete listing of possible applications for these alloys; however, it does provide some indication of the literally thousands of pounds of aluminum-lithium parts that can be designed into a new or existing aircraft. In addition to the commercial transport uses for these alloys, helicopter, commuter, and business aviations applications are in production or under study (Ref 17, 18, 19, 20, 21, 22, 23, 24). The viability of using aluminum-lithium for parts can be evaluated on the basis of primary design criteria, such as requirements for strength, stiffness, minimum gage, damage tolerance, and corrosion resistance; also, product form classifications (Table 1) can be consulted to identify suitable aluminum-lithium materials to investigate for use in a particular application.

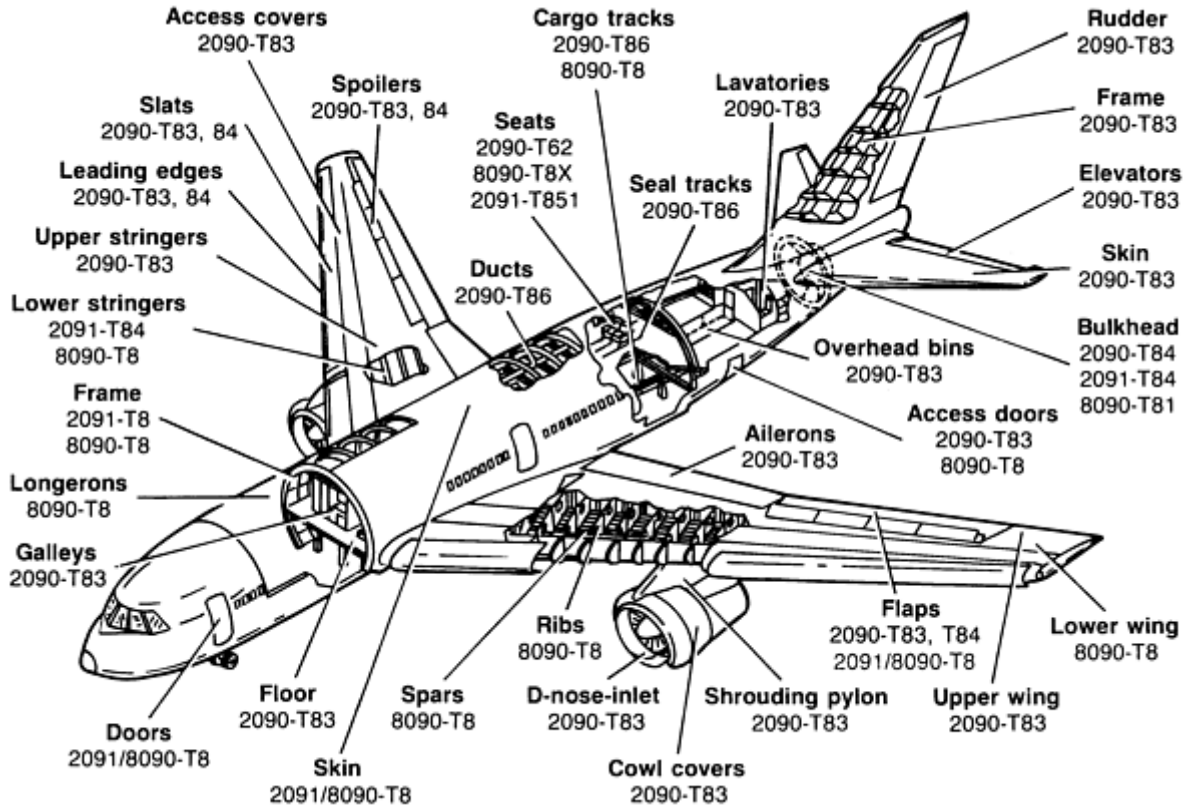

Fig. 5 Use of aluminum-lithium alloys in a commercial aircraft

Military Applications. In many cases, military applications are treated as classified information; for the most part, however, they can be generically viewed in much the same way as commercial applications. Certain types of military aircraft parts (Fig. 6) are likely candidates for the use of aluminum-lithium alloys; in particular, minimum-gage and stiffness-dominated designs are good candidates for the replacement of conventional aluminum alloys with existing aluminum-lithium alloys. Steady progress has been made in using superplastic-formed aluminum-lithium sheet parts (Ref 25), conventionally formed 2090, 2091, and 8090 sheet (Ref 22, 26, 27, 28, 29, 30, 31, 32) for structures and wing skins, and plate parts. Representative parts include access covers and wing skins. The lack of a material with good short-transverse stress-corrosion cracking resistance and good short-transverse ductility and toughness has kept aluminum-lithium from capturing a major metal bulkhead application, but such applications should become possible with continuing progress in research and development.

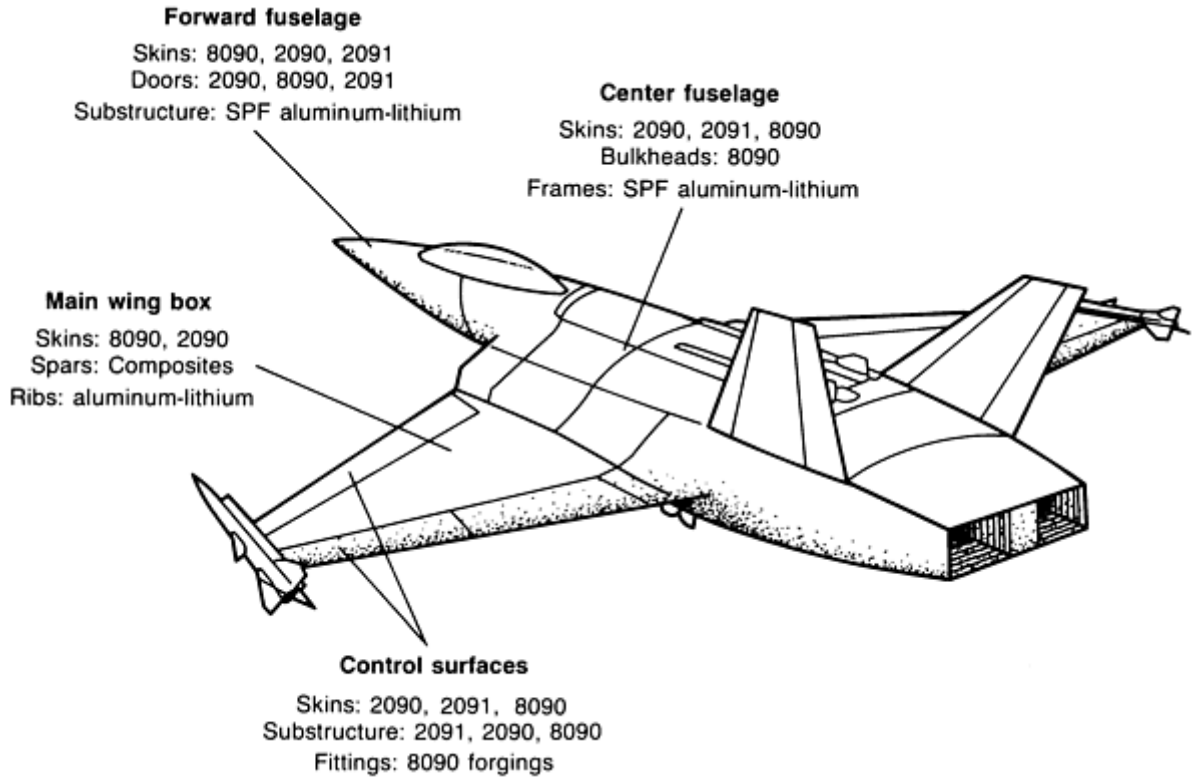

Fig. 6 Use of aluminum-lithium alloys and superplastic-forming (SPF) aluminum-lithium alloys in a fighter aircraft

Space Applications. Of all the benefits offered by the use of aluminum-lithium alloys, weight savings is the most critical in space applications. Applications under production and evaluation include chemically milled aluminum-lithium alloys for integrally stiffened primary structures and tankage, as well as products for sheet and stringer construction of shrouds, formings, and adapters. Aluminum-lithium alloy 2090-T81 is a candidate alloy for the cryogenic tankage of booster systems. The cryogenic properties of 2090-T81 have been extensively studied and are summarized in Ref 33. Early test data revealed that there may be an oxygen compatibility problem with aluminum-lithium alloys. However, the latest testing by the National Institute of Science and Technology (Ref 34) has shown that aluminum-lithium alloys are as compatible as 2219 (the presently used cryogenic tankage alloy) with liquid-oxygen environments.

Manufacturing. The rolling, extruding, and forging operations for aluminum-lithium alloys are comparable to those for conventional aluminum alloys. However, there are a number of differences in other areas, particularly ingot production and recycling, that require attention.

Explosion Potential With Water. The explosion potential of molten aluminum-lithium alloys in contact with water is significantly greater than that of conventional molten aluminum alloys. A number of variables affect the explosion potential, including the lithium content of the alloy, the depth and containment of the water, the metal temperature, and the size (diameter) and velocity of the molten metal stream being introduced to the water. Any operation that generates molten aluminum-lithium poses a potential explosion hazard in the presence of water; the melting range for aluminum-lithium alloys is between 500 and 600 °C (930 and 1100 °F). Safe casting practices have been developed by primary producers, but caution is still necessary (Ref 35, 36, 37).

Fabricating Ingot Quality. The control of ingot quality--in particular, the control of inclusions, impurities, hydrogen content, grain size, and composition--is critical to attaining good properties following rolling, extrusion, or forging and heat treatment. The reactivity of lithium with air and refractories has necessitated the development of specialized equipment and processes to melt, remelt, or cast aluminum-lithium ingots of sufficient size and quality. The need for specialized equipment to meet quality requirements has contributed to the higher cost of aluminum-lithium alloys (Ref 2).

Explosion Potential With Salt Bath. Like other aluminum alloys, aluminum-lithium alloys may cause severe exothermic reactions or explosions if heat treated in salt baths under conditions in which melting or incipient melting occurs. Limited

testing and user experience indicate that aluminum-lithium alloys can be safely handled in salt baths so long as melting is precluded and normal precautions are observed.

Explosion Potential (Fires). Like the dust of any aluminum alloy, finely divided aluminum-lithium dust in sufficient concentration is explosive in the presence of an ignition source. The finer the dust, the greater the chance of ignition and the more severe the explosion. Aluminum-lithium fires, like those involving conventional aluminum alloys, can generate hydrogen gas in the presence of water, and this gas may be explosive in the presence of an ignition source. Hydrogen generation in confined spaces is of particular concern.

Heat Treating. During the heating of aluminum-lithium alloys to elevated temperatures (>260 °C, or 500 °F), surface oxidation occurs, and lithium oxide and hydroxide are formed. The formation of these compounds is of concern because of the possible skin, eye, and upper respiratory tract irritation or damage they can cause. Lithium oxide/hydroxide is a strong alkali and is potentially corrosive to any tissue with which it comes in contact. Inhalation of the dust may result in upper respiratory tract irritation. Contact with the skin or eyes may cause irritation and, with greater exposure, possible burns.

The American Industrial Hygiene Association has recommended a Workplace Environmental Exposure Level (WEEL) for lithium oxide and hydroxide particulate of 1 milligram per cubic meter (mg/m^3) of air for a maximum exposure time of 1 min. The potential for exceeding the recommended ceiling exposure limit is most likely to exist when these alloys are heated to temperatures greater than ~260 °C (~500 °F) to form significant amounts of lithium oxide/hydroxide on metallic surfaces and when this surface material becomes airborne during operations such as dry machining (Ref 36).

Recycling. The recovery of finished aluminum-lithium products from semifabrication facilities varies with the product form, but it is generally somewhat lower than that of conventional aluminum alloy products. The buy-to-fly ratios of finished aircraft parts in the fabrication processes of aircraft manufacturers also generate large quantities of scrap. Some of the scrap produced by these processes is heavy, relatively easily segregated, and can be taken back for direct recycling into aluminum-lithium ingots. However, the bulk is in the form of machining swarf, which is unsuitable for direct recycling because it is contaminated with other aluminum alloys and other aircraft materials such as stainless steel and titanium.

For conventional aircraft aluminum alloys of the 2*xxx* and 7*xxx* series, the recycling of process scrap from both metal suppliers and aircraft manufacturers is a well-established worldwide industry. For the most part, primary aluminum suppliers internally recycle their own scrap back into aircraft products. Their customers sell off their scrap to secondary aluminum smelters, who convert it into aluminum-silicon foundry alloys.

The introduction of aluminum-lithium alloys will not eliminate conventional recycling activities. However, additional processing steps will have to be introduced, and existing commercial arrangements will need to be modified. The need for these changes stems from three attributes of lithium metal: First, its high price; second, its high reactivity; and, third, its absence from the specifications of all registered alloys other than the currently rather limited number of alloys based on aluminum-copper-lithium (such as 2090) and aluminum-lithium-copper-magnesium (8090 and 2091).

Secondary recyclers must be aware of the problems that can occur if they remelt scraps that contain aluminum-lithium alloys. The major problem areas are:

- Metallurgical property changes that can affect recovered alloys
- Adverse effects on refractories
- Adverse effects on metal cleanliness
- Increased melt losses
- Safety and industrial hygiene
- Environmental issues
- Higher costs

Each of these problem areas has specific technological definitions. Also, many of them overlap and have interactive reactions. Potential solutions to these problems have been reviewed many times in the literature and have been implemented for the numerous existing applications. However, the scrap loop should be taken into consideration as part of the review for deciding whether or not to use aluminum-lithium for a specific program (Ref 36, 38, 39, 40, 41).

Aluminum-Lithium Alloys

Richard S. James, Aluminum Company of America

Commercial Aluminum-Lithium Alloys

Development of commercially available aluminum-lithium-base alloys was started by adding lithium to aluminum-copper, aluminum-magnesium, and aluminum-copper-magnesium alloys. These alloys were chosen to superimpose the precipitation-hardening characteristics of aluminum-copper-, aluminum-copper-magnesium-, and aluminum-magnesium-base precipitates to the hardening of lithium-containing precipitates. Proceeding in this manner, alloys 2020 (Al-Cu-Li-Cd), 01429 (Al-Mg-Li), 2090 (Al-Cu-Li), and 2091 and 8090 (Al-Cu-Mg-Li) evolved. Besides these registered alloys, other commercial aluminum-lithium alloys include Weldalite 049 and CP276.

This section focuses on alloys 2090, 2091, 8090, and Weldalite 049. Compositions of these alloys are listed in Table 3. General application characteristics and producers are listed in Tables 1 and 2, respectively.

Table 3 Aluminum-lithium alloy compositions

Element	Composition, wt%

Weldalite 049

The trade name Weldalite refers to alloys (Ref 42, 43, 44, 45, 46) designed and developed at Martin Marietta Laboratories for welded aerospace applications. The leading alloy, Weldalite 049, was designed to replace mainstay alloys 2219 and 2014 for launch systems applications. In these applications, Weldalite is a candidate for propellant tankage, which constitutes the bulk of the dry weight of space launch systems. These tanks are most often fabricated by welding because the propellants are usually contained under pressure. Liquid hydrogen and liquid oxygen are the fuel/oxidizer combination of choice; therefore, cryogenic properties are also an important factor in the overall compatibility of these alloys for launch systems applications.

The effect of cryogenic temperatures on the strengths of Weldalite 049 and one other aluminum-lithium alloy is shown in Fig. 7. The toughness of Weldalite 049 remains relatively constant at cryogenic temperatures (Table 4); other aluminum-lithium alloys, on the other hand, show a marked increase in in-plane toughness at cryogenic temperatures. Weldalite has a density of 2.7 g/cm^3 (0.098 lb/in.^{3}) and an elastic modulus of 76 GPa (11×10^6 psi). Other physical properties have not yet been determined.

Table 4 Plane-strain fracture toughness (K_{Ic}) of Weldalite 049 extruded bar

Temperature		Temper designation	Orientation[(a)]	K_{Ic}		Tensile strength		Yield strength	
°C	°F			MPa $\sqrt{m}$	ksi $\sqrt{in}$	MPa	ksi	MPa	ksi
21	70	T3	L-T	36.9	33.6	530	77	405	59

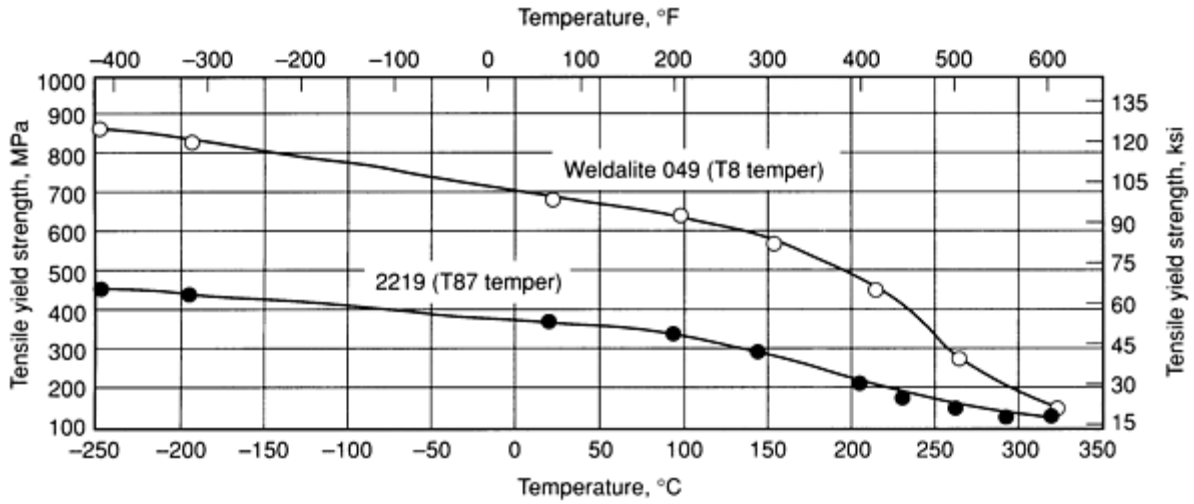

Fig. 7 Yield strengths of two aluminum-lithium candidate alloys for cryogenic tankage applications. Strain rate, 4×10^{-4}/s with a 0.5-h hold at temperature

Weldalite 049 shows high strength in a variety of products and tempers (Table 5). Its natural aging response is extremely strong with cold work (temper T3), and even stronger without cold work (T4); in fact, it has a stronger natural aging response than that of any other known aluminum alloy. Weldalite 049 undergoes reversion during the early stages of artificial aging, and its ductility increases significantly up to 24%. Tensile strengths of 700 MPa (100 ksi) have been attained in both T6 and T8 tempers produced in the laboratory. As shown in Fig. 8, specimens of Weldalite 049 in the

peak-aged condition all have essentially the same level of hardness despite varying degrees (from 0.5 to 9%) of cold work prior to aging; the yield strength of Weldalite 049 is also relatively unaffected by prior cold work.

Table 5 Mean longitudinal tensile properties of Weldalite 049 in various tempers and product forms

Data for 2219-T8 provided for comparison

Description and/or temper	Yield strength		Ultimate tensile strength		Elongation in 50 mm (2 in.), %

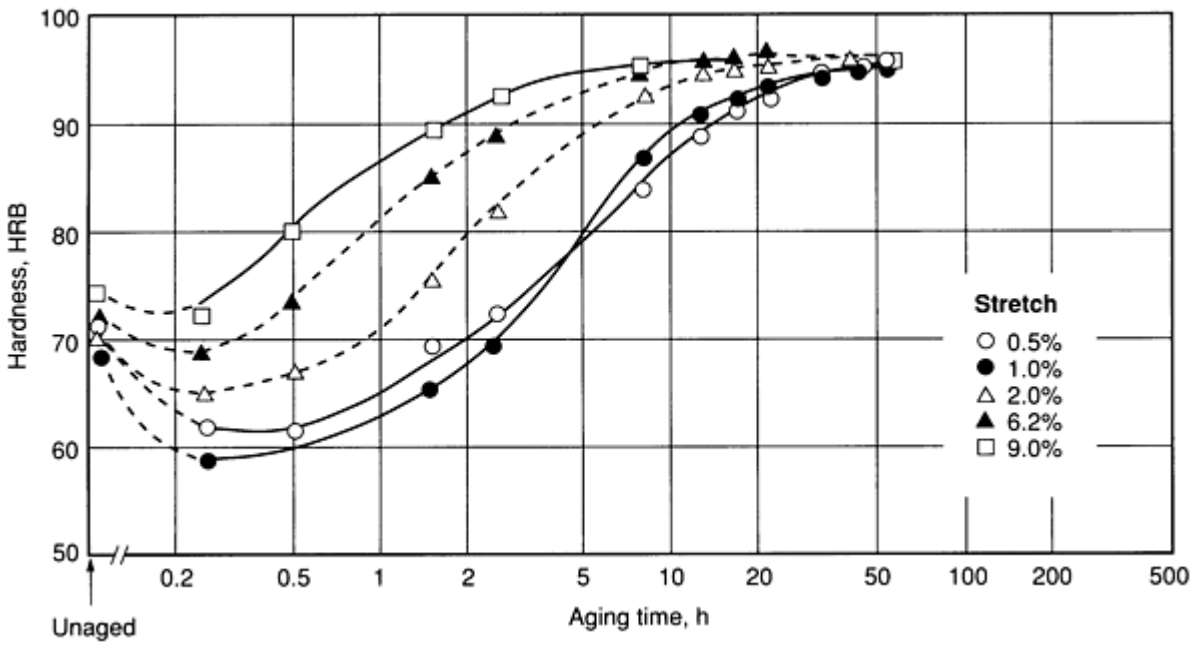

Fig. 8 Aging response of Weldalite 049 with various amounts of deformation prior to aging. Approximate aging temperature, 170 °C (340 °F)

The ability of Weldalite 049 to attain high strength without cold work is particularly beneficial for forgings, where the uniform introduction of cold work is often impractical (Table 5). Weldalite 049 small-scale forgings and commercial Boeing hook forgings have displayed tensile strengths of greater than 700 MPa (100 ksi).

Weldalite 049 has very good weldability; for example, it displays no discernable hot cracking in highly restrained weldments made by gas tungsten arc, gas metal arc, and variable polarity plasma arc (VPPA) welding. Extremely high weldment strengths have been reported using conventional 2319 filler, and even higher weldment strengths have been obtained with the use of a proprietary Weldalite filler (Table 6). As shown by the data of Table 6, a mean VPPA

weldment strength of 370 MPa (54 ksi) has been obtained by welding Weldalite 049 with 049 filler. High strengths (310 MPa, or 45 ksi, ultimate tensile strength) have also been attained with tungsten inert-gas welds.

Table 6 Mean tensile properties of Weldalite 049, 2090, and 2219 weldments with conventional and Weldalite filler

Weldalite 049 has been used in the fabrication of a subscale prototype cryogenic tank. Because of this successful fabrication and the combination of properties offered by Weldalite 049 (such as ultrahigh strength at room and cryogenic temperatures, and good weldability), the alloy has been proposed as a baseline structural material for the now-defunct Advanced Launch System. In addition, one of the Weldalite alloys is under consideration for use in the National Aerospace Plane and in the Titan family of missiles.

Alloy 2090

Alloy 2090 was developed to be a high-strength alloy with 8% lower density and 10% higher elastic modulus than 7075-T6, a major high-strength alloy used in current aircraft structures (Ref 19, 47). Alloy 2090 is intended for use in applications where high- and medium-strength sheet, plate, and extrusions are used. Its excellent weldability and cryogenic properties make it suitable for cryogenic tankage structures. In addition, 2090 is suited for superplastic-forming (SPF) applications.

The chemical composition of alloy 2090 (Table 3) was registered with the Aluminum Association in 1984. A variety of tempers (Table 7) are being developed to offer useful combinations of strength, toughness, corrosion resistance, damage tolerance, and fabricability. Physical properties of 2090 are given in Table 8. The microstructure of 2090 products (Fig. 9) is controlled and is primarily unrecrystallized.

Table 7 Tempers and corresponding products forms for alloy 2090

Temper	Characteristics	Product forms
O	Annealed, lowest strength, maximum formability	Sheet, plate
T31[(a)]	Good formability, will approach T83 or T84 properties after aging by user	Sheet, extrusions
T3[(a)]	Moderate formability, can be aged to T83 and T84 properties by customer	Sheet, extrusions
T86	Strengths similar to those of 7075-T6511	Extrusions
T83[(a)]	Strengths similar to those of 7075-T6	Sheet
T81[(a)]	Strengths similar to those of 7075-T651	Plate
T84[(a)]	Strength and toughness similar to those of 7075-T76	Sheet, plate
T6[(a)]	Solution heat treated and aged by user	Sheet, plate

Strength and Toughness. Because alloy 2090 and its tempers are relatively new and in different phases of registration and characterization, data may be incomplete for some forms; however, current capabilities are given with the specifications as they now exist in Table 9. Properties of selected tempers of 2090 at various temperatures are shown in Fig. 10, 11, 12. Their behavior is similar to that of other 2*xxx* and 7*xxx* alloys, although the 2090 tempers show a higher strength at elevated temperatures than other alloys. Changes in strength and toughness at cryogenic temperatures are more pronounced in 2090 than in conventional aluminum alloys; alloy 2090 has a substantially higher toughness at cryogenic temperatures (Fig. 13).

Table 9 Tentative mechanical property limits of 2090 products

Typical values are given in parentheses. Data for alloy 7075-T6 are included for comparison.

2090 temper	Thickness		Specification	Tensile properties						Toughness

The shaded region represents the range of strength/toughness combinations for typical aerospace aluminum alloys. Data for alloy 2219-T87 as a function of temperature are shown for comparison. Source: Ref 33

Design Considerations. In general, the engineering characteristics of aluminum-lithium alloys are similar to those of the current 2*xxx* and 7*xxx* high-strength alloys used by the aerospace industry. However, some material features of the 2090

products vary somewhat from those of the conventional aluminum alloys and should be considered during the design and material selection phase. These distinct characteristics of 2090 include:

- An in-plane anisotropy of tensile properties that is higher than in conventional alloys. In 2090, more importance is placed on 45° and shear properties. These properties of 2090 are well characterized and can easily be checked for individual design application
- An elevated-temperature exposure for the peak-aged tempers (T86, T81, and T83) that shows good stability within 10% of original properties. However, for the underaged temper (T84), there will be significant additional aging
- Excellent fatigue crack growth behavior. However, the large advantage 2090 has over conventional alloys is reduced with high overloads or compression-dominated regimes
- The need for cold work to achieve optimum properties. In this characteristic, 2090 is similar to 2219 and 2024
- Shape-dependent behavior for extrusions with very high strengths. Extrusions with a low-aspect-ratio section may exhibit shape-dependent behavior when only a small difference exists between the yield and ultimate tensile strengths. This may be a result of a change in the strain-hardening coefficient in these sections. The ductility may remain at acceptable levels

Corrosion. Alloy 2090 sheet and plate, and 2090-T86 extrusions have demonstrated excellent resistance to exfoliation corrosion (Ref 48) in extensive seacoast exposure tests (Table 10). The resistance of these alloys and tempers is superior to that of 7075-T6, which, in some product forms, can suffer very severe exfoliation during a two-year seacoast exposure.

Table 10 Exfoliation results for 2090-T83 sheet, 2090-T81 plate, and 2090-T86 extrusions

Product	Source	Thickness		Plane location[a]	Rating[b]

(a) T/2 and T/10 represent location as a function of thickness (T).

(b) Exfoliation rating per ASTM G 34 exfoliation corrosion (EXCO) test: N, no appreciable attack; P, pitting; EA, superficial--tiny blisters, thin slivers, flakes, or powder, with only slight separation of metal.

(c) Modified ASTM acetic acid salt intermittent spray.

(d) Seacoast exposure at Point Judith, RI.

(e) Samples exposed 26 January 1988 and will be evaluated after 1, 2, and 4 years.

The stress-corrosion cracking (SCC) resistance of 2090 is strongly influenced by artificial aging. Tempers that are underaged, such as T84, may be more susceptible to SCC than the near-peak-aged T83, T81, and T86 tempers. This is particularly true for products subjected to sustained tensile loading in the short-transverse direction. Peak-aged tempers are resistant to SCC in the short-transverse direction with up to 170 MPa (25 ksi) applied stress in alternate immersion and atmospheric exposure (Table 11).

Table 11 Stress-corrosion cracking results for 2090-T81 plate and 2090-T86 extrusions tested in the short-transverse direction

(b) Number of failed specimens/total specimens.

(c) Number of days to failure.

(d) Seacoast exposure at Point Judith, RI.

(e) Exposed at Point Judith for 1000 days

Sheet, thin plate (<25 mm, or 1 in., thick) and thinner extrusions have been extensively tested to evaluate stress-corrosion resistance in the long-transverse direction. The grain structure of wrought unrecrystallized aluminum products makes the long-transverse direction much less sensitive to factors that cause SCC than the short-transverse direction. Both alternate immersion and seacoast exposure tests indicate that 2090-T83, -T84, and -T86 have excellent long-transverse SCC resistance. All three tempers survive alternate immersion testing at stress levels equivalent to 75% of tensile yield strength specification minimums.

Table 12 lists the corrosion potentials of several tempers of 2090 along with those of several other high-strength alloys. The addition of up to between 2 and 2.5% Li to an aluminum alloy does not significantly affect the electrochemical properties of the alloy. For 2090, the amount of copper in solid solution controls the corrosion potential values. The potentials of 2090-T83, -T84, -T81, and -T86 coincide closely enough with those of artificially aged tempers of 2*xxx* and 7*xxx* alloys that galvanic corrosion is not expected to be a major problem when the different alloys are connected to each other. Pitting corrosion results show that 2090 is subject to slightly greater pitting than 7075 (Table 13).

Table 12 Typical corrosion potentials for alloy 2090 and other selected aluminum alloys

Fatigue. The results of smooth and notched axial stress fatigue tests for alloy 2090 are shown in Fig. 14(a), 14(b), and 14(c) for extrusions, plate, and sheet, respectively. The performance of 2090 is comparable to that of 7075-T6 up to 10^5 cycles for smooth tests and through failure for notched tests. The results of constant-amplitude fatigue crack growth tests (Fig. 15) show that for most stress ratios (R) the fatigue crack growth rate of 2090 is better than that of 7075. However, there may be a considerable variation among the fatigue crack growth rates for 2090, depending on crack size (Fig. 16).

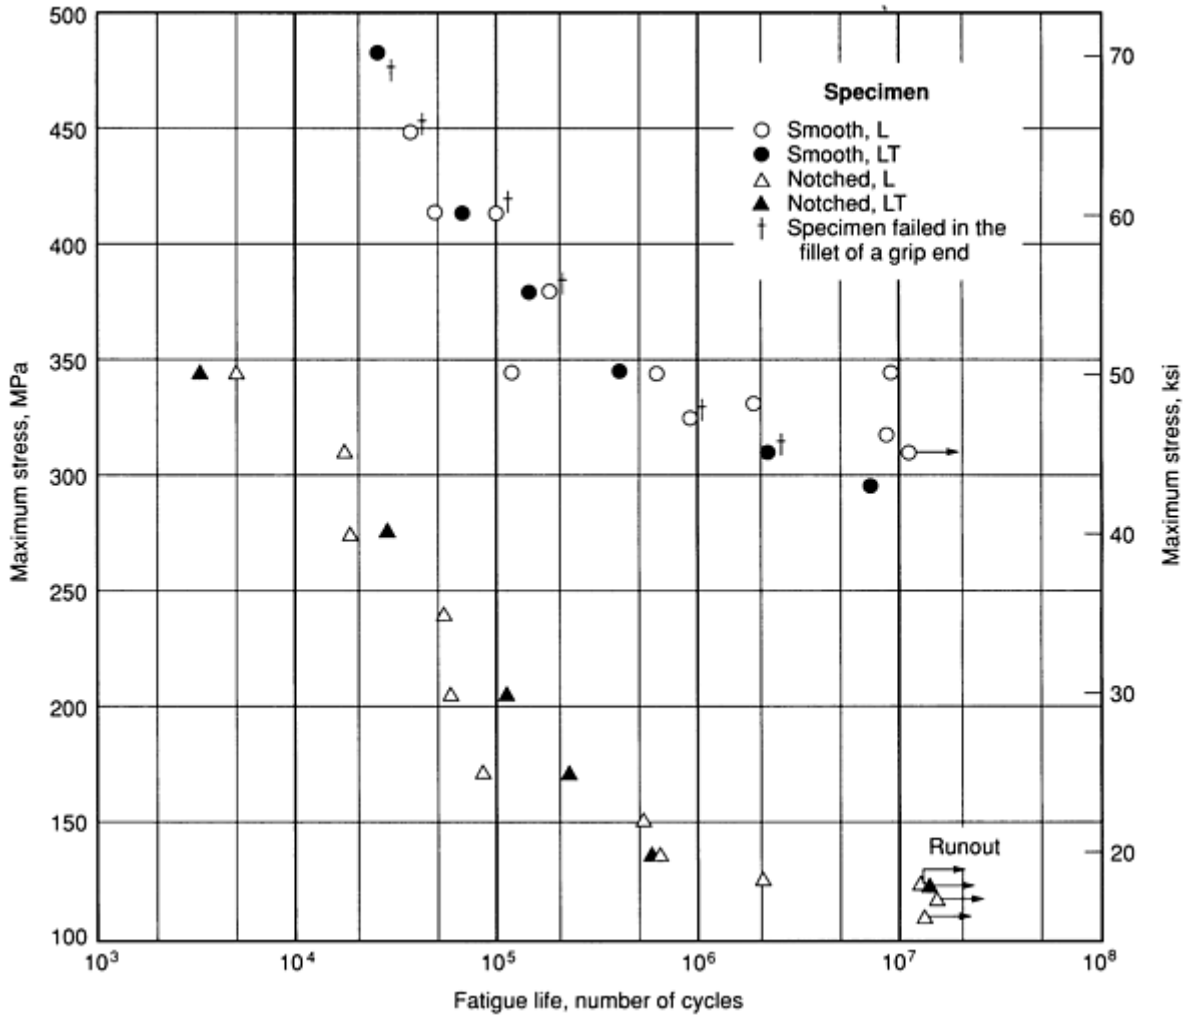

Fig. 14(a) Smooth and notched axial stress fatigue data for commercially produced 2090-T86 extruded tee shapes. Extrusion thickness, 19 mm (0.75 in.); stress ratio (R), 0.1; specimen location, T-2. Fig. 16 Comparison of the growth rates of long (greater than ~5 mm) and naturally occurring small (2 to 1000 μm) fatigue cracks in 2090-T8E41 alloy as a function of the nominal and effective stress intensity ranges, ΔK and ΔK_{eff}, respectively. Data are presented for L-T, T-L, and T-S orientations at a stress ratio (R) of 0.1. Growth rates of small cracks exceed those of long cracks by several orders of magnitude when compared on the basis of ΔK; however, they show close correspondence when characterized in terms of ΔK_{eff}. CCT, center-cracked tension. Source: Ref 1

Forming. Tests have been conducted to evaluate the formability of 2090-O, -T31, -T3, and -T83 sheet in the bending, stretch-bending, and biaxial-stretching modes (Ref 49). Results for 2090 were compared with those for 2024-T3 and 7075-T6.

Table 14 gives the 90° down flange minimum bend test results expressed as a bend radius/thickness (R/t) ratio; smaller R/t ratios suggest better formability. According to these preliminary test results, the O, T31, and T3 tempers of 2090 and 7075-T6 performed better than alloy 2090-T83. Generally, smaller bend radii were achieved when the bend line was oriented parallel to the rolling direction of the material.

Table 14 90° bend test results for various tempers of 2024, 2090, 2091, and 7075 sheet

Results expressed as the ratio of bend radius to thickness (R/t)

(a) Lower *R*/*t* ratios suggest better formability.

The stretch-bend test was used to measure formability in the bending under tension mode. Comparative results of tests performed on various tempers of 2090, 2024, and 7075 are given in Table 15. When the principal axis of stress is parallel to the rolling direction, the tests showed that 2024-O had the best stretch-bend capability followed by, in decreasing order, 2024-T3, 2090-O, 2090-T31, 2090-T3, 7075-T6, and 2090-T83.

In the limiting dome height (LDH) test, rectangular blanks are rigidly clamped in the longer direction and stretched by a hemispherical punch. The height of the dome at fracture, which indicates the combined effect of strain hardening characteristics and limiting strain capability of the material, may be considered as a measure of stretch formability. The results of single-lot LDH tests for 2090, 2024, and 7075 sheet are shown in Table 16. The T31 temper provided the best results of all those tested for 2090. Further, the plane-strain limiting dome height was about 50% lower for 2090-T83 than for 7075-T6. Results for 2090-O are not shown in Table 16, but they can be expected to be slightly better than those for 2090-T31.

Table 16 Limiting dome height test results for 2090, 2024, and 7075 sheet

Finishing Characteristics (Ref 50, 51, 52). The deoxidizing response of alloy 2090 in the T31 and T83 tempers is similar to that of 2024-T3 and 7075-T6 with regard to weight loss and roughness. Metallographic examinations show smaller but more densely populated pits on the 2090. Detailed weight loss and roughness data have been obtained using conventional deoxidizers such as chromic sulfuric acid, triacid, sulfuric acid, proprietary nonchromated iron sulfate solution, nitric acid, and nitric-hydrofluoric acid. After prolonged treatments (20 min) in hot (71.7 °C, or 161 °F) chromic sulfuric acid, 2090 showed end grain and intergranular attack less than that for 2024-T3 and to about the same depth as on 7075-T6.

Coating weights produced on 2090 by anodizing treatments with various agents, including sulfuric acid, 40 and 20 V chromic acid, and phosphoric acid, are about the same if not somewhat heavier than those produced on 2024-T3 and 7075-T6 (Table 17). However, when these alloys are anodized simultaneously in sulfuric acid, 2024 produces the lightest coating weight, 7075 produces the heaviest, and 2090 falls in between the two. This exception is due to the different voltage requirements of these alloys. The conversion coating response of 2090 is also quite good, with coating weights

comparable to those on 7075-T6 for identical processing. Salt spray testing of the anodic coatings (applied and tested per MIL 8625) and conversion coatings (MIL C5541) show that the corrosion resistance of 2090 is as good as or better than that of 2024-T3 and 7075-T6 (Table 17).

Table 17 Anodizing, conversion coating, and deoxidizing responses of aluminum-lithium alloys 2090 and 2091 compared with those of aluminum alloys 2024 and 7075

Treatment characteristic	**2090**	**2024/7075**	**2091**
Sulfuric anodizing coating weight, g/cm^2	7.23-9.91	4.57-21.0	Similar to 2090

Triacid deoxidizing weight loss, mg/cm^2	. . .	11	17
Chromic/sulfuric acid deoxidizing weight loss, mg/cm^2	4.8-5.0	2.8-5.1	5.2
Salt spray results with anodic and conversion coatings	82-89% passed	36-75% passed	. . .

Chemical milling studies conducted by airframe manufacturers indicate that an acceptable finish can be obtained by using a standard chemical milling solution. The 2090 alloy develops a slightly rougher finish than 7075 and 2024 from the standard chemical milling process (Table 18).

Table 18 Response of aluminum-lithium alloys 2090 and 2091 to chemical milling

Response characteristic	**Alloy response**		
	2090	**2024/7075**	**2091**
Standard chemical milling solution ($NaOH + Na_2S$)			
Roughness, μm (μin.)	3.4-3.8 (135-150)	0.9-1.0 (36-41)	1.8 (70)
Etch rate per side, μm/min (mils/min)	38-46 (1.5-1.8)	40 (1.6)	63.5 (2.5)
TEA-modified chemical milling solution[(a)]			
Roughness, μm (μin.)	2.25-2.35 (89-93)	0.80-0.85 (31-34)	1.65 (65)

(a) Sodium hydroxide, triethanolamine (TEA), and sodium sulfide

Machining. Machinability tests conducted on 2090 plate indicate that the material has machinability comparable to that of the B-rated aerospace alloys, 2024-T351 and 7075-T651. The machinability of B-rated alloys is characterized by curled or easily broken chips and good-to-excellent finish. Recent field machining trials have shown that certain practices should be followed when machining 2090:

- The part should be well supported and braced by adequate fixturing, and vertical flanges should be supported during machining whenever possible
- Sharp positive-rake tooling specifically designed for machining aluminum should be used
- Adequate amounts of coolant should be continuously directed to the cutting area

Welding. Gas metal arc, gas tungsten arc, and electron beam welding processes have been used to evaluate the fusion weldability characteristics of alloy 2090. All three methods show good results (Table 19).

Table 19 Typical mechanical properties of gas metal arc welds of 13 mm (0.50 in.) thick 2090 plate with 2319 filler alloy

Alloy, temper, and condition	Ultimate tensile strength		Yield strength		Elongation in 50 mm (2 in.), %
	MPa	ksi	MPa	ksi	
2090-T81, as-welded	232	33.6	204	29.6	5.2
2090-T4, postweld aged	258	37.5	(a)	(a)	0
2090-T81, postweld solution heat treated and aged	386	56.1	(a)	(a)	0

(a) Failure occurred before reaching 0.2% offset, indicating nil elongation.

Alloy 2091

Alloy 2091 was developed to be a damage-tolerant alloy with 8% lower density and 7% higher modulus than 2024-T3, a major high-toughness damage-tolerant alloy currently used for most aircraft structures (Ref 53). Alloy 2091 is also suitable for use in secondary structures where high strength is not critical.

The chemical composition of alloy 2091 has been registered with the Aluminum Association (Table 3). A variety of tempers (Table 20) are being developed to offer useful combinations of strength, corrosion resistance, damage tolerance, and fabricability. Typical physical properties of 2091 are given in Table 8. The microstructure of 2091 varies according to product thickness and producer; in general, gages above 3.5 mm (0.140 in.) have an unrecrystallized microstructure, and lighter gages feature an elongated recrystallized grain structure.

Table 20 Registered temper designations of alloy 2091 bare and aluminum-clad sheet

Temper	Characteristics	Forms

O	Annealed, lowest strength, maximum formability	Sheet, plate
T3	Solution heat treated and stretched; can be aged to T84 temper	Sheet, plate
T8, T84[(a)]	Underaged temper; has the best combination of strength, toughness, and corrosion resistance for damage-tolerant applications	Sheet
T851	Medium-strength product	Plate
T8X51	Underaged damage-tolerant product	Thick sheet and plate

(a) Only T84 is registered with the Aluminum Association at this time.

Because alloy 2091 and its tempers are relatively new and in different phases of registration and characterization, data may be incomplete for some forms. In the underaged (T8) temper, alloy 2091 has a plane-stress fracture toughness (K_c) of about 130 to 140 MPa$\sqrt{m}$ (120 to 130 ksi$\sqrt{in}$) and a compressive modulus of 76 to 80 GPa (11 to 11.6 × 10^6 psi.) Properties for 2091 in Preliminary European Normale (prEN) specifications are given in Table 21.

Table 21 Preliminary European Normale (prEN) specifications for minimum tensile properties of bare and aluminum-clad 2091 sheet and light-gage plate

(a) Elongation in 50 mm (2 in.).

(b) prEN specifications issued by the AECMA standards organization in Europe

In general, the behavior of 2091 is similar to that of other 2*xxx* and 7*xxx* alloys. Material characteristics that have been cause for concern in other aluminum-lithium alloys are of less concern in 2091. Alloy 2091 depends less on cold work to attain its properties than does 2024 (Fig. 17). The properties of 2091 after elevated-temperature (≤125 °C, or 260 °F) exposure are relatively stable (Fig. 18) in that changes in properties during the lifetime of a component are acceptable for most commercial applications.

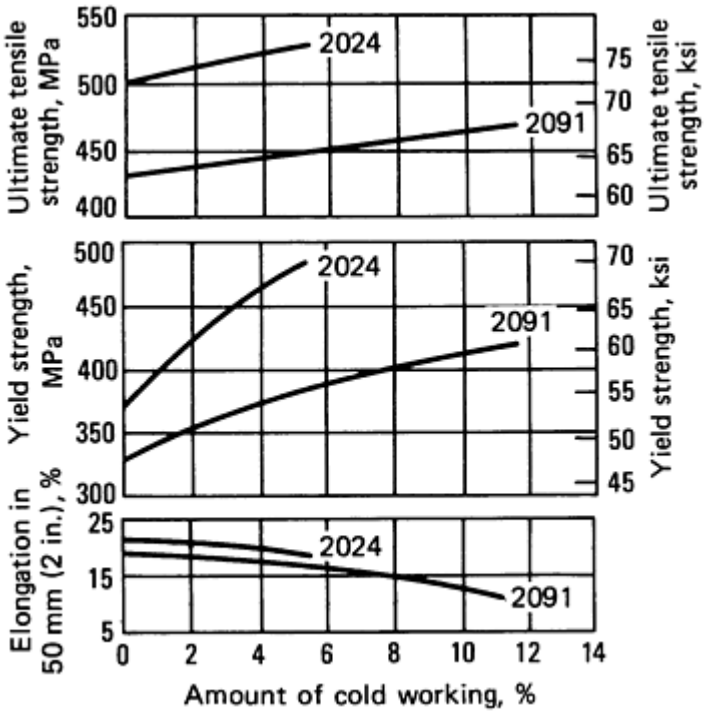

Fig. 17 Longitudinal tensile properties of alloys 2091 and 2024 as a function of cold working prior to aging. Aluminum alloy 2024 is naturally aged; aluminum-lithium alloy 2091 is aged to temper T8X.

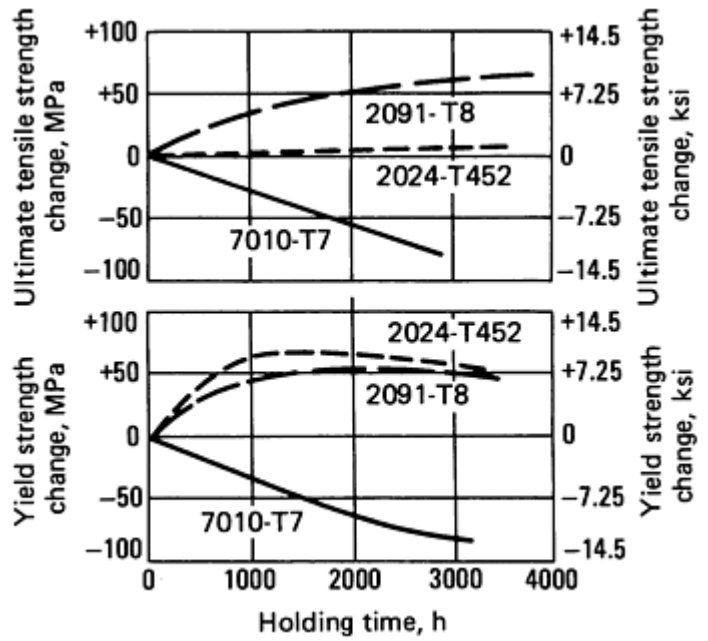

Fig. 18 Variation in room-temperature ultimate tensile strength and yield strength for aluminum-lithium alloy 2091 after holding at 130 °C (265 °F) at indicated times. Data for aluminum alloys 2024 and 7010 are included for comparison.

Corrosion (Ref 48, 53, 54). The exfoliation resistance of 2091-T84, like that of 2024, varies depending on the microstructure of the product and its quench rate. The more unrecrystallized the structure, the more even the exfoliation attack. However, the exfoliation resistance of 2091 (Table 22) is generally comparable to that of similar gages of 2024-T3.

Table 22 Alloy 2091 exfoliation from seacoast exposure and EXCO testing

Product	Gage		Temper	Plane	EXCO testing[a] 4-day exfoliation rating[b]	Seacoast exposure[c]	
	mm	in.				Months	Exfoliation rating[b]

(a) Exfoliation corrosion (EXCO) testing per ASTM G 34.

(b) Exfoliation rating per ASTM G 34; P, pitting; EA (superficial), tiny blisters, thin slivers, flakes, or powders with only slight separation of metal; EB (moderate), notable layering and penetration into metal.

(c) Seacoast exposure at Point Judith, RI.

(d) Pechiney data.

(e) Sheet and plate fabricated at Davenport, IA facility.

(f) Exfoliation more advanced on Point Judith panel than on EXCO panel.

(g) Fokker data.

The microstructural relationship for stress-corrosion cracking in sheet products is the converse of that for exfoliation. As the microstructure becomes more fibrous, the SCC threshold increases. For thicker unrecrystallized structures and thinner elongated recrystallized structures, it is possible to attain as SCC threshold of 240 MPa (35 ksi), which is quite good compared to that of 2024-T3 (Ref 54). For thinner products, the threshold varies by gage and producer; it may be as low as 50 to 60% of the yield strength or as high as 75% of the yield strength.

Fatigue. Although fatigue testing on 2091 has been done by a number of labs, producers, and users (Ref 53, 55, 56), the results have been difficult to interpret. The results for 2091 have been superior to those for 2024 (Fig. 19), roughly equivalent to those for 2024 (Ref 55, 56), or inferior to those for 2024. In general, the consensus is that under controlled and similar circumstances, the fatigue properties of 2091-T84 are sufficient to allow it to be used as a substitute for 2024.

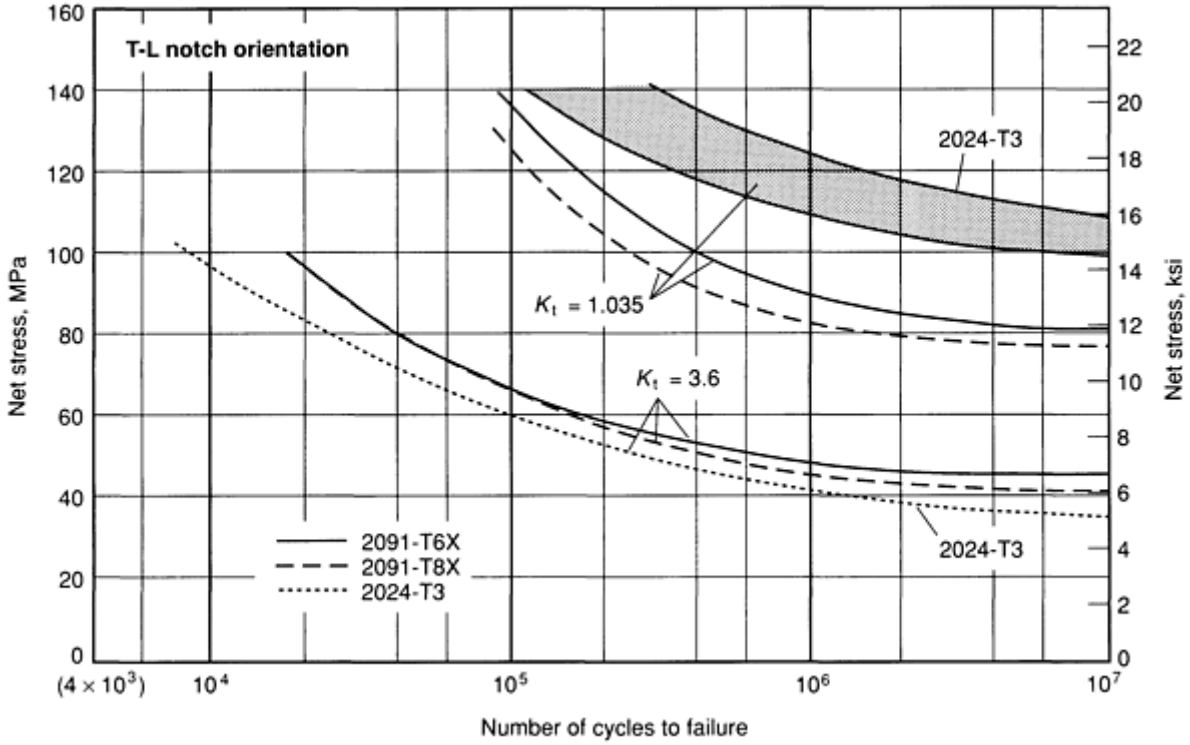

Fig. 19 Longitudinal fatigue resistance of notched 2091-T6X, 2091-T8X, and 2024-T3 sheet. Alloys 2091-T8X and 2024-T3 were stretched 2% before aging. Stress ratio (R), 0.1. K_t, theoretical stress concentration factor. T-L notch orientation as defined in Fig. 23

Finishing. The responses of 2091 to chemical milling, anodizing, conversion coating, and deoxidizing are similar to those of other aluminum or aluminum-lithium alloys (Tables 17 and 18). The same bath that is used for 2024 or 7075 can be used for 2091, or the bath can be adjusted to give improved surface roughness to 2091. The adjustment may be necessary because the etch rates for 2091 may be different than those for other aluminum alloys, or because batch processing of 2091 parts may be necessary. Results from salt spray tests indicate that 2091 gains better protection from anodic and conversion coatings than do the conventional aluminum alloys.

Forming. As a general rule, the as-quenched condition provides the best forming ability for aluminum-lithium alloys. In this temper, the forming ability of 2091 recrystallized sheets exceeds that of 2024. The n and r (Lankford) coefficients are respectively 0.33 and 1.0 for 2091 and 0.22 and 0.70 for 2024. The outstanding behavior indicated by the values for 2091 facilitates forming operations: It allows a decrease in the number of forming steps for 2091 as compared with 2024. This benefit has been confirmed in bending, drawing, and rubber-forming tests by airframe manufacturers.

Because of grain coarsening, the critical lower work-hardening strain (e_c) limits the maximum intermediate strain in the forming sequence for 2091 before the last solution heat treatment. The same limitation exists on conventional alloys: the actual e_c values are 5 to 13% for 2091, 6% for 2091-CPHK, and 6% for 2024 sheets. The stretch-bend and 90° bend test results given in Tables 14 and 15 indicate that, in similar applications, the formability of 2091 compares favorably with

that of 2024. The relatively slow natural aging response of 2091 (Fig. 20) allows considerably more latitude in forming parts on the shop floor than is possible with conventional alloys.

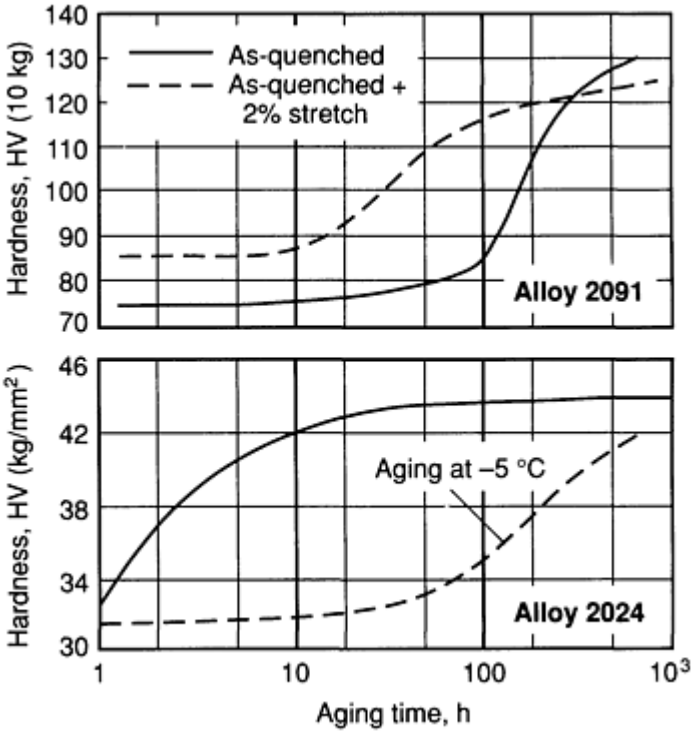

Fig. 20 Natural aging of 2091 and 2024 aluminum alloys. Aging done at room temperature (22 °C, or 71 °F) except where indicated

Alloy 8090

Alloy 8090 was developed to be a damage-tolerant medium-strength alloy with about 10% lower density and 11% higher modulus than 2024 and 2014, two commonly used aluminum alloys. Its use is aimed at applications where damage tolerance and the lowest possible density are critical. The alloy is available as sheet, plate, extrusions, and forgings, and it can also be used for welded applications.

The chemical composition of 8090 has been registered with the Aluminum Association (Table 3). A variety of tempers have been developed that offer useful combinations of strength, corrosion resistance, damage tolerance, and fabricability. Unfortunately, there has been no official temper registration in the United States for any of these tempers for any of the variety of product forms. Descriptions of commonly used unofficial temper designations are given in Table 23. Typical physical properties of 8090 are given in Table 8. Plate, extrusions, and forgings have an unrecrystallized microstructure; damage-tolerant sheet has a recrystallized microstructure. Higher-strength sheet is available with a recrystallized or unrecrystallized microstructure (Fig. 21).

Table 23 Temper designations for aluminum-lithium alloy 8090

Temper[(a)]	Characterization	Forms
T8, T8X	Near-peak-aged medium-strength sheet product	Sheet
T81	Underaged damage-tolerant sheet	Sheet
T8771, T651, T7E20	Near-peak-aged plate	Plate
T8151, T8E57	Underaged damage-tolerant plate	Plate
T6511, T8511/10	Medium-to-high-strength peak-aged extrusions	Extrusions
T8771, T852	Medium-strength peak-aged forgings	Forgings

(a) Temper designations are not registered; this listing is a recap of designations that producers and users have used.

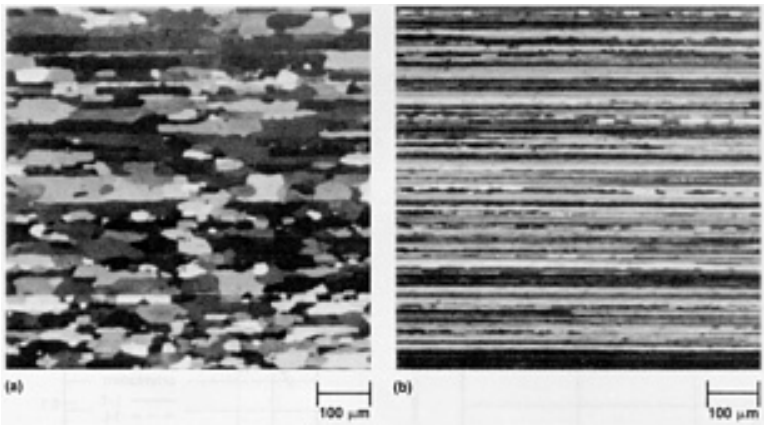

Fig. 21 Microstructures of 8090 sheet. (a) Recrystallized grain structure. (b) Unrecrystallized grain structure

Strength and Toughness. Because alloy 8090 and its tempers and product forms are relatively new and unregistered, property data are incomplete. However, available data for the current capabilities of 8090 products and tempers are given in Table 24. The medium-strength products of alloy 8090 are aged to near-peak strength and show small changes in properties after elevated-temperature exposure (Fig. 22). The very underaged (damage-tolerant) products will undergo additional aging upon exposure to elevated temperatures. Changes in strength and toughness at cryogenic temperatures are more pronounced in 8090 than in conventional aluminum alloys; 8090 has a substantially higher strength and toughness at cryogenic temperatures (Table 25).

Table 24 Tensile properties and fracture toughness of aluminum-lithium alloy 8090

Temper	Product form	Grain structure[a]	Minimum and typical[b] tensile properties					Minimum and typical[b] fracture toughness values

(b) Toughness with a T-L crack orientation (crack plane and growth direction parallel to the rolling direction)

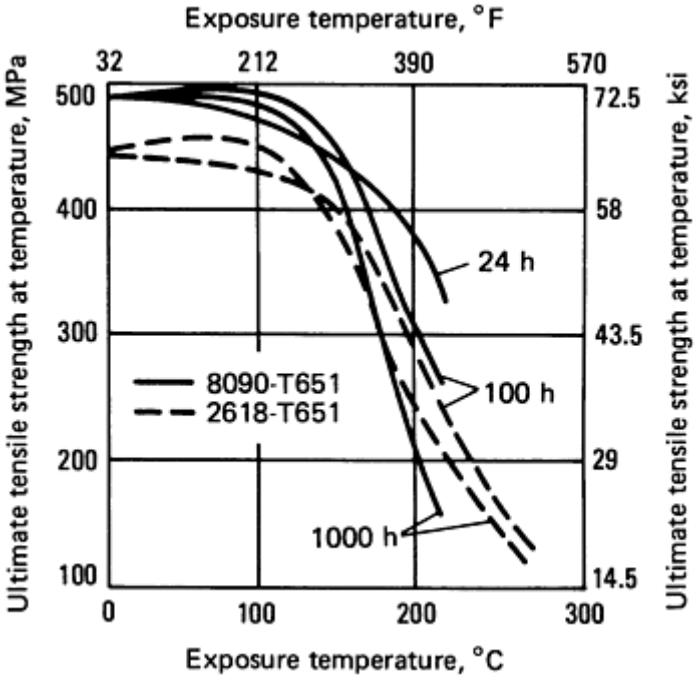

Fig. 22 Ultimate tensile strength for 8090-T651 plate tested at temperature after different exposure times. Data for 2618-T651 provided for comparison

The improving quality of commercially available aluminum-lithium alloys such as 8090 has resulted in significant improvements in short-transverse ductility and, consequently, short-transverse tensile strength. Research on the short-transverse fracture toughness of 8090 has shown that the property reaches a minimum plateau (Fig. 23) at an aging temperature of 190 °C (375 °F). The level of the plateau toughness is affected by impurity content. Sodium content, for example, has been claimed to control toughness; however, once the sodium level in lithium additions is reduced to a practical level of typical battery grade lithium, the fracture toughness of the 8090 alloy achieves a constant value.

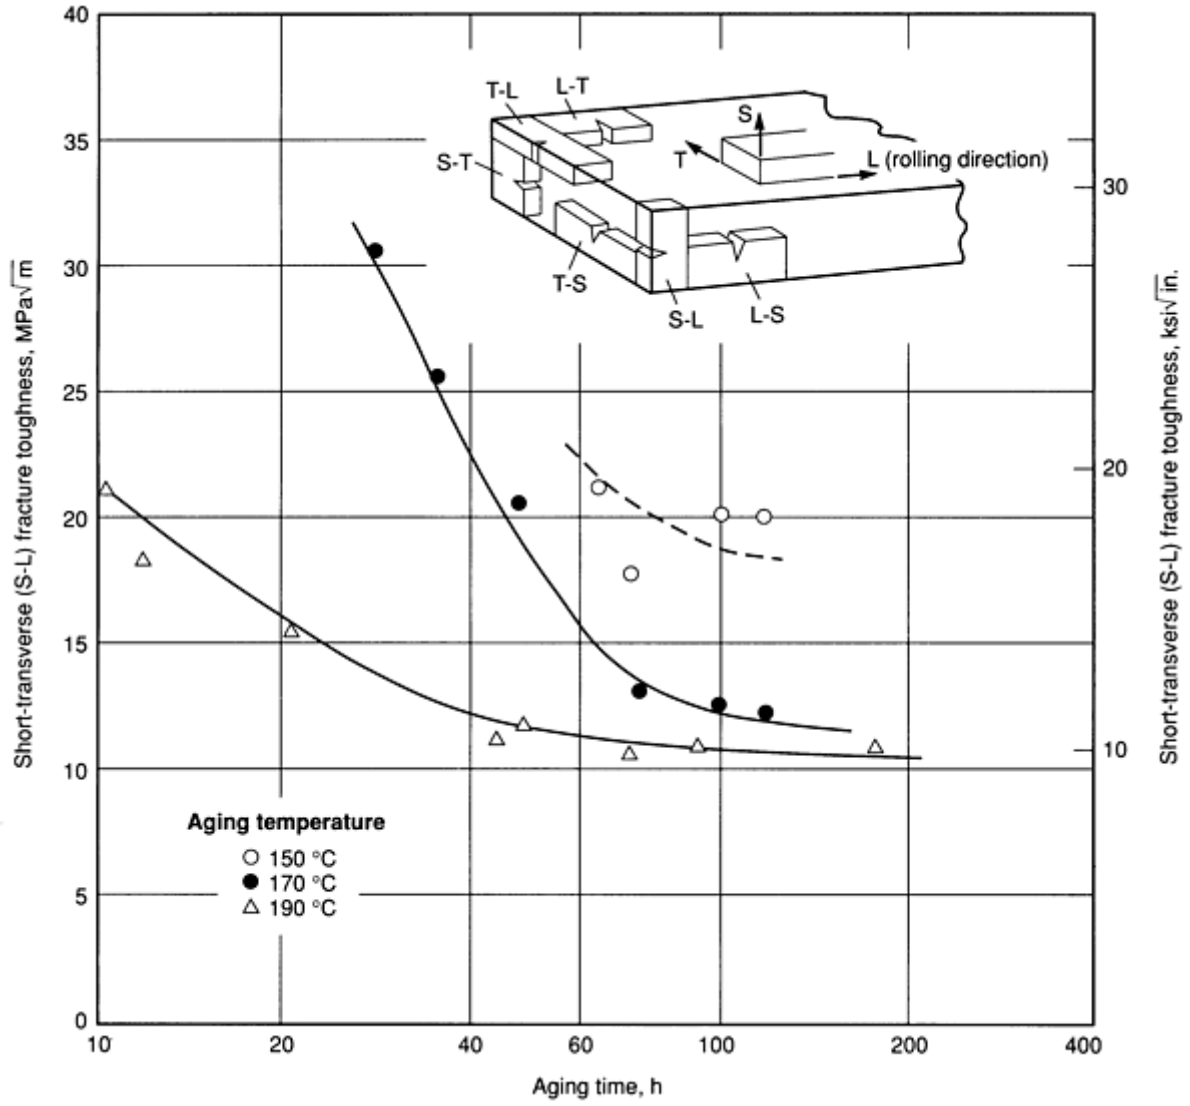

Fig. 23 Effect of aging temperature and time on the short-transverse (S-L) toughness of 8090-T651 plate. The S-L designation indicates a crack plane perpendicular to the S axis and a crack growth in the longitudinal (L) direction.

Design Considerations. In general, the engineering considerations involved in the application of aluminum-lithium alloys are similar to those for the 2*xxx* and 7*xxx* alloys used by the aerospace industry. However, just as with 2090, there are some unique factors that need to be considered when using 8090:

- The in-plane anisotropy of tensile properties for unrecrystallized products (plate, extrusions, forgings, and some medium-strength sheet) is higher in 8090 than in conventional alloys, placing more importance on 45° and shear properties
- Recrystallized damage-tolerant sheet and recrystallized medium-strength sheet show much less anisotropy of tensile properties than do the unrecrystallized products
- Cold work is required to achieve good properties in 8090 products, although to a lesser extent than with 2090
- Fatigue crack growth behavior is excellent, but the advantage 8090 has over conventional alloys is reduced in overload situations

Corrosion performance for 8090 is a strong function of the degree of artificial aging and the microstructure. Table 26 summarizes corrosion performance by product and temper for various types of corrosion tests. Care needs to be taken when selecting an accelerated test for judging the corrosion resistance of 8090. The modified ASTM acetic acid salt

intermittent spray (MASTMAASIS) test seems to be a better indicator of exfoliation resistance than the ASTM G 34 exfoliation corrosion (EXCO) test. Alloy 8090 has displayed generally good exfoliation resistance in atmospheric exposure. For thick products, short-transverse SCC resistance is best in the peaked-aged temper. Thick products with unrecrystallized microstructures have good SCC resistance in the long-transverse direction, whereas those with recrystallized structures have a lower SCC threshold.

Table 26 Exfoliation ratings and SCC thresholds for aluminum-lithium alloy 8090

Temper	Product	Microstructure	Exfoliation rating[a]			SCC threshold
			EXCO test[b]	MASTMAASIS test[c]	Atmospheric exposure	
8090-T81 (underaged)	Sheet	Recrystallized	EA	EA	P, EA	60% of yield strength in the L-T direction
8090-T8 (peak aged)	Sheet	Recrystallized	ED	EA	P	
8090-T8510/11 (peak aged)	Extrusions	Unrecrystallized	. . .	. . .	. . .	75% of yield strength in the L-T direction
8090-T8771, 8090-T651 (peak aged)	Plate	Unrecrystallized	Surface P	. . .	Surface P	105-140 MPa (15-20 ksi) short-transverse threshold
8090-T851	Plate	Unrecrystallized	EC[d]	EB[d]	P, EA	
8090-T8 (peak aged)	Sheet	Unrecrystallized	EC	EB	. . .	75% of yield strength in the L-T direction
8090 (peak aged)	Forgings	Unrecrystallized	. . .	. . .	. . .	140 MPa (20 ksi) short-transverse threshold

(a) Exfoliation rating per ASTM G 34; P, pitting; EA, superficial--tiny blisters, thin slivers, flakes or powders with only slight separation of metal; EB, moderate, notable layering and penetration in metal; EC, more severe surface attack; ED, very severe--penetration to a considerable depth and loss of metal.

(b) Exfoliation corrosion test per ASTM G 34.

(c) MASTMAASIS, modified ASTM acetic acid salt intermittent spray.

(d) Rating at a plane location of T/2, where T is plate thickness

Fatigue. The improved fatigue life of aluminum-lithium alloys as compared with conventional aluminum alloys is viewed by most researchers to be due to crack branching and closure effects. While this improved fatigue performance is valuable, the application designer needs to consider the impact that overloads and negative stress ratios have on the fatigue life of aluminum-lithium alloys to determine the overall advantage that can be obtained with these alloys.

Fatigue of 8090 Sheet. The results of fatigue testing for damage-tolerant 8090 sheet (8090-T81) are shown in Fig. 24. The fatigue crack growth rate of 8090-T81 is up to an order of magnitude slower than that of 2024-T3 at a stress ratio of 0.1 (Fig. 25). The advantage that 8090 has in this area diminishes at higher stress ratios. Both the smooth and notched fatigue strengths of 8090-T81 sheet are higher than those of 2024. Microstructure appears to have some effect on fatigue life: An elongated recrystallized structure provides the best fatigue life results (Fig. 26). There is little fatigue data available for 8090 medium-strength sheet product, but what little there is suggests that an elongated recrystallized microstructure provides the best combination of strength and damage tolerance.

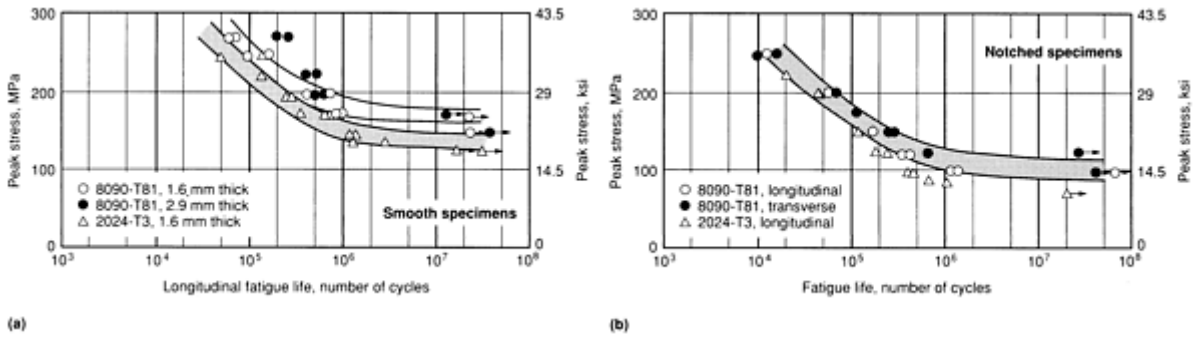

Fig. 24 *S-N* fatigue life curves for damage-tolerant 8090 sheet (8090-T81) and clad 2024-T3 sheet. Stress ratio (*R*), 0.1; cyclic frequency, 80 Hz. (a) Smooth specimens. Theoretical stress concentration factor (K_t) = 1. (b) Notched specimens. K_t = 2.6

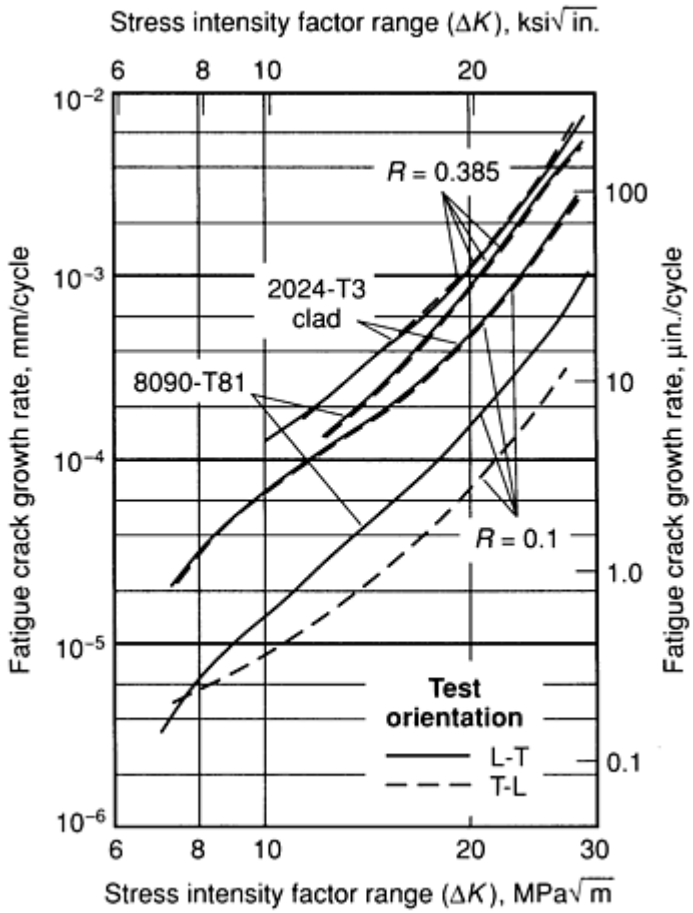

Fig. 25 Effect of test orientation and stress ratio (*R*), on the fatigue crack growth rates of 8090-T81 and clad 2024-T3 sheet. L-T, crack plane and direction perpendicular to the principal direction of rolling; T-L, crack plane and direction parallel to the principal direction of rolling

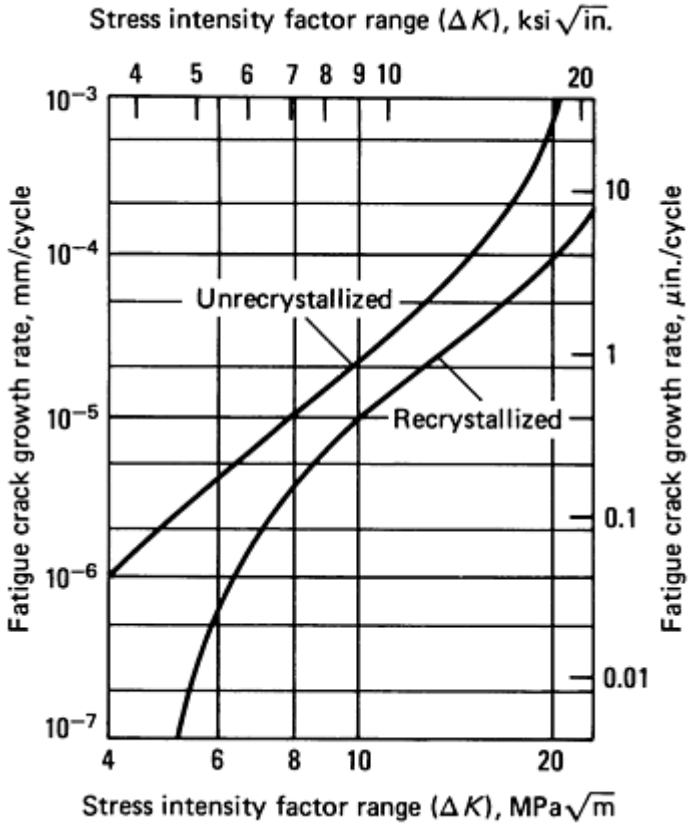

Fig. 26 Effect of microstructure on the fatigue crack growth rate of 8090 sheet under constant-amplitude loading

Fatigue of 8090 Plate. Alloy 8090 in plate form also comes in both the damage-tolerant and medium-strength tempers. Fatigue data for the medium-strength temper (T651) are shown in Fig. 27. Data for the damage-tolerant temper are not available. A comparison of the results for the medium-strength tempers to those for 2024 indicates that 8090 has the superior fatigue crack growth rate (Fig. 28), with a higher fatigue stress for both smooth and notched specimens.

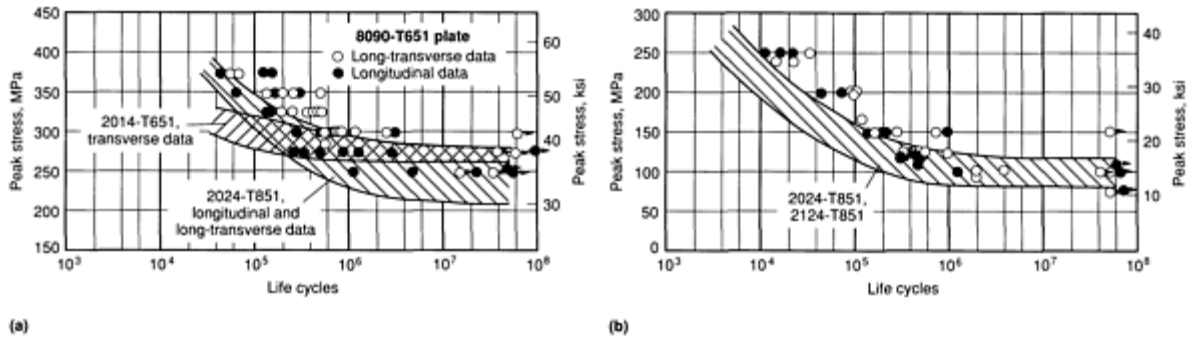

Fig. 27 *S-N* fatigue data for 8090-T651 and selected 2*xxx* alloys. Stress ratio (*R*), 0.1. Specimens tested in laboratory air. (a) Smooth specimens. (b) Notched specimens (K_t = 3)

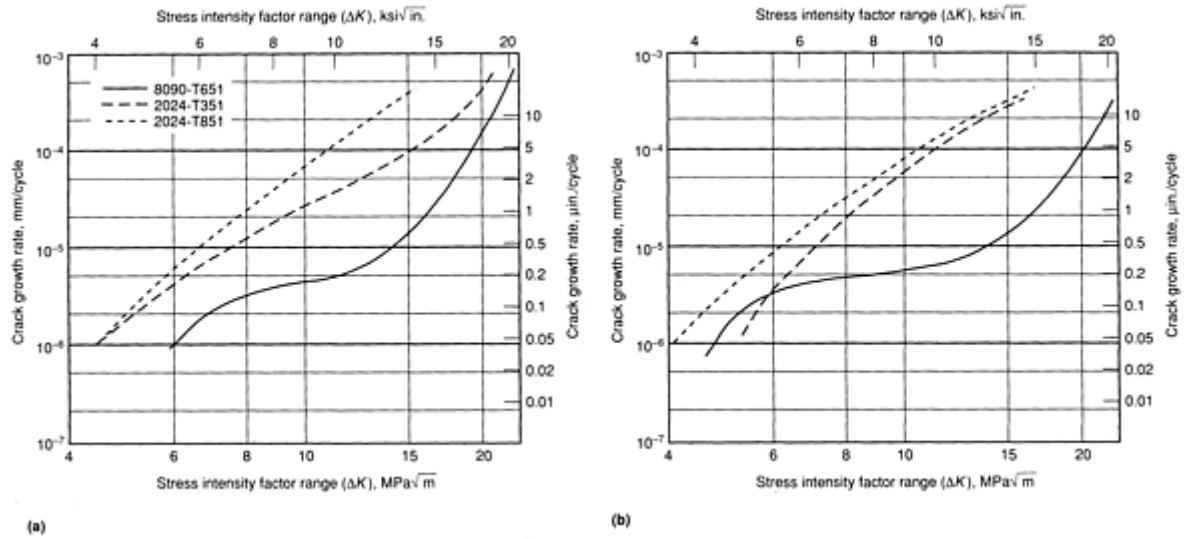

Fig. 28 Fatigue crack growth curves for 8090-T651 and two tempers of 2024 plate. Specimens tested in laboratory air. Stress ratio (*R*), 1.0. (a) L-T specimens (crack plane and direction perpendicular to the principal direction of rolling). (b) T-L specimens (crack plane and direction parallel to the principal direction of rolling)

The fatigue performance of 8090 forgings is similar to that of 8090 sheet.

Forming. Bend tests indicate that 8090 has a lower material springback than that associated with conventional aluminum alloys (Fig. 29). Materials in the as-received condition were subjected to a bend of 90°, approaching at 0°, 45°, and 90° to the rolling direction. The average results for 8090 were lower than those for the other two alloys. Tests on 8090 going down to 2*t* bend radius were successfully completed without damage to the testpiece. Tests with an unaged (solutionized) temper of 8090 produced springback results averaging 2° lower than those for traditional alloy 2014. However, 2014 shows a relatively constant springback with regard to orientation to the rolling direct, whereas the 8090 alloy shows a marked increase after 45°.

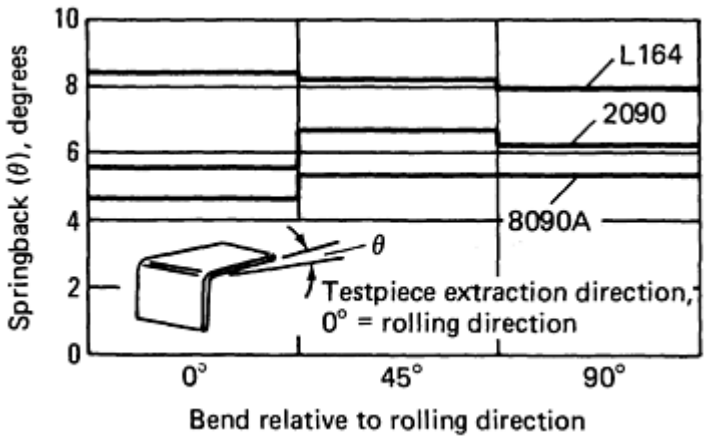

Fig. 29 Average springback from 90° bend of aluminum-lithium alloy 8090 and two conventional alloys. All three alloys were tested in the as-received condition.

Careful preparation of flanged hole surfaces is required to minimize edge cracking when using 8090 in the T8 temper condition. With satisfactory edge preparation, holes can be formed with good results.

Stretch forming is a process in which sheet is wrapped around a forming block and then control stretched to form items such as airfoil sections. The process has been carried out with sufficient success to indicate that it can be used to produce typical aircraft forms. The following factors need to be considered when stretch forming 8090:

- 8090 forms better in the solutionized condition
- 2*t* bends appear to be practical
- Bending springback values may be less than those for conventional alloys
- Flanged holes require a fine edge finish

Finishing Characteristics. The finishing work done to date indicates that 8090 can be chemically milled with existing solutions to achieve a satisfactory surface roughness (Table 27). The higher etch rate of 8090 necessitates batch processing of parts; however better protection against corrosive environments is obtained with anodized 8090 than with conventional alloys (Fig. 30).

Table 27 Response of aluminum-lithium alloy 8090 to chemical milling

Data for 2024 provided for comparison

Alloy	Etch rate		Undercut ratio	Setback	Surface finish, RHR[(a)]	
	mm/min	mils/min			Before chemical milling	After chemical milling
8090	0.084	3.3	1.3	0.3	140	55
2024	0.066	2.6	1.0	0.4	20	35

(a) RHR, roughness height rating

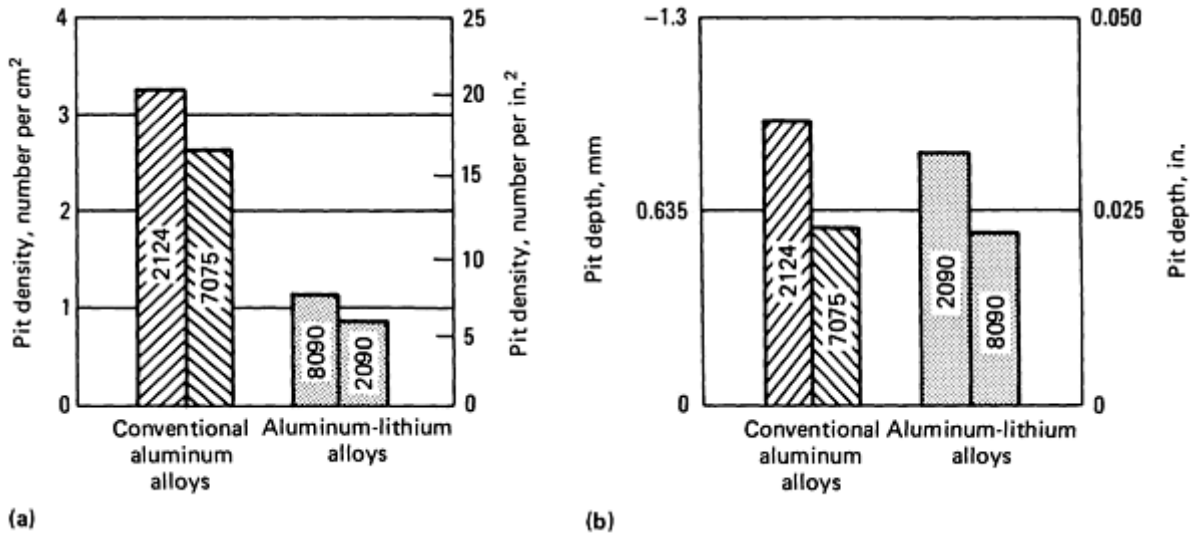

Fig. 30 Pitting characteristics of selected aluminum and aluminum-lithium alloys exposed to an SO_2 salt fog for 32 days. (a) Pit density. (b) Pit depth

Welding. Gas metal arc, gas tungsten arc, and electron beam welding processes have been used to evaluate the fusion weldability characteristics of 8090. Results with all three methods indicate that 8090 is commercially weldable (Table 28).

Table 28 Tensile behavior of 8090-T6 weldments

Data for two other weldable aluminum alloys provided for comparison

Alloy	Filler	Heat treatment	Tensile strength		Yield strength		Elongation in 50 mm (2 in.), %	Specific tensile strength[(a)]		Specific yield strength[(b)]	
			MPa	ksi	MPa	ksi		MPa/g/cm^3	ft × 10^3	MPa/g/cm^3	ft × 10^3

High-Strength Aluminum Powder Metallurgy Alloys

J.R. Pickens, Martin Marietta Laboratories

Introduction

POWDER METALLURGY (P/M) technology provides a useful means of fabricating net-shape components that enables machining to be minimized, thereby reducing costs. Aluminum P/M alloys can therefore compete with conventional aluminum casting alloys, as well as with other materials, for cost-critical applications. In addition, P/M technology can be used to refine microstructures compared with those made by conventional ingot metallurgy (I/M), which often results in improved mechanical and corrosion properties. Consequently, the usefulness of aluminum alloys for high-technology applications, such as those in aircraft and aerospace structures, is extended. This article describes and reviews the latter of these two areas of aluminum P/M technology where high strength and improved combinations of properties are obtained by exploiting the inherent advantages of P/M for alloy design.

The metallurgical reason for the microstructural refinement made possible by P/M are discussed. The two broad high-strength P/M technologies--rapid solidification (RS) and mechanical attrition (mechanical alloying/dispersion strengthening)--are described. The various steps in aluminum P/M technology are explained to produce an appreciation for the interrelationship between powder processing and resultant properties. Finally, the major thrust areas of P/M alloy design and development are reviewed and some properties of the leading aluminum P/M alloys discussed. No attempt is made to provide design-allowable mechanical properties, and the data presented for the various P/M alloys may not be directly comparable because of differences in product forms. Nevertheless, the properties presented will enable the advantages of aluminum P/M alloys to be appreciated. Greater details of aluminum P/M alloys are provided in other reviews (Ref 1, 2, 3, 4, 5, 6, 7). Conventional pressed and sintered aluminum P/M alloys for less demanding applications are described in the Appendix to this article.

Advantages of Aluminum P/M Technology

Aluminum alloys have numerous technical advantages that have enabled them to be one of the dominant structural material families of the 20th century. Aluminum has low density (2.71 g/cm^3) compared with competitive metallic alloy systems, good inherent corrosion resistance because of the continuous, protective oxide film that forms very quickly in air, and good workability that enables aluminum and its alloys to be economically rolled, extruded, or forged into useful shapes. Major alloying additions to aluminum such as copper, magnesium, zinc, and lithium--alone, or in various combinations--enable aluminum alloys to attain high strength. Designers of aircraft and aerospace systems generally like using aluminum alloys because they are reliable, reasonably isotropic, and low in cost compared to more exotic materials such as organic composites.

Aluminum alloys do have limitations compared with competitive materials. For example, Young's modulus of aluminum (about 70 GPa, or 10×10^6 psi) is significantly lower than that of ferrous alloys (about 210 GPa, or 30×10^6 psi) and titanium alloys (about 112 GPa, or 16×10^6 psi). This lower modulus is almost exactly offset by the density advantage of aluminum compared to iron- and titanium-base alloys. Nevertheless, designers could exploit higher-modulus aluminum alloys in many stiffness-critical applications.

Although aluminum alloys can attain high strength, the strongest such alloys have often been limited by stress-corrosion cracking (SCC) susceptibility in the highest-strength tempers. For example, the high-strength 7*xxx* alloys (Al-Zn-Mg and Al-Zn-Mg-Cu) can have severe SCC susceptibility in the highest-strength (T6) tempers. To remedy this problem, overaged (T7) tempers have been developed that eliminate SCC susceptibility, but with a 10 to 15% strength penalty.

The melting point of aluminum, 660 °C (1220 °F), is lower than that of the major competitive alloy systems: iron-, nickel-, and titanium-base alloys. As might be expected, the mechanical properties of aluminum alloys at elevated temperatures are often not competitive with these other systems. This limitation of aluminum alloys is of particular concern to

designers of aircraft and aerospace structures, where high service temperatures preclude the use of aluminum alloys for certain structural components.

The number of alloying elements that have extensive solid solubility in aluminum is relatively low. Consequently, there are not many precipitation-hardenable aluminum alloy systems that are practical by conventional I/M. This can be viewed as a limitation when alloy developers endeavor to design improved alloys. Aluminum P/M technology enables the aforementioned limitations of aluminum alloys to be overcome to various extents, while still maintaining most of the inherent advantages of aluminum.

Structure/Property Benefits. The advantages of P/M stem from the ability of small particles to be processed. This enables:

- The realization of RS rates
- The uniform introduction of strengthening features, that is, barriers to dislocation, motion, from the powder surfaces

The powder processes of rapid solidification and mechanical attrition lead to microstructural grain refinement and, in general, better mechanical properties of the alloy. Specifically, the smaller the mean free path between obstacles to dislocation motion, the greater the strengthening. In addition, finer microstructural features are also less apt to serve as fracture-initiating flaws, thereby increasing toughness.

The RS rate made possible by P/M enable microstructural refinement by several methods. For example, grain size can be reduced because of the short time available for nuclei to grow during solidification. Finer grain size results in a smaller mean free path between grain boundaries, which are effective barriers to dislocation motion, leading to increased "Hall-Petch" strengthening. In addition, RS can extend the alloying limits in aluminum by enhancing super-saturation and thereby enabling greater precipitation hardening without the harmful segregation effects from overalloyed I/M alloys. Moreover, elements that are essentially insoluble in the solid state, but have significant solubility in liquid aluminum, can be uniformly dispersed in the powder particles during RS. This can lead to the formation of novel strengthening phases that are not possible by conventional I/M, while also suppressing the formation of equilibrium phases that are deleterious to toughness and corrosion resistance. The photomicrograph shown in Fig. 1 exemplifies the microstructural refinement possible by RS-P/M processing. This experimental A1-6.7Zn-2.4Mg-1.4Cu-0.8Co alloy has a grain size of 2 to 5 μm and a fine distribution of Co_2Al_9 particles of about 0.1 to 0.4 μm. Comparable I/M alloys have a grain size that is almost an order of magnitude larger. In addition, making this alloy by I/M would lead to very coarse cobalt-containing particles because of the low solid-solubility of cobalt in aluminum. These coarse particles would significantly degrade toughness. Thus, RS processes constitute one of the two major classes of high-strength P/M technology.

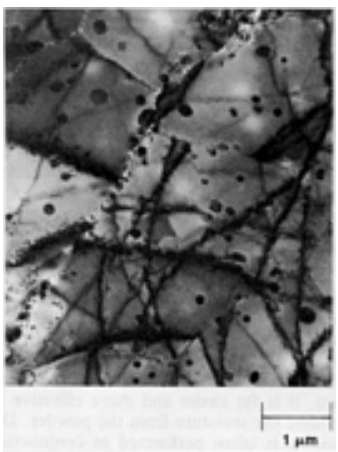

Fig. 1 Experimental Al-Zn-Mg-Cu-Co RS alloy that contains a fine distribution of spherical Co_2Al_9 particles and fine grain size (2 to 5 μm). Courtesy of L. Christodoulou, Martin Marietta Laboratories

The other class of high-strength P/M technology relies on the introduction of strengthening features from powder surfaces, which can be accomplished on a fine scale because of the high surface-area-to volume ratio of the powder particles. Most, but not all, such processes involve ball milling and are called mechanical attrition processes.

Oxides can be easily introduced from powder surfaces by consolidating the powder and hot working the product (see the section "Mechanical Attrition Process" in this article). The fine oxides can improve strength by oxide dispersion strengthening (ODS), and in addition, by substructural strengthening resulting from the dislocations created during working, which are generated by dislocation-oxide interactions. However, ODS can be increased by mechanically attriting the powder particles to more finely disperse the oxides. Ball milling in the presence of organic surfactants allows carbides to be dispersed in a similar fashion. Finally, ball milling aluminum and other powders can enable fine intermetallic dispersoids to form during milling or subsequent thermomechanical processing.

The interplay between dispersed oxides, carbides (or other ceramics), intermetallics, and dislocations during hot, warm, or cold working can enable great refinement in grain and subgrain size. This can result in significant strengthening because grain and subgrain boundaries can be effective barriers to dislocation motion. For example, an experimental Al-1.5Li-0.9O-0.6C mechanically alloyed material had an extremely fine grain/subgrain size of 0.1 μm (Fig. 2). The ultrafine oxides and carbides, coupled with this fine grain size, enabled the alloy to have a tensile strength of nearly 800 MPa (115 Ksi) with 3% elongation. An I/M alloy containing this much oxygen and carbon that is effectively contained in finely dispersed particles is not viable.

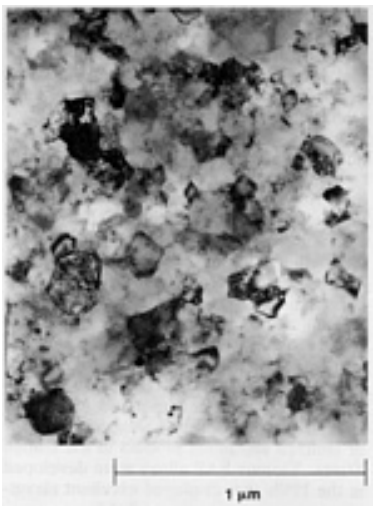

Fig. 2 Experimental mechanically alloyed Al-1.5Li-0.9O-0.6C alloy featuring an ultrafine grain/subgrain size. Courtesy of J.R. Pickens, unpublished research

P/M processing, including both rapid solidification and mechanical attrition processes, provides alloy designers with additional flexibility resulting from the inherent advantage of working with small bits of matter. In addition to refinement of strengthening features, different metallic powders can be mixed to form duplex microstructures. Furthermore, ceramic powders may be mixed with aluminum alloy powders to form metal-matrix composites (MMCs). However, the fine particles of matter must be consolidated and formed into useful shapes. The potential benefits of P/M technology can be realized, or lost, in the critical consolidation-related and forming processes.

Aluminum P/M Processing

There are several steps in aluminum P/M technology that can be combined in various ways, but they will be conveniently described in three general steps:

- Powder production
- Powder processing (optional)
- Degassing and consolidation

Powder can be made by various RS processes including atomization, splat quenching to form particulates, and melt spinning to form ribbon. Alternatively, powder can be made by non-RS processes such as by chemical reactions including precipitation, or by machining bulk material. Powder-processing operations are optional and include mechanical attrition (for example, ball milling) to modify powder shape and size or to introduce strengthening features, or comminution such as that used to cut melt-spun ribbon into powder flakes for subsequent handling.

Aluminum has a high affinity for moisture, and aluminum powders readily adsorb water. The elevated temperatures generally required to consolidate aluminum powder causes the water of hydration to react and form hydrogen, which can result in porosity in the final product, or under confined conditions, can cause an explosion. Consequently, aluminum powder must be degassed prior to consolidation. This is often performed immediately prior to consolidation at essentially the same temperature as that for consolidation to reduce fabrication costs. Consolidation may involve forming a billet that can be subsequently rolled, extruded, or forged conventionally, or the powder may be consolidated during hot working directly to finished-product form. The various steps in aluminum P/M technology will now be discussed in greater detail.

Powder Production

Atomization is the most widely used process to produce aluminum powder Aluminum is melted, alloyed, and sprayed through a nozzle to form a stream of very fine particles that are rapidly cooled--most often by an expanding gas. Atomization techniques have been reviewed extensively in Ref 8 and 9 and in *Powder Metal Technologies and Applications,* Volume 7 of *ASM Handbook.* Cooling rates of 10^3 to 10^6 K/s are typically obtained.

Splat cooling is a process that enables cooling rates even greater than those obtained in atomization. Aluminum is melted and alloyed, and liquid droplets are sprayed or dropped against a chilled surface of high thermal conductivity--for example, a copper wheel that is water cooled internally. The resultant splat particulate is removed from the rotating wheel to allow subsequent droplets to contact the bare, chilled surface. Cooling rates of 10^5 K/s are typical, with rates up to 10^9 K/s reported.

Melt-spinning techniques are somewhat similar to splat cooling. The molten aluminum alloy rapidly impinges a cooled, rotating wheel, producing rapidly solidified product that is often in ribbon form. The leading commercial melt-spinning process is the planar flow casting (PFC) process developed by M.C. Narisimhan and co-workers at Allied-Signal Inc. (Ref 10). The liquid stream contacts a rotating wheel at a carefully controlled distance to form a thin, rapidly solidified ribbon and also to reduce oxidation. The ribbon could be used for specialty applications in its PFC form but is most often comminuted into flake powder for subsequent degassing and consolidation.

In the aforementioned RS powder-manufacturing processes, partitionless (that is, no segregation) solidification can occur, and with supersaturation RS can ultimately lead to greater precipitation strengthening. Furthermore, with the highest solidification rates, crystallization can be suppressed. The novelties of RS aluminum microstructures and nonequilibrium phase considerations have been reviewed (Ref 11, 12).

Other Methods. Powder can also be made from machining chips or via chemical reactions (Ref 1, 13). Such powders should be carefully cleaned before degassing and consolidation.

Mechanical Attrition Process

Mechanical attrition processes often involve ball milling in various machines and environments. Such processes can be used to control powder size and distribution to facilitate flow or subsequent consolidation, introduce strengthening features from powder surfaces, and enable intermetallics or ceramic particles to be finely dispersed. The two leading mechanical attrition processes today--mechanical alloying in the United States, and reaction milling in Europe--are improvements on sinter-aluminum-pulver (SAP) technology developed by Irmann in Austria (Ref 14, 15).

SAP Technology. In 1946, Irmann and co-workers were preparing rod specimens for spectrographic analysis by hot pressing mixtures of pure aluminum and other metal powders. They noticed the unexpectedly high hardness of the resulting rods. Mechanical property evaluations revealed that the hot-pressed material had strength approaching that of aluminum structural alloys. Based on microstructural evaluations, Irmann attributed the high strength of the hot-pressed compacts to the breakdown of the surface oxide film on the powder particles during hot pressing. Irmann performed mechanical tests at elevated temperatures and showed that these alloys not only had surprisingly high elevated-temperature strength, but retained much of their room-temperature strength after elevated-temperature exposure.

Irmann also ball milled aluminum powder and noticed that is was similar to the flaky powder used in paint pigment. Hüttig studied the formation of the flaky powder during ball milling and noticed the competition between comminution and welding of the powder particles (Ref 16). This fracture and welding of the powder particles caused the surface oxide film to be ruptured and become somewhat dispersed in the powder particles. Irmann called these hot-pressed materials sinter-aluminum-pulver (SAP), latter referred to as sintered aluminum powder or sintered aluminum product in the United States. Various SAP alloys were developed in the 1950s that displayed excellent elevated-temperature properties (Ref 1).

The mechanical alloying process is a high-energy ball-milling process that employs a stirred ball mill called an attritor, a shaken ball mill, or a conventional rotating ball mill (Ref 17, 18). The process is performed in the presence of organic surfactants, for example, methanol, stearic acid, and graphite, to control the cold welding of powder particles and provide oxygen and carbon for dispersion strengthening (Ref 19, 20). Mechanical alloying claims the advantage of milling under "dry" conditions--that is, not in mineral oil, as in some SAP processing, which must be removed after milling--although dry SAP ball milling in the presence of stearic acid was reported in the 1950s (Ref 1).

Elemental powders may be milled with aluminum powders to effect solid-solution strengthening or to dispersed intermetallics. The dispersed oxides, carbides, and/or intermetallics create effective dislocation sources during the milling

process and suppress dislocation annihilation during subsequent working operations, which result in greatly increased dislocation density. Thus, mechanical alloying enables the effective superimposition of numerous strengthening mechanisms (Ref 2, 19, 20, 21), including:

- Oxide dispersion
- Carbide dispersion
- Fine grain size
- High dislocation density and substructure
- Solid-solution strengthening

Consequently, high strength can be obtained without reliance on precipitation strengthening, which may introduce problems such as corrosion and SCC susceptibility, and propensity for planar slip. Nevertheless, the aforementioned five strengthening contributions can be augmented by precipitation strengthening as well as intermetallic dispersion strengthening.

Reaction milling is another mechanical attrition process derived from SAP technology (Ref 22, 23, 24). It is extremely similar to mechanical alloying, and subtle differences between the two processes appear to have little appreciable effect on the compositions that can be processed and the resulting microstructures produced. Investigations in Europe have also successfully superimposed numerous strengthening features in aluminum P/M alloys, as described above.

Powder Degassing and Consolidation

The water of hydration that forms on aluminum powder surfaces must be removed to prevent porosity in the consolidated product. Although solid-state degassing has been used to reduce the hydrogen content of aluminum P/M wrought products, it is far easier and more effective to remove the moisture from the powder. Degassing is often performed in conjunction with consolidation, and the most commonly used techniques are described below. The various aluminum fabrication schemes are summarized in Fig. 3.

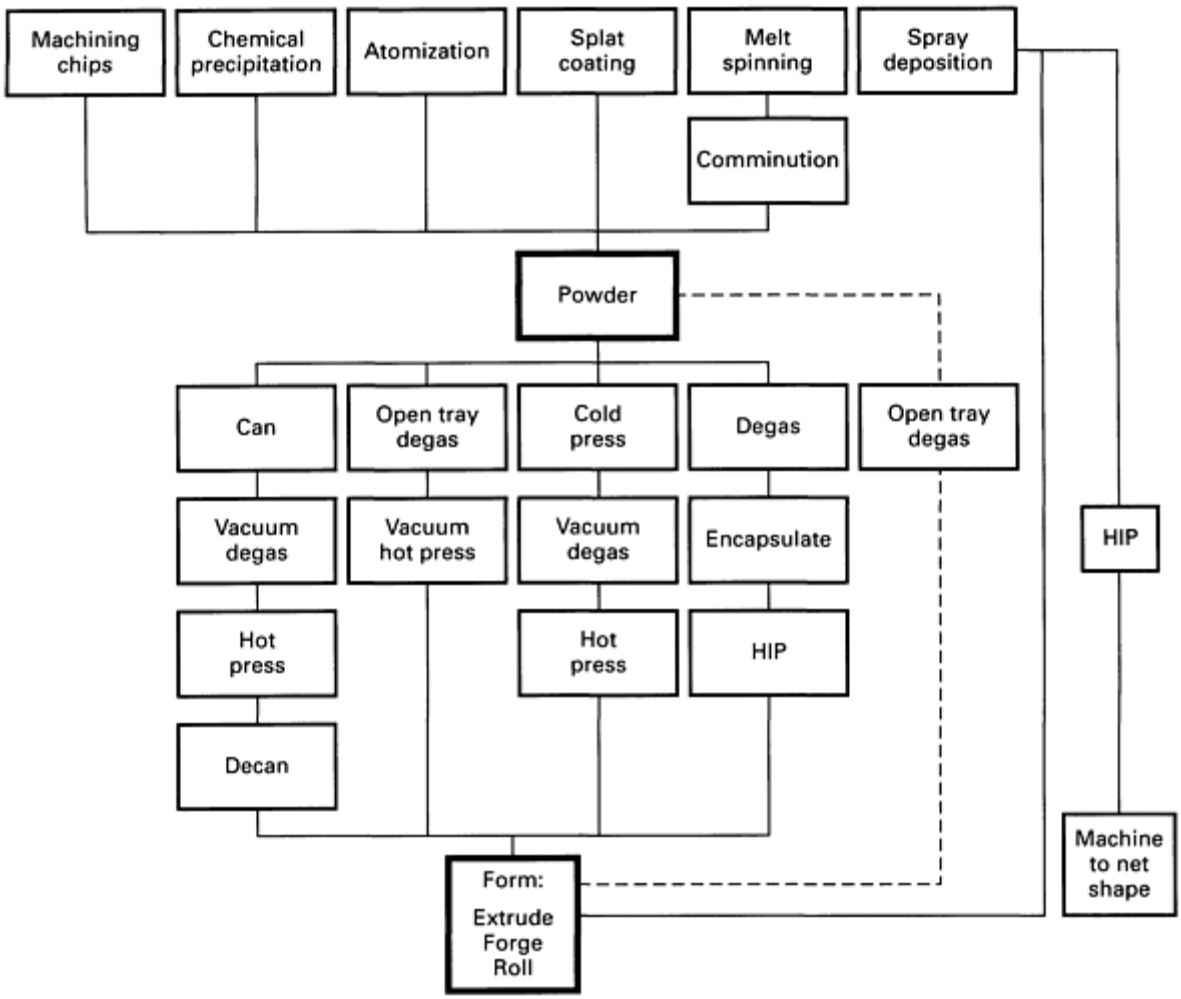

Fig. 3 Aluminum P/M fabrication schemes

Can Vacuum Degassing. This is perhaps the most widely used technique for aluminum degassing because it is relatively non-capital intensive. Powder is encapsulated in a can, usually aluminum alloys 3003 or 6061, as shown schematically in Fig. 4. A spacer is often useful to increase packing and to avoid safety problems when the can is welded shut. The author has found that packing densities are typically 60% of theoretical density when utilizing this method on mechanically alloyed powders. Care must be used to allow a clear path for evolved gases through the spacer to prevent pressure buildup and explosion.

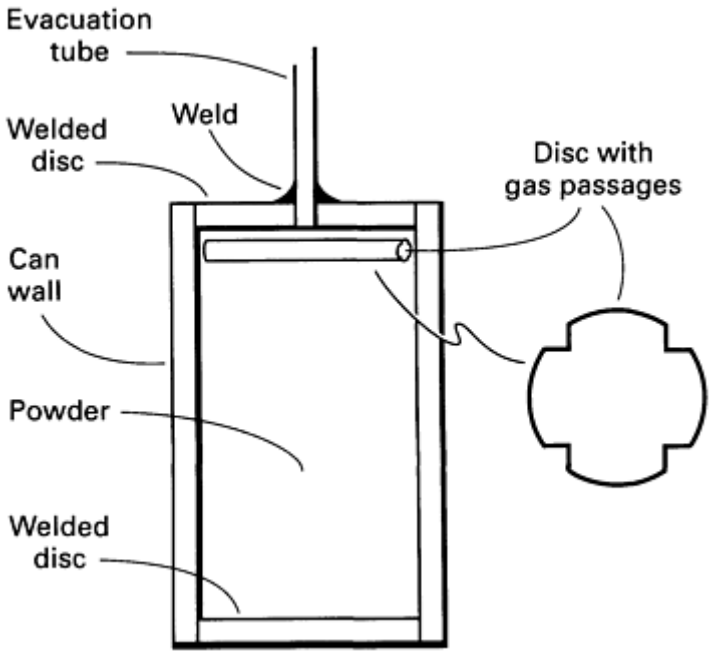

Fig. 4 Degassing can used for aluminum P/M processing. Source: Ref 2

To increase packing density, the powder is often cold isostatically pressed (CIP) in a reusable polymeric container before insertion into the can. Powder densities in the CIPed compact of 75 to 80% theoretical density are preferred because they have increased packing density with respect to loose-packed powder, yet allow sufficient interconnected porosity for gas removal. At packing densities of about 84% and higher, effective degassing is not possible for several atomized aluminum-alloy powders (Ref 25, 26). Furthermore, one must control CIP parameters to avoid inhomogeneous load transfer through the powder, which can lead to excessive density in the outer regions of the cylindrical compact and much lower densities in the center. Such CIP parameters often must be developed for a specific powder and compact diameter (see the article "Cold Isostatic Pressing" in *Powder Metal Technologies and Applications,* Volume 7 of *ASM Handbook*).

The canned powder is sealed by welding a cap that contains an evacuation tube as shown in Fig. 4. After ensuring that the can contains no leaks, the powder is vacuum degassed while heating to elevated temperatures. The rate in gas evolution as a function of degassing temperature depends on powder size, distribution, and composition. The ultimate degassing temperature should be selected based on powder composition, considering tradeoffs between resulting hydrogen content and microstructural coarsening. For example, an RS-P/M precipitation-hardenable alloy that is to be welded would likely be degassed at a relatively high temperature to minimize hydrogen content (hotter is not always better). Coarsening would not significantly decrease the strength of the resulting product because solution treatment and aging would be subsequently performed and provide most of the strengthening. On the other hand, a mechanically attrited P/M alloy that relies on substructural strengthening and will serve in a mechanically fastened application might be degassed at a lower temperature to reduce the annealing out of dislocations and coarsening of substructure.

When a suitable vacuum is achieved (for example, <5 millitorr), the evacuation tube is sealed by crimping. The degassed powder compact can then be immediately consolidated to avoid the costs of additional heating. An extrusion press using a blind die (that is, no orifice) is often a cost-effective means of consolidation.

Dipurative Degassing. Roberts and co-workers at Kaiser Aluminum & Chemical Corporation have developed an improved degassing method called "dipurative" degassing (Ref 27). In this technique, the vacuum-degassed powder, which is often canned, is backfilled with a dipurative gas (that is, one that effectively removes water of hydration) such as extra-dry nitrogen, and then re-evacuated. Several backfills and evacuations can be performed resulting in lower hydrogen content. In addition, the degassing can often be performed at lower temperatures to reduce microstructural coarsening.

Vacuum Degassing in a Reusable Chamber. The cost of canning and decanning adversely affects the competitiveness of aluminum P/M alloys. This cost can be alleviated somewhat by using a reusable chamber for vacuum hot pressing. The powder or CIPed compact can be placed in the chamber and vacuum degassed immediately prior to compaction in the same chamber. Alternatively, the powder can be "open tray" degassed, that is, degassed in an unconfined fashion, prior to loading into the chamber. The processing time to achieve degassing in an open tray can be much less than that required in a chamber or can, thereby increasing productivity. Care must be exercised to load the powder into the chamber using suitable protection from ambient air and moisture. The compacted billet can then be formed by conventional hot-working operations.

Direct Powder Forming. One of the most cost-effective means of powder consolidation is direct powder forming. Degassed powder, or powder that has been manufactured with great care to avoid contact with ambient air, can be consolidated directly during the hot-forming operation. Direct powder extrusion and rolling have been successfully demonstrated numerous times over the past two decades (Ref 28, 29). It still remains an attractive means for decreasing the cost of aluminum P/M.

Hot Isostatic Pressing (HIP). In HIP, degassed and encapsulated powder is subjected to hydrostatic pressure in a HIP apparatus (see the article "Hot Isostatic Pressing of Metal Powders" in *Powder Metal Technologies and Applications,* Volume 7 of *ASM Handbook.*). Can vacuum degassing is often used as the precursor step to HIP. Furthermore, net-shape encapsulation of degassed powder can be used to produce certain near net-shape parts. Relatively high HIP pressures (~200 MPa, or 30 ksi) are often preferred. Unfortunately, the oxide layer on the powder particle surfaces is not sufficiently broken up for optimum mechanical properties. A subsequent hot-working operation that introduces shear-stress components is often necessary to improve ductility and toughness.

Rapid Omnidirectional Consolidation. Engineers at Kelsey-Hayes Company have developed a technique to use existing commercial forging equipment to consolidate powders in several alloy systems (Ref 30). Called rapid omnidirectional consolidation (ROC), it is a lower-cost alternative to HIP. In ROC processing, degassed powder is loaded into a thick-walled "fluid die" that is made of a material that plastically flows at the consolidation temperature and pressure, and which enables the transfer of hydrostatic stress to the powder. Early fluid dies were made of mild steels or a Cu-10Ni alloy, with subsequent dies made from ceramics, glass, or composites.

The preheated die that contains powder can be consolidated in less that 1 s in a forging press, thereby reducing thermal exposure that can coarsen RS microstructures. In addition, productivity is greatly increased by minimizing press time. Depending upon the type of fluid die material being used, the die can be machined off, chemically leached off, melted off, or designed to "pop off" the net-shape component while cooling from the consolidation temperature. For aluminum-alloy powders, unconfined degassing is critical to optimize the cost effectiveness of the ROC process. An electrodynamic degasser was developed for this purpose.

Just as in the case of HIP, the stress state during ROC is largely hydrostatic. Consequently, there may not be sufficient shear stresses to break the oxide layer and disperse the oxides, which can lead to prior powder-particle boundary (PPB) failure. Consequently, a subsequent hot-working step of the ROC billet is often necessary for demanding applications. More detailed information on this technique can be found in the article "Conventional Aluminum Powder Metallurgy Alloys" in *Powder Metal Technologies and Applications,* Volume 7 of *ASM Handbook.*

Dynamic Compaction. Various ultrahigh strain-rate consolidation techniques, that is, dynamic compaction, have been developed and utilized for aluminum alloys (Ref 31, 32). In dynamic compaction, a high-velocity projectile impacts the degassed powders that are consolidated by propagation of the resultant shock wave through the powder. The bonding between the powder particles is believed to occur by melting of a very thin layer on the powder surfaces, which is caused by the heat resulting from friction between the powder particles that occurs during impact. The melted region is highly localized and self-quenched by the powder interiors shortly after impact. Thus, dynamic compaction has the advantage of minimizing thermal exposure and microstructural coarsening, while breaking up the PPBs.

New Directions in Powder Consolidation. Perhaps the most promising area in powder consolidation to have matured over the past decade is actually a bridge between RS-P/M technology and I/M technology. Spray-forming techniques such as the Osprey process (Ref 33), liquid dynamic compaction (Ref 34, 35), and vacuum plasma structural deposition (Ref 36) build consolidated product directly from the atomized stream. Solidification rates greater than those in conventional I/M are attained, but they are not as high as those in RS-P/M processes such as atomization or splat cooling. Spray-forming technology, which will be discussed briefly later, is also described in the article "Spray Forming" in *Powder Metal Technologies and Applications,* Volume 7 of *ASM Handbook.*

High-Strength Aluminum Powder Metallurgy Alloys

J.R. Pickens, Martin Marietta Laboratories

Alloy Design Research

Aluminum P/M technology is being used to improve the limitations of aluminum alloys and also to push the inherent advantages of aluminum alloys to new limits. The alloy design efforts can be described in three areas (Ref 4):

- High ambient-temperature strength with improved corrosion and SCC resistance
- Improved elevated-temperature properties so aluminum alloys can more effectively compete with titanium alloys
- Increased stiffness and/or reduced density for aluminum alloys to compete with organic composites

This third area includes aluminum-lithium alloys, aluminum-beryllium-lithium alloys, and metal-matrix composites.

High Ambient-Temperature Strength and Improved Corrosion/SCC Resistance

RS Alloys. Rapid-solidification processing has been used to develop improved aluminum alloys for ambient-temperature service for over 25 years. Much of the early work has been conducted by investigators at the Aluminum Company of America (Alcoa) (Ref 37, 38, 39). The most successful work in this area was in the Al-Zn-Mg alloy subsystem (7*xxx* alloys), where more highly alloyed 7*xxx* alloy variants with dispersed transition-metal intermetallic phases were investigated. The leading alloys developed have been cobalt-containing alloys 7091 and 7090 (Ref 39), and a subsequent nickel- and zirconium-containing alloy CW67 (Ref 40). Compositions of aluminum alloys for ambient-temperature service are provided in Table 1. Mechanical properties, of course, depend upon mill product form and thermo-mechanical history. Tensile properties of extrusions are provided in Table 2 to allow an appreciation for the strengths that are possible.

Table 1 Nominal compositions of aluminum P/M alloys for ambient-temperature service

Alloy	Composition, wt%									
	Zn	Mg	Cu	Co	Zr	Ni	Cr	Li	O	C
7090	8.0	2.5	1.0	1.5	. . .	. . .	. . .	. . .	. . .	. . .
7091	6.5	2.5	1.5	0.4	. . .	. . .	. . .	. . .	. . .	. . .
CW67	9.0	2.5	1.5	. . .	0.14	0.1	. . .	. . .	. . .	. . .
7064	7.4	2.4	2.1	0.75	0.3	. . .	0.15	. . .	0.2	. . .
Al-9052	. . .	4.0	. . .	. . .	. . .	. . .	. . .	. . .	0.5	1.1

Table 2 Longitudinal tensile properties from experimental extrusions of aluminum P/M alloys designed for ambient-temperature service

Alloy	Temper	Yield strength, MPa (ksi)	Ultimate tensile strength, MPa (ksi)	Elongation, %	Reference
7091	T6E192	600 (87)	640 (93)	13	41[(b)]

	T7	545 (79)	595 (86)	11	41[b]

The SCC resistance of 7090 and 7091 is improved with respect to I/M 7*xxx* alloys. In fact, SCC resistance generally increases with cobalt content from 0 to 1.6 wt%, but general corrosion resistance, as assessed by weight-loss tests, decreases (Ref 41). For example, in the peak-strength condition, alloy 7091 with 0.4 wt% Co has a similar SCC plateau crack velocity to I/M 7075, but with 1.5 wt% Co, 7090 has a lower plateau velocity (Fig. 5). Alloy CW67 also has improved combinations of strength and SCC resistance with respect to conventional 7*xxx* I/M alloys and it has replaced 7090 and 7091 as Alcoa's leading RS-P/M aluminum alloy for ambient-temperature service (Ref 40).

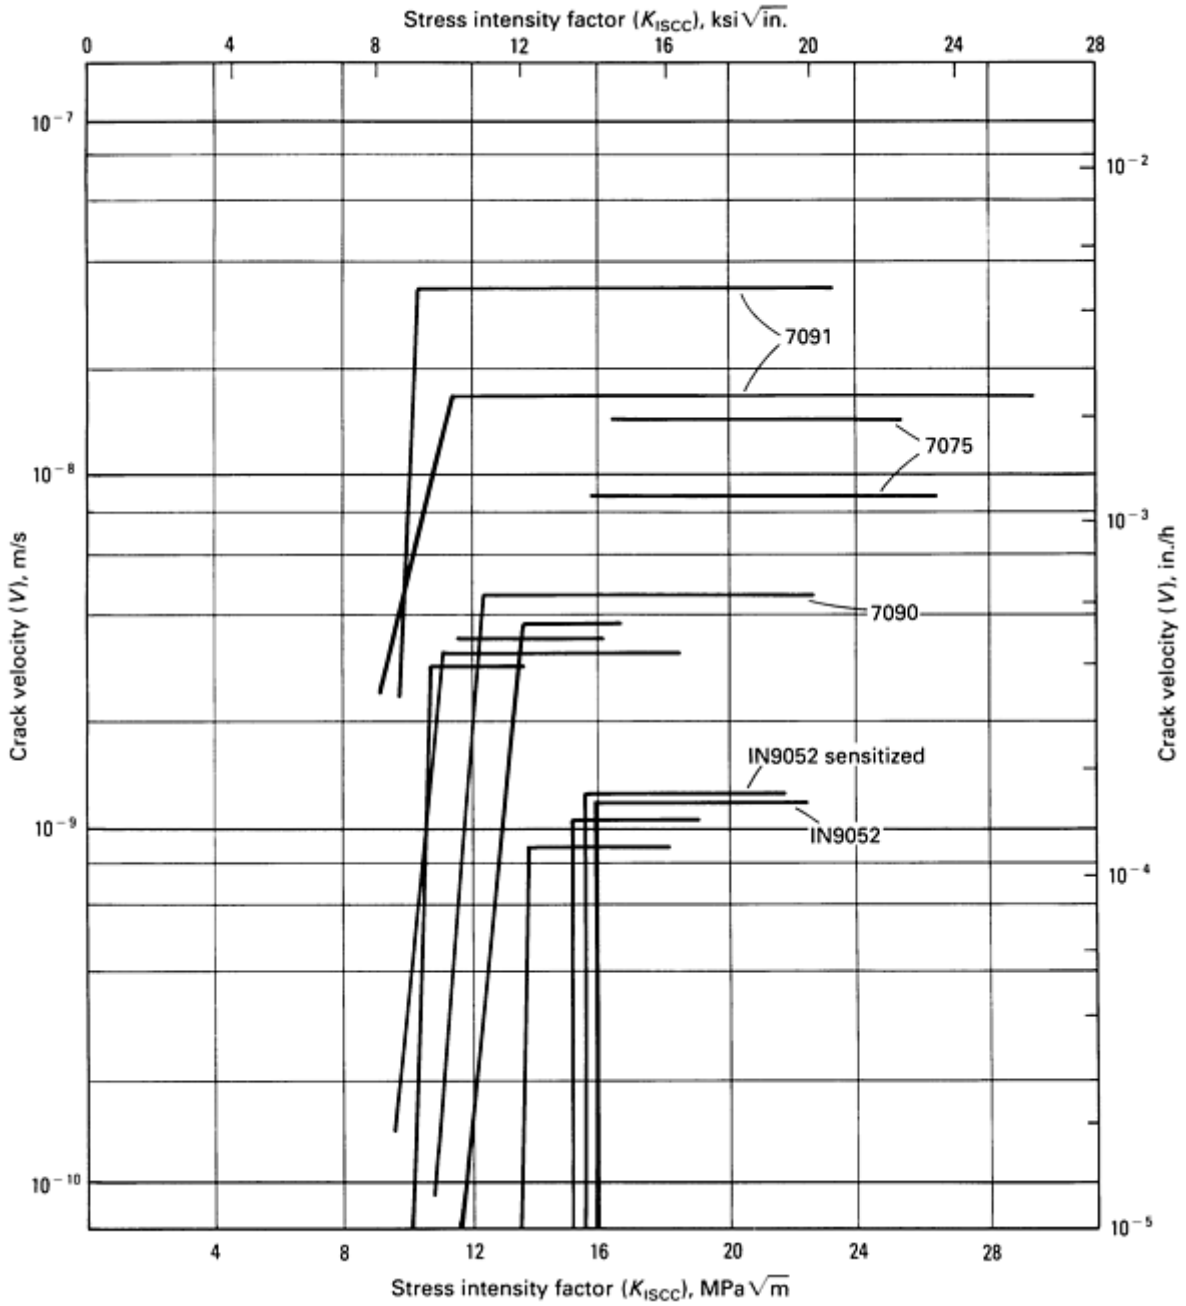

Fig. 5 Stress-corrosion cracking characteristics for the three P/M alloys and I/M 7075, all in their highest-strength (peak aged) conditions. Source: Ref 41

The effect of P/M processing on the fatigue behavior of aluminum alloys is complex. In general, resistance to fatigue-crack initiation is improved by P/M processing, in part because of the refinement of constituent particles at which fatigue cracks can nucleate. On the other hand, resistance to fatigue-crack growth can be decreased by P/M processing because of the refinement in grain size. For fine-grain P/M aluminum alloys, the plastic zone size may span several grains, thereby enabling the transfer of deformation across grain boundaries. In coarser-grain I/M alloys, the plastic zone may be contained within one grain.

Voss compared the fatigue-crack growth rate under constant load amplitude of 7075-T6510 made by I/M and P/M and enhanced-purity I/M alloy of similar composition, 7475-T651 (Ref 42). Typical results are shown in Fig. 6. The I/M alloys generally displayed better resistance to fatigue-crack propagation in laboratory air. This behavior can change under spectrum fatigue testing, that is, testing designed to simulate service conditions by altering amplitude, where P/M aluminum alloys can perform better than I/M counterparts. The prospective user should exercise care in selecting the proper fatigue testing for aluminum alloys by performing tests that are relevant to service.

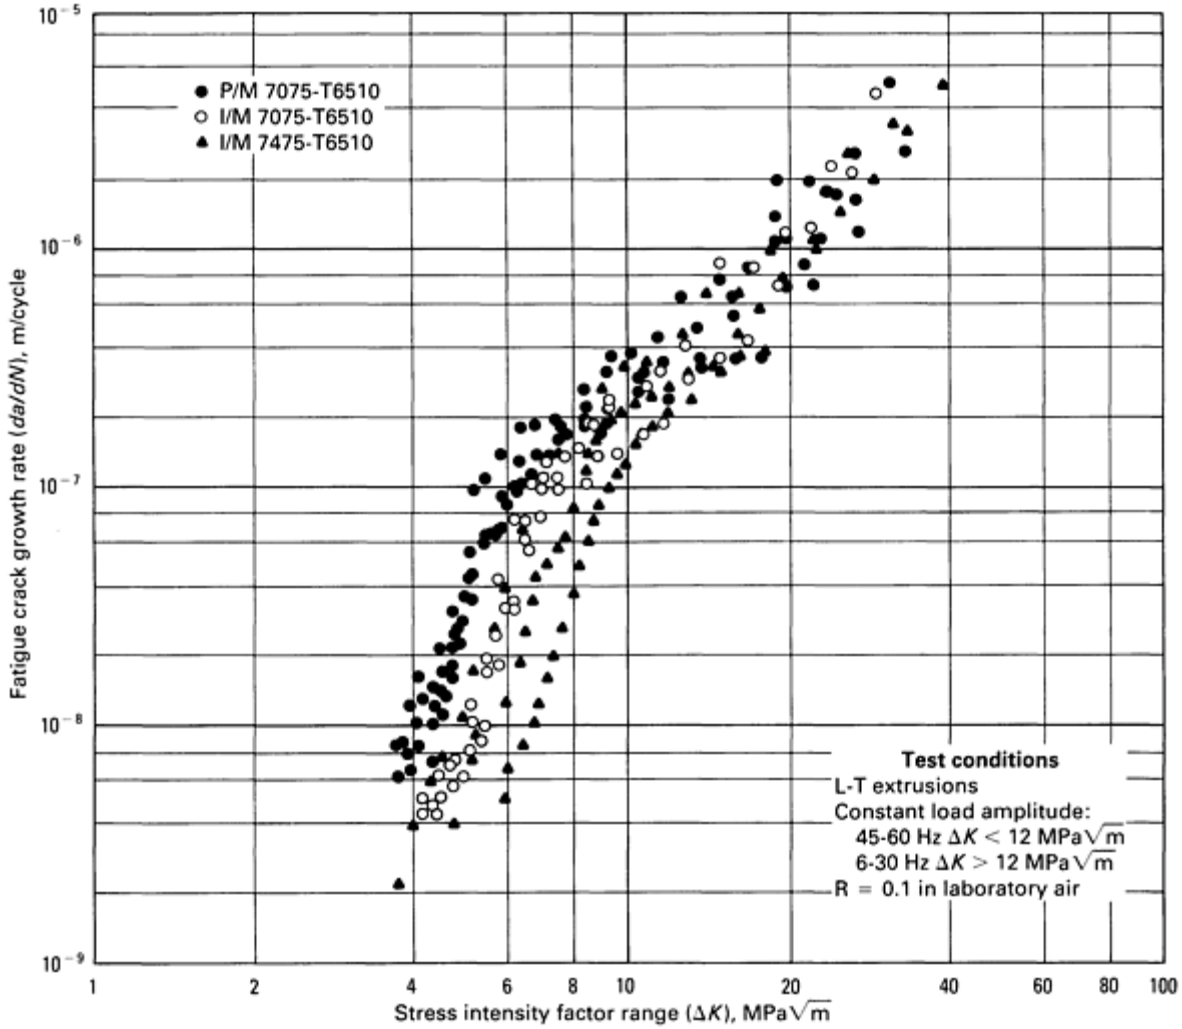

Fig. 6 Fatigue crack growth behavior of equivalent yield strength P/M 7075-T6510, I/M 7075-T6510, and I/M 7475-T6510 in a laboratory air environment. Source: Ref 43

Scientists at Kaiser Aluminum & Chemical Corporation have also developed RS-P/M 7*xxx* alloys (Ref 43). The leading such alloy, 7064 (formerly called PM-64), is in parts strengthened by zirconium-, chromium-, and cobalt-containing dispersoids (see Table 1). It also displays attractive combinations of strength and SCC resistance, and in addition, has been shown to be superplastically formable.

Wear-Resistant RS Alloys. Japanese researchers have also been developing alloys for ambient-temperature service by RS-P/M. However, they have been more interested in wear resistance than corrosion resistance. For example, Honda Motor Company, Ltd. (Ref 44) has been developing duplex powder alloys that contain atomized aluminum-silicon or aluminum-iron "hard alloy" powders with more ductile aluminum powders (Ref 44). The wear resistance is provided by the hard alloy powders, and good forgeability is provided by the more ductile powders.

Japanese researchers at Sumitomo Electric Industries and Kobe Steel are also looking at RS-P/M Al-Si alloys for wear-resistant applications (Ref 45, 46). For example, Kobe Steel has patented an Al-Si-Cu-Mg family of alloys that contain dispersoid-forming elements for compressor pistons and connecting rods. The leading composition is an Al-20Si-5Fe-2Cu-1Mg-1Mn (wt%) alloy.

Researchers at Tokoku University in Japan have developed RS amorphous alloys that can be produced in films, fibers, plates, or pipes (Ref 47). These alloys contain various combinations of yttrium, nickel, and lanthanum, producing unprecedented strengths as high as 1140 MPa (165 ksi) on, presumably, small samples. Although it is doubtful that such alloys could be scaled up to large wrought products that have such strengths, the alloys are aimed at wear-resistant applications in pistons, valves, gears, brakes, bearings, and rotors (Ref 47).

Mechanically Alloyed Materials. Mechanical attrition processes have also been used to develop improved alloys for ambient-temperature service. Mechanically alloyed Al-4Mg-1.1C-0.5O alloy Al-9052 (formerly IN-9052) (Ref 19, 20, 21) and Al-4Mg-1.3Li-1.1C-0.4O alloy Al-905XL (formerly IN-905XL) (Ref 48) were designed to obtain high strength from dispersion and substructural strengthening, while minimizing corrosion and SCC susceptibility that might be introduced by certain precipitates. In addition, Al-905XL was designed to have increased specific stiffness, introduced by the lithium addition. Each of these alloys has been fabricated over a wide range of strength levels by controlling dispersoid content and thermomechanical processing to vary substructural strengthening. In general, these alloys are hot worked at relatively high values of temperature-compensated strain rate, referred to as the Zener Holloman parameter, which is defined by:

$$Z = \varepsilon \exp(Q/RT) \qquad \textbf{(Eq 1)}$$

where ε is the mean strain rate, Q is the activation energy of the rate-controlling process in the deformation mechanism, R is the universal gas constant, and T is absolute temperature. Such strain rates lead to increased substructural strengthening. For example, extruding at a relatively low temperature and high speed produces a high Z, which can lead to a fine array of subgrains. Hot working at too high a value of Z can result in sufficient stored energy to cause recrystallization. However, the relatively high-volume fraction of finely dispersed oxides and carbides tends to stabilize the fine grain or subgrain structure and inhibit the formation of coarse recrystallized grains.

Alloy Al-9052 is dispersion strengthened by magnesium oxides, aluminum oxides, and aluminum carbide; solid-solution strengthened by magnesium; and fine grain/subgrain strengthened (Ref 19, 20). Alloy Al-905XL is strengthened by similar features, although it does display a slight artificial aging response from lithium-containing precipitates (Ref 49, 50, 51). The SCC behavior of a high-strength variant of Al-9052 was compared with RS-P/M 7091 and 7090 in their peak strength (T6) conditions (Ref 41). The nonheat-treatable mechanically alloyed material displayed the lowest susceptibility in these peak strength conditions (see Fig. 5). However, the RS-P/M alloys were immune to SCC in the overaged T7 conditions, which resulted in a 10% decrease in strength. The higher cobalt-containing RS-P/M alloy 7090 displayed lower susceptibility and higher strength than 7091, although the higher-volume fraction of cobalt-containing dispersoids did increase pitting susceptibility with respect to 7091. The three P/M alloys showed clear SCC resistance advantages over competitive I/M alloys (Fig. 5). This work concluded with the following generalization concerning the SCC susceptibility of aluminum P/M alloys.

SCC Susceptibility. P/M alloys made by RS or by mechanical alloying achieve excellent combinations of high strength and superb SCC resistance because they enable the uniform introduction of microstructural features that either improve SCC resistance (for example, Co_2Al_9 intermetallic particles), or increase strength without degrading SCC resistance (for example, oxide and carbide dispersion strengthening) (Ref 41).

Al-905XL is currently the leading mechanically alloyed material under commercialization. The alloy is primarily aimed at forging applications where its attractive strength (Table 3), low density, and good corrosion and SCC resistance offer advantages over conventional aluminum alloys. A mechanically alloyed 2*xxx* alloy, Al-9021, is also under development, but its corrosion resistance is not as good as that of Al-9052 and Al-905XL.

Concluding Remarks. Attractive alloys have been developed by both RS-P/M and mechanical attrition processes for ambient-temperature service. Their primary advantage is improved combinations of strength and SCC/corrosion resistance. However, their advantage over high-strength aluminum I/M alloys is often viewed as not significant enough to effect alloy changes in existing applications. Furthermore, the extensive, successful efforts in developing aluminum-lithium I/M alloys has provided additional competition for these P/M alloys.

P/M Alloys With Improved Elevated-Temperature Properties

Powder metallurgy technology is inherently suited to alloy design for elevated-temperature service. Rapid solidification technology allows formation of finely dispersed intermetallic strengthening phases that resist coarsening and are not practical, or in some cases are not even possible, by conventional I/M. In addition, mechanical attrition processes can similarly disperse intermetallics and also disperse oxides and carbides on an extremely fine scale. These oxides and carbides are extremely resistant to coarsening at the service temperatures envisioned for aluminum alloys.

Early efforts focused on extending the service temperature of aluminum alloys to 315 to 345 °C (600 to 650 °F). In the mid-1980s, a U.S. Air Force initiative sought to extend the possible service temperature to an extremely challenging 480 °C (900 °F).

RS-P/M Alloys. Much of the development in this area sought to disperse slow-diffusivity transition metals as intermetallic phases in aluminum. Most of the successful alloys developed contain iron.

Scientists at Alcoa (Ref 52, 53, 54) investigated numerous such RS-P/M alloys, and Al-Fe-Ce alloys CU78 and CZ42 were the leading alloys developed (compositions of elevated-temperature service alloys are given in Table 4; a typical microstructure is shown in Fig. 7). The alloys displayed good tensile strength up to 315 °C (600 °F) as indicated in Tables 5 and 6, good room-temperature properties after elevated-temperature exposure (Fig. 8), and surprisingly good resistance to environmentally assisted cracking (Ref 54). No failures were observed in 180 days in a 3.5% NaCl solution under conditions of alternate immersion at a stress of 275 MPa (40 ksi). Pratt & Whitney has found that molybdenum additions to RS-P/M Al-Fe produce attractive properties also (Ref 56).

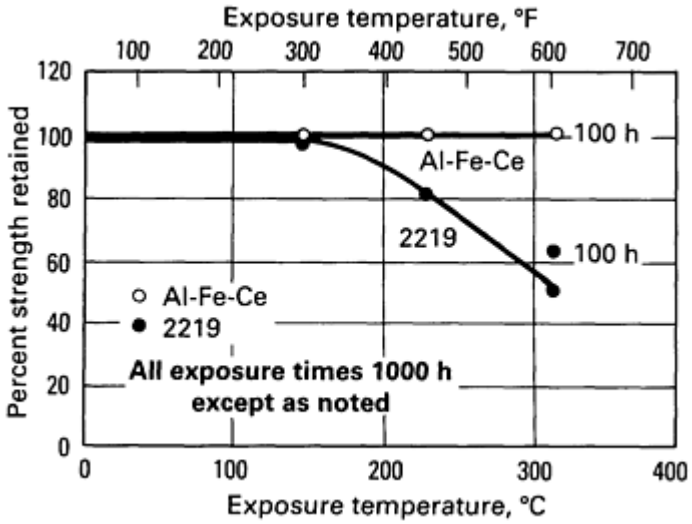

Fig. 8 Percent of room-temperature strength retained after elevated-temperature exposure of Al-Fe-Ce alloys

Perhaps the leading RS-P/M aluminum alloys developed are the Al-Fe-V-Si alloys by Allied-Signal Inc. that are made using planar flow casting (Ref 57, 58). For example, alloys FVS-0812 and FVS-1212 display exceptionally high strengths at 315 °C (600 °F) and usable strengths at 425 °C (800 °F) (see Tables 7 and 8). Furthermore, the alloys contain high-volume fractions of silicides that increase modulus. Both alloys have good corrosion resistance in salt-fog environments and good resistance to SCC in saline environments. The dispersed silicides are so fine that they contribute greatly to strength over a wide temperature range (Fig. 9), but do not degrade corrosion and SCC resistance. The silicides are apparently so stable that alloy FVS-0812 can be exposed to 425 °C (800 °F) for up to 1000 h without degradation of room-temperature properties.

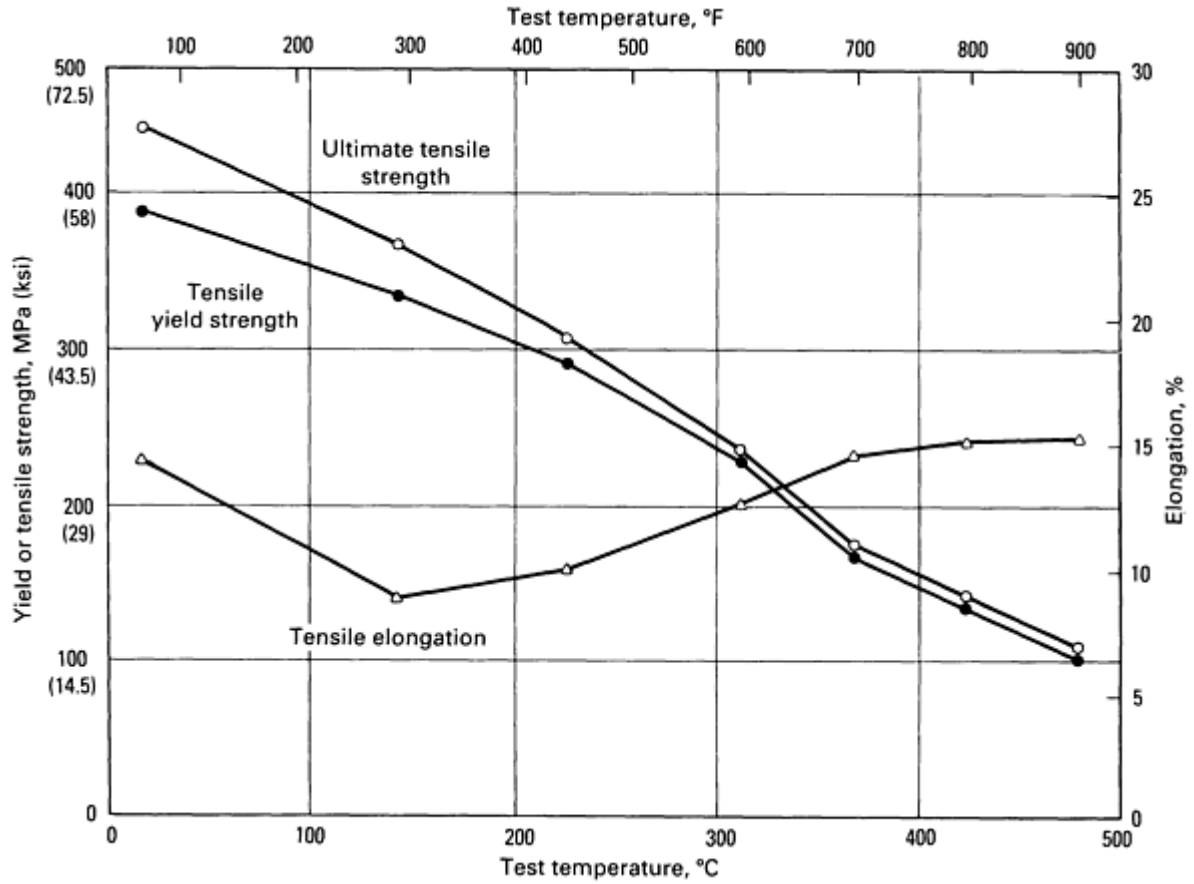

Fig. 9 Tensile properties of FVS-0812 alloy extrusions

Alloy FVS-0812 has been forged into air-craft wheels and is now under consideration as a replacement for conventional alloy 2014, the mainstay aircraft wheel alloy. In addition, the stability of the alloy after elevated-temperature exposure, coupled with its high strength at 300 °C (575 °F), is enabling the alloy to challenge titanium alloys in certain engine components.

Allied-Signal, Inc. is also developing RS-P/M alloy FVS-0611 for applications where good formability is necessary. It is lower in alloying content (Table 4) than the other PFC alloys for elevated-temperature service and is aimed for applications such as rivets and thin-walled tubing.

Scientists at Alcan International Limited took a different approach to designing RS-P/M alloys for elevated-temperature service (Ref 59). They pursued the Al-Cr-Zr system to develop an alloy that could attain attractive elevated-temperature properties from powder that is less sensitive to cooling rate and also has better hot workability. Both chromium and

zirconium can produce thermally stable solid solutions in aluminum at modest solidification rates (10^3 K/s). The consolidated billet could then be extruded or rolled with a relatively low flow stress at the lower end of the hot-working range and then aged at a higher temperature to form stable intermetallics that provide elevated-temperature strength.

This alloy design approach provides a potential advantage over RS-P/M Al-Fe-*X* alloys, which often attain their highest hardness just after RS (see Fig. 10). Hardness, and consequently yield strength, can be lost in each thermomechanical processing step from degassing/consolidation through hot working. In addition, elevated-temperature flow stress of the as-compacted billet can make extrusion, forging, and rolling difficult and expensive. Another advantage over RS-P/M Al-Fe-*X* alloys is that the leading Al-Cr-Zr compositions have lower density.

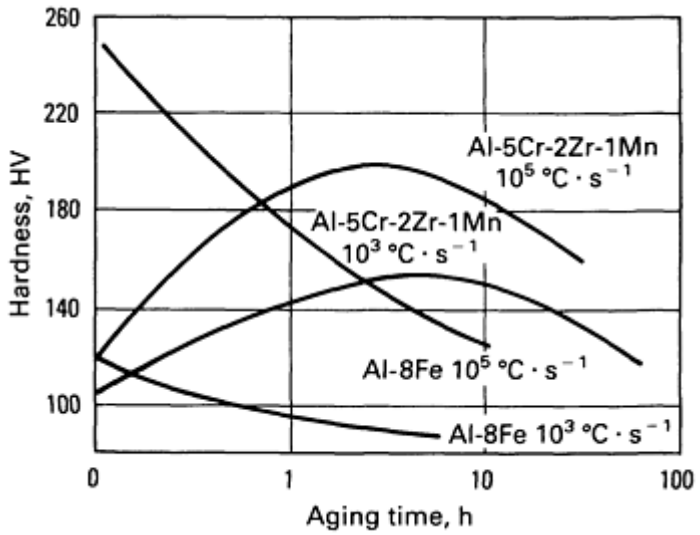

Fig. 10 Variation of microhardness with aging time at 400 °C for Al-5.2Cr-1.9Zr-1Mn alloy compared to Al-8Fe alloy. Source: Ref 59

Palmer *et al.* (Ref 59) present analysis by Ekvall *et al.* (Ref 60) and other data comparing the modulus and density of various RS-P/M alloys for elevated-temperature service (Table 9). They compare two parameters that are related to weight-savings ability--specific modulus $E \div \rho$and the parameter $E^{1/3} \div \rho$. Specific modulus is the weight-controlling parameter where the predominant failure mode involves aeroelastic stiffness, and the parameter $E^{1/3} \div \rho$ applies in certain buckling-limited applications. The leading Al-Cr-Zr alloys, Al-5Cr-2Zr and Al-5Cr-2Zr-1Mn, compare favorably to other RS-P/M alloys and have a substantial advantage over leading I/M alloys such as 2219.

Mechanically Attrited Alloys. Reaction milling is an SAP-derived process developed by Jangg (Ref 22, 23) and co-workers in Europe. It is claimed to be an attritor milling process that mills without a process control agent (PCA) (Ref 24), such as the stearic acid often used in mechanical alloying. Reaction milling is often performed in the presence of lampblack, or graphite, the latter of which the author has found to act as a PCA (Ref 19, 20) that introduces carbon. Oxygen is introduced by careful control of the milling atmosphere and forms oxides that are finely dispersed by the reaction milling process. Oxygen in the milling atmosphere may be considered a PCA by reducing the degree of cold welding when powder particles are impacted during ball milling.

The leading reaction-milled alloys (DIS-PAL alloys) are not as strong as most other elevated-temperature P/M alloys at ambient or intermediate temperatures (Ref 24). However, their decrease in strength with increasing temperature is rather flat, so they have reasonable strength and also good stability at higher temperatures, for example, 150 MPa (22 ksi) tensile strength at 400 °C (750 °F).

Several mechanically alloyed aluminum alloys for elevated-temperature service were designed in 1978 by the author while working for the International Nickel Company (now Inco Alloys International, Inc.) (Ref 61). Various low-solid solubility transition-metal elements were mechanically alloyed to potentially form stable dispersoids, as were electropositive solid-solution elements (for example, lithium and magnesium) to potentially form stable oxides. The leading alloy developed in the program was an Al-4Ti alloy that contained carbon and oxygen from the mechanical alloying process. A yield strength of 159 MPa (23 ksi) and a tensile strength of 186 MPa (27 ksi) were attained at 345 °C (650 °F) on the first heat investigated. In addition, room-temperature strengths (325 MPa, or 47 ksi yield strength and 383 MPa, or 56 ksi ultimate tensile strengths) were essentially unchanged after 100 h at 345 °C (650 °F). In recent work in the mechanically alloyed Al-Ti system by Wilsdorf *et al.* (Ref 62), higher titanium levels and yttria additions were investigated that improved strength at 345 °C (650 °F). In addition, yield and tensile strengths at 425 °C (800 °F), as high as 113 MPa (16 ksi) and 133 MPa (19 ksi), respectively, were attained.

Concluding Remarks. This is the area where aluminum P/M has perhaps the best chance for replacing conventional aluminum or titanium alloys. In fact, the attractive room-temperature properties of these alloys and their surprisingly good corrosion resistance will enable them to compete for warm- and ambient-temperature applications. RS-P/M alloys generally attain higher strength than those made by mechanical attrition processes up to about 350 °C (660 °F), with the Allied-Signal Inc. FVS series alloys showing particular promise. The mechanically attrited materials display superb stability--that is, room-temperature strength after elevated-temperature exposure--and high strengths for aluminum alloys at 425 °C (800 °F).

High-Modulus and/or Low-Density Alloys

Aluminum P/M is useful to attain stiffer and/or lighter alloys in several ways. First, the alloying limits of elements that increase modulus (E) or decrease density (ρ) can be extended by either RS or mechanical attribution processes. Lithium and beryllium are the only elements that generally do both in aluminum, and RS aluminum-lithium and aluminum-lithium-beryllium alloys have been made that contain alloying levels not practical by I/M. In addition, attempts to

mechanically alloy aluminum-lithium alloys have been fruitful at modest lithium levels, but not so at very high levels (3.5 to 4 wt%) (Ref 48). Powder metallurgy technology is also useful in producing metal-matrix composites (MMCs).

The development of P/M alloys that have increased stiffness and/or decreased density is not receiving as much emphasis as it did less than a decade ago (early 1980s). This is largely due to the success of aluminum-lithium alloys made by I/M, which have the advantage of being producible using modified conventional equipment (see the article "Aluminum-Lithium Alloys" in this Volume). In addition, several technologies have arisen that enable MMCs to be made by I/M--for example, Alcan Aluminum Limited's Dural technology for SiC in aluminum, and Martin Marietta's XD technology for TiB_2 or TiC in aluminum. Several high $E \div \rho$ aluminum P/M alloys will be briefly described to show how P/M technology can be utilized in this area.

Al-Li and Al-Li-Be Alloys. Scientists at Allied-Signal Inc. investigated 3 to 4 wt% Li aluminum-lithium alloys made by the PFC technique. The rapid cooling rate allows lithium levels to be attained that are higher than those practical by conventional I/M using commercial direct-chill casting technology. The practical limit for lithium in aluminum by commercial-scale direct-chill casting is about 2.7 wt%. The decreased thermal conductivity caused by lithium additions results in slower cooling rates, which lead to unacceptable segregation at high lithium levels. In addition, the potential explosive hazard increases with lithium content.

Several of the high-lithium-containing PFC alloy compositions were assessed in an Air Force program in cooperation with The Boeing Company (Ref 63). The leading such alloy, 644B, is an Al-3.2Li-lCu-0.5Mg-0.5Zr alloy with a density of 2.537 g/cm^3. The high zirconium content, which is over 3 times the effective maximum (about 0.14 wt%) in commercial-scale direct-chill casting, was added to form composite Al_3Zr-Al_3Li precipitates that would hopefully be less shearable than $Al_3Li(\delta')$.

The alloy attained a mean yield strength of 424 MPa (62 ksi), tensile strength of 521 MPa (76 ksi), with 7% elongation in the longitudinal direction in extruded form. Unfortunately, toughness was low, so subsequent alloy variations contained lower lithium content (Ref 64). The alloy also displayed SCC susceptibility.

As mentioned earlier, mechanically alloyed Al-905XL attains moderate to high strength and good corrosion resistance. The 1.3 wt% Li in the alloy coupled with lithium-, magnesium-, and aluminum-containing oxides also increases elastic modulus, which is 80 GPa (11.6×10^6 psi). Lithium levels of up to 4% were investigated in the early development of mechanically alloyed aluminum-lithium alloys (Ref 48), but oxygen contamination caused ductility to be low. More recently, various other lithium-containing compositions were integrated into the aforementioned Air Force program (Ref 63).

As pointed out by Perepezko, the aluminum-beryllium alloy system is one that can benefit greatly from the RS-P/M approach (Ref 65). The solid-solubility limit of beryllium in aluminum is low (0.3 at %), as is the eutectic composition (2.5 wt%), so the extension of solubility by RS-P/M techniques is particularly useful.

Lewis and co-workers at Lockheed Corporation have examined Al-Be-Li alloys made by RS-P/M and have attained values of specific modulus that are significantly higher than those attained in conventional aluminum alloys (Ref 66). They used melt spinning to examine Al-Be-Li and Al-Be alloys designed to be age hardenable and to have ultralow density. The alloys were designed to be strengthened by δ' and possibly α-Be dispersoids. The ability of RS-P/M technology to extend solubility limits can be appreciated by the Al-20.5Be-2.4Li and Al-29.6Be-1.3Li alloys that displayed perhaps the best properties (Table 10).

Table 10 Properties of RS-P/M aluminum-beryllium-lithium alloys

Composition, wt%	Temper	Yield strength		Ultimate tensile strength		Elongation, %	Young's modulus		Density g/cm^3
		MPa	ksi	MPa	ksi		GPa	10^6 psi	
Al-20.5Be-2.4Li	As-quenched	321	46.5	451	65	6.4	123	18	2.298

	Peak aged	483	70	531	77	3.3	123	18	2.298
Al-29.6Be-1.3Li	Underaged	434	63	494	72	5.0	142	21	. . .
	Peak aged	497	72	536	78	2.6	142	21	. . .

Metal-Matrix Composites. A significant amount of work has been undertaken to produce aluminum MMCs using P/M technology (Ref 2, 3, 4, 5, 6). Much of this work has emphasized SiC for reinforcement, although work with Al_2O_3, TiB_2, and other ceramics has received attention. P/M technology enables unique matrix alloys to be designed to accept specific ceramic particles. The alloy designer has the flexibility to select compositions that might not be practical by I/M to improve wetability and/or the nature of the ceramic matrix interface. In addition, P/M allows fine-scale mixing of ceramic and alloy powder (or powders for duplex matrices) and provides the option of "slushy state" consolidation, that is, at a consolidation temperature between the solidus and liquidus of the matrix alloy. DWA Corporation and Arco Metals (formerly Silag Corporation) have extended significant effort in this area throughout the past decade and each produced alloys with high strength and stiffness. Some of the more interesting aluminum MMC work has involved reinforcing high-strength P/M alloy matrices. For example, Agarwala *et al.* examined 7091-SiC composites and found attractive mechanical properties, but decreased corrosion resistance (Ref 67). Unfortunately, no one alloy has gained widespread commercial acceptance.

Mechanical alloying can also be used to make MMCs. A low-volume fraction of Al_2O_3 can be easily dispersed by the attrition process (Ref 19, 20). More recently, Nieh *et al.* demonstrated that 15 vol% SiC could be introduced into Al-4Cu-1.5Mg-1.1C-0.8O alloy Al-9021 and produce an MMC with a modulus of 81.8 GPa (11.8×10^6 psi) (Ref 68).

It appears that MMC research by RS-P/M is losing favor to spray-deposition forming technologies, which, as mentioned earlier, are a bridge between P/M and I/M.

Spray Deposition. In spray-deposition processes, the atomized stream of alloyed particles is deposited onto a chilled substrate and builds up a compact directly. With proper control of atmosphere, this obviates degassing and consolidation, thereby reducing costs. For more demanding applications, a subsequent hot-working step is often necessary. The as-sprayed compact can be hot worked conventionally into useful shapes that exhibit improved ductility. The details of the leading such processes, Osprey (Ref 33) and liquid dynamic compaction (LDC) (Ref 34, 35, 69), have been described in detail.

Very high strengths have been obtained on LDC-processed 7075 containing 1% Ni and 0.8% Zr. For extrusions, an ultimate tensile strength of 816 MPa (118 ksi) and yield strength of 740 MPa (107 ksi) with 9% elongation have been achieved. More recently, preliminary LDC work on the Al-4-6.3Cu-1.3Li-0.4Ag-0.4Mg-0.14Zr alloy (Weldalite 049)--which was designed to be a greater than 700 MPa (102 ksi) tensile strength I/M alloy (Ref 70)--showed extremely high ductility in very underaged tempers by refinement of constituent particles (42% elongation and 484 MPa, or 70 ksi, tensile strength).

The vacuum plasma structural deposition process is currently being explored by Pechiney Aluminum Company to produce properties equivalent to those in isothermally forged products. The process is being used for titanium alloys and titanium aluminide matrix systems aimed for elevated-temperature applications.

Scientists at Alcan Aluminum, Limited have combined Osprey Corporation technology with proprietary ceramic powder-spray technology to make MMCs (Ref 71). They call their technology COSPRAY, and have introduced SiC or B_4C into aluminum-lithium matrix alloy 8090 and I/M alloy 2618. The strength of the 8090 + 10 vol% SiC was slightly higher than that of unreinforced 8090, but ductility decreased. However, modulus increased from 79.5 to 95.9 GPa (11.5 to 14×10^6 psi). Similar behavior was observed in 2618 + 14 vol% SiC, but with a greater strength increment. Unfortunately, the B_4C reacted with aluminum, and possibly with lithium, and degraded mechanical properties.

Concluding Remarks. Aluminum-lithium I/M alloys and new techniques of making MMCs by I/M are now competing with high $E \div \rho$ alloys made by P/M. It is likely that research and development resources will be decreased in this area.

However, spray-forming technologies like Osprey and liquid dynamic compaction will probably receive increased research and development resources and may be cost competitive for near net-shape components.

New Directions in Aluminum P/M Research

Intermetallics. The need for improved elevated-temperature properties over the range 300 to 1500 °C (570 to 2730 °F) has generated considerable interest in ordered intermetallics. With the inherent low density of aluminum-rich aluminide intermetallics, and some promising compositions that have cubic structures, it is likely that RS and mechanical attrition processes will be extended to aluminides to an increasing extent (see the article "Ordered Intermetallics" in this Volume). In addition, the RS-P/M aluminum alloys have a good chance to displace conventional aluminum I/M alloys, and perhaps titanium alloys in certain applications because the elevated-temperature properties required by designers likely cannot be attained by I/M. Combinations of P/M processes will likely improve properties such as mechanically alloying RS powder or attrited PFC ribbon, both with and without ceramic reinforcement (Ref 72, 73).

Superplastic forming (SPF) is a process attractive for reducing costs in aerospace structures (Ref 74, 75). Superplasticity is generally attainable with a fine array of high-angle grain boundaries that are stabilized by fine dispersoids. Such microstructures have been attained readily by P/M, both with and without ceramic reinforcement. It is likely that research and development in this promising area will continue.

Appendix: Conventionally Pressed and Sintered Aluminum P/M Alloys

CONVENTIONALLY PRESSED AND SINTERED aluminum powder metal parts have been commercially available for many years. Sintered aluminum P/M parts are competitive with many aluminum castings, extrusions, and screw machine products that require expensive and time-consuming finishing operations. In addition, sintered aluminum P/M parts compete with other metal powder parts in applications where some of the attractive physical and mechanical properties of aluminum can be used.

Commercially available aluminum powder alloy compositions (Table 11) consist of blends of atomized aluminum powders mixed with powders of various alloying elements such as zinc, copper, magnesium, and silicon. The most common heat-treatable grades are comparable to the 2*xxx* and 6*xxx* series wrought aluminum alloys. Alloys 201AB and MD-24 are most similar to wrought alloy 2014. They develop high strength and offer moderate corrosion resistance. Alloys 601AB and MD-69 are similar to wrought alloy 6061. These alloys offer high strength, good ductility, corrosion resistance, and can be specified for anodized parts. Alloy 601AC is the same as 601AB, but does not contain an ad-mixed lubricant. It is used for isostatic and die-wall-lubricated compaction. When high conductivity is required, alloy 602AB often is used. Conductivity of 602AB ranges from 24×10^6 to 28×10^6 S/m (42.0 to 49% IACS), depending on the type of heat treatment selected.

Table 11 Compositions of typical aluminum P/M alloy powders

Grade	Composition, %				
	Cu	Mg	Si	Al	Lubricant
601AB	0.25	1.0	0.6	bal	1.5
201AB	4.4	0.5	0.8	bal	1.5
602AB	. . .	0.6	0.4	bal	1.5
202AB	4.0	. . .	. . .	bal	1.5
MD-22	2.0	1.0	0.3	bal	1.5
MD-24	4.4	0.5	0.9	bal	1.5
MD-69	0.25	1.0	0.6	bal	1.5

Aluminum P/M Part Processing

Basic design details for aluminum P/M parts involve the same manufacturing operations, equipment, and tooling that are used for iron, copper, and other metal-powder compositions. Detailed information on P/M design and processing can be found in *Powder Metal Technologies and Applications*, Volume 7 of *ASM Handbook.*

Compacting. Aluminum P/M parts are compacted at low pressures and are adaptable to all types of compacting equipment. The pressure density curve, which compares the compacting characteristics of aluminum with other metal powders, indicates that aluminum is simpler to compact. Figure 11 shows the relative difference in compacting characteristics for aluminum and sponge iron or copper.

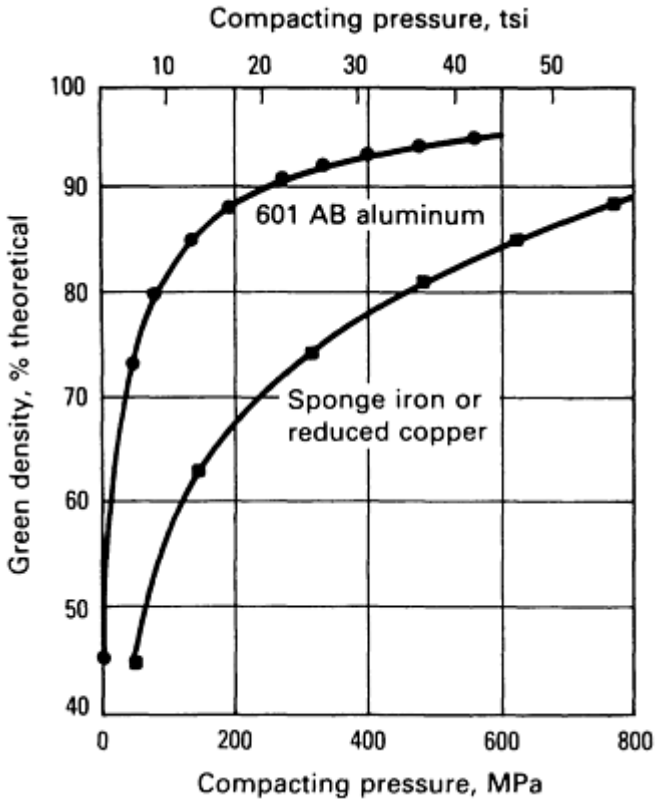

Fig. 11 Relationship of green density and compacting pressure

The lower compacting pressures required for aluminum permit wider use of existing presses. Depending on the press, a larger part often can be made by taking advantage of maximum press force. For example, a part with a 130 cm^2 (20 $in.^2$) surface area and 50 mm (2 in.) depth is formed readily on a 4450 kN (500 ton) press. The same part in iron would require a 5340 kN (600 ton) press. In addition, because aluminum responds better to compacting and moves more readily in the die, more complex shapes having more precise and finer detail can be produced.

Sintering. Aluminum P/M parts can be sintered in a controlled, inert atmosphere or in vacuum. Sintering temperatures are based on alloy composition and generally range from 595 to 625 °C (1100 to 1160 °F). Sintering time varies from 10 to 30 min. Nitrogen, dissociated ammonia, hydrogen, argon, and vacuum have been used for sintering aluminum; however, nitrogen is preferred because it results in high as-sintered mechanical properties (Table 12). It is also economical in bulk quantities. If a protective atmosphere is used, a dew point of -40 °C (-40 °F) or below is recommended. This is equivalent to a moisture content of 120 mL/m^3 (120 ppm) maximum.

Table 12 Typical properties of nitrogen-sintered aluminum P/M alloys

(a) Tensile properties determined using powder metal flat tension bar (MPIF standard 10-63), sintered 15 min at 620 °C (1150 °F) in nitrogen

Aluminum preforms can be sintered in batch furnaces or continuous radiant tube mesh or cast belt furnaces. Optimum dimensional control is best attained by maintaining furnace temperature at ±2.8 °C (±5 °F). Typical heating cycles for aluminum parts sintered in various furnaces are illustrated in Fig. 12.

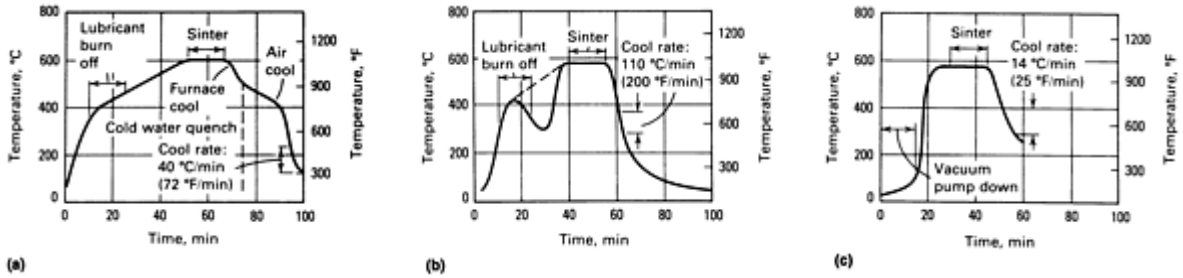

Fig. 12 Typical heating cycles for aluminum P/M parts sintered in (a) A batch furnace. (b) A continuous furnace. (c) A vacuum furnace

Mechanical properties are directly affected by thermal treatment. All compositions respond to solution heat treating, quenching, and aging in the same manner as conventional heat-treatable alloys. More detailed information on sintering of aluminum can be found in the article "Production Sintering Practices" in *Powder Metal Technologies and Applications,* Volume 7 of the *ASM Handbook.*

Re-Pressing. The density of sintered compacts may be increased by re-pressing. When re-pressing is performed primarily to improve the dimensional accuracy of a compact, it usually is termed "sizing" when performed to improve configuration, it is termed "coining." Re-pressing may be followed by resintering, which relieves stress due to cold work in re-pressing and may further consolidate the compact. By pressing and sintering only, parts of over 80% theoretical density can be produced. By re-pressing, with or without resintering, parts of 90% theoretical density or more can be produced. The density attainable is limited by the size and shape of the compact.

Forging of aluminum is a well-established technology. Wrought aluminum alloys have been forged into a variety of forms, from small gears to large aircraft structures, for many years (see the article "Forging of Aluminum Alloys" in *Forming and Forging,* Volume 14 of *ASM Handbook,* formerly 9th Edition *Metals Handbook*). Aluminum lends itself to the forging of P/M preforms to produce structural parts.

In forging of aluminum preforms, the sintered aluminum part is coated with a graphite lubricant to permit proper metal flow during forging. The part is either hot or cold forged; hot forging at 300 to 450 °C (575 to 850 °F) is recommended for parts requiring critical die fill. Forging pressure usually does not exceed 345 MPa (50 ksi). Forging normally is performed in a confined die so that no flash is produced and only densification and lateral flow result from the forging step. Scrap loss is less than 10% compared to conventional forging, which approaches 50%. Forged aluminum P/M parts have densities of over 99.5% of theoretical density. Strengths are higher than nonforged P/M parts, and in many ways, are similar to conventional forging. Fatigue endurance limit is doubled over that of nonforged P/M parts.

Alloys 601AB, 602AB, 201AB, and 202AB are designed for forgings. Alloy 202AB is especially well suited for cold forging. All of the aluminum powder alloys respond to strain hardening and precipitation hardening, providing a wide range of properties. For example, hot forging of alloy 601AB-T4 at 425 °C (800 °F) followed by heat treatment gives ultimate tensile strengths of 221 to 262 MPa (32 to 38 ksi), and a yield strength of 138 MPa (20 ksi), with 6 to 16% elongation in 25 mm (1 in.).

Heat treated to the T6 condition, 601 AB has ultimate tensile strengths of 303 to 345 MPa (44 to 50 ksi). Yield strength is 303 to 317 MPa (44 to 46 ksi), with up to 8% elongation. Forming pressure and percentage of reduction during forging influence final properties.

Ultimate tensile strengths of 358 to 400 MPa (52 to 58 ksi), and yield strengths of 255 to 262 MPa (37 to 38 ksi), with 8 to 18% elongation, are possible with 201AB heat treated to the T4 condition. When heat treated to the T6 condition, the tensile strength of 201AB increases from 393 to 434 MPa (57 to 63 ksi). Yield strength for this condition is 386 to 414 MPa (56 to 60 ksi), and elongation ranges from 0.5 to 8%.

Properties of cold-formed aluminum P/M alloys are increased by a combination of strain-hardened densification and improved interparticle bonding. Alloy 601AB achieves 257 MPa (37.3 ksi) tensile strength and 241 MPa (34.9 ksi) yield strength after forming to 28% upset. Properties for the T4 and T6 conditions do not change notably between 3 and 28% upset. Alloy 602AB has moderate properties with good elongation. Strain hardening (28% upset) results in 221 MPa (32

ksi) tensile and 203 MPa (29.4 ksi) yield strength. The T6 temper parts achieve 255 MPa (37 ksi) tensile strength and 227 MPa (33 ksi) yield strength. Highest cold-formed properties are achieved by 201AB. In the as-formed condition, yield strength increases from 209 MPa (30.3 ksi) for 92.5% density, to 281 MPa (40.7 ksi) for 96.8% density.

Alloy 202AB is best suited for cold forming. Treating to the T2 condition, or as-cold formed, increases the yield strength significantly. In the T8 condition, 202AB develops 280 MPa (40.6 ksi) tensile strength and 250 MPa (36.2 ksi) yield strength, with 3% elongation at the 19% upset level.

Properties of Sintered Parts

Mechanical Properties. Sintered aluminum P/M parts can be produced with strength that equals or exceeds that of iron or copper P/M parts. Tensile strengths range from 110 to 345 MPa (16 to 50 ksi), depending on composition, density, sintering practice, heat treatment, and repressing procedures. Table 12 lists typical properties of four nitrogen-sintered P/M alloys. Properties of heat-treated, pressed, and sintered grades are provided in Table 13.

Table 13 Typical heat-treated properties of nitrogen-sintered aluminum P/M alloys

Heat-treated variables and properties	**Grades**			
	MD-22	**MD-24**	**MD-69**	**MD-76**
Solution treatment

(a) T_6, solution heat treated, quenched, and artificially age hardened

Impact tests are used to provide a measure of toughness of powder metal materials, which are somewhat less ductile than similar wrought compositions. Annealed specimens develop the highest impact strength, whereas fully heat-treated parts have the lowest impact values. Alloy 201AB generally exhibits higher impact resistance than alloy 601AB at the same percent density, and impact strength of 201AB increases with increasing density. A desirable combination of strength and impact resistance is attained in the T4 temper for both alloys. In the T4 temper, 95% density 201AB develops strength and impact properties exceeding those for as-sintered 99Fe-1C alloy, a P/M material frequently employed in applications requiring tensile strengths under 345 MPa (50 ksi).

Fatigue is an important design consideration for P/M parts subject to dynamic stresses. Fatigue strengths of pressed and sintered P/M parts may be expected to be about half those of the wrought alloys of corresponding compositions (see comparisons of two P/M alloys with two wrought alloys in Fig. 13). These fatigue-strength levels are suitable for many applications.

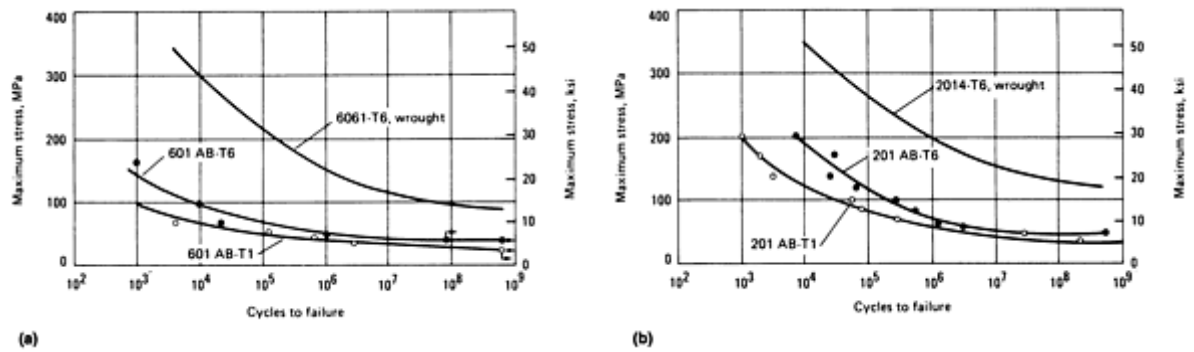

Fig. 13 Fatigue curves for (a) P/M 601AB. (b) P/M 201AB

Electrical and Thermal Conductivity. Aluminum has higher electrical and thermal conductivities than most other metals. Table 14 compares the conductivities of sintered aluminum alloys with wrought aluminum, brass, bronze, and iron.

Table 14 Electrical and thermal conductivity of sintered aluminum alloys, wrought aluminum, brass, bronze, and iron

Material	**Temper**	**Electrical conductivity[(a)] at 20 °C (68 °F), %IACS**	**Thermal conductivity[(b)] at 20 °C (68 °F), cgs units**

Machinability. Secondary finishing operations such as drilling, milling, turning, or grinding can be performed easily on aluminum P/M parts. Aluminum P/M alloys provide excellent chip characteristics; compared to wrought aluminum alloys, P/M chips are much smaller and are broken more easily with little or no stringer buildup, as can be seen in Fig. 14. This results in improved tool service life and higher machinability ratings.

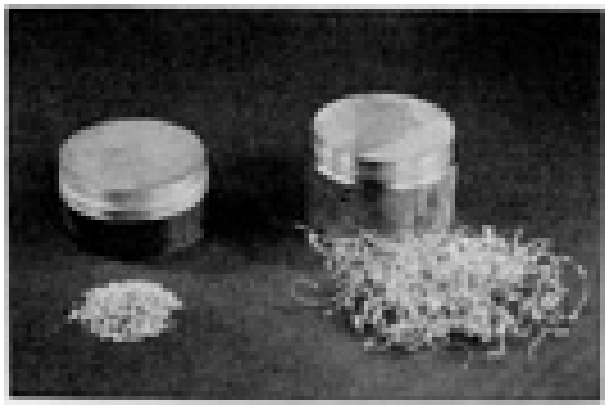

Fig. 14 Machining chips from a wrought aluminum alloy (right) and from a P/M aluminum alloy (left)

Applications for Sintered Parts

Aluminum P/M parts are used in an increasing number of applications. The business machine market currently uses the greatest variety of aluminum P/M parts. Other markets that indicate growth potential include automotive components, aerospace components, power tools, appliances, and structural parts. Due to their mechanical and physical properties, aluminum P/M alloys provide engineers with flexibility in material selection and design. These factors, coupled with the economic advantages of this technology, should continue to expand the market for aluminum P/M parts. A variety of pressed and sintered aluminum P/M parts are shown in Fig. 15.

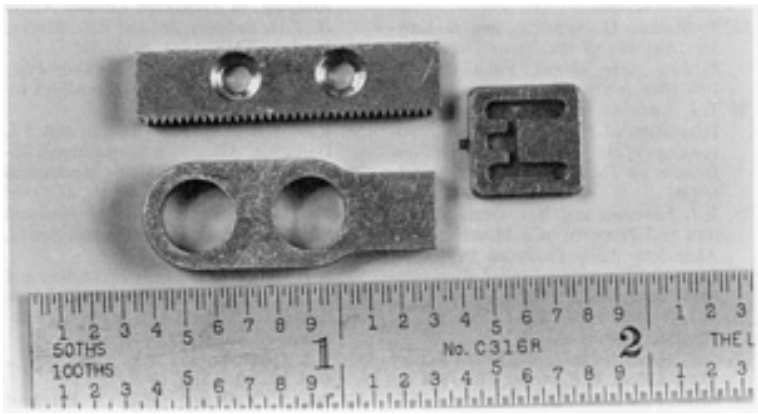

Fig. 15 Typical pressed and sintered aluminum P/M parts made from alloy 601AB. Top: gear rack used on a disc drive. Bottom: link flexure used on a print tip for a typewriter. Right: header/cavity block used on a high-voltage vacuum capacitor. Courtesy of D. Burton, Perry Tool & Research Company

Introduction to Copper and Copper Alloys

Derek E. Tyler, Olin Corporation, and William T. Black, Copper Development Association Inc.

Introduction

COPPER and copper alloys constitute one of the major groups of commercial metals. They are widely used because of their excellent electrical and thermal conductivities, outstanding resistance to corrosion, ease of fabrication, and good strength and fatigue resistance. They are generally nonmagnetic. They can be readily soldered and brazed, and many coppers and copper alloys can be welded by various gas, arc, and resistance methods. For decorative parts, standard alloys having specific colors are readily available. Copper alloys can be polished and buffed to almost any desired texture and luster. They can be plated, coated with organic substances, or chemically colored to further extend the variety of available finishes.

Pure copper is used extensively for cables and wires, electrical contacts, and a wide variety of other parts that are required to pass electrical current. Coppers and certain brasses, bronzes, and cupronickels are used extensively for automobile radiators, heat exchangers, home heating systems, panels for absorbing solar energy, and various other applications

requiring rapid conduction of heat across or along a metal section. Because of their outstanding ability to resist corrosion, coppers, brasses, some bronzes, and cupronickels are used for pipes, valves, and fittings in systems carrying potable water, process water, or other aqueous fluids.

In all classes of copper alloys, certain alloy compositions for wrought products have counterparts among the cast alloys; this enables the designer to make an initial alloy selection before deciding on the manufacturing process. Most wrought alloys are available in various cold-worked conditions, and the room-temperature strengths and fatigue resistances of these alloys depend on the amount of cold work as well as the alloy content. Typical applications of cold-worked wrought alloys (cold-worked tempers) include springs, fasteners, hardware, small gears, cams, electrical contacts, and components.

Certain types of parts, most notably plumbing fittings and valves, are produced by hot forging simply because no other fabrication process can produce the required shapes and properties as economically. Copper alloys containing 1 to 6% Pb are free-machining grades. These alloys are widely used for machined parts, especially those produced in screw machines.

Although fewer alloys are produced now than in the 1930s, new alloys continue to be developed and introduced, in particular to meet the challenging requirements of the electronics industry. Information on the use of copper alloys for lead frames, conductors, and other electronic components can be found in *Packaging*, Volume 1 of the *Electronic Materials Handbook* published by ASM INTERNATIONAL.

Properties and applications of wrought copper alloys are presented in Tables 1 and 2. Similar data for cast copper alloys are presented in Table 3. More detailed information on the properties and applications of both wrought and cast copper alloys is presented in the articles that follow in this Section.

Table 2 Fabrication characteristics and typical applications of wrought copper and copper alloys

Alloy number (and name)	Fabrication characteristics and typical applications
C10100 (oxygen-free electronic copper)	Excellent hot and cold workability; good forgeability. Fabricated by coining, coppersmithing, drawing and upsetting, hot forging and pressing, spinning, swaging, stamping. Uses: busbars, bus conductors, waveguides, hollow conductors, lead-in wires and anodes for vacuum tubes, vacuum seals, transistor components, glass-to-metal seals, coaxial cables and tubes, klystrons, microwave tubes, rectifiers
C10200 (oxygen-free copper)	Fabrication characteristics same as C10100. Uses: busbars, waveguides
C10300 (oxygen-free, extra-low-phosphorus copper)	Fabrication characteristics same as C10100. Uses: busbars, electrical conductors, tubular bus, and applications requiring good conductivity and good welding or brazing properties
C10400, C10500, C10700 (oxygen-free, silver-bearing copper)	Fabrication characteristics same as C10100. Uses: auto gaskets, radiators, busbars, conductivity wire, contacts, radio parts, winding, switches, terminals, commutator segments, chemical process equipment, printing rolls, clad metals, printed circuit foil
C10800 (oxygen-free, low-phosphorus copper)	Fabrication characteristics same as C10100. Uses: refrigerators; air conditioners; gas heater lines; oil burner tubes; plumbing pipe and tube; brewery tubes; condenser and heat exchanger tubes; dairy and distiller tubes; pulp and paper lines; tanks; air, gasoline, hydraulic, and oil lines
C11000 (electrolytic tough pitch copper)	Fabrication characteristics same as C10100. Uses: downspouts, gutters, roofing, gaskets, auto radiators, busbars, nails, printing rolls, rivets, radio parts, flexible circuits
C11100 (electrolytic tough	Fabrication characteristics same as C10100. Uses: electrical power transmission where resistance to

pitch anneal-resistant copper)	softening under overloads is desired
C11300, C11400, C11500, C11600 (silver-bearing tough pitch copper)	Fabrication characteristics same as C10100. Uses: gaskets, radiators, busbars, windings, switches, chemical process equipment, clad metals, printed circuit foil
C12000, C12100	Fabrication characteristics same as C10100. Uses: busbars, electrical conductors, tubular bus, and applications requiring welding or brazing
C12200 (phosphorus-deoxidized copper, high residual phosphorus)	Fabrication characteristics same as C10100. Uses: gas and heater lines; oil burner tubing; plumbing pipe and tubing; condenser, evaporator, heat exchanger, dairy, and distiller tubing; steam and water lines; air, gasoline, and hydraulic lines
C12500, C12700, C12800, C12900, C13000 (fire-refined tough pitch with silver)	Fabrication characteristics same as C10100. Uses: same as C11000
C14200 (phosphorus-deoxidized arsenical copper)	Fabrication characteristics same as C10100. Uses: plates for locomotive fireboxes, staybolts, heat exchanger and condenser tubes
C14300	Fabrication characteristics same as C10100. Uses: anneal-resistant electrical applications requiring thermal softening and embrittlement resistance, lead frames, contacts, terminals, solder-coated and solder-fabricated parts, furnace-brazed assemblies and welded components, cable wrap
C14310	Same as C14300
C14500 (phosphorus-deoxidized, tellurium-bearing copper)	Fabrication characteristics same as C10100. Uses: forgings and screw machine products and parts requiring high conductivity, extensive machining, corrosion resistance, copper color, or a combination of these properties; electrical connectors, motor and switch parts, plumbing fittings, soldering coppers, welding torch tips, transistor bases, and furnace-brazed articles
C14700 (sulfur-bearing copper)	Fabrication characteristics same as C10100. Uses: screw machine products and parts requiring high conductivity, extensive machining, corrosion resistance, copper color, or a combination of these properties; electrical connectors; motor and switch components; plumbing fittings; cold-headed and machined parts; cold forgings; furnace-brazed articles; screws; soldering coppers; rivets; and welding torch tips
C15000, C15100 (zirconium-copper)	Fabrication characteristics same as C10100. Uses: switches, high-temperature circuit breakers; commutators, stud bases for power transmitters, rectifiers, soldering welding tips, lead frames
C15500	Fabrication characteristics same as C10100. Uses: high-conductivity light-duty springs, electrical contacts, fittings, clamps, connectors, diaphragms, electronic components, resistance welding electrodes
C15710	Excellent cold workability. Fabricated by extrusion, drawing, rolling, impacting, heading, swaging, bending, machining, blanking, roll threading. Uses: electrical connectors, light-duty current-carrying springs, inorganic insulated wire, thermocouple wire, lead wire, resistance welding electrodes for aluminum, heat sinks
C15720	Excellent cold workability. Fabricated by extrusion, drawing, rolling, impacting, heading, swaging, machining, blanking. Uses: relay and switch springs, lead frames contact supports, heat sinks, circuit

	breaker parts, rotor bars, resistance welding electrodes and wheels, connectors, high-strength high-temperature parts
C15735	Excellent cold workability. Fabricated by extrusion, drawing, heading, impacting, machining. Uses: resistance welding electrodes, circuit breakers, feed-through conductors, heat sinks, motor parts, high-strength high-temperature parts
C15760	Excellent cold workability. Fabricated by extrusion and drawing. Uses: resistance welding electrodes, circuit breakers, electrical connectors, wire feed contact tips, plasma spray nozzles, high-strength high-temperature parts
C16200 (cadmium-copper)	Excellent cold workability; good hot formability. Uses: trolley wire, heating pads, electric-blanket elements, spring contacts, rail bands, high-strength transmission lines, connectors, cable wrap, switch gear components, and waveguide cavities
C16500	Fabrication characteristics same as C16200. Uses: electrical springs and contacts, trolley wire, clips, flat cable, resistance welding electrodes
C17000 (beryllium-copper)	Fabrication characteristics same as C16200. Commonly fabricated by blanking, forming and bending, turning, drilling, tapping. Uses: bellows, Bourdon tubing, diaphragms, fuse clips, fasteners, lock washers, springs, switch parts, roll pins, valves, welding equipment
C17200 (beryllium-copper)	Similar to C17000, particularly for its nonsparking characteristics
C17300 (beryllium-copper)	Combines superior machinability with the good fabrication characteristics of C17200
C17500 (copper-cobalt-beryllium alloy)	Fabrication characteristics same as C16200. Uses: fuse clips, fasteners, springs, switch and relay parts, electrical conductors, welding equipment
C18200, C18400, C18500 (chromium-copper)	Excellent cold workability, good hot workability. Uses: resistance welding electrodes, seam welding wheels, switch gear, electrode holder jaws, cable connectors, current-carrying arms and shafts, circuit breaker parts, molds, spot-welding tips, flash welding electrodes, electrical and thermal conductors requiring strength, switch contacts
C18700 (leaded copper)	Good cold workability; poor hot formability. Uses: connectors, motor and switch parts, screw machine parts requiring high conductivity
C18900	Fabrication characteristics same as C10100. Uses: welding rod and wire for inert-gas tungsten arc and metal arc welding and oxyacetylene welding of copper
C19000 (copper-nickel-phosphorus alloy)	Fabrication characteristics same as C10100. Uses: springs, clips, electrical connectors, power tube and electron tube components, high-strength electrical conductors, bolts, nails, screws, cotter pins, and parts requiring some combination of high strength, high electrical or thermal conductivity, high resistance to fatigue and creep, and good workability
C19100 (copper-nickel-phosphorus-tellurium alloy)	Good hot and cold workability. Uses: forgings and screw machine parts requiring high strength, hardenability, extensive machining, corrosion resistance, copper color, good conductivity, or a combination of these properties; bolts, bushings, electrical connectors, gears, marine hardware, nuts, pinions, tie rods, turnbuckle barrels, welding torch tips

C19200	Excellent hot and cold workability. Uses: automotive hydraulic brake lines, flexible hose, electrical terminals, fuse clips, gaskets, gift hollowware, applications requiring resistance to softening and stress corrosion, air conditioning and heat exchanger tubing
C19400, C19700	Fabrication characteristics same as C19200. Uses: electrical terminals, cable wrap, electronic connectors, lead frames, applications requiring resistance to softening and stress relaxation of greater-than-ambient temperatures
C19400	Excellent hot and cold workability. Uses: circuit breaker components, contact springs, electrical clamps, electrical springs, electrical terminals, flexible hose, fuse clips, gaskets, gift hollowware, plug contacts, rivets, welded condenser tubes
C19500	Excellent hot and cold workability. Uses: electrical springs, sockets, terminals, connectors, clips, and other current-carrying parts having strength
C21000 (gilding, 95%)	Excellent cold workability, good hot workability for blanking, coining, drawing, piercing and punching, shearing, spinning, squeezing and swaging, stamping. Uses: coins, medals, bullet jackets, fuse caps, primers, plaques, jewelry base for gold plate
C22000 (commercial bronze, 90%)	Fabrication characteristics same as C21000, plus heading and upsetting, roll threading and knurling, hot forging and pressing. Uses: etching bronze, grillwork, screen cloth, weather stripping, lipstick cases, compacts, marine hardware, screws, rivets
C22600 (jewelry bronze, 87.5%)	Fabrication characteristics same as C21000, plus heading and upsetting, roll threading and knurling. Uses: angles, channels, chain, fasteners, costume jewelry, lipstick cases, compacts, base for gold plate
C23000 (red brass, 85%)	Excellent cold workability, good hot formability. Uses: weather stripping, conduit, sockets, fasteners, fire extinguishers, condenser and heat exchanger tubing, plumbing pipe, radiator cores
C24000 (low brass, 80%)	Excellent cold workability. Fabrication characteristics same as C23000. Uses: battery caps, bellows, musical instruments, clock dials, pump lines, flexible hose
C26000 (cartridge brass, 70%)	Excellent cold workability. Fabrication characteristics same as C23000, except for coining, roll threading, and knurling. Uses: radiator cores and tanks, flashlight shells, lamp fixtures, fasteners, locks, hinges, ammunition components, plumbing accessories, pins, rivets
C26800, C27000 (yellow brass)	Excellent cold workability. Fabrication characteristics same as C23000. Uses: same as C26000 except not used for ammunition
C28000 (Muntz metal)	Excellent hot formability and forgeability for blanking, forming and bending, hot forging and pressing, hot heading and upsetting, shearing. Uses: architectural panel sheets, large nuts and bolts, brazing rod, condenser plates, heat exchanger and condenser tubing, hot forgings
C31400 (leaded commercial bronze)	Excellent machinability. Uses: screws, machine parts, pickling crates
C31600 (leaded commercial bronze, nickel-bearing)	Good cold workability; poor hot formability. Uses: electrical connectors, fasteners, hardware, nuts, screws, screw machine parts

C33000 (low-leaded brass tube)	Combines good machinability and excellent cold workability. Fabricated by forming and bending, machining, piercing, punching. Uses: pump and power cylinders and liners, ammunition primers, plumbing accessories
C33200 (high-leaded brass tube)	Excellent machinability. Fabricated by piercing, punching, machining. Uses: general-purpose screw machine parts
C33500 (low-leaded brass)	Similar to C33200. Commonly fabricated by blanking, drawing, machining, piercing and punching, stamping. Uses: butts, hinges, watch backs
C34000 (medium-leaded brass)	Similar to C33200. Fabricated by blanking, heading and upsetting, machining, piercing, and punching, roll threading and knurling, stamping. Uses: butts, gears, nuts, rivets, screws, dials, engravings, instrument plates
C34200 (high-leaded brass)	Combines excellent machinability with moderate cold workability. Uses: clock plates and nuts, clock and watch backs, gears, wheels, channel plate
C34900	Good cold workability, fair hot workability for bending and forming, heading and upsetting, machining, roll threading and knurling. Uses: building hardware, rivets and nuts, plumbing goods, and parts requiring moderate cold working combined with some machining
C35000 (medium-leaded brass)	Fair cold workability; poor hot formability. Uses: bearing cages, books dies, clock plates, engraving plates, gears, hinges, hose couplings, keys, lock parts, lock tumblers, meter parts, sink strainers, strike plates, templates, type characters, washers, wear plates
C35300 (high-leaded brass)	Similar to C34200
C35600 (extra-high-leaded brass)	Excellent machinability. Fabricated by blanking, machining, piercing and punching, stamping. Uses: same as C34200 and C35300
C36000 (free-cutting brass)	Excellent machinability. Fabricated by machining, roll threading and knurling. Uses: gears, pinions, automatic high-speed screw machine parts
C36500 to C36800 (leaded Muntz metal)	Combines good machinability with excellent hot formability. Uses: condenser tube plates
C37000 (free-cutting Muntz metal)	Fabrication characteristics similar to C36500 to C36800. Uses: automatic screw machine parts
C37700 (forging brass)	Excellent hot workability. Fabricated by heading and upsetting, hot forging and pressing, hot heading and upsetting, machining. Uses: forgings and pressings of all kinds
C38500 (architectural bronze)	Excellent machinability and hot workability. Fabricated by hot forging and pressing, forming, bending and machining. Uses: architectural extrusions, store fronts, thresholds, trim, butts, hinges, lock bodies, forgings
C40500	Excellent cold workability. Fabricated by blanking, forming, drawing. Uses: meter clips, terminals, fuse clips, contact and relay springs, washers

C40800	Excellent cold workability. Fabricated by blanking, stamping, shearing. Uses: electrical connectors
C41100	Excellent cold workability, good hot formability. Fabricated by blanking, forming, drawing. Uses: bushings, bearing sleeves, thrust washers, terminals, connectors, flexible metal hose, electrical conductors
C41300	Excellent cold workability; good hot formability. Uses: plater bar for jewelry products, flat springs for electrical switchgear
C41500	Excellent cold workability. Fabricated by blanking, drawing, bending, forming, shearing, stamping. Uses: spring applications for electrical switches
C42200	Excellent cold workability; good hot formability. Fabricated by blanking, forming, drawing. Uses: sash chains, fuse clips, terminals, spring washers, contact springs, electrical connectors
C42500	Excellent cold workability. Fabricated by blanking, piercing, forming, drawing. Uses: electrical switches, springs, terminals, connectors, fuse clips, pen clips, weather stripping
C43000	Excellent cold workability; good hot formability. Fabricated by blanking, coining, drawing, forming, bending, heading, upsetting. Uses: same as C42500
C43400	Excellent cold workability. Fabricated by blanking, drawing, bonding, forming, stamping, shearing. Uses: electrical switch parts, blades, relay springs, contacts
C43500	Excellent cold workability for fabrication by forming and bending. Uses: Bourdon tubing and musical instruments
C44300, C44400, C44500 (inhibited admiralty)	Excellent cold workability for forming and bending. Uses: condenser evaporator, and heat exchanger tubing; condenser tubing plates; distiller tubing; ferrules
C46400 to C46700 (naval brass)	Excellent hot workability and hot forgeability. Fabricated by blanking, drawing, bending, heading and upsetting, hot forging, pressing. Uses: aircraft turnbuckle barrels, balls, bolts, marine hardware, nuts, propeller shafts, rivets, valve stems, condenser plates, welding rod
C48200 (naval brass, medium-leaded)	Good hot workability for hot forging, pressing, and machining operations. Uses: marine hardware, screw machine products, valve stems
C48500 (leaded naval brass)	Combines excellent hot forgeability and machinability. Fabricated by hot forging and pressing, machining. Uses: marine hardware, screw machine parts, valve stems
C50500 (phosphor bronze, 1.25% E)	Excellent cold workability; good hot formability. Fabricated by blanking, bending, heading and upsetting, shearing and swaging. Uses: electrical contacts, flexible hose, pole-line hardware
C51000 (phosphor bronze, 5% A)	Excellent cold workability. Fabricated by blanking, drawing, bending, heading and upsetting, roll threading and knurling, shearing, stamping. Uses: bellows, Bourdon tubing, clutch discs, cotter pins, diaphragms, fasteners, lock washers, wire brushes, chemical hardware, textile machinery, welding rod
C51100	Excellent cold workability. Uses: bridge bearing plates, locator bars, fuse clips, sleeve bushings, springs, switch parts, truss wire, wire brushes, chemical hardware, perforated sheets, textile machinery, welding

	rod
C52100 (phosphor bronze, 8% C)	Good cold workability for blanking, drawing, forming and bending, shearing, stamping. Uses: generally for more severe service conditions than C51000
C52400 (phosphor bronze, 10% D)	Good cold workability for blanking, forming and bending, shearing. Uses: heavy bars and plates for severe compression; bridge and expansion plates and fittings; articles requiring good spring qualities, resiliency, fatigue resistance, and good wear and corrosion resistance
C54400 (free-cutting phosphor bronze)	Excellent machinability; good cold workability. Fabricated by blanking, drawing, bending, machining, shearing, stamping. Uses: bearings, bushings, gears, pinions, shafts, thrust washers, valve parts
C60800 (aluminum bronze, 5%)	Good cold workability; fair hot formability. Uses: condenser, evaporator, and heat exchanger tubes; distiller tubes; ferrules
C61000	Good hot and cold workability. Uses: bolts, pump parts, shafts, tie rods, overlay on steel for wearing surfaces
C61300	Good hot and cold formability. Uses: nuts, bolts, stringers and threaded members, corrosion-resistant vessels and tanks, structural components, machine parts, condenser tube and piping systems, marine protective sheathing and fastening, munitions mixing troughs and blending chambers
C61400 (aluminum bronze, D)	Similar to C61300
C61500	Good hot and cold workability. Fabrication characteristics similar to C52100. Uses: hardware, decorative metal trim, interior furnishings, and other articles requiring high tarnish resistance
C61800	Fabricated by hot forging and hot pressing. Uses: bushings, bearings, corrosion-resistant applications, welding rods
C61900	Excellent hot formability for fabricating by blanking, forming, bending, shearing, and stamping. Uses: springs, contacts, switch components
C62300	Good hot and cold formability. Fabricated by bending, hot forging, hot pressing, forming, welding. Uses: bearings, bushings, valve guides, gears, valve seats, nuts, bolts, pump rods, worm gears, and cams
C62400	Excellent hot formability for fabrication by hot forging and hot bending. Uses: bushings, gears, cams, wear strips, nuts, drift pins, tie rods
C62500	Excellent hot formability for fabrication by hot forging and machining. Uses: guide bushings, wear strips, cams, dies, forming rolls
C63000	Good hot formability. Fabricated by hot forming and forging. Uses: nuts, bolts, valve seats, plunger tips, marine shafts, valve guides, aircraft parts, pump shafts, structural members
C63200	Good hot formability. Fabricated by hot forming and welding. Uses: nuts, bolts, structural pump parts, shafting requiring corrosion resistance

C63600	Excellent cold workability; fair hot formability. Fabricated by cold heading. Uses: components for pole-line hardware, cold-headed nuts for wire and cable connectors, bolts and screw products
C63800	Excellent cold workability and hot formability. Uses: springs, switch parts, contacts, relay springs, glass sealing, porcelain enameling
C64200	Excellent hot formability. Fabricated by hot forming, forging, machining. Uses: valve stems, gears, marine hardware, pole-line hardware, bolts, nuts, valve bodies and components
C65100 (low-silicon bronze, B)	Excellent hot and cold workability. Fabricated by forming and bending, heading and upsetting, hot forging and pressing, roll threading and knurling, squeezing and swaging. Uses: hydraulic pressure lines, anchor screws, bolts, cable clamps, cap screws, machine screws, marine hardware, nuts, pole-line hardware, rivets, U-bolts, electrical conduits, heat exchanger tubing, welding rod
C65400	Excellent hot and cold workability. Fabricated by forming, bending, blanking. Uses: springs, switch parts, contacts and relay springs in above-ambient-temperature conditions demanding superior stress relaxation
C65500 (high-silicon bronze, A)	Excellent hot and cold workability. Fabricated by blanking, drawing, forming and bending, heading and upsetting, hot forging and pressing, roll threading and knurling, shearing, squeezing, swaging. Uses: similar to C65100 including propeller shafts
C66700 (manganese brass)	Excellent cold formability. Fabricated by blanking, bending, forming, stamping, welding. Uses: brass products resistance welded by spot, seam, and butt welding
C67400	Excellent hot formability. Fabricated by hot forging and pressing, machining. Uses: bushings, gears, connecting rods, shafts, wear plates
C67500 (manganese bronze, A)	Excellent hot workability. Fabricated by hot forging and pressing, hot heading and upsetting. Uses: clutch discs, pump rods, shafting, balls, valve stems and bodies
C68700 (aluminum brass, arsenical)	Excellent cold workability for forming and bending. Uses: condenser, evaporator, and heat exchanger tubing; condenser tubing plates; distiller tubing; ferrules
C68800	Excellent hot and cold formability. Fabricated by blanking, drawing, forming and bending, shearing and stamping. Uses: springs, switches, contacts, relays, drawn parts
C69000	Fabricating characteristics same as C68800. Uses: wiring devices, relays, switches, springs, high-strength shells
C69400 (silicon red brass)	Excellent hot formability for fabrication by forging, screw machine operations. Uses: valve stems where corrosion resistance and high strength are critical
C70250	Excellent hot and cold workability. Fabricated by blanking, forming, bending. Uses: relays, switches, springs, lead frames for use at service temperatures above ambient where superior stress relaxation is required
C70400	Excellent cold workability; good hot formability. Fabricated by forming, bending, welding. Uses: condensers, evaporators, heat exchangers, ferrules, saltwater piping, lithium bromide absorption tubing,

	shipboard condenser intake systems
C70600 (copper-nickel, 10%)	Good hot and cold workability. Fabricated by forming and bending, welding. Uses: condensers, condenser plates, distiller tubing, evaporator and heat exchanger tubing, ferrules, saltwater piping
C71000 (copper-nickel, 20%)	Good hot and cold formability. Fabricated by blanking, forming and bending, welding. Uses: communication relays, condensers, condenser plates, electrical springs, evaporator and heat exchanger tubes, ferrules, resistors
C71300	Good hot and cold formability. Fabricated by blanking. Uses: U.S. 5-cent coin and, when clad to C11000, U.S. 10-cent, 25-cent, 50-cent, and $1 coins
C71500 (copper-nickel, 30%)	Similar to C70600
C71700	Good hot and cold formability. Uses: high-strength constructional parts for seawater corrosion resistance, hydrophone cases, mooring cable wire, springs, retainer rings, bolts, screws, pins for ocean telephone cable applications
C72500	Excellent cold and hot formability. Fabricated by blanking, brazing, coining, drawing, etching, forming and bending, heading and upsetting, roll threading and knurling, shearing, spinning, squeezing, stamping and swaging. Uses: relay and switch springs, connectors, brazing alloy, lead frames, control and sensing bellows
C73500	Fabrication characteristics same as C74500. Uses: hollowware, medallions, jewelry, base for silver plate, cosmetic cases, musical instruments, nameplates, contacts
C74500 (nickel silver, 65-10)	Excellent cold workability. Fabricated by blanking, drawing, etching, forming and bending, heading and upsetting, roll threading and knurling, shearing, spinning, squeezing and swaging. Uses: rivets, screws, slide fasteners, optical parts, etching stock, hollowware, nameplates, platers' bars
C75200 (nickel silver, 65-18)	Fabrication characteristics similar to C74500. Uses: rivets, screws, table flatware, truss wire, zippers, bows, camera parts, core bars, temples, base for silver plate, costume jewelry, etching stock, hollowware, nameplates, radio dials
C75400 (nickel silver, 65-15)	Fabrication characteristics similar to C74500. Uses: camera parts, optical equipment, etching stock, jewelry
C75700 (nickel silver, 65-12)	Fabrication characteristics similar to C74500. Uses: slide fasteners, camera parts, optical parts, etching stock, nameplates
C76200	Fabrication characteristics same as C77000. Uses: electrical terminals, contact springs, release brackets, ornamental bits and spurs, optical parts, surgical instruments, electrical contacts
C77000 (nickel silver, 55-18)	Good cold workability. Fabricated by blanking, forming and bending, shearing. Uses: optical goods, springs, resistance wire
C72200	Good hot and cold workability. Fabricated by forming, bending and welding. Uses: condenser and heat exchanger tubing, saltwater piping

C78200 (leaded nickel silver, 65-8-2)	Good cold formability. Fabricated by blanking, milling and drilling. Uses: key blanks, watch plates, watch parts

Table 3 Properties and applications of cast copper and copper alloys

UNS designation[a]	Nominal composition, %[a]	Typical mechanical properties, as-cast (heat treated)[b]								Machinability rating, %[c]	Casting types[d]	Typical applications
		Tensile strength		Yield strength		Elongation in 50 mm (2 in.), %	Hardness					
							Rockwell	Brinell				
		MPa	ksi	MPa	ksi			500 kg	3000 kg			
C80100	99.95 Cu + Ag min, 0.05 other max	172	25	62	9	40	. . .	44	. . .	10	C, T, I, M, P, S	Electrical and thermal conductors; corrosion- and oxidation-resistant applications
C80300	99.95 Cu + Ag min, 0.034 Ag min, 0.05 other max	172	25	62	9	40	. . .	44	. . .	10	C, T, I, M, P, S	Electrical and thermal conductors; corrosion- and oxidation-resistant applications
C80500	99.75 Cu + Ag min, 0.034 Ag min, 0.02 B max, 0.23 other max	172	25	62	9	40	. . .	44	. . .	10	C, T, I, M, P, S	Electrical and thermal conductors; corrosion- and oxidation-resistant applications
C80700	99.75 Cu + Ag min, 0.02 B max, 0.23 other max	172	25	62	9	40	. . .	44	. . .	10	C, T, I, M, P, S	Electrical and thermal conductors; corrosion- and oxidation-resistant applications
C80900	99.70 Cu + Ag min, 0.034 Ag min, 0.30 other max	172	25	62	9	40	. . .	44	. . .	10	C, T, I, M, P, S	Electrical and thermal conductors; corrosion- and oxidation-resistant applications
C81100	99.70 Cu + Ag min, 0.30 other max	172	25	62	9	40	. . .	44	. . .	10	C, T, I, M, P, S	Electrical and thermal conductors; corrosion- and oxidation-resistant applications

High-copper alloys												
C81300	98.5 Cu min, 0.06 Be, 0.80 Co, 0.40 other max	(365)	(53)	(248)	(36)	(11)	. . .	(39)	. . .	20	C, T, I, M, P, S	Higher-hardness electrical and thermal conductors
C81400	98.5 Cu min, 0.06 Be, 0.80 Cr, 0.40 other max	(365)	(53)	(248)	(36)	(11)	(B 69)	. . .	. . .	20	C, T, I, M, P, S	Higher-hardness electrical and thermal conductors
C81500	98.0 Cu min, 1.0 Cr, 0.50 other max	(352)	(51)	(276)	(40)	(17)	. . .	(105)	. . .	20	C, T, I, M, P, S	Electrical and/or thermal conductors used as structural members where strength and hardness greater than that of C80100-C81100 are required
C81700	94.25 Cu min, 1.0 Ag, 0.4 Be, 0.9 Co, 0.9 Ni	(634)	(92)	(469)	(68)	(8)	. . .	. . .	(217)	30	C, T, I, M, P, S	Electrical and/or thermal conductors used as structural members where strength and hardness greater than that of C80100-C81100 are required. Also used in place of C81500 where electrical and/or thermal conductivities can be sacrificed for hardness and
C81800	95.6 Cu min, 1.0 Ag, 0.4 Be, 1.6 Co	345 (703)	50 (102)	172 (517)	25 (75)	20 (8)	B 55 (B 96)	. . .	. . .	20	C, T, I, M, P, S	Resistance welding electrodes, dies
C82000	96.8 Cu, 0.6 Be, 2.6 Co	345 (689)	50 (100)	138 (517)	20 (75)	20 (8)	B 55 (B 95)	. . .	(195)	20	C, T, I, M, P, S[(e)]	Current-carrying parts, contact and switch blades, bushings and bearings, soldering iron, resistance welding tips
C82100	97.7 Cu, 0.5 Be, 0.9 Co, 0.9 Ni	(634)	(92)	(469)	(68)	(8)	. . .	. . .	(217)	30	C, T, I, M, P, S	Electrical and/or thermal conductors used as structural members where strength and hardness greater than that of C80100-C81100 are required. Also used in place of C81500 where electrical and/or thermal conductivities can be sacrificed for hardness and

Red brasses and leaded red brasses												
C83300	93 Cu, 1.5 Sn, 1.5 Pb, 4 Zn	221	32	69	10	35	. . .	35	. . .	35	S	Terminal ends for electrical cables
C83400	90 Cu, 10 Zn	241	35	69	10	30	F 50	. . .	. . .	60	C, S	Moderate-strength, moderate-conductivity castings; rotating bands
C83600	85 Cu, 5 Sn, 5 Pb, 5 Zn	255	37	117	17	30	. . .	60	. . .	84	C, T, I, S	Valves, flanges, pipe fittings, plumbing goods, pump castings, water pump impellers and housings, ornamental fixtures, small gears

C83800	83 Cu, 4 Sn, 6 Pb, 7 Zn	241	35	110	16	25	. . .	60	. . .	90	C, T, S	Low-pressure valves and fittings, plumbing supplies and fittings, general hardware, air-gas-water fittings, pump components, railroad catenary fittings
Semired brasses and leaded semired brasses												
C84200	80 Cu, 5 Sn, 2.5 Pb, 12.5 Zn	193	28	103	15	27	. . .	60	. . .	80	C, T, S	Pipe fittings, elbows, Ts, couplings, bushings, lock nuts, plugs, unions
C84400	81 Cu, 3 Sn, 7 Pb, 9 Zn	234	34	103	15	26	. . .	55	. . .	90	C, T, S	General hardware, ornamental castings, plumbing supplies and fixtures, low-pressure valves and fittings
C84500	78 Cu, 3 Sn, 7 Pb, 12 Zn	241	35	97	14	28	. . .	55	. . .	90	C, T, S	Plumbing fixtures, cocks, faucets, and stops; waste, air, and gas fittings; low-pressure valve fittings
C84800	76 Cu, 3 Sn, 6 Pb, 15 Zn	248	36	97	14	30	. . .	55	. . .	90	C, S	Plumbing fixtures, cocks, faucets, stops, waste, air and gas fittings, general hardware, and low-pressure valve fittings
Yellow brasses and leaded yellow brasses												
C85200	72 Cu, 1 Sn, 3 Pb, 24 Zn	262	38	90	13	35	. . .	45	. . .	80	C, T	Plumbing fittings and fixtures, ferrules, valves, hardware, ornamental brass, chandeliers, and irons
C85400	67 Cu, 1 Sn, 3 Pb, 29 Zn	234	34	83	12	35	. . .	50	. . .	80	C, T, M, P, S	General-purpose yellow casting alloy not subject to high internal pressure. Furniture hardware, ornamental castings, radiator fittings, ship trimmings, cocks, battery clamps, valves, and fittings
C85500	61 Cu, 0.8 Al, bal	414	60	159	23	40	B 55	85	. . .	80	C, S	Ornamental castings

	Zn											
C85700	63 Cu, 1 Sn, 1 Pb, 34.7 Zn, 0.3 Al	345	50	124	18	40	. . .	75	. . .	80	C, M, P, S	Bushings, hardware fittings, ornamental castings
C85800	58 Cu, 1 Sn, 1 Pb, 40 Zn	379	55	207	30	15	B 55	. . .	. . .	80	D	General-purpose die casting alloy having moderate strength
Manganese and leaded manganese bronze alloys												
C86100	67 Cu, 21 Zn, 3 Fe, 5 Al, 4 Mn	655	95	345	50	20	. . .	. . .	180	30	C, I, P, S	Marine castings, gears, gun mounts, bushings and bearings, marine racing propellers
C86200	64 Cu, 26 Zn, 3 Fe, 4 Al, 3 Mn	655	95	331	48	20	. . .	. . .	180	30	C, T, D, I, P, S	Marine castings, gears, gun mounts, bushings and bearings
C86300	63 Cu, 25 Zn, 3 Fe, 6 Al, 3 Mn	793	115	572	83	15	. . .	. . .	225	8	C, I, P, S	Extra-heavy-duty high-strength alloy. Large valve stems, gears, cams, slow-speed heavy-load bearings, screwdown nuts, hydraulic cylinder parts
C86400	59 Cu, 1 Pb, 40 Zn	448	65	172	25	20	. . .	90	105	65	C, D, M, P, S	Free-machining manganese bronze. Valve stems, marine fittings, lever arms, brackets, light-duty gears
C86500	58 Cu, 0.5 Sn, 39.5 Zn, 1 Fe, 1 Al	490	71	193	28	30	. . .	100	130	26	C, I, P, S	Machinery parts requiring strength and toughness, lever arms, valve stems, gears
C86700	58 Cu, 1 Pb, 41 Zn	586	85	290	42	20	B 80	. . .	155	55	C, S	High-strength free-machining manganese bronze. Valve stems
C86800	55 Cu, 37 Zn, 3 Ni, 2 Fe, 3 Mn	565	82	262	38	22	. . .	. . .	80	30	S	Marine fittings, marine propellers

Silicon bronzes and silicon brasses												
C87200	89 Cu min, 4 Si	379	55	172	25	30	. . .	85	. . .	40	C, I, M, P, S	Bearings, bells, impellers, pump and valve components, marine fittings, corrosion-resistant castings
C87400	83 Cu, 14 Zn, 3 Si	379	55	165	24	30	. . .	70	100	50	C, D, I, M, P, S	Bearings, gears, impellers, rocker arms, valve stems, clamps
C87500	82 Cu, 14 Zn, 4 Si	462	67	207	30	21	. . .	115	134	50	C, D, I, M, P, S	Bearings, gears, impellers, rocker arms, valve stems, small boat propellers
C87600	90 Cu, 5.5 Zn, 4.5 Si	455	66	221	32	20	B 76	110	135	40	S	Valve stems

Source: Copper Development Association Inc.

(a) Nominal composition, unless otherwise noted. For seldom-used alloys, only compositions are available.

(b) Values for C82700, C84200, C96200, and C96300 are minimum, not typical. As-cast values are for sand casting except C93900, continuous cast; and C85800, C87800, C87900, die cast. Heat-treated values, in parentheses, indicate that the alloy responds to heat treatment. If heat-treated values are not shown, the copper or copper alloy does not respond.

(c) Based on a value of 100% for free-cutting brass.

(d) C, centrifugal; T, continuous; D, die; I, investment; M, permanent mold; P, plaster; S, sand.

(e) Also pressure cast.

(f) Property and application data not available from the Copper Development Association Inc.

(g) As heat-treated value for C94700, 20; for C94800, 40.

Properties of Importance

Along with strength, fatigue resistance, and ability to take a good finish, the primary selection criteria for copper and copper alloys are:

- Corrosion resistance
- Electrical conductivity
- Thermal conductivity
- Color
- Ease of fabrication

Corrosion Resistance. Copper is a noble metal but, unlike gold and other precious metals, can be attacked by common reagents and environments. Pure copper resists attack quite well under most corrosive conditions. Some copper alloys, however, sometimes have limited usefulness in certain environments because of hydrogen embrittlement or stress-corrosion cracking (SCC).

Hydrogen embrittlement is observed when tough pitch coppers, which are alloys containing cuprous oxide, are exposed to a reducing atmosphere. Most copper alloys are deoxidized and thus are not subject to hydrogen embrittlement.

Stress-corrosion cracking most commonly occurs in brass that is exposed to ammonia or amines. Brasses containing more than 15% Zn are the most susceptible. Copper and most copper alloys that either do not contain zinc or are low in zinc content generally are not susceptible to SCC. Because SCC requires both tensile stress and a specific chemical species to be present at the same time, removal of either the stress or the chemical species can prevent cracking. Annealing or stress relieving after forming alleviates SCC by relieving residual stresses. Stress relieving is effective only if the parts are not subsequently bent or strained in service; such operations reintroduce stresses and resensitize the parts to SCC.

Dealloying is another form of corrosion that affects zinc-containing copper alloys. In dealloying, the more active metal is selectively removed from an alloy, leaving behind a weak deposit of the more noble metal.

Copper-zinc alloys containing more than 15% Zn are susceptible to a dealloying process called dezincification. In the dezincification of brass, selective removal of zinc leaves a relatively porous and weak layer of copper and copper oxide. Corrosion of a similar nature continues beneath the primary corrosion layer, resulting in gradual replacement of sound brass by weak, porous copper. Unless arrested, dealloying eventually penetrates the metal, weakening it structurally and allowing liquids or gases to leak through the porous mass in the remaining structure.

Corrosion ratings for wrought and cast copper alloys in a variety of media are given in Tables 4 and 5, respectively. An extensive review on the corrosion properties of copper can be found in *Corrosion,* Volume 13 of *ASM Handbook,* formerly 9th Edition *Metals Handbook.*

Table 4 Corrosion ratings of wrought copper alloys in various corrosive media

The letters E, G, F, and P have the following significance: E (excellent), resists corrosion under almost all conditions of service; G (good), some corrosion will take place, but satisfactory service can be expected under all but the most severe conditions; F (fair), corrosion rates are higher than for the G classification, but the metal can be used if needed for a property other than corrosion resistance and if either the amount of corrosion does not cause excessive maintenance expense or the effects of corrosion can be lessened, such as by use of coatings or inhibitors; P (poor), corrosion rates are high, and service is generally unsatisfactory.

Note: This table is intended to serve only as a general guide to the behavior of copper and copper alloys in corrosive environments. It is impossible to cover in a simple tabulation the performance of a material for all possible variations of temperature, concentration, velocity, impurity content, degree of aeration, and stress. The ratings are based on general performance; they should be used with caution, and then only for the purpose of screening candidate alloys.

(a) Copper and copper alloys are resistant to corrosion by most food products. Traces of copper may be dissolved and affect taste or color of the products. In such cases, copper alloys are often tin coated.

(b) Acetylene forms an explosive compound with copper when moisture or certain impurities are present and the gas is under pressure. Alloys containing less than 65% Cu are satisfactory; when the gas is not under pressure, other copper alloys are satisfactory.

(c) Precautions should be taken to avoid SCC.

(d) At elevated temperatures, hydrogen will react with tough pitch copper, causing failure by embrittlement.

(e) Where air is present, corrosion rate may be increased.

(f) Below 150 °C (300 °F), corrosion rate is very low; above this temperature, corrosion is appreciable and increases rapidly with temperature.

(g) Aeration and elevated temperature may increase corrosion rate substantially.

(h) Excessive oxidation may begin above 120 °C (250 °F). If moisture is present, oxidation may begin at lower temperatures.

(i) Use of high-zinc brasses should be avoided in acids because of the likelihood of rapid corrosion by dezincification. Copper, low-zinc brasses, phosphor bronzes, silicon bronzes, aluminum bronzes, and copper-nickels offer good resistance to corrosion by hot and cold dilute H_2SO_4 and to corrosion by cold concentrated H_2SO_4. Intermediate concentrations of H_2SO_4 are sometimes more corrosive to copper alloys than either concentrated or dilute acid. Concentrated H_2SO_4 may be corrosive at elevated temperatures due to breakdown of acid and formation of metallic sulfides and sulfur dioxide, which cause localized pitting. Tests indicate that copper alloys may undergo pitting in 90-95% H_2SO_4 at about 50 °C (122 °F), in 80% acid at about 70 °C (160 °F), and in 60% acid at about 100 °C (212 °F).

(j) Wetting agents may increase corrosion rates of copper and copper alloys slightly to substantially when carbon dioxide or oxygen is present by preventing formation in a film on the metal surface and by combining (in some instances) with the dissolved copper to produce a green, insoluble compound.

Table 5 Corrosion ratings of cast copper alloys in various media

The letters A, B, and C have the following significance: A, recommended; B, acceptable; C, not recommended

Note:This table is intended to serve only as a general guide to the behavior of copper and copper alloys in corrosive environments. It is impossible to cover in a simple tabulation the performance of a material for all possible variations of temperature, concentration, velocity, impurity content, degree of aeration, and stress. The ratings are based on general performance; they should be used with caution, and then only for the purpose of screening candidate alloys.

(a) Acetylene forms an explosive compound with copper when moist or when certain impurities are present and the gas is under pressure. Alloys containing less than 65% Cu are satisfactory for this use. When gas is not under pressure, other copper alloys are satisfactory.

(b) Copper and copper alloys resist corrosion by most food products. Traces of copper may be dissolved and affect taste or color. In such cases, copper metals are often tin coated.

Electrical and Thermal Conductivity. Copper and its alloys are relatively good conductors of electricity and heat. In fact, copper is used for these purposes more often than any other metal. Alloying invariably decreases electrical conductivity and, to a lesser extent, thermal conductivity. The amount of reduction due to alloying does not depend on the conductivity or any other bulk property of the alloying element, but only on the effect that the particular solute atoms have on the copper lattice. For this reason, coppers and high-copper alloys are preferred over copper alloys containing more than a few percent total alloy content when high electrical or thermal conductivity is required for the application.

Color. Copper and certain copper alloys are used for decorative purposes alone, or when a particular color and finish is combined with a desirable mechanical or physical property of the alloy. Table 6 lists the range of colors that can be obtained with standard copper alloys.

Table 6 Standard color-controlled wrought copper alloys

UNS number	Common name	Color description
C1100	Electrolytic tough pitch copper	Soft pink
C21000	Gilding, 95%	Red-brown
C22000	Commercial bronze, 90%	Bronze-gold
C23000	Red brass, 85%	Tan-gold
C26000	Cartridge brass, 70%	Green-gold
C28000	Muntz metal, 60%	Light brown-gold
C63800	Aluminum bronze	Gold
C65500	High-silicon bronze, A	Lavender-brown
C70600	Copper-nickel, 10%	Soft lavender
C74500	Nickel silver, 65-10	Gray-white
C75200	Nickel silver, 65-18	Silver

Ease of Fabrication. Copper and its alloys are generally capable of being shaped to the required form and dimensions by any of the common fabricating processes. They are routinely rolled, stamped, drawn, and headed cold; they are rolled, extruded, forged, and formed at elevated temperature. Copper alloys are readily stamped and formed into components. Most countries in the world employ copper alloys for coinage. There are casting alloys for all of the generic families of coppers and copper alloys. Copper metals can be polished, textured, plated, or coated to provide a wide variety of functional or decorative surfaces.

Copper and copper alloys are readily assembled by any of the various mechanical or bonding processes commonly used to join metal components. Crimping, staking, riveting, and bolting are mechanical means of maintaining joint integrity. Soldering, brazing, and welding are the most widely used processes for bonding copper metals. Selection of the best joining process is governed by service requirements, joint configuration, thickness of the components, and alloy composition(s). These factors are discussed in detail in *Welding, Brazing, and Soldering,* Volume 6 of *ASM Handbook.*

Mechanical Working

High-purity copper is a very soft metal. It is softest in its undeformed single-crystal form and requires a shear stress of only 3.9 MPa (570 psi) on {111} crystal planes for slip. Annealed tough pitch copper is almost as soft as high-purity copper, but many of the copper alloys are much harder and stiffer, even in annealed tempers.

Copper is easily deformed cold. Once flow has been started, it takes little energy to continue, and thus extremely large changes in shape or reductions in section are possible in a single pass. The only limitation appears to be the ability to design and build the necessary tools. Very heavy reductions are possible, especially with continuous flow. Rolling reductions of more than 90% in one pass are used for rolling strip.

Copper and many of its alloys also respond well to sequential cold working. Tandem rolling and gang-die drawing are common. Some copper alloys work harden rapidly; therefore, the number of operations that can be performed before annealing to resoften the metal is limited.

Copper can be cold reduced almost limitlessly without annealing, but heavy deformation (more than about 80 to 90%) may induce preferred crystal orientation, or texturing. Textured metal has different properties in different directions, which is undesirable for some applications.

Both the cold-working and the hot-working characteristics of copper are described below. For more detailed information, see *Forming and Forging,* Volume 14 of *ASM Handbook,* formerly 9th Edition *Metals Handbook.*

Cold working increases both tensile strength and yield strength, but it has a more pronounced effect on the latter. For most coppers and copper alloys, the tensile strength of the hardest cold-worked temper is approximately twice the tensile strength of the annealed temper. For the same alloys, the yield strength of the hardest cold-worked temper can be as much as five to six times that of the annealed temper.

Hardness as a measure of temper is inaccurate: The relation between hardness and strength is different for different alloys. Usually, hardness and strength for a given alloy can be correlated only over a rather narrow range of conditions. Also, the rangeof correlation is often different for different methods of hardness determination.

Hot Working. Not all shaping is confined to cold deformation. Hot working is commonly used for alloys that remain ductile above the recrystallization temperature. Hot working permits more extensive changes in shape than cold working, and thus a single operation often can replace a sequence of forming and annealing operations. To avoid preferred orientation and textures, and to achieve processing economy, copper and many copper alloys are hot worked to nearly finished size. Hot working reduces the as-cast grain size from about 1 to 10 mm (0.04 to 0.4 in.) to about 0.1 mm (0.004 in.) or less and yields a soft texture-free structure suitable for cold finishing.

Some hot-working operations may produce strengths that exceed that of the annealed temper. However, property control by hot working is very difficult and is rarely attempted.

Heat Treating

Work-hardened metal can be returned to a soft state by heating, or annealing. During the annealing of simple single-phase alloys, deformed and highly stressed crystals are transformed into unstressed crystals by recovery, recrystallization, and grain growth. In severely deformed metal, recrystallization occurs at lower temperatures than in lightly deformed metal. Also, the grains are smaller and more uniform in size when severely deformed metal is recrystallized.

Grain size can be controlled by proper selection of cold-working and annealing practices. Large amounts of prior cold work, fast heating to annealing temperature, and short annealing times favor fine grain sizes. Larger grain sizes are normally produced by a combination of limited deformation and long annealing times. In normal commercial practice, annealed grain sizes are controlled to about a median value in the range of 0.01 to 0.10 mm (0.0004 to 0.004 in.).

Variations in annealed grain size produce variations in hardness and other mechanical properties that are smaller than those that occur in cold-worked material, but these variations are by no means negligible. Fine grain sizes often are required to enhance end-product characteristics such as load-carrying capacity, fatigue resistance, resistance to SCC, and surface quality for polishing and buffing of either annealed or cold-formed parts.

Heat-treating processes can also be applied to copper and copper alloys to achieve homogenization, stress relieving, solutionizing, precipitation hardening, and quench hardening and tempering. These aspects are referred to throughout the articles that follow in this Section, and they are reviewed in more detail in *Heat Treating,* Volume 4 of *ASM Handbook.*

Temper Designations

The temper designations for wrought copper and copper alloys were traditionally specified on the basis of cold reduction imparted by rolling or drawing. This scheme related the nominal temper designations to the amount of reduction stated in Brown & Sharpe (B & S) gage numbers for rolled sheet and drawn wire (Table 7). Heat-treatable alloys and product forms such as rod, tube, extrusions, and castings were not readily described by this system. To remedy this situation, ASTM B 601, "Standard Practice for Temper Designations for Copper and Copper Alloys--Wrought and Cast," was developed. This standard established an alphanumeric code that can be assigned to each of the standard descriptive temper designations (Table 8).

Table 7 Temper designations for wrought copper and brass based on cold reduction

Nominal temper designation	Rolled sheet	Drawn wire

designation	Increase in B and S gage numbers	Reduction in thickness and area, %	True strain[(a)]	Reduction in diameter, %	Reduction in area, %	True strain[(a)]
$\frac{1}{4}$ hard	1	10.9	0.116	10.9	20.7	0.232
$\frac{1}{2}$ hard	2	20.7	0.232	20.7	37.1	0.463
$\frac{3}{4}$ hard	3	29.4	0.347	29.4	50.1	0.694
Hard	4	37.1	0.463	37.1	60.5	0.926
Extra hard	6	50.1	0.696	50.1	75.1	1.39
Spring	8	60.5	0.928	60.5	84.4	1.86
Extra spring	10	68.6	1.16	68.6	90.2	2.32
Special spring	12	75.1	1.39	75.1	93.8	2.78
Super spring	14	80.3	1.62	80.3	96.1	3.25

(a) True strain equals ln A_0/A, where A_0 is the initial cross-sectional area and A is the final area.

Table 8 ASTM B 601 temper designation codes for copper and copper alloys

Temper designation	Temper name or material condition
Cold-worked tempers[(a)]	
H00	$\frac{1}{8}$ hard
H01	$\frac{1}{4}$ hard
H02	$\frac{1}{2}$ hard

H03	$\frac{3}{4}$ hard
H04	Hard
H06	Extra hard
H08	Spring
H10	Extra spring
H12	Special spring
H13	Ultra spring
H14	Super spring
Cold-worked tempers[(b)]	
H50	Extruded and drawn
H52	Pierced and drawn
H55	Light drawn; light cold rolled
H58	Drawn general purpose
H60	Cold heading; forming
H63	Rivet
H64	Screw
H66	Bolt
H70	Bending
H80	Hard drawn
H85	Medium-hard-drawn electrical wire

H86	Hard-drawn electrical wire
H90	As-finned
Cold-worked and stress-relieved tempers	
HR01	H01 and stress relieved
HR02	H02 and stress relieved
HR04	H04 and stress relieved
HR08	H08 and stress relieved
HR10	H10 and stress relieved
HR20	As-finned
HR50	Drawn and stress relieved
Cold-rolled and order-strengthened tempers[(c)]	
HT04	H04 and order heat treated
HT08	H08 and order heat treated
As-manufactured tempers	
M01	As-sand cast
M02	As-centrifugal cast
M03	As-plaster cast
M04	As-pressure die cast
M05	As-permanent mold cast
M06	As-investment cast
M07	As-continuous cast

M10	As-hot forged and air cooled
M11	As-forged and quenched
M20	As-hot rolled
M30	As-hot extruded
M40	As-hot pierced
M45	As-hot pierced and rerolled
Annealed tempers[(d)]	
O10	Cast and annealed (homogenized)
O11	As-cast and precipitation heat treated
O20	Hot forged and annealed
O25	Hot rolled and annealed
O30	Hot extruded and annealed
O31	Extruded and precipitation heat treated
O40	Hot pierced and annealed
O50	Light annealed
O60	Soft annealed
O61	Annealed
O65	Drawing annealed
O68	Deep-drawing annealed
O70	Dead-soft annealed

O80	Annealed to temper, $\frac{1}{8}$ hard
O81	Annealed to temper, $\frac{1}{4}$ hard
O82	Annealed to temper, $\frac{1}{2}$ hard
Annealed tempers[(e)]	
OS005	Average grain size, 0.005 mm
OS010	Average grain size, 0.010 mm
OS015	Average grain size 0.015 mm
OS025	Average grain size 0.025 mm
OS035	Average grain size 0.035 mm
OS050	Average grain size 0.050 mm
OS060	Average grain size 0.060 mm
OS070	Average grain size 0.070 mm
OS100	Average grain size 0.100 mm
OS120	Average grain size 0.120 mm
OS150	Average grain size 0.150 mm
OS200	Average grain size 0.200 mm
Solution-treated temper	
TB00	Solution heat treated
Solution-treated and cold-worked tempers	

TD00	TB00 cold worked to $\frac{1}{8}$ hard
TD01	TB00 cold worked to $\frac{1}{4}$ hard
TD02	TB00 cold worked to $\frac{1}{2}$ hard
TD03	TB00 cold worked to $\frac{3}{4}$ hard
TD04	TB00 cold worked to full hard
Solution-treated and precipitation-hardened temper	
TF00	TB00 and precipitation hardened
Cold-worked and precipitation-hardened tempers	
TH01	TD01 and precipitation hardened
TH02	TD02 and precipitation hardened
TH03	TD03 and precipitation hardened
TH04	TD04 and precipitation hardened
Precipitation-hardened and cold-worked tempers	
TL00	TF00 cold worked to $\frac{1}{8}$ hard
TL01	TF00 cold worked to $\frac{1}{4}$ hard
TL02	TF00 cold worked to $\frac{1}{2}$ hard
TL04	TF00 cold worked to full hard

TL08	TF00 cold worked to spring
TL10	TF00 cold worked to extra spring
Mill-hardened tempers	
TM00	AM
TM01	$\frac{1}{4}$ HM
TM02	$\frac{1}{2}$ HM
TM04	HM
TM06	XHM
TM08	XHMS
Quench-hardened tempers	
TQ00	Quench hardened
TQ50	Quench hardened and temper annealed
TQ55	Quench hardened and temper annealed, cold drawn and stress relieved
TQ75	Interrupted quench hardened
Precipitation-hardened, cold-worked, and thermal-stress-relieved tempers	
TR01	TL01 and stress relieved
TR02	TL02 and stress relieved
TR04	TL04 and stress relieved
Solution-treated and spinodal-heat-treated temper	
TX00	Spinodal hardened

Tempers of welded tubing[f]	
WH00	Welded and drawn to $\frac{1}{8}$ hard
WH01	Welded and drawn to $\frac{1}{4}$ hard
WH02	Welded and drawn to $\frac{1}{2}$ hard
WH03	Welded and drawn to $\frac{3}{4}$ hard
WH04	Welded and drawn to full hard
WH06	Welded and drawn to extra hard
WM00	As welded from H00 ($\frac{1}{8}$-hard) strip
WM01	As welded from H01 ($\frac{1}{4}$-hard) strip
WM02	As welded from H02 ($\frac{1}{2}$-hard) strip
WM03	As welded from H03 ($\frac{3}{4}$-hard) strip
WM04	As welded from H04 (full-hard) strip
WM06	As welded from H06 (extra-hard) strip
WM08	As welded from H08 (spring) strip
WM10	As welded from H10 (extra-spring) strip
WM15	WM50 and stress relieved
WM20	WM00 and stress relieved

WM21	WM01 and stress relieved
WM22	WM02 and stress relieved
WM50	As welded from annealed strip
WO50	Welded and light annealed
WR00	WM00; drawn and stress relieved
WR01	WM01; drawn and stress relieved
WR02	WM02; drawn and stress relieved
WR03	WM03; drawn and stress relieved
WR04	WM04; drawn and stress relieved
WR06	WM06; drawn and stress relieved

(a) Cold-worked tempers to meet standard requirements based on cold rolling or cold drawing.

(b) Cold-worked tempers to meet standard requirements based on temper names applicable to specific products.

(c) Tempers produced by controlled amounts of cold work followed by a thermal treatment to produce order strengthening.

(d) Annealed to meet specific mechanical property requirements.

(e) Annealed to meet prescribed nominal average grain size.

(f) Tempers of fully finished tubing that has been drawn or annealed to produce specified mechanical properties or that has been annealed to produce a prescribed nominal average grain size are commonly identified by the appropriate H, O, or OS temper designation.

Electrical Coppers

Commercially pure copper is represented by UNS numbers C10100 to C13000. The various coppers within this group have different degrees of purity and therefore different characteristics. Fire-refined tough pitch copper C12500 is made by deoxidizing anode copper until the oxygen content has been lowered to a value of 0.02 to 0.04%. Both the traditional method of poling (or pitching) a bath of molten anode copper and the more modern method of deoxidizing with hydrocarbons produce metal with essentially the same high ductility and excellent electrical conductivity. Fire-refined tough pitch copper contains a small amount of residual sulfur, normally 10 to 30 ppm, and a somewhat larger amount of cuprous oxide, normally 500 to 3000 ppm.

Electrolytic tough pitch copper C11000 is made from cathode copper, that is, copper that has been refined electrolytically. C11000 is the most common of all the electrical coppers. It has high electrical conductivity, in excess of 100% IACS. It has the same oxygen content as C12500 but contains less than 50 ppm total metallic impurities (including sulfur).

Oxygen-free coppers C10100 and C10200 are made by melting prime-quality cathode copper under nonoxidizing conditions, which are produced by a granulated graphite bath covering and a protective reducing atmosphere that is low in hydrogen. Oxygen-free coppers are particularly suitable for applications requiring high conductivity coupled with exceptional ductility, low gas permeability, freedom from hydrogen embrittlement, or low out-gassing tendency.

If resistance to softening at slightly elevated temperature is required, C11100 is often specified. This copper contains a small amount of cadmium, which raises the temperature at which recovery and recrystallization occur. Oxygen-free copper, electrolytic tough pitch copper, and fire-refined tough pitch copper are available as silver-bearing coppers having specific minimum silver contents. The silver, which may be present as an impurity in anode copper or may be intentionally alloyed to molten cathode copper, also imparts resistance to softening to cold-worked metal. Silver-bearing coppers and cadmium-bearing coppers are used for applications such as automotive radiators and electrical conductors that must operate at temperatures above about 200 °C (400 °F).

If good machinability is required, C14500 (tellurium-bearing copper) or C14700 (sulfur-bearing copper) can be selected. As might be expected, machinability is gained at a modest sacrifice in electrical conductivity.

Adding small amounts of elements such as silver, cadmium, iron, cobalt, and zirconium to deoxidized copper imparts resistance to softening at the times and temperatures encountered in soldering operations, such as those used to join components of automobile and truck radiators, and those used in semiconductor packaging operations. Thermal and electrical conductivities and room-temperature mechanical properties are unaffected by small additions of these elements. However, cadmium-copper and zirconium-copper work harden at higher rates than either silver-bearing copper or electrolytic tough pitch copper (Fig. 1).

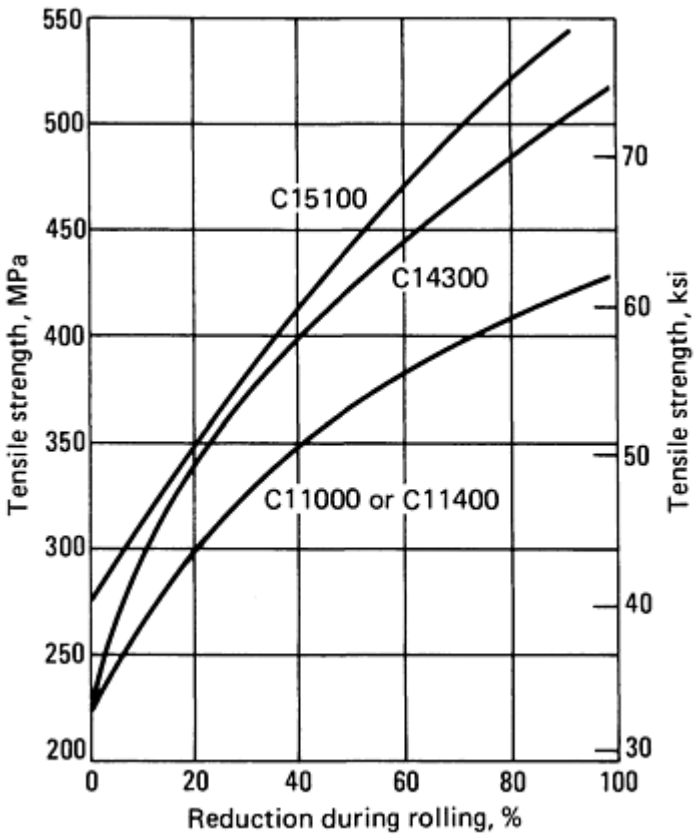

Fig. 1 Tensile strength versus reduction during rolling for cadmium-copper (C14300), zirconium-copper (C15100), and tough pitch copper (C11000)

Cold-rolled silver-bearing copper is used extensively for automobile radiator fins. Usually such strip is only moderately cold rolled because heavy cold rolling makes silver-bearing copper more likely to soften during soldering or baking operations. Some manufacturers prefer cadmium-copper C14300 because it can be severely cold rolled without making it susceptible to softening during soldering. Figure 2 illustrates the softening characteristics of C14300 and C11400 as measured for several temperatures and two tempers. As shown in Fig. 2(b), C14300 cold rolled to a tensile strength of 440 MPa (64 ksi) retains 91% of its strength after a typical core bake of 3 min at 345 °C (650 °F). Silver-bearing copper C11400 given the same cold reduction retains only 60% of its tensile strength after the same baking schedule.

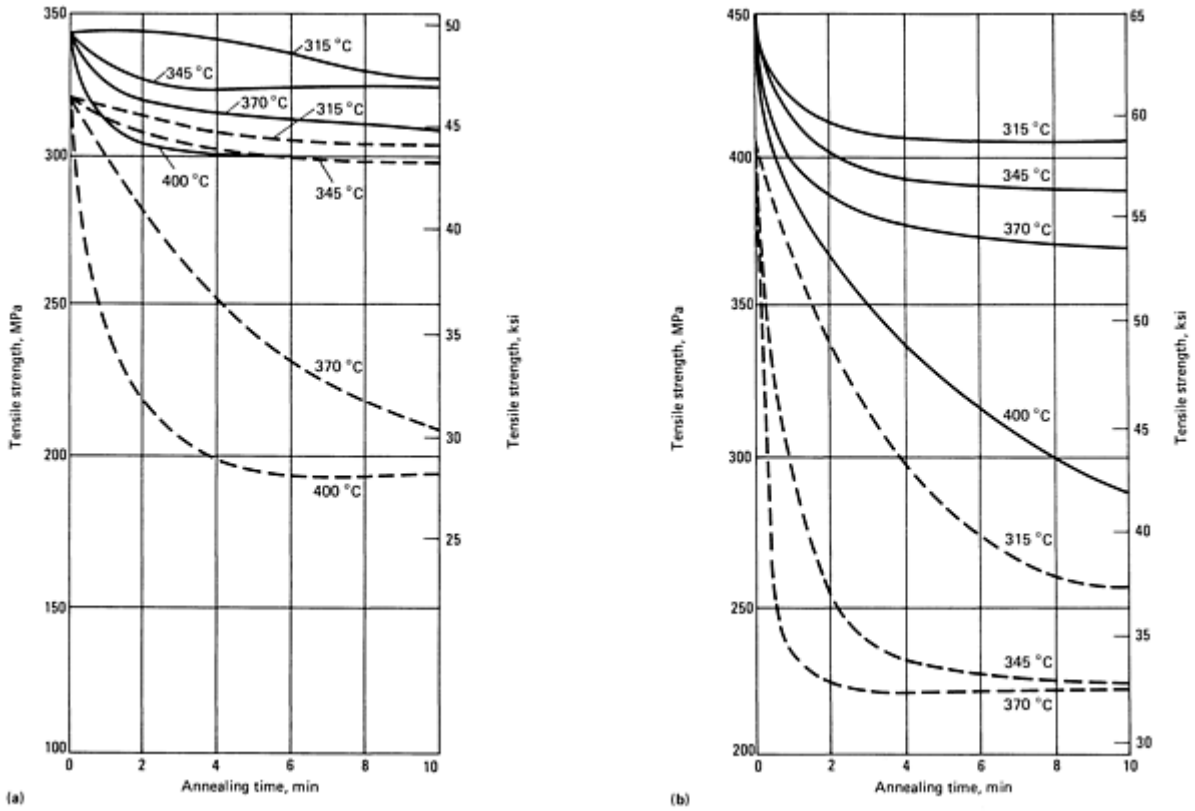

Fig. 2 Softening characteristics of cadmium-bearing copper and silver-bearing tough pitch copper. (a) Softening curves for material cold reduced 21% in area, from 0.1 to 0.075 mm (0.0038 to 0.0030 in.) in thickness. (b) Softening curves for material cold reduced 90% in area, from 0.75 to 0.075 mm (0.0300 to 0.0030 in.) in thickness

Another application in which softening resistance is of paramount importance is lead frames for electronic devices, such as plastic dual-in-line packages. During packaging and assembly, lead frames may be subjected to temperatures up to 350 °C (660 °F) for several minutes and up to 500 °C (930 °F) for several seconds. The leads must maintain good strength because they are pressed into socket connectors, often by automated assembly machines; softened leads collapse, causing spoilage. See the article "Lead Frame Materials" in *Packaging*, Volume 1 of the *Electronic Materials Handbook* for additional information.

Alloy C15100 (copper-zirconium), alloy C15500 (copper-silver-magnesium-phosphorus), alloy C19400 (copper-iron-phosphorus-zinc), and alloy C19500 (copper-iron-cobalt-tin-phosphorus) are popular for these applications because they have good conductivity, good strength, and good softening resistance. Figures 3 and 4 compare the softening resistance of these alloys with electrolytic copper C11000.

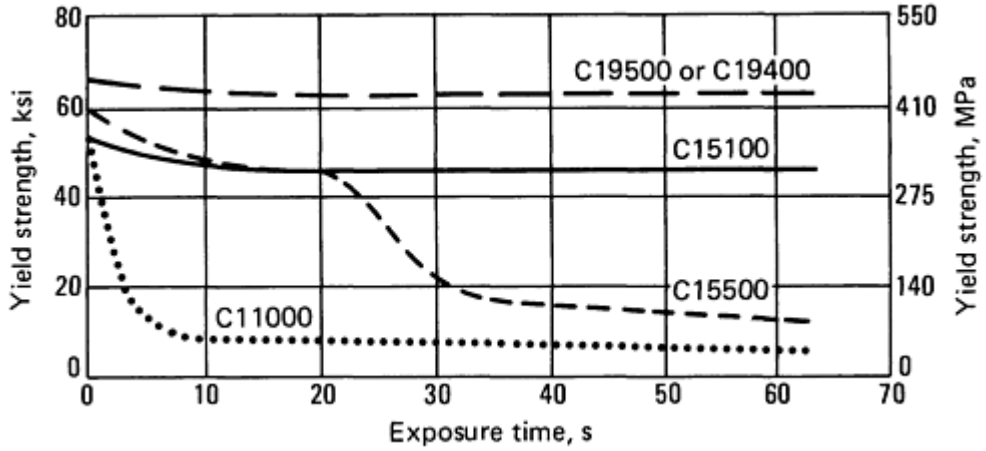

Fig. 3 Softening resistance of lead frame materials at the upper temperature limit (500 °C, or 930 °F)

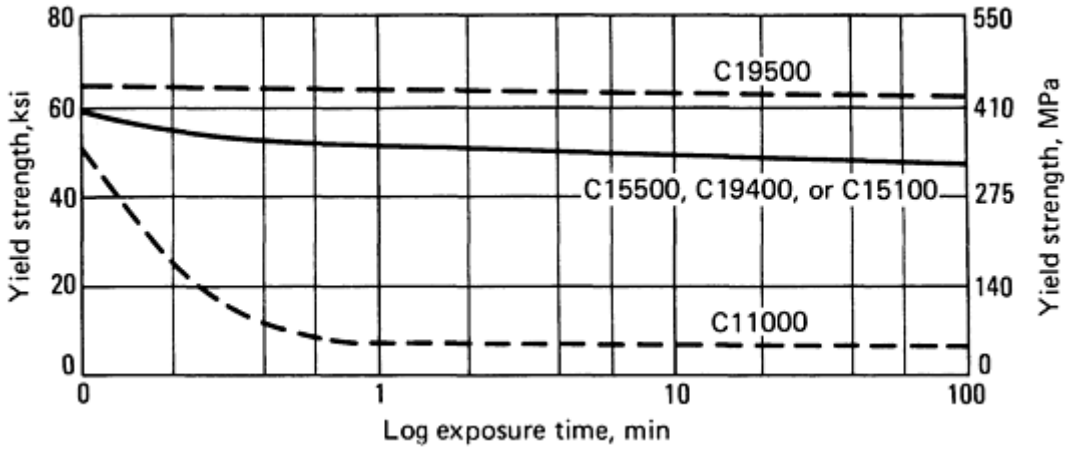

Fig. 4 Softening resistance of lead frame materials at an intermediate temperature level (350 °C, or 660 °F)

Copper Alloys

The most common way to catalog copper and copper alloys is to divide them into six families: coppers, dilute-copper (or high-copper) alloys, brasses, bronzes, copper nickels, and nickel silvers. The first family, the coppers, is essentially commercially pure copper, which ordinarily is soft and ductile and contains less than about 0.7% total impurities. The dilute-copper alloys contain small amounts of various alloying elements, such as beryllium, cadmium, chromium, or iron, each having less than 8 at.% solid solubility; these elements modify one or more of the basic properties of copper. Each of the remaining families contains one of five major alloying elements as its primary alloying ingredient:

Family	**Alloying elements**	**Solid solubility, at.%[(a)]**
Brasses	Zinc	37
Phosphor bronzes	Tin	9

Aluminum bronzes	Aluminum	19
Silicon bronzes	Silicon	8
Copper-nickels, nickel silvers	Nickel	100

(a) At 20 °C (70 °F)

A general classification for wrought and cast copper alloys is given in Table 9.

Table 9 Generic classification of copper alloys

Generic name	**UNS numbers**	**Composition**
Wrought alloys		
Coppers	C10100-C15760	>99% Cu
High-copper alloys	C16200-C19600	>96% Cu
Brasses	C20500-C28580	Cu-Zn
Leaded brasses	C31200-C3890	Cu-Zn-Pb
Tin brasses	C40400-C49080	Cu-Zn-Sn-Pb
Phosphor bronzes	C50100-C52400	Cu-Sn-P
Leaded phosphor bronzes	C53200-C54800	Cu-Sn-Pb-P
Copper-phosphorus and copper-silver-phosphorus alloys	C55180-C55284	Cu-P-Ag
Aluminum bronzes	C60600-C64400	Cu-Al-Ni-Fe-Si-Sn
Silicon bronzes	C64700-C66100	Cu-Si-Sn
Other copper-zinc alloys	C66400-C69900	. . .
Copper-nickels	C7000-C79900	Cu-Ni-Fe
Nickel silvers	C73200-C79900	Cu-Ni-Zn

Cast alloys		
Coppers	C80100-C81100	>99% Cu
High-copper alloys	C81300-C82800	>94 Cu
Red and leaded red brasses	C83300-C85800	Cu-Zn-Sn-Pb (75-89% Cu)
Yellow and leaded yellow brasses	C85200-C85800	Cu-Zn-Sn-Pb (57-74% Cu)
Manganese bronzes and leaded manganese bronzes	C86100-C86800	Cu-Zn-Mn-Fe-Pb
Silicon bronzes, silicon brasses	C87300-C87900	Cu-Zn-Si
Tin bronzes and leaded tin bronzes	C90200-C94500	Cu-Sn-Zn-Pb
Nickel-tin bronzes	C94700-C94900	Cu-Ni-Sn-Zn-Pb
Aluminum bronzes	C95200-C95810	Cu-Al-Fe-Ni
Copper-nickels	C96200-C96800	Cu-Ni-Fe
Nickel silvers	C97300-C97800	Cu-Ni-Zn-Pb-Sn
Leaded coppers	C98200-C98800	Cu-Pb
Miscellaneous alloys	C99300-C99750	. . .

Solid-Solution Alloys. The most compatible alloying elements with copper are those that form solid-solution fields. These include all elements forming useful alloy families (see Table 9) plus manganese. Hardening in these systems is great enough to make useful objects without encountering brittleness associated with second phases or compounds.

Cartridge brass is typical of this group. It consists of 30% Zn in copper and exhibits no β phase except an occasional small amount due to segregation; the β phase normally disappears after the first anneal. Provided that there are no tramp elements such as iron, cold-working and grain growth relationships are easily reproduced in practice.

Modified Solid-Solution Alloys. The solid solution-strengthened alloys of copper are noted for their strength and formability. Because they are single phase and are not transformed by heating or cooling, their maximum strength is developed by cold working methods such as cold rolling or cold drawing. Formability is reduced in proportion to the amount of cold work applied.

Modifications of some solid-solution alloys were developed by adding elements that react to form dispersions of intermetallic particles. These dispersions have a grain-refining and strengthening effect. As a result, higher strengths can be produced with less cold working, resulting in better formability at higher strength levels. Because these modifications do not require large amounts of costly elements, the gains are reasonably economical.

Alloy C63800 (95Cu-2.8Al-1.8Si-0.4Co) is a high-strength alloy with a nominal annealed tensile strength of 570 MPa (82 ksi) and nominal tensile strengths of 660 to 900 MPa (96 to 130 ksi) for the standard-rolled tempers. Cobalt provides the dispersion of strengthening intermetallic particles.

Alloy C68800 (73.5Cu-22.7Zn-3.4Al-0.4Co) is a high-strength modified aluminum brass. Its bend formability parallel to the direction of rolling is outstanding relative to its strength. It owes some of its unique properties to a dispersion of intermetallic particles resulting from the presence of cobalt. Its strength range is essentially the same as that of alloy C63800.

Alloy C65400 (95.44Cu-3-Si-1.5Sn-0.06Cr) is a very high-strength alloy that has excellent stress-relaxation resistance at temperatures up to 105 °C (220 °F). Its nominal strength range in rolled tempers is 570 to 945 MPa (82 to 137 ksi). Electrical contact and connector springs are heat treated at 200 to 250 °C (390 to 480 °F) for 1 h to stabilize internal stresses and maximize stress-relaxation resistance.

Alloy C66-400 (86.5Cu-11.5Zn-1.5Fe-0.5Co) is a low-zinc brass modified by the addition of iron and cobalt. The dispersion of intermetallic particles resulting from these additions strengthens the alloy. At the same time, conductivity is only moderately reduced, and resistance to SCC is very high. A high-zinc brass of the same strength and conductivity would be subject to SCC unless plated for protection.

Other modified solid-solution-strengthened alloys are probably described in the literature of the brass mill industries. Those described above should serve as examples of this additional class of copper alloys, which is expanding through the development efforts of the producers of brass mill products throughout the world.

Age-Hardenable Alloys. Age hardening produces very high strengths but is limited to those few copper alloys in which the solubility of the alloying element decreases sharply with decreasing temperature. The beryllium-coppers can be considered typical of the age-hardenable copper alloys.

Wrought beryllium-coppers can be precipitation hardened to the highest strength levels attainable in copper-base alloys. There are two commercially significant alloy families employing two ranges of beryllium with additions of cobalt or nickel. The so-called red alloys contain beryllium at levels ranging from approximately 0.2 to 0.7 wt%, with additions of nickel or cobalt totaling 1.4 to 2.7 wt%, depending on the alloy. Alloys C17500 and C17510 are examples of red alloys; these low-beryllium alloys achieve relatively high conductivity (for example, 50% IACS) and retain the pink luster of other low-alloy coppers. The red alloys achieve yield strengths ranging from about 170 to 550 MPa (25 to 80 ksi) with no heat treatment to greater than 895 MPa (130 ksi) after precipitation hardening, depending on degree of cold work.

The more highly beryllium-alloyed systems can contain from 1.6 to 2.0 wt% Be and about 0.25 wt% Co, for example, alloys C17000 and C17200. These alloys frequently are called the gold alloys because of the shiny luster imparted by the substantial amount of beryllium present (~12 at.%). The gold alloys are the high-strength beryllium-coppers because they can attain yield strengths ranging from approximately 205 to 690 MPa (30 to 100 ksi) in the age-hardenable condition to above 1380 MPa (200 ksi) after aging. The conductivity of the gold alloys is lower than that of the red alloy family by virtue of the high beryllium content. However, conductivity ranging from about 20% to higher than 30% IACS is obtained in wrought products depending on the amount of cold work and the heat treatment schedule. For enhanced machinability in rod and wire, lead is added (as in alloy C17300). More detailed information on beryllium-containing copper alloys can be found in the article "Beryllium-Copper and Other Beryllium-Containing Alloys" in this Section.

Other age-hardenable alloys include C15000; C15100 (zirconium-copper); C18200, C18400, and C18500 (chromium-coppers); C19000 and C19100 (copper-nickel-phosphorus alloys); and C64700 and C70250 (copper-nickel-silicon alloys). Some age-hardening alloys have different desirable characteristics, such as high strength combined with better electrical conductivity than the beryllium-coppers.

Alloy C71900 (copper-nickel-tin) and other similar alloys can be hardened by spinodal decomposition. By combining cold working with hot working, these alloys can achieve high strengths that are equivalent to those of the hardenable beryllium-coppers. These alloys are unique in that their forming characteristics are isotropic and thus do not reflect the directionality normally associated with wrought alloys.

Other Alloys. Certain aluminum bronzes, most notably those containing more than about 9% Al, can be hardened by quenching from above a critical temperature. The hardening process is a martensitic-type process, similar to the martensitic hardening that occurs when iron-carbon alloys are quenched. Mechanical properties of aluminum bronzes can

be varied somewhat by temper annealing after quenching or by using an interrupted quench instead of a standard quench. Aluminum bronzes alloyed with nickel or zinc use reversible martensitic transformations to provide shape memory effects (see the article "Shape Memory Alloys" in this Volume).

Insoluble Alloying Elements. Lead, tellurium, and selenium are added to copper and copper alloys to improve machinability. These elements, along with bismuth, make hot rolling and hot forming nearly impossible and severely limit the useful range of cold working. The high-zinc brasses avoid these limitations, however, because they become fully β phase at high temperature. The β phase can dissolve lead, thus avoiding a liquid grain-boundary phase at hot forging or extrusion temperatures. Most free-cutting brass rod is made by β extrusion. Alloy C37700, one of the leaded high-zinc brasses, is so readily hot forged that it is the standard alloy against which the forgeability of all copper alloys is measured.

Deoxidizers

Lithium, sodium, beryllium, magnesium, boron, aluminum, carbon, silicon, and phosphorus can be used to deoxidize copper. Calcium, manganese, and zinc can sometimes be considered deoxidizers, although they normally fulfill different roles.

The first requirement of a deoxidizer is that it have an affinity for oxygen in molten copper. Probably the second most important requirement is that it be relatively inexpensive compared to copper and any other additions. Thus although zinc normally functions as a solid-solution strengthener, it is sometimes added in small amounts to function as a deoxidizer because it has a high affinity for oxygen and is relatively low in cost. In tin bronze, phosphorus has traditionally been the deoxidizer, hence the name phosphor bronzes for these alloys. Silicon, rather than phosphorus, is the deoxidizer for chromium-coppers because phosphorus severely reduces electrical conductivity. Most deoxidizers contribute to hardness and other quantities, thus obscuring their role in alloy deoxidization.

Production of Copper Metals

The copper industry in the United States, broadly speaking, is composed of two segments: producers (mining, smelting, and refining companies) and fabricators (wire mills, brass mills, foundries, and powder plants). The end products of copper producers, the most important of which are refined cathode copper and wire rod, are sold almost entirely to copper fabricators. The end products of copper fabricators can be generally described as mill products and foundry products, and they consist of wire and cable, sheet, strip, plate, rod, bar, mechanical wire, tubing, forgings, extrusions, castings, and powder metallurgy shapes. These products are sold to wide variety of industrial users. Certain mill products--chiefly wire, cable, and most tubular products--are used without further metalworking. On the other hand, most flat-rolled products, rod, bar, mechanical wire, forgings, and castings go through multiple metalworking, machining, finishing, and/or assembly operations before emerging as finished products.

Copper Producers. Figure 5 is a simplified flow chart of the copper industry. The box at upper left represents mining companies, which remove vast quantities of low-grade material, mostly from open-pit mines, to extract copper from the crust of the earth. Approximately 2 tons of overburden must be removed along with each ton of copper ore. (The ratio of overburden to ore is sometimes as high as 5 to 1.) The ore itself averages only about 0.7% Cu.

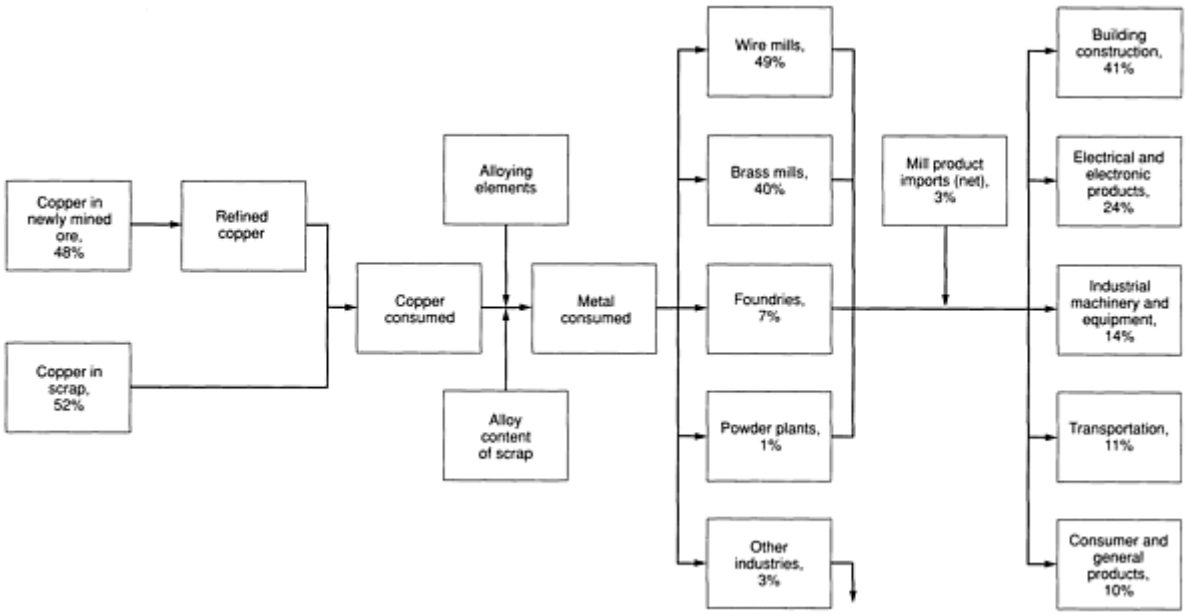

Fig. 5 Flow of copper in the U.S. economy. Percentages are based on 1989 data.

Copper ore normally is crushed, ground, and concentrated, usually by flotation, to produce a beneficiated ore containing about 25% Cu. The ore concentrates are then reduced to the metallic states, most often by a pyrometallurgical process. Traditionally, the concentrated ore is processed in a primary smelting reactor, such as a reverberatory furnace, to produce a copper sulfide-iron sulfide matte containing up to 60% Cu. Reverberatory technology is rapidly being replaced by oxygen/flash smelting, which greatly reduces the volume of off gases. Sulfuric acid is manufactured from the sulfur dioxide contained in these off gases and is an important co-product of copper smelting. The matte is oxidized in a converter to transform the iron sulfides to iron oxides, which separate out in a slag, and to reduce the copper sulfide to blister copper, which contains at least 98.5% Cu. Current technology combines the converter step with the preceding smelting step. Fire refining of blister copper then removes most of the oxygen and other impurities, leaving a product at least 99.5% pure, which is cast into anodes. Finally, most anode copper is electrolytically refined, usually to a purity of at least 99.95%.

The resulting cathodes are the normal end product of the producer companies and are a common item of commerce. In recent years, many producers have installed continuous casting rod mills to directly convert cathode copper to wire rod (typically, 8 mm, or $\frac{5}{16}$ in., in diameter), which is the feed material for the wire mills. Primary producers may also convert the cathode to cakes or billets of copper for sale to brass mills. The consumption of refined copper (mostly cathodes) in the United States was about 2.2×10^6 Mg (2.4×10^6 tons) in 1989, about 26% of the free-world total of 8.5×10^6 Mg (9.3×10^6tons).

Hydrometallurgical processing is an increasingly important alternative to pyprometallurgy, particularly for nonsulfide ores such as oxides, silicates, and carbonates. In this process, weak acid is percolated through ore of waste dumps of rejected materials. Copper is leached out and recovered from the pregnant leach liquor, most often by solvent extraction, to produce an electrolyte suitable for electrowinning. In electrowinning, copper is extracted electrolytically in much the same way as anode copper is electrorefined. Copper extractedby electrowinning is equal in quality to that produced by electrolytic refining.

The box at the lower left in Fig. 5 represents the portion of the copper supply provided by scrap. In recent years, well over half the copper consumed in the United States has been derived from recycled scrap, and this percentage has grown somewhat over the last two decades. About 55% of this scrap has been new scrap, such as turnings from screw-machined rod, as opposed to old scrap, such as used electrical cable or auto radiators. Scrap recycled within a particular plant or company (runaround scrap) is not included in these statistics. About one-third of the scrap recycled in the United States is fed into the smelting or refining stream and quickly loses its identity. The remainder is consumed directly by brass mills;

by ingot makers, whose main function is to process scrap into alloy ingot for use by foundries; by foundries themselves; by powder plants; and by others, such as the chemical, aluminum, and steel industries.

The box labeled "copper consumed" in Fig. 5 represents the total tonnage of refined copper plus the copper content of scrap consumed directly by fabricator companies. The various alloying elements used in producing copper alloys and the alloy content of the directly consumed scrap added to obtain the total metal consumed by copper fabricators and other industries.

Copper Fabricators. The four classes of copper fabricators together account for about 97% of the total copper (including alloying metal) consumed each year in the United States (Fig. 5). Other industries, such as steel, aluminum, and chemical producers, consume the remaining 3%.

The share of metal consumed by wire rod mills has grown sharply over the last 20 years to its present (1989) level of about 49%; consumption by brass mills has dropped to 40%. Foundries account for about 7% of fabricated mill products, and powder plants use less than 1% of the U.S. supply of copper.

Wire mill products are destined for use as electrical conductors. Starting with wire rod, these mills cold draw the material (with necessary anneals) to final dimensions through a series of dies. The individual wires may be stranded and normally are insulated before being gathered into cable assemblies.

Brass mills melt and alloy feedstock to make strip, sheet, plate, tube, rod, bar, mechanical wire, forgings, and extrusions. Less than half the copper input to brass mills is refined; the rest is scrap. Fabricating processes such as hot rolling, cold rolling, extrusion, and drawing are employed to convert the melted and cast feedstock into mill products.

About 45% of the output of U.S. brass mills is unalloyed copper and high-copper alloys, chiefly in such forms as plumbing and air-conditioning tube, busbar and other heavy-gage current-carrying flat products, and roofing sheet. Copper alloys make up the remaining 55% (Table 10). Free-cutting brass rod, which exhibits outstanding machinability and good corrosion resistance, and brass strip, which has high strength, good corrosion resistance, excellent formability, and good electrical properties, together constitute about 80% of the total tonnage of copper alloys shipped from U.S. brass mills. Other alloys types of major commercial significance include tin bronzes (phosphor bronzes), which are noted for their excellent cold-forming behavior and strength; tin brasses, known for outstanding corrosion resistance; copper-nickels, which are strong and particularly resistant to seawater; nickel silvers, which combine a silvery appearance with good formability and corrosion resistance; beryllium-coppers, which provide outstanding strength when hardened; and aluminum bronzes, which have high strength along with good resistance to oxidation, chemical attack, and mechanical abrasion.

Table 10 Major wrought copper and copper-base alloy systems used in the United States

Copper or copper alloy group	Designation	Approximate U.S. shipments in 1989		Remarks
		Mg × 10^3	lb × 10^6	
Wire mill products				
Coppers	C10000-C15900	1522	3356	C11000 is the predominant material.
Brass mill products				
	C10000-			Includes modified coppers, cadmium copper, and chromium

	C15900			copper
	C16000-C16900			
	C18000-C18900			
Common brasses	C20000-C29900	219	482	Of this amount, 90% is strip, sheet, and plate.
Leaded brasses	C30000-C39900	347	766	Of this amount, 96% is rod.
Tin bronzes (phosphor bronzes)	C50000-C53900	14	31	Unleaded only
Aluminum bronzes, silicon bronzes, and manganese bronzes	C60000-C68400	13	28	
Copper-nickels	C70000-C72900	32	71	
Nickel silvers	C73000-C79900	4	9	
Others	C17000-C17900	49	107	Includes beryllium-coppers, copper-iron alloys, tin brasses, leaded tin bronzes, aluminum brasses, and silicon brasses
	C19000-C19900			
	C40000-C49900			
	C54000-C54900			
	C68500-C69900			
Total		**2770**	**6107**

Foundries use prealloyed ingot, scrap, and virgin metal as raw materials. Their chief products are shaped castings for many different industrial and consumer goods, the most important of which are plumbing products and industrial valves. Centrifugal and continuously cast products find major application as bearings, cylinders, and other symmetrical

components (see the article "Selection and Application of Copper Alloy Castings" in this Section). Powder plants produce powder and flake for further fabrication into powder metallurgy parts, chiefly small sintered bronze bushings (see the article "Copper P/M Products" in this Section). Net imports (imports less exports) of mill and foundry products have fluctuated in recent years, from a high of 7% in the period from 1984 to 1986 to less than 3% in 1989.

Industry Structure

The structure of the U.S. copper and copper alloy industry has undergone dramatic changes during the last two decades. In 1966, for example, the United States was easily the largest producer and consumer of newly mined copper. In addition, U.S. companies accounted for most of the output of Chilean mines; thus, the United States had effective control of about 45% of free-world production. However, the U.S.-owned mines in Chile began to be nationalized in the late 1960s, and the government of Chile has greatly expanded the output of these mines. The present U.S. share of world mine production is about 16%. Chile also accounts for 18%, nearly all of which is exported, and has the largest copper reserves in the world. Other important free-world producers are, in order of 1989 mine production, Canada, Zambia, Zaire, and Peru. The centrally controlled economies, including both the Eastern bloc and some free-world countries, today account for perhaps 60% of world mine production of copper, versus about 40% 20 years ago. World copper mine production statistic are provided in Fig. 6.

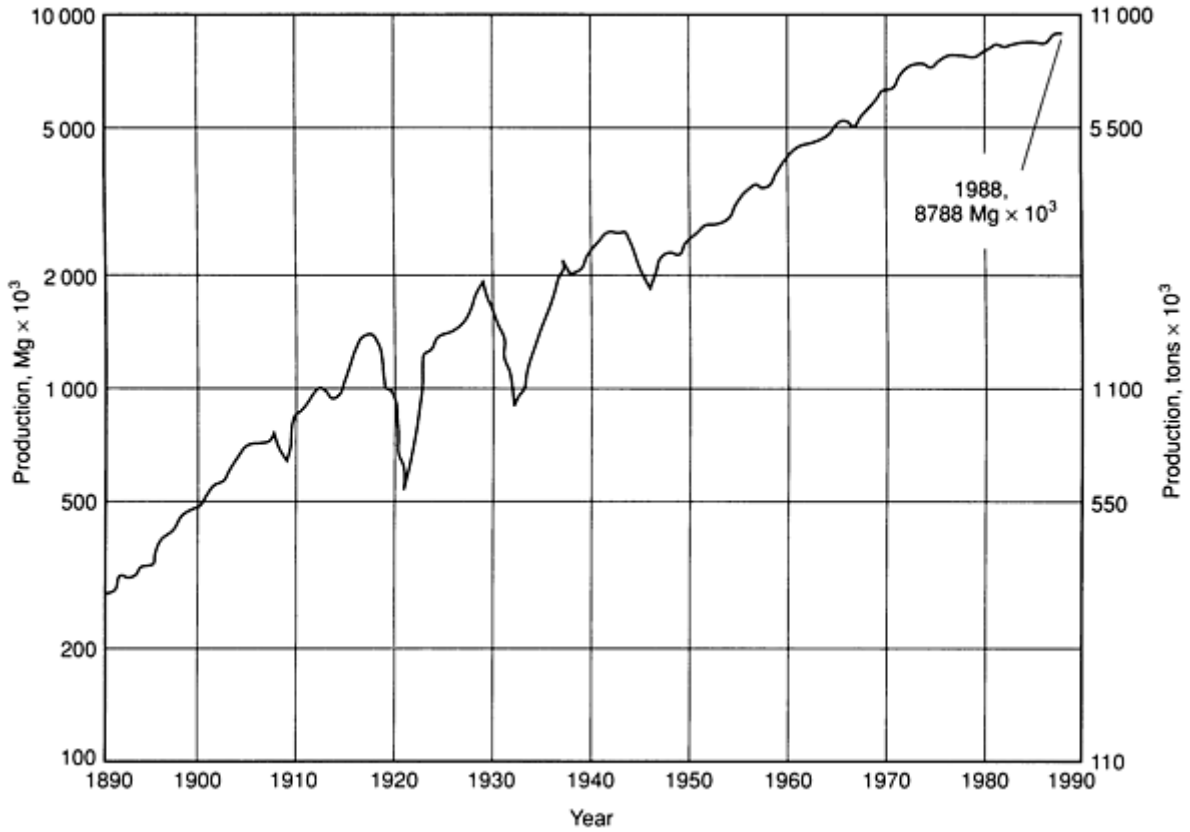

Fig. 6 World copper mine production. Despite the 10,000-year history of copper, about three-quarters of all copper ever consumed has been used in the period since World War II. 1989 production: 9178 Mg × 10^3. Source: Metallgesellschaft and the World Bureau of Metal Statistics

U.S. Companies. Many of the U.S. copper mining, smelting, and refining companies were purchased by oil companies in the 1970s. A string of unprofitable years in the early 1980s led to divestiture. These events, along with expanding international competition, led managements to institute cost controls and production efficiencies perhaps unprecedented in the U.S. metals industry. At present, despite the high cost of complying with the strictest environmental standards in the world, U.S. copper companies are well positioned to live with low price levels and to profit from the increasing demand for copper.

The U.S. brass mill industry has also undergone a significant restructuring in the past few years. The same economic factors at work in recent years in the mining industry have squeezed the profit margins of brass mills. In the recent past, this industry had been dominated by large full-line mills producing a wide range of products, including strip, sheet, plate, rod, bar, forgings, mechanical wire, and tubing. At present, only one full-line mill is in operation, as compared with eight in 1970. Instead, single-product operations have come to the forefront, many with the most up-to-date production equipment to enable them to compete on a worldwide scale. Many older mills have been closed, and other companies have been restructured through leveraged buyouts and employee stock ownership plans.

The wire and cable mills have seen some restructuring, particularly in the breakup of some of the large multiproduct operations that had equity ties to mining companies; also, numerous mergers and buyouts have taken place. Overall, however, these changes have not been profound as those experienced by the copper companies and brass mills.

In contrast to other metal industries, today almost no top-to-bottom integration exists in the U.S. copper industry. The only move toward integration in the last 20 years has been the addition of continuous casting wire rod mills to the end of the production process by several refining companies.

Applications of Copper and Copper Alloys

The five major market categories shown at the far right in Fig. 5 constitute the chief customer industries of the copper fabricators. Of the chief customer industries, the largest is building construction, which purchases large quantities of electrical wire, tubing, and parts for building hardware and for electrical, plumbing, heating, and air-conditioning systems. The second largest category is electrical and electronic products, including those for telecommunications, electronics, wiring devices, electric motors, and power utilities. The industrial machinery and equipment category includes industrial valves and fittings; industrial, chemical, and marine heat exchangers; and various other types of heavy equipment, off-road vehicles, and machine tools. Transportation applications include road vehicles, railroad equipment, and aircraft parts; automobile radiators and wiring harnesses are the most important products in this category. Finally, consumer and general products include electrical appliances, fasteners, ordinance, coinage, and jewelry.

Table 11 is a more detailed listing of the largest markets for copper and copper alloys in the United States and compares 1989 markets with those for 1980. Building wiring and plumbing constitute the two highest end-use applications. Both have benefited from an extended housing boom and from an increasing intensity of use (that is, more electrical loads and more bathrooms in new homes). Plastics are an ongoing threat to replace copper in plumbing applications, but they are susceptible to permeation by gasoline and other organic materials and to mechanical damage. They also do not exhibit the bactericidal properties of copper.

Table 11 Major end-use applications for copper and copper alloys in the United States in 1989

Application	**% of total**	
	1989	**1980**
Building wiring	16.9	10.7
Plumbing and heating	14.9	13.4
Autos, trucks, and buses	9.8	8.7
Telecommunications	8.1	13.1
Power utilities	7.7	7.4

Air conditioning and commercial refrigeration	7.1	6.3
In-Plant equipment	7.1	8.4
Electronics	5.7	4.2
Industrial valves and fittings	3.4	3.5
Appliances and extension cords	2.7	2.9
Coinage	0.9	2.7
Other	15.7	18.7
Total	**100.0**	**100.0**

Source: Copper Development Association Inc.

Automotive applications represent the third largest market for copper. In 1989, about 23 kg (50 lb) of copper and copper alloys were used in an average U.S.-built passenger car; this compares to a use of 16 kg (36 lb) per car in 1980.

Telecommunications applications, on the other hand, have dropped from second to fourth place in less than a decade. The development of technological innovations such as subscriber carrier (that is, the piggybacking of many phone conversations on a single pair of copper wires), fiber optics (to a lesser degree), and the use of wires of smaller cross section have been the cause of this decrease.

In the power utilities market, the greatest competition to copper comes from aluminum, which is used almost exclusively in overhead transmission and distribution cable. An area of potentially significant growth, however, is that of superconductors, which may open up new markets for copper, such as for transmission lines, and energy storage devices. See the Section "Superconducting Materials" in this Volume for more detailed information.

The copper end-use market that experienced the largest decrease between 1980 and 1989 was coinage. In 1982, a copper alloy was replaced by zinc in the penny. This caused a significant drop in the use of copper for coinage because roughly three-quarters of all U.S. coins minted are pennies. A move is now afoot to create a new copper-base dollar coin to eventually replace the dollar bill. The dollar of today has a value equal to that of a quarter in the early 1960s, and Australia, Britain. Canada, and other countries have replaced their smallest-denomination bill with a coin.

Copper Supply and Reserves

In the future, the market for copper has the potential of expanding into such promising areas as superconductivity applications; marine uses, such as ship hulls and sheathing for offshore platforms; electric vehicles and solar energy (both of which will inevitably reemerge at some point when oil supplies tighten); fire sprinkler systems; and agricultural applications. However, the maintenance of present markets for copper and attempts to open up new ones must be balanced against the prospects for future copper availability. Table 12 gives the 1989 U.S. mine production of copper as compared with estimates for the U.S. copper reserve base, the worldwide reserve base, and the total worldwide copper resources. The projected U.S. reserves have grown over time from the 24×10^6 Mg (52×10^9 lb) estimated by the Paley Commission in 1952 to almost 90×10^6 Mg (198×10^9 lb) in 1989, despite the fact that tens of billions of pounds have been mined and put into service in the interim. One reason for this increase is that the continuous development of better extraction techniques has enabled worthless rock to be reclassified as useful ore.

Table 12 1988 U.S. mine production compared with estimates of copper reserves and resources

Production or reserves	Amount	
	Mg × 10^6	**lb × 10^9**
U.S. mine production	1.5	3.3
U.S. reserve base	90	198
World reserve base	566	1248
Total world resources	2300	5070
Land-base resources	1600	3530
Deep-sea nodules	700	1540

Going into the 1990s, the United States is nearly self-sufficient in copper and has averaged about 89% self-sufficiency over the last ten years; in comparison, the United States is only about 20% self-sufficient in aluminum.

Wrought Copper and Copper Alloy Products

Revised by Derek E. Tyler, Olin Corporation

Introduction

COPPER AND COPPER ALLOYS are produced in various mill-product forms for a variety of applications (Table 1). High electrical conductivity, corrosion resistance, ease of fabrication (including good machinability) and good heat-transfer properties are typical reasons for selecting copper alloys. About 90% of the total tonnage of wrought copper alloys sold by U.S. manufacturers is represented by the 16 application categories listed in Table 1.

Table 1 Major end-use applications for copper and copper alloys in the United States

Application	Mill products	Principal reason(s) for using copper[(a)]
Telecommunications	Copper wire	Electrical properties
Automotive: automobiles, trucks, and buses	Brass and copper strip, copper wire	Corrosion resistance, heat transfer, electrical properties
Plumbing and heating	Copper tube, brass rod, castings	Corrosion resistance, machinability

Building wiring	Copper wire	Electrical properties
Heavy industrial equipment	All	Corrosion resistance, wear resistance, electrical properties, heat transfer, machinability
Air conditioning and commercial refrigeration	Copper tube	Heat transfer, formability
Industrial valves and fittings	Brass rod, castings	Corrosion resistance, machinability
Power utilities	Copper wire and bar	Electrical properties
Appliances	Copper wire and tube	Electrical properties, heat transfer
Lighting and wiring devices	Alloy strip, copper wire	Electrical properties
Electronics	Alloy strip, copper wire	Electrical properties
Fasteners	Brass wire	Machinability, corrosion resistance
Military and commercial ordnance	Brass strip and tube	Ease of fabrication
Coinage	Alloy and copper strip	Ease of fabrication, corrosion resistance, electrical properties, aesthetics
Builders' hardware	Brass rod and strip	Corrosion resistance, formability, aesthetics
Heat exchangers	Alloy tube and plate	Heat transfer, corrosion resistance

(a) Although not specifically listed as a principal reason in all applications, ease of fabrication is a factor in all application categories.

This article describes the manufacturing processes used to produce wrought copper and copper alloys in the form of sheet and strip products, tubular products, and wire or cable. The stress-relaxation characteristics of copper alloys are also discussed in this article. Information on the properties, applications, and comparisons of specific wrought copper alloys is given in the articles "Introduction to Copper and Copper Alloys" and "Properties of Wrought Coppers and Copper Alloys" in this Volume.

Sheet and Strip*

OF THE VARIOUS WROUGHT COPPER alloys covered in the article "Introduction to Copper and Copper Alloys" in this Volume, several alloys are covered in ASTM specifications for sheet and strip products (Table 2). Composition limits and mechanical properties of these wrought alloys are given in the applicable ASTM specifications. Additional information on the properties of specific copper alloys used as sheet or strip is given in the article "Properties of Wrought Coppers and Copper Alloys" in this Volume.

Table 2 ASTM specifications for copper and copper alloy sheet and strip

Specification	Product description
B 36	Brass plate, sheet, strip, and roller bar
B 96 and B 96M (metric)	Copper-silicon alloy plate, sheet, strip, and rolled bar for general purposes
B 103	Phosphor bronze plate, sheet, strip, and rolled bar
B 121	Leaded brass plate, sheet strip, and rolled bar
B 122	Copper-nickel-tin alloy, copper-nickel-zinc alloy (nickel silver), and copper-nickel alloy plate, sheet, strip, and rolled bar
B 152 and B 152M (metric)	Copper sheet, strip, plate, and rolled bar
B 169 and B 169M (metric)	Aluminum bronze plate, sheet, strip, and rolled bar
B 194	Copper-beryllium alloy plate, sheet, strip, and rolled bar
B 291	Copper-zinc-manganese alloy (manganese brass) sheet and strip
B 422	Copper-aluminum-silicon-cobalt alloy, copper-nickel-aluminum-silicon alloy, copper-nickel-aluminum-magnesium alloy sheet and strip
B 465	Copper-iron alloy plate, sheet, strip, and rolled bar
B 534	Copper-cobalt-beryllium alloy, copper-nickel-beryllium alloy plate, sheet, strip, and rolled bar
B 591	Copper-zinc-tin alloy plate, sheet, strip, and rolled bar
B 592	Copper-zinc-aluminum-cobalt or nickel-alloy plate, sheet, strip, and rolled bar
B 694	Copper, copper alloy, and copper-clad stainless steel sheet and strip for electrical cable shielding
B 740	Copper-nickel-tin spinodal alloy strip

This section describes the manufacturing of copper alloy sheet and strip and how properties are controlled in the manufacturing process. The manufacture of sheet and strip in the modern brass mill begins with one of two basic casting operations: either the molten metal is cast in the form of slabs that are subsequently heated and hot rolled to coils of heavy-gage strip, or the metal is directly cast in strip form and coiled. The coils, in either case, then have their surfaces

milled to remove any defects from casting or hot rolling. The next set of operations provides the desired final gage and temper by a series of cold-rolling, annealing, and cleaning operations. Finally, the sheet or strip may be slit into narrower widths, leveled, edge rolled or otherwise treated, and packaged for shipment.

Raw Materials, Melting, and Casting

Raw materials from which the melt is prepared consist primarily of virgin copper, either electrolytic or fire-refined; selected clean scrap of known origin, carefully checked for composition; and special alloy elements such as virgin zinc, lead, tin, or nickel. Scrap is baled to make it dense, so it sinks below the surface of the molten metal in the furnace and melts rapidly. This is the first of many operations in which the quality of the finished product can be affected. In this case the impurities that can alter the processing characteristics of the copper alloys can be avoided or controlled to established tolerance levels. In copper-aluminum alloys, for example, excessive amounts of lead, zinc, silicon, or phosphorus will cause hot shortness and cracking during hot working and welding. In copper-zinc alloys (brasses), the effects of various impurities are as follows:

- *Lead* should be kept under 0.01% for hot rolling, although additions of lead up to 4% improve machinability in material processed by extrusion and cold working. Lead lowers room-temperature ductility in brass, and also leads to hot shortness above 315 °C (600 °F)
- *Aluminum* as high as 2% has no adverse effect on hot or cold working. However, annealing and grain size are affected
- *Arsenic* does not affect hot or cold working, but tends to refine the grain size, and thus to lower the ductility
- *Cadmium* is controversial; some claim as much as 0.10% has little effect, others would keep it under 0.05%
- *Chromium* affects temperature of anneal and grain size. This condition is aggravated when iron is present
- *Iron* chiefly affects annealing and magnetic properties
- *Nickel* restrains grain growth
- *Phosphorus* has no adverse effect up to 0.04%; it does, however, restrain grain growth, increase tensile strength, and lower ductility to some extent

Additional information on the effect of impurities in some specific copper is given in the article "Properties of Wrought Coppers and Copper Alloys" in this Volume.

Melting. In one melting method, the raw materials are discharged into hoppers that feed electric-induction melting furnaces. With this type of melting, the analysis of the raw materials is carefully controlled and few or no impurities are introduced during melting. The metal is protected from atmospheric oxidation by a cover of carbon or bone ash. When the composition and temperature have been determined to meet the requirements of the alloy being melted, the molten metal is transferred to a holding furnace.

Casting in Book Molds. For many years in brass mills, the molten metal was poured from the melting furnace into a pouring box that distributed it into long, rectangular book molds (split molds, hinged like a book). The slab cast in these molds is about 50 to 100 mm (2 to 4 in.) thick, $\frac{1}{2}$ to $\frac{3}{4}$ m (2 to 2.5 ft) wide, and about 2.5 m (8 ft) long. The book mold method has some important disadvantages: The maximum weight of a casting, and therefore the length of finished coil, are limited; molten metal is dropped 2.5 m (8 ft) from a pouring box to the base of the mold resulting in oxide generation and entrapment; and metal splash causes the bottom end of the bar to be spongy. The casting also varies from bottom to top in temperature and solidification rate with potential problems from shrinkage cavities, gas entrapment, surface laps, and mold coating defects.

Semicontinuous and Continuous Casting. During the period of 1960 to 1975, two other casting processes began to supplant book molds. These two methods are:

- Vertical direct-chill semicontinuous casting
- Horizontal continuous casting

The vertical direct-chill (DC) semicontinuous casting process (Fig. 1) is used to produce slabs of large cross section, which are subsequently reheated, hot rolled into heavy-gage strip, and coiled. The continuous casting process (Fig. 2) uses a horizontal mold and casts a thin, rectangular section in much longer lengths that are coiled directly without hot rolling. Both processes provide a cast product that is fine grained, sound, and generally free of nonmetallic inclusions.

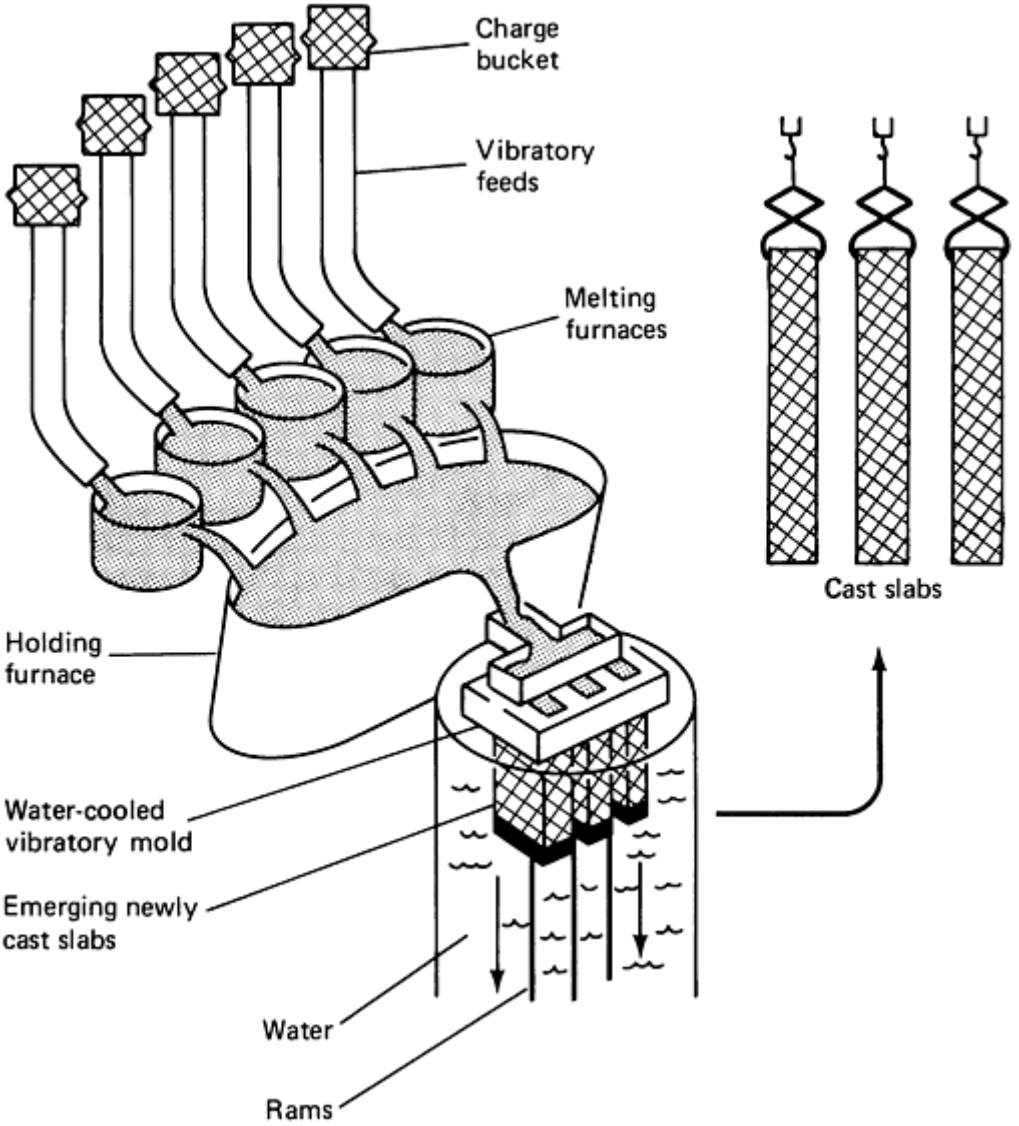

Fig. 1 Schematic sketch of vertical direct-chill (DC) semicontinuous casting of slabs

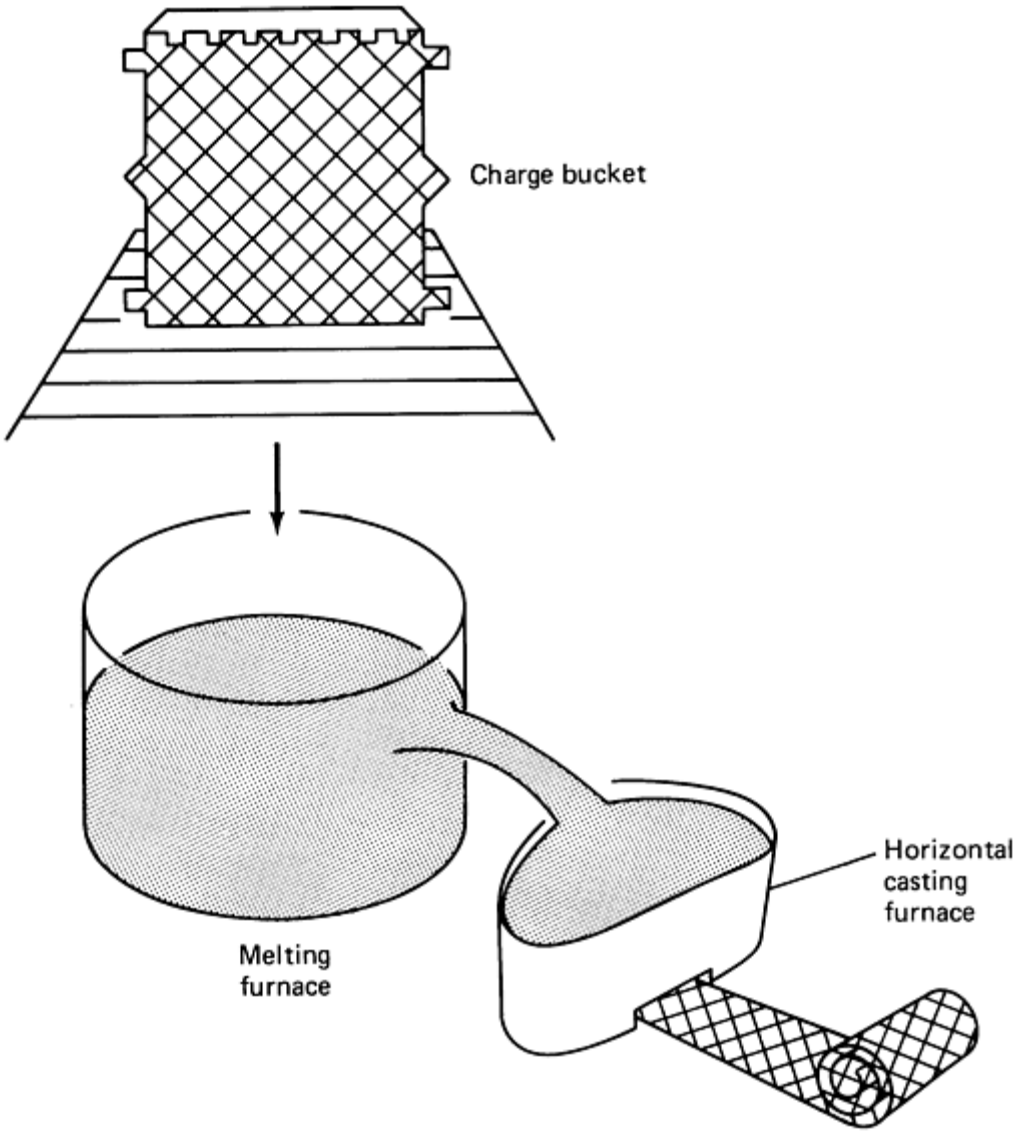

Fig. 2 Schematic sketch of horizontal continuous casting and coiling of strip. The cast product is coiled directly without hot rolling.

Vertical Semicontinuous Casting. In this method, molten metal flows into a short, rectangular, water-cooled mold, which initially is closed at one end by a plug on a movable ram or a starter bar (Fig. 1). The metal freezes to the plug and forms a shell against the mold surface. The ram is then steadily withdrawn, pulling the shell with it. As the shell exits the bottom of the mold, cold water is sprayed on it, cooling it rapidly and causing the contained molten metal to freeze. In this manner a continuously cast slab of the desired length is produced.

The vertical DC semicontinuous cast method is designed to produce large slabs from which heavy-weight finished coils can be made. Such large coils are the most economical to handle through the subsequent rolling and annealing processes at the brass mill, and later by the user who is fabricating finished parts.

Direct-chill slabs are hot rolled to produce coils, but not all alloys can be rolled by this method. Such alloys must be cold rolled, and the amount of reduction in thickness that can be achieved before annealing becomes necessary is small when compared to hot-rolling reductions. The problem with alloys that are hard to hot work is overcome with the horizontal continuous casting method. It offers a means of producing relatively thin castings in long lengths that can be coiled in the cast state and later reduced by cold rolling. Tedious, costly cold breakdown rolling and the attendant annealing are avoided.

In the DC casting process, more than one slab can be cast from each pour. A typical DC casting station consists of multiple melting furnaces and a large holding furnace. When the metal in each of the melting furnaces has been melted, the composition has been established, and the proper temperature attained, the motel metal is transferred to the holding furnace. Casting then proceeds from the holding furnace. Typically, three 6800 kg (15,000 lb) slabs of uniform composition are cast at one time. Smaller versions of this same process exist in the industry as well.

The horizontal continuous casting process (Fig. 2) also provides a product of excellent quality. Typically, one low-frequency electric-induction furnace is used as a melter. When the proper analysis is established and the pouring temperature attained, part of the metal is poured into a second, smaller electric-induction holding furnace. This furnace is constantly monitored to maintain the metal at the desired casting temperature. The casting mold is attached to the lower front of this furnace. It is a graphite mold contained in a copper, water-cooled jacket. A silicon carbide plate in the front of the furnace contains a slot that opens into the mold. At the beginning of a cast, a starter bar is inserted into the mold and the metal freezes to it. The mold is typically inches long.

The cast bar, frozen to the starter bar, is continuously withdrawn as the metal freezes in the mold. Although it is a simple process, its practice requires that tolerances on mold dimensions be held to a fraction of a millimeter (a few ten-thousandths of an inch) and exceptional meld cleanliness be maintained. Any dross or other foreign material that enters the graphite mold will quickly destroy it. Mold sizes range from 250 to over 600 mm (10 to 24 in.) in width and from about 10 to 15 mm ($\frac{3}{8}$ to $\frac{5}{8}$ in.) in thickness. A saw or shear in the withdrawal line cuts the bars off at the desired length, and they are coiled in preparation for subsequent processing. This process lends itself to in-line coil milling and to maximum coil lengths, dependent only on handling equipment capacity and practical processing of the material itself.

The rapid chilling of the small amount of metal in the horizontal mold produces a fine, equiaxed cast grain structure. The metal drawn from the furnace as it solidifies always has a pool of molten liquid above it where gases and nonmetallic impurities tend to collect. The cast bar is generally free of porosity and defects caused by solid inclusions.

Some smaller mills depend almost entirely on horizontal casting, regardless of alloy, because the process is readily adaptable to the casting of small quantities of several alloys.

Hot Rolling of Direct-Chill Semicontinuous-Cast Slabs

The rolling of slab into sheet or strip products is performed for reduction in thickness and/or grain refinement. The initial rolling of slabs is for grain refinement as well as to begin reduction in thickness. For copper and copper alloys that can be hot worked, the quickest and most economical method of reduction is hot rolling.

To prepare the slab for hot rolling, the top or gate end is trimmed by sawing and then it is conveyed into a furnace for heating. Slabs or bars of the same alloy are grouped together in a lot and processed through the furnace and the hot mill. The furnace temperature and the time for each bar to pass through the furnace are adjusted in order to allow the bar to reach the appropriate temperature throughout its thickness, length, and width by the time it passes through to the exit conveyor.

Temperature control is an important factor in hot rolling. Hot rolling can be accomplished only within a certain temperature range for each alloy. The bars will be damaged and have to be scrapped if hot rolling is attempted at a temperature that is too high or too low. Further, for all alloys, the grain size of the hot-rolled product is determined by the temperature at the last rolling pass. Subsequent processing (that is, cold working and annealing) to meet specified properties, is dependent on this grain size. In some alloys, elements go into solution above certain temperatures and then precipitate out at lower temperatures. By completing hot rolling at a temperature above the precipitation temperature and quenching in a high-pressure water spray, solution heat treatment can be accomplished. This also affects both the physical and the mechanical properties attained in subsequent processing.

The roll stand used for hot rolling is a very sturdy mill having two rolls (two-high) whose direction of rotation can be rapidly reversed so the strip can be passed back and forth between them. The large horizontal rolls that reduce the thickness are supplemented by a pair of vertical edging rolls. The vertical rolls are needed to maintain the proper width by rolling edges because an appreciable spread in width takes place during hot rolling. The rolls are water cooled to avoid overheating, which would cause the surfaces to crack and check. Further, a polishing stone continuously dresses the rolls as they operate. As the thickness is reduced, the bar length increases proportionately. After the final rolling pass, the metal is spray cooled and coiled. Rolling temperatures and the percent of reduction per pass are designed to suit each alloy.

Milling or Scalping

Along with continuous casting, an equipment development that significantly advanced production is the high-speed coil milling machine. All coppers and copper alloys, produced with the good surface expected of brass mill sheet and strip, have their surfaces removed or scalped by a machining operation after breakdown rolling to remove all surface oxides remaining from casting or hot rolling. This operation is accomplished in a specially designed milling machine having rolls with inset blades that cut or mill away the surface layer of metal. The capability of this machine to handle the product in coiled form means that a much longer bar can be conveniently and economically milled.

Following hot rolling the DC cast bars are coil milled, and after careful surface inspection are ready to be applied on orders for processing to final gage, temper, and width. Horizontally continuous-cast bars arrive at this stage by a somewhat different processing path. The coiled cast bars are annealed to provide a stress-free structure of maximum ductility. They are then cold rolled to work the structure sufficiently, so a fully recrystallized wrought grain structure will develop in the subsequent anneal. The bars are then scalped by milling. Both hot-reduced and cold-reduced milled bars are typically in the thickness range of 7.5 to 10 mm (0.300 to 0.400in.).

Cold Rolling to Final Thickness

The sequence of operations for processing metal from milled condition to finish thickness or gage is designed to meet specified requirements for each application.

The earliest stages of cold rolling and annealing are designed to achieve the largest practical reduction in thickness (limits to the amount of reduction are discussed in the section "Effect on Properties" in this article). In the final rolling operations, where the strip is brought to finish gage, the cold reductions are designed to meet the specified property (temper) requirement. Meeting the tensile strength requirement, which is the basic mechanical property requirement for rolled tempers, is accomplished by cold rolling to the appropriate ready-to-finish gage, annealing to the desired grain size, and then rolling to finish gage. The percent reduction between ready-to-finish and finish gage is chosen to provide the amount of work hardening needed to produce the tensile strength required. Unavoidable small variations in thickness at both ready-to-finish and finish gages and in grain size from the ready-to-finish anneal require that the tensile strength requirement be given as range, rather than a single value.

Rolling Mills. All thickness reduction is accomplished by cold rolling, and a variety of rolling mills are used. Cold rolling of coppers and copper alloys into sheet and strip of excellent quality requires a combination of skillful workmanship, knowledge, and good rolling mills. To keep cost as low as possible and competitive, the reduction in thickness to final gage needs to be accomplished in the fewest operations compatible with quality requirements. The basic problem is to reduce the thickness as much as possible in each rolling operation while maintaining uniformity of thickness across the width and length of a coil that is 60 to 180 m (200 to 600 ft) long at the first rolling pass and could be 7500 m (25,000 ft) long if rolled to 0.1 mm (0.004 in.) finish gage. Coupled with the need to maintain uniformity of thickness through all processing stages is the need to maintain flatness across the width and length of the coiled metal. Metal with uniformity of flatness across and long its length is described as having good shape. It is free of humps, waves, and buckles.

A rolling mill is capable of applying a large, but still limited, force upon the surfaces of the metal as it passes between the rolls to reduce its thickness. The applied force is spread across the contact area of the rolls on the metal. The larger the contact area, the smaller the force that is applied per unit of area and the smaller the reduction in thickness that can be achieved per pass through the rolls. Rolls of small diameter will have a small contact area, and greater force per unit of area. Small-diameter work rolls are most desirable for providing maximum utilization of roll force in reducing metal thickness, but they lack the stiffness required. The wider the metal to be rolled, the longer the rolls, and the greater the tendency for the rolls to bend or spring. To overcome the tendency, four-high and cluster rolling mills are used for cold rolling in the brass mill.

Four-high rolling mills contain a pair of work rolls of relatively small diameter (for example, 300 mm, or 12 in.). A second pair of rolls, of large diameter (for example, 900 mm, or 36 in.), is placed above and below the work rolls in the stand to back them up and prevent them from springing. This arrangement allows the advantage of the small contact area of small work rolls and the transmittal of high force through the large backup rolls, while maintaining the rigidity required for gage control. The minimum size of the work rolls is limited by the forces in rolling, which tend to bow them backward or forward during rolling.

Cluster rolling mills (for example, Sendzimir or "Z" mills) were designed to counteract both the vertical and horizontal elements of the rolling forces and thus enable the use of minimum-diameter work rolls. In cluster mills the work rolls are backed up by a cluster of backup rolls placed with respect to the work rolls so they contain the rolling forces and prevent bending or springing of the work rolls. By the use of such rolling mills, the thickness from width edge to edge across the 600 to 915 mm (24 to 36 in.) metal coils can be kept uniform through each gage reduction by rolling. This edge-to-edge gage control contributes to the maintenance of good shape. Good shape contributes to the production of flat, straight metal when slitting to the final specified width needed by the consumer.

The control equipment included in the rolling mill is a feature that bears directly on control of the gage from end to end of a coil of metal during rolling. For thickness control during high-speed rolling, continuous measurement of this dimension is a necessity. Rolling mills are equipped with x-ray and beta-ray instruments, which continuously gage the metal and provide a continuous readout of thickness. There are also control devices that actuate the screws in the roll housings and automatically open or close the gap between the work rolls to adjust the thickness being produced as required. These gages may also adjust back tension and forward tension applied by payoff and recoil arbors to effect changes in the thickness of the rolled metal.

Roll Lubricants. Rolling also exerts considerable influence on the surface quality of the metal. Work rolls are made of hardened steel, much harder than the copper alloy being rolled. As the rolls squeeze the metal to reduce its thickness, forward and backward slip between the rolls and the metal surfaces takes place. The frictional forces between the roll and metal surfaces, if direct contact was made, would tear the surface of the metal and load the roll surfaces with bits of the metal. To avoid damaging the surfaces in this manner, the metal and roll surfaces are flooded with cushioning lubricants. The selection of roll lubricants that will provide the protection needed without staining the metal, will be readily removable from the metal surfaces, and will not interfere with the rolling mill performance is an important engineering function that influences the economic production of high-quality copper alloy strip.

Effect on Properties. The more metal is cold worked, the harder and stronger it becomes. The hardening that occurs when copper and copper alloys are cold rolled allows each of them to be produced with a range of strengths or tempers that are suitable for a variety of applications. Starting with annealed temper, the metal will increase in strength approximately proportionally by the amount of reduction by cold rolling. A series of standard cold-rolled tempers for each copper and copper alloy has been established. A typical plot of reduction versus tensile properties and hardness is shown in Fig. 3 for C26000 (cartridge brass). Figures 4 and 5 show, respectively, the variation of tensile strength and elongation for various degrees of reduction (and the associated rolling "temper" name). More information on the properties of rolled tempers for specific copper alloys is given in the article "Properties of Wrought Coppers and Copper Alloys."

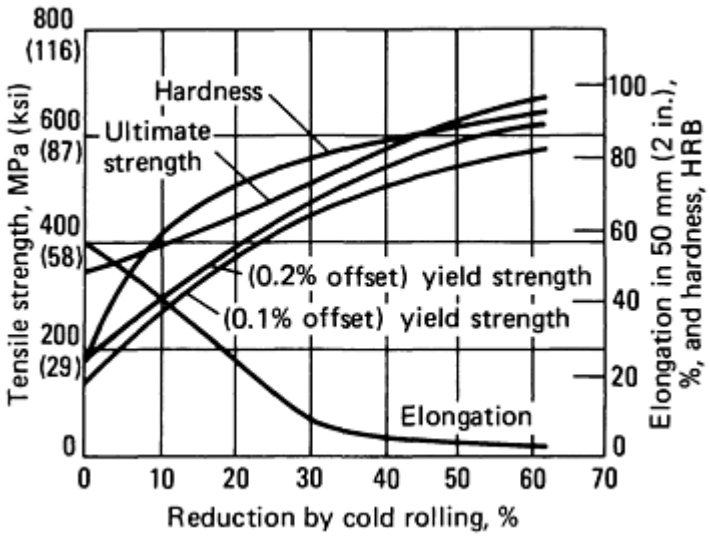

Fig. 3 The effect of cold rolling on the strength, hardness, and ductility of annealed Alloy C26000 when it is cold rolled in varying amounts up to 62% reduction in thickness

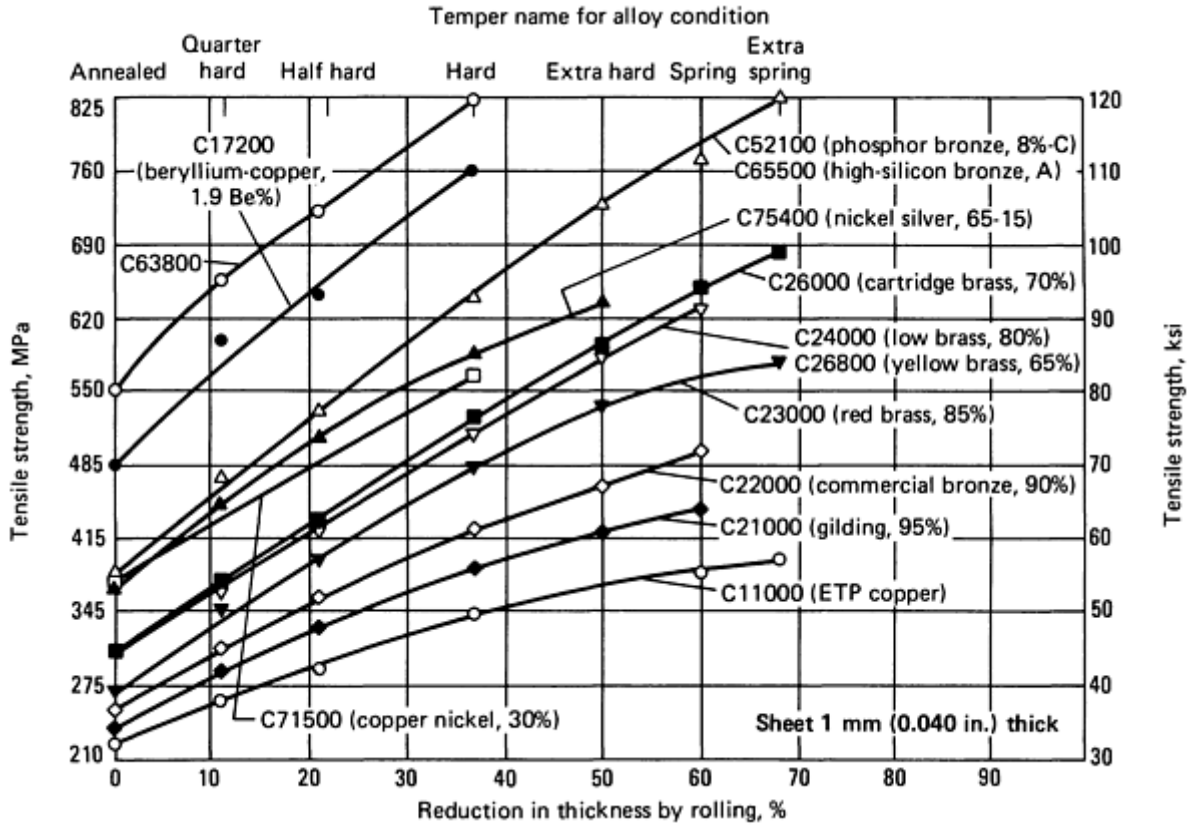

Fig. 4 Tensile strength of single-phase copper alloys as affected by percentage reduction in thickness by rolling (temper). Curves of lesser slope indicate a lower rate of work hardening and a higher capacity for redrawing.

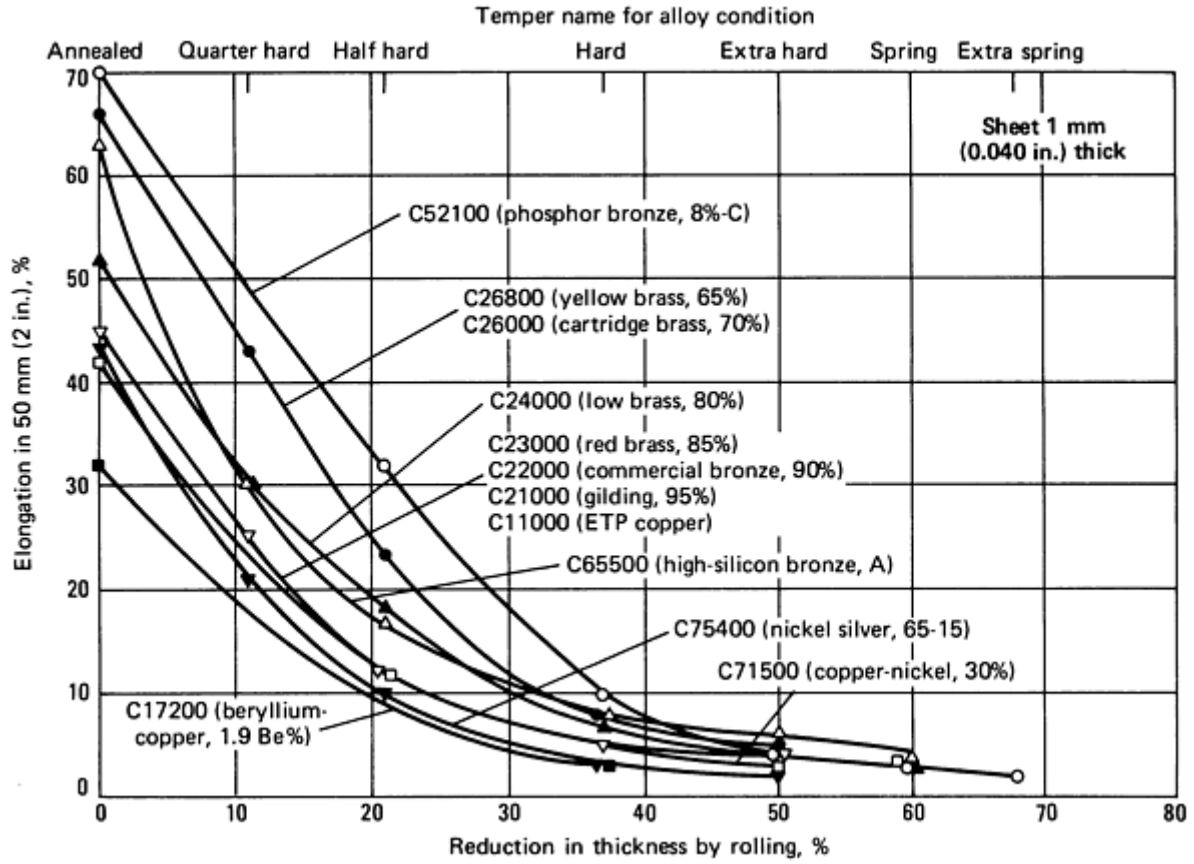

Fig. 5 Elongation of single-phase copper alloys as affected by percentage reduction in thickness by rolling (temper). The elongation values for a given percentage of cold reduction indicate the remaining capacity for deep drawing in a single operation.

For each of the coppers and copper alloys there are limits to the amount of cold reduction that is desirable before annealing the metal to provide a recrystallized soft structure for further cold reduction. Some alloys, such as the phosphor bronzes, the high-zinc-content nickel silvers, and the aluminum-containing high-zinc brasses work harden rapidly . As they are cold rolled, they quickly become too hard for further reduction and must be annealed.

With large amounts of cold reduction prior to annealing, some coppers and copper alloys will develop differences in their strength and ductility when these properties are measured along the direction of rolling, compared to measurements across the direction of rolling. This directionality in mechanical properties arises from the fact that the normal random orientation of the atomic planes from grain to grain is gradually forced into a pattern conforming to the constant working of the metal in one direction. This directionality can affect the fabricability and final performance of the strip or sheet. Its control requires that the amount of reduction between anneals and the temperature of successive anneals be carefully controlled.

Annealing

The basic purpose of annealing is recrystallization and softening to prepare the metal for further cold working in the mill or by the consumer. Anneals are usually designed to produce a chosen grain size for a specified tensile strength, which in annealed copper and copper alloys is largely dependent on grain size, with few exceptions. The effect of grain size on the tensile strength of copper and brass strip is shown in Fig. 6. The effect of grain size on the elongation of C26000 is shown in Fig. 7.

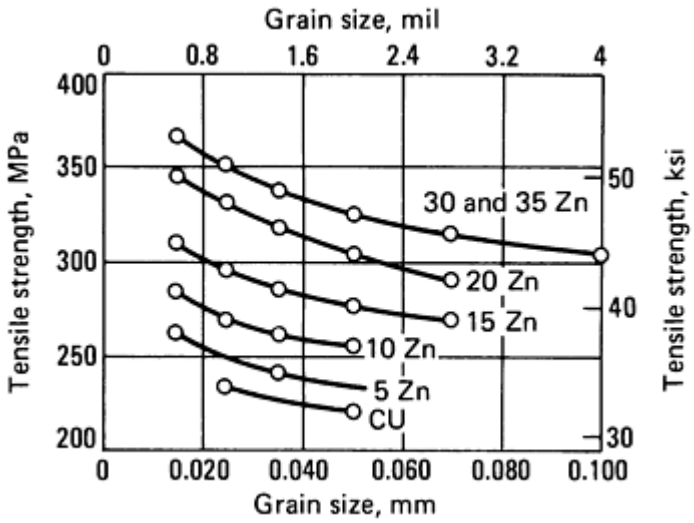

Fig. 6 Effect of grain size on tensile strength of annealed 0.040 in. strip of copper and brasses of designated zinc contents. Source: Ref 1

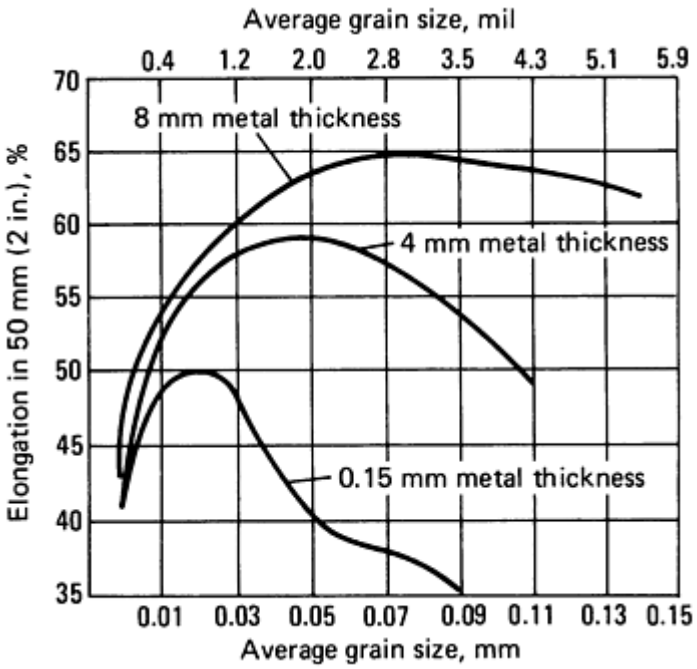

Fig. 7 The relationship between grain size and thickness versus elongation for Alloy C26000

Besides strength, grain size also affects workability, the control of directionality, and surface roughness. The consistent performance of the metal in subsequent cold working is dependent on grain-size uniformity. All these factors are considered when selecting the grain size to be established by any of the anneals included in the processing of each coil. Table 3 lists recommended applications of grain size ranges. Uniformity of grain size is influenced by the type of annealing furnaces and the method of operation. Each type of annealing method has certain advantages and disadvantages.

Table 3 Available grain-size ranges and recommended applications

Average grain size, mm	**Type of press operation and surface characteristics**
0.005-0.015	Shallow forming or stamping. Parts will have good strength and very smooth surface. Also used for very thin metal
0.010-0.025	Stampings and shallow drawn parts. Parts will have high strength and smooth surface. General use for metal under 0.25 mm (0.010 in.) thick
0.015-0.030	Shallow drawn parts, stampings, and deep drawn parts that require buffable surfaces. General use for gages under 0.3 mm (0.012 in.)
0.020-0.035	This grain size range includes the largest average grain that will produce parts essentially free of orange peel. For this reason it is used for all sorts of drawn parts produced from brass up to 0.8 mm (0.032 in.) thick.
0.025-0.040	Brass with 0.040 mm average grain size begins to show some roughening of the surface when severely stretched. Good deep drawing quality for 0.4 to 0.5 mm (0.015 to 0.020 in.) gage range

0.030-0.050	Drawn parts from 0.4 to 0.635 mm (0.015 to 0.025 in.) thick brass requiring relatively good surface, or stamped parts requiring no polishing or buffing
0.040-0.060	Commonly used grain size range for general applications for deep and shallow drawings of parts from brass in 0.5 to 1.0 mm (0.020 to 0.040 in.) gages. Moderate orange peel may develop on drawn surfaces
0.050-0.080, 0.060-0.090, 0.070-0.120	Large average-grain-size ranges are used for deep drawing of difficult shapes or deep drawing parts for gages 1.0 mm (0.040 in.) and greater. Drawn parts will have rough surfaces with orange peel except where smoothed by ironing

Coil Annealing. When annealing coiled metal, heat from the furnace must be absorbed through the coil surface and then penetrate to the innermost wraps, mostly by conduction. Temperature tends to vary in the coil with distance from the heat-absorbing surfaces. Coil annealing must be carefully controlled, by slowly applying heat at a rate that will avoid overheating the surface, while the temperature of the inner wraps rises and equalizes with that of the outer wraps.

Coil annealing may be done in a roller hearth furnace where the coils are slowly moved through the furnace as they are gradually heated to the annealing temperature. This type of furnace usually does not have a prepared atmosphere, but the products of combustion fill the furnace and reduce the metal oxidation rate. More commonly, coil annealing is done in bell furnaces where a controlled atmosphere can be maintained. The annealing unit consists of a base on which the coils are stacked. Under the base is a fan for circulating the hot gases through the load, to provide more uniform and rapid heating. Surrounding the base is a trough, which may be filled with water, oil, or some other material to seal the inner hood when it is placed over the metal load to enclose it for atmosphere control.

In this type of batch annealing, bell furnaces capable of annealing up to 45 Mg (100,000 lb) of metal at a time are used. After the metal is stacked on the base, temperature-control thermocouples are placed throughout the load to continuously measure the temperature. The inner hood or retort is placed over the load and sealed. Controlled atmosphere begins to flow trough the hood, purging the air. The furnace is placed over the hood and heating is begun.

In the well-equipped brass mill, large groups of such annealing units may be connected to a central process-control computer. As the furnace and load thermocouples measure the temperatures and relay them to the control unit, the heat input is constantly adjusted to maintain temperature uniformity in the load. This controlled temperature rise also allows roll lubricants to vaporize and be carried off before the metal gets so hot that surfaces can be harmed. After the metal has reached the annealing temperature, it is held there for a short period or soaked to provide maximum uniformity. Then the furnace is turned off and removed, and the metal cools in the controlled atmosphere under the inner hood. Cooling may be aided by a cooling cover containing a water spray system. The inner hood is not removed until the metal temperature is low enough that no discoloring or oxidation of the metal takes place.

The controlled atmosphere is produced in gas-cracking units. Combustible gases are burned with sufficient air to oxidize all the gaseous elements. The products of this combustion are then refined, and all gases that would be harmful to the metal surfaces are removed by chemical means. Those remaining pass into the annealing hoods, where they expel the air and protect the metal during annealing. For most coppers and copper alloys a slightly oxidizing atmosphere is desirable. For copper Alloy C11000, the atmosphere must be nearly free of hydrogen and the annealing temperature low enough to avoid hydrogen embrittlement. For alloys containing zinc, the small amount of oxygen in the atmosphere combines with the zinc fumes given off and prevents them from attacking the metal parts in the annealing unit. The oxide film that forms on the surface is very thin and readily removed in the subsequent cleaning processes.

Advantages and Disadvantages. One of the advantages of coil annealing in a controlled atmosphere furnace is that the surface of the metal can be readily restored to its natural color by appropriate cleaning following the anneal. The rather rare exception is when an abnormally high annealing temperature is required that causes excessive oxidation or dezincification of a high-zinc brass. Special cleaning methods that remove surface metal are then required to correct this condition. The more common situation is that annealing is done in a well-controlled atmosphere and followed by normal cleaning practices. This produces a metal furnaces uniform in color and free from detrimental oxides.

A disadvantage of coil annealing is that large coils of some alloys in thinner gages can be easily damaged. When the coiled metal is heated, it expands and the coil wraps get tighter. One wrap can become welded to the next because of the high temperature and pressure encountered, usually making the coil unsuitable for further processing. Coil annealing is also time consuming. A large bell furnace full of metal may require from 24 to 40 h to complete an annealing cycle; additional is the time needed for cleaning, done as a separate operation.

Continuous Strand Annealing. In the late 1940s continuous strand, or strip annealing lines came into use in brass mills. From these early beginnings, the high-speed vertical strip annealers were developed in the 1960s. Annealing lines of this type are now used for annealing copper and copper alloy strip in thicknesses from under 0.25 mm to over 3 mm (0.010 to over 0.125 in.). When several such lines are available, a variety of thickness ranges can be rapidly annealed, providing great flexibility in production scheduling and enabling fast delivery of finished strip.

Because every foot of a coil is exposed to the same temperature as it passes through the strip-annealing furnaces, grain size from end to end should be uniform. Furnace instrumentation continuously records the furnace temperature and controls the heat input. Strip speed through the furnace is similarly monitored. The combination of furnace temperature and speed determines the temperature attained in the metal, and, therefore, the grain size. Samples commonly are cut from each end of each coil after strip or coil annealing, and the grain size or mechanical properties are determined as a further control on the quality uniformity of the product.

The continuous-strip anneal lines include payoff reels, a stitcher for joining the front end of a coil to the trailing end of the preceding one, a degreaser for removing roll lubricants, looping towers for metal storage, a seven-story-high vertical furnace that includes a heating zone, a controlled-atmosphere cooling zone, and a water quench tank. This is followed by acid cleaning tanks, a water rinse, a drying oven, and a reel for recoiling the metal. The fact that the metal is uncoiled before passing through the furnace removes annealing limitations on coil length. Degreasing units remove roll lubricants from the metal surfaces before the metal enters the furnace, so a clean, uniform surface is presented for annealing. The metal passes over a large roller outside the furnace at the top and does not touch anything inside while it is being heated. It then passes under another large roller at the bottom in the cooling water tank. This arrangement avoids any possibility of surface damage to the hot metal, which was common in the earlier horizontal-strip anneal furnaces. Although the furnace temperature is high, the metal is exposed to it for only a few seconds.

The furnace atmosphere may consist of hot burned gases that are blown against the strip surfaces to heat the metal. The metal is rapidly and uniformly raised to the annealing temperature as it passes through the heating zone of the furnace, and is then cooled rapidly by cold burned gases as it passes through the cooling zone, still protected from excessive oxidation.

Following a water quench, which completes the cooling cycle, the metal passes through the cleaning tanks. A normal cleaning solution is dilute sulfuric acid, which dissolves most of the oxide film left on the metal be annealing. As noted earlier, the atmosphere in the furnace must be slightly oxidizing to prevent zinc fumes from attacking the furnace steel framework. For most coppers and copper alloys this small amount of surface oxidation is not detrimental after normal cleaning, and they are regularly strip annealed throughout processing, including finish gage. They have a faintly different color than does bell-annealed and cleaned metal, but the difference is so slight that it is insignificant in most applications. In fact, brasses containing 15% or more of zinc have surfaces that many users feel are better suited for later fabricating if the strip has been continuously annealed. The metal surface holds lubricants well and has a low coefficient of friction against tool steels, making it desirable for press forming and deep drawing. It is likely that some zinc oxide remains on the surface and acts as a natural lubricant. After acid cleaning, rinsing, and drying, the surface is usually coated with a detergent solution or a light sulfur-free oil to protect it during handling in transit.

Stress-relief heat treatments are sometimes required after the harder rolling tempers such as Extra Hard, Spring, and Extra Spring (Fig. 5). Although the internal residual stresses left in the strip, from edge to edge and along the length, from this severe working are relatively uniform, small variations sometimes exist that can cause a difference in spring-back during subsequent forming operations. To reduce such residual-stress variations, the metal is heated to a temperature below the recrystallization temperature, usually between 200 and 350 °C (390 and 660 °F), and held there for 0.5 to 1 h. Such treatment results in a product with uniform spring-back.

Heating for stress relief also can change other properties. In phosphor bronzes tensile elongation is increased and strength slightly decreased. These changes are an advantage in the case of difficult-to-form parts requiring maximum strength. In the high-zinc alloys, stress-relief heat treatment increases strength and decreases tensile elongation. In this case, the formability may be decreased.

Cleaning

As noted, following each anneal or heat treatment the metal is cleaned. After cleaning in the appropriate solution the metal is thoroughly washed in water, including brushing with wire or synthetic brushes when needed. The rinse water usually contains a tarnish inhibitor, such as tolutriazole or benzotriazole, to protect the metal. For product at finish gage the rinse tank has a detergent solution added that further protects the metal when dried and also lubricates it slightly to reduce the danger of friction scratches during coiling and uncoiling. Squeegee rolls are used to remove the bulk of the rinse water, and drying ovens in the cleaning lines complete the job.

If desired for subsequent working, annealed strip can also be coated with a film of light nontarnishing oil for protection and lubrication. Metal that is finished in a rolled temper will normally contain a light film of rolling lubricant on the surfaces to protect and lubricate it during coiling and uncoiling and in transit.

Slitting, Cutting, and Leveling

Following the final rolling or the final annealing and cleaning, the strip or sheet product is slit to its final width. Slitting is accomplished by opposing rotary discs mounted on rotating arbors. These knife sets mesh as the metal passes between them and shear it into a variety of widths. Slitter knife sets are assembled on arbors. The sets are assemblies of disc knives, cylindrical metal and rubber fillers, and shims. Clearance between the opposing knife edges must be exact for the thickness, alloy, and temper of the metal to be slit. The distance between knife edges on each arbor must be set accurately to cut the specified width within the tolerance allowed. Knife edges must be sharp and continuously lubricated. Dull knives or incorrect clearance between knives for the particular material being slit causes distorted or burred edges.

Camber, that is, departure from edgewise straightness, has often been attributed incorrectly to poor slitting practice. It is true that strips can be pulled crooked when slitting a large number of them from a wide bar, because the slit strips are sometimes fanned out for subsequent coiling using divider plates. This difficulty is diminished on slitters equipped with over-arm separators because strips need not be fanned out as much. This kind of problem can be anticipated, and, if necessary, the bar split at an intermediate stage in processing prior to the final slitting, so fewer cuts are made in this last operation.

Instead of slitting practice, it is the maintenance of good shape during each of the rolling operations that is most important in the control of camber. If good control of thickness across the width is maintained at each rolling operation, the edges and centers of the bar will have elongated uniformly, and when narrow strips are slit they will remain satisfactorily straight.

The shape of the slit edge of strip depends to a great extent on the properties of the metal being slit. The metal may be thick, soft, and ductile, at one extreme of shearing characteristics, to thin, hard, and brittle, at the other extreme. Between these fall all the variations that are characteristic of the gage, alloy, and temper required for the final application. A certain amount of edge distortion cannot be avoided when slitting thick, soft metals (Fig. 8). Even with the best slitter setup, the cross section of a narrow strip will tend to have a "loaf" shape. By contrast, thin hard phosphor bronze or nickel silver in narrow widths will have a cross section of rectangular shape with square cut edges. Leaded brasses shear cleanly because the lead, present as microscopic globules, lowers the ductility and shear strength. It is for this purpose--ease of cutting and machinability--that lead is added to copper alloys.

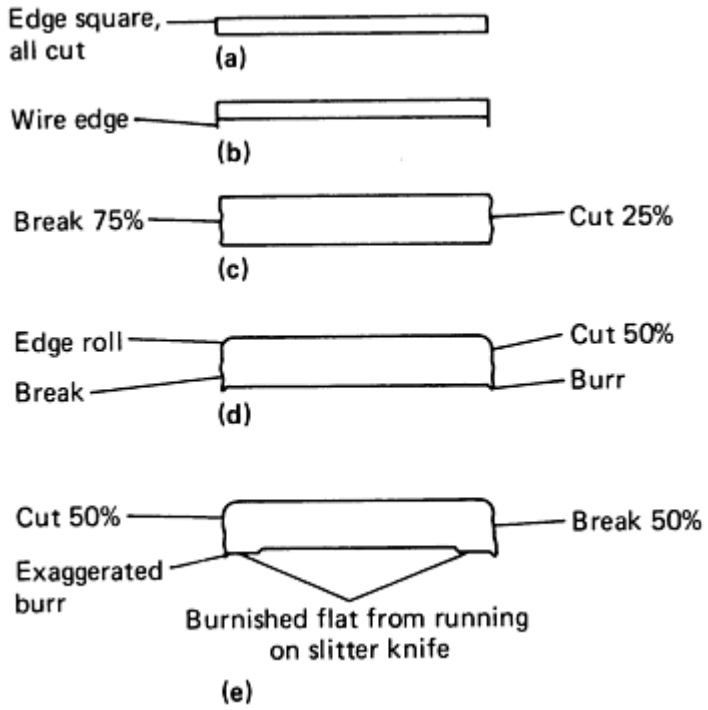

Fig. 8 The different edge contours that can result from slitting, depending on thickness, temper, and alloy. (a) Thin gages; all alloys. Edges square with almost no break. (b) Thin gages. On soft metal, set must be adjusted to avoid wire edges. (c) Heavy gages; hard metal; all alloys. Edges square with 25% cut balanced break. (d) Heavy gages; soft metal; all alloys. Edge square with slight roll. (e) As a rule, the heavy-gage, high-copper alloys have the greatest tendency to roll and burr.

As the metal comes from the slitter, both edges of each strip, if distorted, will be distorted in the same direction. The immediately adjacent strips will have edges distorted in the opposite direction. There are some applications for which it is desirable that any edge distortions be in the same direction relative to the part being produced. The user recognizes that the edges of every other coil will be opposite and arranges to uncoil either over or under the coil so the edge condition entering the press is always the same (Fig. 9).

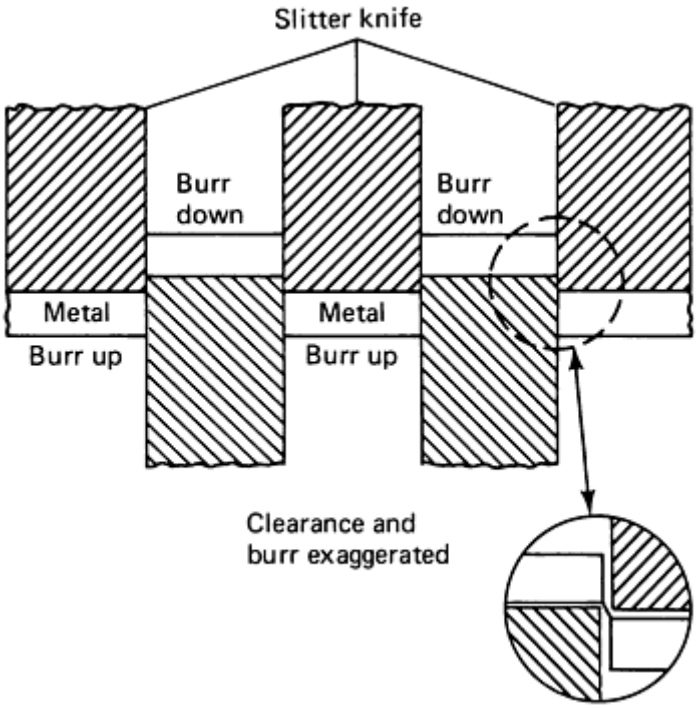

Fig. 9 Burr up/burr down relationship in slitting setup. Such burrs are never excessive on strip released for shipment.

Coil set, the curvature that remains in a strip when it is unwound from a coil, is an inherent characteristic. The degree of this coil set is dependent on a number of factors. The final coiling operation takes place after slitting, and some measure of control over coil set can be exercised at this process stage. However, there are frequently other considerations that also have a bearing. For annealed tempers and the lightly cold-rolled tempers such as $\frac{1}{4}$Hard and $\frac{1}{2}$Hard, coil set may be established during final coiling. The degree of set will be lowest when the largest inside diameter compatible with the specified gage and weight can be used. For the harder rolled tempers and lighter gages, the coil set is actually controlled in the final rolling operation, rather than during coiling, and is usually kept to a minimum.

Processing operations after final slitting are occasionally required. Blanking and edge rolling are two such operations.

Blanking of squares or rectangles is generally done by cutting to length. The metal is first flattened and then cut to length on a flying shear. If the tolerance on length cannot be achieved on the automatic cutting lines, the cut lengths are resheared by hand. When circular blanks are required, they are die cut on a press. The tolerances for the diameter of circular blanks are the same as those for slit metal of corresponding width.

Edge rolling can produce rolled square edges, rounded edges, rounded corners, or rolled full-rounded edges. It can only be done on a limited range of gage, width, and temper combinations. Properties and tolerances are generally the same as those for similar slit-edge products.

Tubular Products

TUBE AND PIPE made of copper or copper alloys are used extensively for carrying potable water in buildings and homes. These products also are used throughout the oil, chemical, and process industries to carry diverse fluids, ranging from various natural and process waters, to seawater, to an extremely broad range of strong and dilute organic and inorganic chemicals. In the automotive and aerospace industries, copper tube is used for hydraulic lines, heat exchangers (such as automotive radiators), air conditioning systems, and various formed or machined fittings. In marine service, copper tube and pipe are used to carry potable water, seawater, and other fluids, but their chief application is in tube bundles for condensers, economizers, and auxiliary heat exchangers. Copper tube and pipe are used in food and beverage industries to carry process fluids for beet and cane sugar refining, for brewing of beer, and for many other food-processing operations. In the building trades, copper tube is used widely for heating and air conditioning systems in homes, commercial buildings, and industrial plants and offices. Table 4 summarizes the copper alloys that are standard tube alloys, and gives ASTM specifications and typical uses for each of the alloys.

Table 4 Copper tube alloys and typical applications

UNS number	Alloy type	ASTM specifications	Typical uses
C10200	Oxygen-free copper	B 68, B 75, B 88, B 111, B 188, B 280, B 359, B 372, B 395, B 447	Bus tube, conductors, wave guides
C12200	Phosphorus deoxidized copper	B 68, B 75, B 88, B 111, B 280, B 306, B 359, B 360, B 395, B 447, B 543	Water tubes; condenser, evaporator and heat-exchanger tubes; air conditioning and refrigeration, gas, heater and oil burner lines, plumbing, pipe and steam tubes; brewery and distillery tubes; gasoline, hydraulic and oil lines; rotating bands
C19200	Copper	B 111, B 359, B 395, B 469	Automotive hydraulic brake lines; flexible hose

C23000	Red brass, 85%	B 111, B 135, B 359, B 395, B 543	Condenser and heat-exchanger tubes, flexible hose; plumbing pipe; pump lines
C26000	Cartridge brass, 70%	B 135	Plumbing brass goods
C33000	Low-leaded brass (tube)	B 135	Pump and power cylinders and liners; plumbing brass goods
C36000	Free-cutting brass		Screw machine parts; plumbing goods
C43500	Tin brass		Bourdon tubes; musical instruments
C44300, C44400, and C44500	Inhibited admiralty metal	B 111, B 359, B 395	Condenser, evaporator and heat-exchanger tubes; distiller tubes
C46400, C46500, C46600, and C46700	Naval brass		Marine hardware, nuts
C60800	Aluminum bronze, 5%	B 111, B 359, B 395	Condenser, evaporator and heat-exchanger tubes; distiller tubes
C65100	Silicon bronze B	B 315	Heat-exchanger tubes; electrical conduits
C65500	Silicon bronze A	B 315	Chemical equipment, heat-exchanger tubes; piston rings
C68700	Arsenical aluminum brass	B 111, B 359, B 395	Condenser, evaporator and heat-exchanger tubes; distiller tubes
C70600	Copper-nickel, 10%	B 111, B 359, B 395, B 466, B 467, B 543, B 552	Condenser, evaporator and heat-exchanger tubes; salt water piping; distiller tubes
C71500	Copper-nickel, 30%	B 111, B 359, B 395, B 446, B 467, B 543, B 552	Condenser, evaporator and heat-exchanger tubes; distiller tubes; salt water piping

Frequently, resistance to corrosion is a critical factor in selecting a tube alloy for a specific application. Information that can help determine the alloy(s) most suitable for a given type of service can be found in the article "Introduction to Copper and Copper Alloys" in this Volume.

Joints

Joints in copper tube and pipe are made in various ways. Permanent joints can be made by brazing or welding. Semipermanent joints are made most often by soldering, usually in conjunction with standard socket-type solder fittings,

but threaded joints also can be considered semipermanent joints for pipe. Detachable joints are almost always some form of mechanical joint--flared joints, flange-and-gasket joints, and joints made using any of a wide variety of specially designed compression fittings are all common.

Properties of Tube

As with most wrought products, the mechanical properties of copper tube depend on prior processing. With copper, it is not so much the methods used to produce tube, but rather the resulting metallurgical condition that has the greatest bearing on properties. Table 5 summarizes tensile properties for the standard tube alloys in their most widely used conditions. Information on other properties of tube alloys can be found in the data compilations for the individual alloys; see the article "Properties of Wrought Coppers and Copper Alloys" in this Volume.

(f) Tube size: 9.5 mm (0.375 in.) OD by 2.5 mm (0.097 in.) wall

Production of Tube Shells

Copper tubular products are typically produced from shells made by extruding or piercing copper billets.

[RUNIN.SECT]

Extrusion of copper and copper alloy tube shells is done by heating a billet of material above the recrystallization temperature, and then forcing material through an orifice in a die and over a mandrel held in position with the die orifice. The clearance between mandrel and die determines the wall thickness of the extruded tube shell.

In extrusion, the dies is located at one end of the container section of an extrusion press; the metal to be extruded is driven through the die by a ram, which enters the container from the end opposite the die. Tube shells are produced either by starting with a hollow billet or by a two-step operation in which a solid billet is first pierced and then extruded.

Extrusion pressure varies with alloy composition. C36000 (61.5Cu-3Pb-35.5Zn) requires a relatively low pressure, whereas C26000 (70Cu-30Zn) and C44300 (71.5Cu-1Sn-27.5Zn-0.06As) require the highest pressure of all the brasses. Most of the coppers require an extrusion pressure intermediate between those for C26000 and C36000. C71500 (70Cu-30Ni) requires a very high extrusion pressure.

Extrusion pressure also depends on billet temperature, extrusion ratio (the ratio of the cross-sectional area of the billet to that of the extruded section), speed of extrusion, and degree of lubrication. The flow of metal during extrusion depends on many factors, including copper content of the metal, amount of lubricant, and die design.

Rotary piercing on a Mannesmann mill is another method commonly used to produce seamless pipe and tube from copper and certain copper alloys. Piercing is the most severe forming operation customarily applied to metals. The process takes advantage of tensile stresses that develop at the center of a billet when it is subjected to compressive forces around its periphery. In rotary piercing, one end of a heated cylindrical billet is fed between rotating work rolls that lie in a horizontal plane and are inclined at an angle to the axis of the billet (Fig. 10). Guide rolls beneath the billet prevent it from dropping from between the work rolls. Because the work rolls are set at an angle to each other as well as to the billet, the billet is simultaneously rotated and driven forward toward the piercing plug, which is held in position between the work rolls.

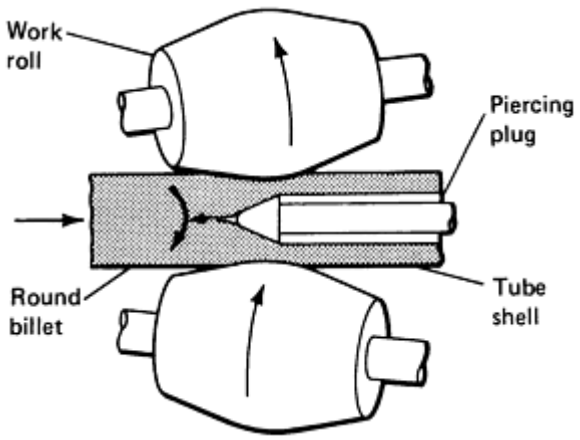

Fig. 10 Schematic diagram of metal piercing. Arrows indicate direction of motion.

The opening between work rolls is set smaller than the billet, and the resultant pressure acting around the periphery of the billet opens up tensile cracks, and then a rough hole, at the center of the billet just in front of the piercing plug. The piercing plug assists in further opening the axial hole in the center of the billet, smooths the wall of the hole, and controls the wall thickness of the formed tube.

Coppers and plain alpha brasses can be pierced, provided the lead content is held to less than 0.01%. Alpha-beta brasses can tolerate higher levels of lead without adversely affecting their ability to be pierced.

When piercing brass, close temperature control must be maintained because the range in which brass can be pierced is narrow. Each alloy has a characteristic temperature range within which it is sufficiently plastic for piercing to take place. Below this range, the central hole does not open up properly under the applied peripheral forces. Overheating may lead to cracked surfaces. Suggested piercing temperatures for various alloys are given below:

Production of Finished Tubes

UNS number	Piercing temperature	
	°C	°F
C11000	815-870	1500-1600
C12200	815-870	1500-1600
C22000	815-870	1500-1600
C23000	815-870	1500-1600
C26000	760-790	1400-1450
C28000	705-760	1300-1400
C46400	730-790	1350-1450

Cold drawing of extruded or pierced tube shells to smaller sizes is done on draw blocks for coppers and on draw benches for brasses and other alloys. With either type of machine, the metal is cold worked by pulling the tube through a die that reduces the diameter. Concurrently, wall thickness is reduced by drawing over a plug or mandrel that may be either fixed or floating. Cold drawing increases the strength of the material and simultaneously reduces ductility. Tube size is reduced--outside diameter, inside diameter, wall thickness, and cross-sectional area all are smaller after drawing. Because the metal work hardens, tubes may be annealed at intermediate stages when drawing to small sizes. However, coppers are so ductile that they frequently can be drawn to finished size without intermediate annealing.

Tube reducing is an alternative process for cold sizing of tube. In tube reducing, semicircular grooved dies are rolled or rocked back and forth along the tube while a tapered mandrel inside the tube controls the inside diameter and wall thickness. The process yields tube having very accurate dimensions and better concentricity than can be achieved by tube drawing.

The grooves in the tube-reducing dies are tapered, one end of the grooved section being somewhat larger than the outside diameter of the tube to be sized. As the dies are rocked, the tube is pinched against the tapered mandrel, which reduces wall thickness and increases tube length. The tube is fed longitudinally, and rotated on its axis to distribute the cold work uniformly around the circumference. Feeding and rotating are synchronized with die motion and take place after the dies have completed their forward stroke.

Tube reducing may be used for all alloys that can be drawn on draw benches. Slight changes in die design and operating conditions may be required to accommodate different alloys. Small-diameter tube may be produced by block or bench drawing following tube reducing.

Product Specifications

Copper tube and pipe are available in a wide variety of nominal diameters and wall thicknesses, from small-diameter capillary tube to 300 mm (12 in.) nominal-diameter pipe. To a certain extent, dimensions and tolerances for copper tube and pipe depend on the type of service for which they are intended. The standard dimensions and tolerances for several kinds of copper tube and pipe are given in the ASTM specifications listed in Table 6, along with other requirements for the tubular products. Seamless copper tube for automotive applications ($\frac{1}{8}$ to $\frac{3}{4}$ in. nominal diameter) is covered by SAE J528. Requirements for copper tube and pipe to be used in condensers, heat exchangers, economizers, and similar unfired pressure vessels are given in the ASME specifications listed in Table 6. (ASME materials specifications are almost always identical to ASTM specifications having the same numerical designation; for example, ASME SB111 is identical to ASTM B 111.) Certain tube alloys are covered in AMS specifications, which apply to materials for aerospace applications. These are given below:

AMS specifications	Product	Copper alloy
4555	Seamless brass tube, light annealed	C26000 C33000

4558	Seamless brass tube drawn	C33200
4625	Phosphor bronze, hard temper	C51000
4640	Aluminum bronze	C63000
4665	Seamless silicon bronze tube, annealed	C65500

Wire and Cable

WIRE made from copper and its alloys has been used since about 3000 to 2000 BC. According to archaeological evidence, the ancient Assyrians, Babylonians, and Egyptians were skilled in producing copper wire for ornamental purposes. Drawing wire through a die is a much more modern development. The earliest evidence of drawn wire comes from sixth century AD Venetian and French artifacts. Theophilus, a German monk, produced the first written records in a treatise on metalworking circa 1110 to 1140 AD. His description of wiredrawing reads, in part, "Two pieces of iron three or four fingers wide, smaller at the top and bottom, rather thin, pierced with three or four holes through which wire may be drawn. . ." By 1270, a set of rules had been passed to govern wiredrawing in Paris, and at least nine wiredrawers were at work in that city.

Development of wiredrawing processes during the Middle Ages concentrated to a large extent on drawing iron and steel wires to make pins and instrument strings. But with the invention of the electric telegraph in 1847 came the requirement for long continuous lengths of electric conductor wire made of copper. In 1850, copper wire was used to make a submarine cable connecting England and France.

At the beginning of the twentieth century, wire was still being drawn through single dies--a process commonly known as "bull-block" drawing. Dies were made by punching a series of holes in a steel plate. These holes were then trimmed to final size with a master punch. Rows of single capstans, power driven from a common drive shaft, were used for drawing single lengths of wire. As each reduction was completed, the steel-plate die was replaced with one containing smaller holes until the final diameter was achieved.

Multiple wire-drawing machines were introduced about 1900. As a result, chilled cast iron plates and dies that could be reamed to size replaced the punch-sized steel-plate dies. Lubricants were introduced because of the considerable heat generated by friction between the wire and draw-capstan and by successive reductions through progressively smaller dies. In turn, use of lubricants permitted wire to be drawn at faster speeds.

The prime development during the 1920s was the introduction of drawing dies made of tungsten carbide. High hardness and lack of porosity made tungsten carbide dies ideal for high-speed wiredrawing and provided longer die life than was usually possible with dies made of chilled cast iron. Tungsten carbide dies are standard today. For very fine wire sizes, below about 1.3 mm (0.05 in.), diamond dies are used because they are harder and last longer than tungsten carbide dies. Some wire mills use diamond dies for high-speed drawing of larger wires, up to 8 mm (0.32 in.) in diameter, to reduce the frequency of shutdowns for die replacement.

Classification of Copper for Conductors

Copper metals used for electrical conductors fall into three general categories: high-conductivity coppers, high-copper alloys, and electrical bronzes.

High-conductivity coppers are covered by ASTM specifications B 4, B 5, B 170, B 442, and B 623. ASTM B 4 covers both high-resistance and low-resistance Lake copper. Lake copper is refined from Lake Superior ore deposits. ASTM B 5 covers copper electrolytically refined from blister copper, converter copper, black copper, or Lake copper, ASTM B 170 covers oxygen-free electrical copper.

Oxygen-free copper is produced by special manufacturing techniques and is used to avoid embrittlement where conductors are subjected to hydrogen or other reducing gases at elevated temperatures.

Some specialty coppers are produced by adding minimal amounts of hardening agents (such as chromium, tellurium, beryllium, cadmium, or zirconium). These are used in applications where high anneal resistance is required.

A series of bronzes has been developed for use as conductors; these alloys are covered by ASTM B 105. These bronzes are intended to provide better corrosion resistance and higher tensile strengths than standard conductor coppers. There are nine conductor bronzes, designated 8.5 to 85 in accordance with their electrical conductivities, as given below:

ASTM B 105 alloy designation	**Alternative alloy types**
8.5	Cu-Si-Fe Cu-Si-Mn Cu-Si-Zn Cu-Si-Sn-Fe Cu-Si-Sn-Zn
13	Cu-Al-Sn Cu-Al-Si-Sn Cu-Si-Sn
15	Cu-Al-Si Cu-Al-Sn Cu-Al-Si-Sn Cu-Si-Sn
20	Cu-Sn
30	Cu-Sn Cu-Zn-Sn
40[(a)]	Cu-Sn Cu-Sn-Cd
55[(a)]	Cu-Sn-Cd
65[(a)]	Cu-Sn Cu-Sn-Cd
80[(a)]	Cu-Cd
85	Cu-Cd

(a) Normally used for trolley-wire applications in either a round or grooved cross-sectional configuration, as set forth in ASTM B 9

The compositions of these alloys must be within the total limits prescribed in the following table, and no alloy may contain more than the allowed maximum of any constituent other than copper.

Element	Composition limit, % max
Fe	0.75
Mn	0.75
Cd	1.50
Si	3.00
Al	3.50
Sn	5.00
Zn	10.50
Cu	89.00 min
Sum of above elements	**99.50 min**

Classification of Wire and Cable

Round Wire. Standard nominal diameters and cross-sectional areas of solid round copper wires used as electrical conductors are prescribed in ASTM B 258. Wire sizes have almost always been designated in the American Wire Gauge (AWG) system. This system is based on fixed diameters for two wire sizes (4/0 and 36 AWG, respectively) with a geometric progression of wire diameters for the 38 intermediate gages and for gages smaller than 36 AWG (see Table 7). This is an inverse series in which a higher number denotes a smaller wire diameter. Each increase of one AWG number is approximately equivalent to a 20.7% reduction in cross-sectional area.

Table 7 Sizes of round wire in the American Wire Gauge (AWG) system and the properties of solid annealed copper wire (ASTM B 3)

Conductor size, AWG	Conductor diameter		Conductor area at 20 °C (68 °F)		Annealed copper (ASMT B 3)

(a) Based on a density of 8.89 g/cm^3 at 20 °C (68 °F).

(b) Minimum elongation in 250 mm (10 in.).

(c) Based on a resistivity value of 0.017241 Ω· mm^2/m (875.20 Ω· lb/mile^2), which is the resistivity for the International Annealed Copper Standard (IACS) of electrical conductivity.

(d) Elongation not specified in ASTM B 3

ASTM B 3 specifies soft (or annealed) copper wire with a maximum volumetric resistivity of 0.017241 Ω· mm^2/m at 20 °C (68 °F), which corresponds to a maximum weight-basis resistivity of 875.20 Ω· lb/$mile^2$ when the density is 8.89 g/cm^3. This type of copper is used as the International Annealed Copper Standard (IACS) for electrical conductivity. Table 7 lists some properties of annealed copper wire for various AWG sizes. Tensile strengths are not specified for annealed copper wire.

Hard-drawn copper wire and hard-drawn copper alloy wire for electrical purposes are specified in ASTM B 1 and B 105, respectively. ASTM B 1 specifies hard-drawn round wire that has been reduced at least four AWG numbers (60% reduction in area). Table 8 lists the mechanical properties of hard-drawn copper wire and several hard-drawn copper alloy wires. The electrical resistivity and conductivity of these hard-drawn wires at 20 °C (68 °F) are as follows:

Alloy (hard drawn)	**Maximum resistivity**		**Conductivity (volume basis), % IACS**
	Ω· mm_2/m	**Ω· lb/$mile_2$**	
Copper (ASTM B 1) wire with diameter of:			
8.25 to 11.68 mm (0.325 to 0.460 in.)	0.017745	900.77	97.16
1.02 to <8.25 mm (0.0403 to <0.325 in.)	0.017930	910.15	96.16
Copper alloys (ASTM B 105):

(a) Tensile strengths cannot always be met if wire is drawn into coils of less than 480 mm (19 in.).

(b) Elongation in 250 mm (10 in.)

Square and Rectangular Wire. ASTM B 48 specifies soft (annealed) square and rectangular copper wire.

Stranded wire is normally used in electrical applications where some degree of flexing is encountered either in service or during installation. In order of increasing flexibility, the common forms of stranded wire are: concentric lay, unilay, rope lay, and bunched.

Concentric-lay stranded wire and cable are composed of a central wire surrounded by one or more layers of helically laid wires, with the direction of lay reversed in successive layers, and with the length of lay increased for each successive layer. The outer layer usually has a left-hand lay.

ASTM B 8 establishes five classes of concentric-lay stranded wire and cable, from AA (the coarsest) to D (the finest). Details of concentric-lay constructions are given in Table 9.

Table 9 Characteristics of concentric-lay stranded copper conductors specified in ASTM B 8

Conductor size, circular mils or AWG	Nominal weight, lb/1000 ft[a]	Nominal resistance[b], Ω/1000 ft[a]	Class AA		Class A		Class B		Class C		Class D

(a) Units used in ASTM B 8 specification; see "Metric Conversion Guide" for conversions.

(b) Uncoated wire

Unilay stranded wire is composed of a central core surrounded by more than one layer of helically laid wires, all layers having a common lay length and direction. This type of wire sometimes is referred to as "smooth bunch." The layers usually have a left-hand lay.

Rope-lay stranded wire and cable are composed of a stranded member (or members) as a central core, around which are laid one or more helical layers of similar stranded members. The members may be concentric or bunch-stranded. ASTM B 173 and B 172 establish five classes of rope-lay stranded conductors: classes G and H, which have concentric members; and classes I, K, and M, which have bunched members. Construction details are shown in Tables 10 and 11. These cables are normally used to make large, flexible conductors for portable service, such as mining cable or apparatus cable.

Bunch stranded wire is composed of any number of wires twisted together in the same direction without regard to geometric arrangement of the individual strands. ASTM B 174 provides for five classes (I, J, K, L, and M); these conductors are commonly used in flexible cords, hookup wires, and special flexible welding conductors. Typical construction details are given in Table 12.

Table 12 Characteristics of bunch stranded copper conductors having uncoated or tinned members specified in ASTM B 174

Tin-Coated Wire. Solid and stranded wires are available with tin coatings. These are manufactured to the latest revisions of ASTM B 33, which covers soft or annealed tinned-copper wires, and B 246, which covers hard-drawn or medium-hard-drawn tinned-copper wires. Characteristics of tinned, round, solid wire are given in Table 13.

(b) In 250 mm (10 in.)

Fabrication of Wire Rod

Wire rod is the intermediate product in the manufacture of wire. Although wire rod is the term used in the U.S. for the intermediate product, the term drawing stock is used in international standards and customs documents.

Rolling. The traditional process for converting prime copper into wire rod involves hot rolling of cast wirebar. Almost all drawing stock is rolled to 8 mm (0.32 in.) diameter. Larger sizes, up to 22 mm (0.87 in.) or more in diameter are available on special order.

Some special oxygen-free copper wirebar is produced by vertical casting, but most wirebar is produced by horizontal casting of tough-pitch copper into open molds. The oxygen content is controlled at 0.03 to 0.06% to give a level surface. Cast wirebars weigh about 110 to 135 kg (250 to 300 lb) each. Their ends are tapered to facilitate entry into the first pass of the hot rolling mill.

Prior to rolling, bars are heated to about 925 °C (1700 °F) in a neutral atmosphere and then rolled on a continuous mill through a series of reductions to yield round rod about 6 to 22 mm ($\frac{1}{4}$ to $\frac{7}{8}$ in.) in diameter. The hot-rolled rod is coiled, water-quenched, and then pickled to remove the black cupric oxide that forms during rolling. This method can produce rod at rates up to 7.5 kg/s (30 tons/h).

Disadvantages of this process include:

- High capital investment to achieve low operating cost
- Relatively small coils that must be welded together for efficient production, where the welded junctions present potential sources of weakness in subsequent wiredrawing operations
- Unsuitability of rod rolled from cast wirebars for certain specialized wire applications

Because of the disadvantages inherent in producing rolled rod from conventionally cast wirebars, processes have been developed for continuously converting liquid metal directly into wire rod, thus avoiding the intermediate wirebar stage.

Continuous Casting. In 1963, the first plant for continuous casting and rolling of copper wirebar began operation. The plant was operated by the Southwire Company in conjunction with Western Electric Company. The Southwire process was an adaptation of a process developed by Ilario Properzi prior to 1950--a process that had been used for many years by aluminum and zinc producers for conversion of prime metal or scrap into wire rod.

Continuously cast wire rod has come to dominate the copper wire rod market and now accounts for more than 1.8×10^6 Mg (2 million tons) annually, or about 50% of the total amount of wire rod produced.

Other casting systems that have been developed include the Hazelett Strip-Casting Corporation and General Electric Company dip-form systems. Smaller-capacity machines have been developed by Outokumpu Metals Inc., Davy Corporation, Wertli, Lamitref, and others.

Advantages of continuous casting and rolling include:

- Large coil weights, up to 10 Mg (11 tons)
- Ability to reprocess scrap at considerable savings
- Improved rod quality and surface condition
- Homogeneous metallurgical conditions and close process control
- Low capital investment and low operating costs for moderate production rates

The standard feed for continuous casting processes is cathode copper, which is charged directly into a melting furnace. An ASARCO, Inc. shaft furnace is used for the Southwire/Properzi and Hazelett systems, but an electric furnace is preferred for the smaller systems, such as the GE dip-form process.

Southwire/Properzi Continuous Rod System. In this system, the casting machine produces a cast copper bar 2500 to 3000 mm^2 (4 to 5 $in.^2$) in cross-sectional area by pouring molten copper between a grooved wheel made of steel or copper and a steel band. The cast bar is cooled by water sprays as the wheel rotates, and is withdrawn by pinch rolls as it exits from the wheel. Next it goes to a bar-conditioning unit, and then to the rolling mill. After passing through a series of reductions in the mill, the rod enters an in-line pickling system, which quenches and cleans the rod prior to final coiling.

GE Dip-Form Process. The GE dip-form process was introduced in 1964. A seed rod approximately 9 mm (0.35 in.) in diameter is passed at a controlled rate through a bath of molten C10100. Copper freezes onto the seed rod, thickening its diameter to about 16.5 mm (0.65 in.). The rod emerging from the copper bath is hot rolled on a 2-stand mill, cooled, and coiled. The entire operation is performed in a controlled atmosphere, from the time C10100 cathodes enter the melting furnace until the rod emerges. This rod is generally used for production of fine and ultrafine wires. Production rates up to 2.5 kg/s (10 tons/h) can be obtained.

Hazelett Process. This process was originally developed in 1957 for zinc slab, and was further refined in conjunction with Métallurgie Hoboken-Overpelt (Belgium) to make it applicable to copper wire rod. Molten copper is passed between two water-cooled, counter rotating steel belts having specially cooled side dams. The resulting bar is sent through a conventional Krupp rolling mill similar to that used in the Southwire system. Production rates of about 6.3 to 7.5 kg/s (25 to 30 tons/h) have been achieved.

Outokumpu Process. In the Outokumpu process, metal is pulled through a graphite die where it solidifies. One end of the die extends into the melt and the other is surrounded by a water-cooled jacket. The Outokumpu process is unique in that the direction of withdrawal is vertically upwards. A 12-strand plant can produce up to 13,000 Mg (14,000 tons) of oxygen-free rod annually.

Wiredrawing and Wire Stranding

Preparation of Rod. In order to provide a wire of good surface quality, it is necessary to have clean wire rod with a smooth, oxide-free surface. Conventional hot-rolled rod must be cleaned in a separate operation, but with the advent of continuous casting, which provides better surface quality, a separate cleaning operation is not required. Instead, the rod passes through a cleaning station as it exits from the rolling mill.

The standard method for cleaning copper wire rod is pickling in hot 20% sulfuric acid followed by rinsing in water. When fine wire is being produced, it is necessary to provide rod of even better surface quality. This can be achieved in a number of ways. One is by open-flame annealing of cold-drawn rod--that is, heating to 700 °C (1300 °F) in an oxidizing atmosphere. This eliminates shallow discontinuities. A more common practice, especially for fine magnet-wire applications, is die shaving, where rod is drawn through a circular cutting die made of steel or carbide to remove approximately 0.13 mm (0.005 in.) from the entire surface of the rod. A further refinement of this cleaning operation for rod made from conventionally cast wirebar involves scalping the top surface of cast wirebar and subsequently die shaving the hot-rolled bar.

Wiredrawing. Single-die machines called bull blocks are used for drawing special heavy sections such as trolley wire. Drawing speeds range from about 1 to 2.5 m/s (200 to 500 ft/min). Tallow is generally used as the lubricant, and the wire is drawn through hardened steel or tungsten carbide dies. In some instances, multiple-draft tandem bull blocks (in sets of 3 or 5 passes) are used instead of single-draft machines.

Tandem drawing machines having 10 to 12 dies for each machine are used for breakdown of hot-rolled or continuous-cast copper rod. The rod is reduced in diameter from 8.3 mm (0.325 in.) to about 2 mm(0.08 in.) by drawing it through dies at speeds up to 25 m/s (5000 ft/min). The drawing machine operates continuously; the operator merely welds the end of each rod coil to the start of the next coil.

Several newer continuous extrusion processes for production of wire are currently under development. These include the Conform process. Data indicate so far that copper wire can be produced successfully by these techniques.

Production of Flat or Rectangular Wire. Depending on size and quantity, flat or rectangular wire is drawn on bull block machines or Turk's Head machines, or is rolled on tandem rolling mills with horizontal and vertical rolls. Larger quantities are produced by rolling, smaller quantities by drawing.

Annealing. Wiredrawing, like any other cold-working operation, increases tensile strength and reduces ductility of copper. Although it is possible to cold work copper up to 99% reduction in area, copper wire usually is annealed after 90% reduction.

In some plants, electrical-resistance heating methods are used to fully anneal copper wire as it exits from the drawing machines. Wire coming directly from drawing passes over suitably spaced contact pulleys that carry the electrical current necessary to heat the wire above its recrystallization temperature in less than a second.

In plants where batch annealing is practiced, drawn wire is treated either in a continuous tunnel furnace, where reels travel through a neutral or slightly reducing atmosphere and are annealed during transit, or in batch bell furnaces under a similar protective atmosphere. Annealing temperatures range from 400 to 600 °C (750 to 1100 °F) depending chiefly on wire diameter and reel weight.

Wire Coating. Four basic coatings are used on copper conductors for electrical applications:

- Lead, or lead alloy (80Pb-20Sn), ASTM B 189
- Nickel, ASTM B 355
- Silver, ASTM B 298
- Tin, ASTM B 33

Intermediate and fine wires are drawn on smaller machines that have 12 to 20 or more dies each. The wire is reduced in steps of 20 to 25% in cross-sectional area. Intermediate machines can produce wire as small as 0.5 mm (0.020 in.) in diameter, and fine wire machines can produce wire in diameters from 0.5 mm (0.020 in.) to less than 0.25 mm (0.010 in.). Drawing speeds are typically 25 to 30 m/s (5000 to 6000 ft/min) and may be even higher.

All drawing is performed with a copious supply of lubricant to cool the wire and prevent rapid die wear. Traditional lubricants are soap and fat emulsions, which are fed to all machines from a central reservoir. Breakdown of rod usually requires a lubricant concentration of about 7%; drawing of intermediate and fine wires, concentrations of 2 to 3%. Today, synthetic lubricants are becoming more widely accepted.

Drawn wire is collected on reels or stem packs, depending on the next operation. Fine wire is collected on reels carrying as little as 4.5 kg (10 lb); large-diameter wire, on stem packs carrying up to 450 kg (1000 lb). To ensure continuous operation, many drawing machines are equipped with dual take-up systems. When one reel is filled, the machine automatically flips the wire onto an adjacent empty reel and simultaneously cut the wire. This permits the operator to unload the full reel and replace it with an empty one without stopping the wiredrawing operation.

Until the early 1970s, hydrostatic extrusion was essentially a batch process and was not considered a competitor to conventional wiredrawing. In 1970, Western Electric Company patented a "viscous drag machine" that uses a pressurized, flowing viscous fluid to feed wire rod into an extrusion chamber and through a die for continuous extrusion of wire. By forcing the viscous fluid to flow along the surface of the wire rod, shear stresses between fluid and rod are used to move the rod through the die. In 1973, a refinement of this process was announced; in the refined system, shear forces transmitted through a viscous medium were used to feed the rod toward the extrusion die. This process has not yet proved economical enough to be a significant commercial process.

Coatings are applied to:

- Retain solderability for hookup-wire applications
- Provide a barrier between the copper and insulation materials such as rubber, that would react with the copper and adhere to it (thus making it difficult to strip insulation from the wire to make an electrical connection)
- Prevent oxidation of the copper during high-temperature service

Tin-lead alloy coatings and pure tin coatings are the most common; nickel and silver are used for specialty and high-temperature applications.

Copper wire can be coated by hot dipping in a molten metal bath, electroplating, or cladding. With the advent of continuous processes, electroplating has become the dominant process, especially because it can be done "on line" following the wiredrawing operation.

Stranded wire is produced by twisting or braiding several wires together to provide a flexible cable. (For a description of various strand constructions, see the section of this article entitled "Classification of Wire and Cable.") Different degrees of flexibility for a given current-carrying capacity can be achieved by varying the number, size, and arrangement of individual wires. Solid wire, concentric strand, rope strand, and bunched strand provide increasing degrees of flexibility; within the last three categories, a larger number of finer wires provides greater flexibility.

Stranded copper wire and cable are made on machines known as bunchers or stranders. Conventional bunchers are used for stranding small-diameter wires (34 AWG up to 10 AWG). Individual wires are payed off reels located alongside the equipment and are fed over flyer arms that rotate about the take-up reel to twist the wires. The rotational speed of the arm relative to the take-up speed controls the length of lay in the bunch. For small, portable, flexible cables, individual wires are usually 30 to 34 AWG, and there may be as many as 150 wires in each cable.

A tubular buncher has up to 18 wire-payoff reels mounted inside the unit. Wire is taken off each reel while it remains in a horizontal plane, is threaded along a tubular barrel, and is twisted together with other wires by a rotating action of the barrel. At the take-up end, the strand passes through a closing die to form the final bunch configuration. The finished strand is wound onto a reel that also remains within the machine.

Supply reels in conventional stranders for large-diameter wire are fixed onto a rotating frame within the equipment and revolve about the axis of the finished conductor. There are two basic types of machines. In one, known as a rigid-frame strander, individual supply reels are mounted in such a way that each wire receives a full twist for every revolution of the strander. In the other, known as a planetary strander, the wire receives no twist as the frame rotates.

These types of stranders are comprised of multiple bays, with the first bay carrying six reels and subsequent bays carrying increasing multiples of six. The core wire in the center of the strand is payed off externally. It passes through the machine center and individual wires are laid over it. In this manner, strands with up to 127 wires are produced in one or two passes through the machine, depending on its capacity for stranding individual wires.

Normally, hard-drawn copper is stranded on a planetary machine so that the strand will not be as springy and will tend to stay bunched rather than spring open when it is cut off. The finished product is wound onto a power-driven external reel that maintains a prescribed amount of tension on the stranded wire.

Insulation and Jacketing

Of the three broad categories of insulation--polymeric, enamel, and paper-and-oil--polymeric insulation is the most widely used.

Polymeric Insulation. The most common polymers are polyvinyl chloride (PVC), polyethylene, ethylene propylene rubber (EPR), silicone rubber, polytetrafluoroethylene (PTFE), and fluorinated ethylene propylene (FEP). Polyimide coatings are used where fire resistance is of prime importance, such as in wiring harnesses for manned space vehicles. Until a few years ago, natural rubber was used, but this has now been supplanted by synthetics such as butyl rubber and EPR. Synthetic rubbers are used wherever good flexibility must be maintained, such as in welding or mining cable.

Many varieties of PVC are made, including several that are flame resistant. PVC has good dielectric strength and flexibility, and is one of the least expensive conventional insulating and jacketing materials. It is used mainly for communication wire, control cable, building wire, and low-voltage power cables. PVC insulation is normally selected for applications requiring continuous operation at temperatures up to 75 °C (165 °F).

Polyethylene, because of its low and stable dielectric constant, is specified when better electrical properties are required. It resists abrasion and solvents. It is used chiefly for hookup wire, communication wire, and high-voltage cable. Cross-linked polyethylene (XLPE), which is made by adding organic peroxides to polyethylene and then vulcanizing the mixture, yields better heat resistance, better mechanical properties, better aging characteristics, and freedom from environmental stress cracking. Special compounding can provide flame resistance in cross-linked polyethylene. Typical uses include building wire, control cables, and power cables. The usual maximum sustained operating temperature is 90 °C (200 °F).

PTFE and FEP are used to insulate jet aircraft wire, electronic equipment wire, and specialty control cables, where heat resistance, solvent resistance, and high reliability are important. These electrical cables can operate at temperatures up to 250 °C (480 °F).

All of the polymeric compounds are applied over copper conductors by hot extrusion. The extruders are machines that convert pellets or powders of thermoplastic polymers into continuous covers. The insulating compound is loaded into a hopper that feeds into a long, heated chamber. A continuously revolving screw moves the pellets into the hot zone where the polymer softens and becomes fluid. At the end of the chamber, molten compound is forced out through a small die over the moving conductor, which also passes through the die opening. As the insulated conductor leaves the extruder it is water cooled and taken up on reels. Cables jacketed with EPR and XLPE go through a vulcanizing chamber prior to cooling to complete the cross-linking process.

Enamel Film Insulation. Film-coated wire, usually fine magnet wire, is composed of a metallic conductor coated with a thin, flexible enamel film. These insulated conductors are used for electromagnetic coils in electrical devices and must be capable of withstanding high breakdown voltages. Temperature ratings range from 105 to 220 °C (220 to 425 °F), depending on enamel composition. The most commonly used enamels are based on polyvinyl acetals, polyesters, and epoxy resins.

Equipment for enamel coating of wire often is custom built, but standard lines are available. Basically, systems are designed to insulate large numbers of wires simultaneously. Wires are passed through an enamel applicator that deposits a controlled thickness of liquid enamel onto the wire. Then the wire travels through a series of ovens to cure the coating, and finished wire is collected on spools. In order to build up a heavy coating of enamel, it may be necessary to pass wires through the system several times. In recent years, some manufacturers have experimented with powder-coating methods. These avoid evolution of solvents, which is characteristic of curing conventional enamels, and thus make it easier for the manufacturer to meet Occupational Safety and Health Administration and Environmental Protection Agency standards. Electrostatic sprayers, fluidized beds, and other experimental devices are used to apply the coatings.

Paper-and Oil Insulation. Cellulose is one of the oldest materials for electrical insulation and is still used for certain applications. Oil-impregnated cellulose paper is used to insulate high-voltage cables for critical power-distribution applications. The paper, which may be applied in tape form, is wound helically around the conductors using special machines in which six to twelve paper-filled pads are held in a cage that rotates around the cable. Paper layers are wrapped alternately in opposite directions, free of twist. Paper-wrapped cables then are placed inside special impregnating tanks to fill the pores in the paper with oil and to ensure that all air has been expelled from the wrapped cable.

The other major use of paper insulation is for flat magnet wire. In this application, magnet-wire strip (with a width-to-thickness ratio greater than 50 to 1) is helically wrapped with one or more layers of overlapping tapes. These may be bonded to the conductor with adhesives or varnishes. The insulation provides highly reliable mechanical separation under conditions of electrical overload.

Stress-Relaxation Characteristics

WHEN AN EXTERNAL STRESS is applied to a piece of metal, it reacts by developing an equal and opposite internal stress. If the metal is held in this strained position, the internal stress will decrease as a function of time. This

phenomenon is called stress relaxation and happens because of the transformation of elastic strain in the material to plastic, or permanent strain. The reduction-of-stress rate will be a function of alloy, temper, temperature, and time.

A useful example for visualizing stress relaxation is a bolt clamping two components together. Tightening the bolt results in a compressive force on the two components that is equal and opposite to the tensile force in the bolt. Over a period of time, stress relaxation in the bolt will reduce this tensile stress and cause a loss of clamping force.

Copper alloys are used in many applications where they are subjected to an applied stress at either ambient or moderately elevated temperature. Examples include electrical and electronic connectors, automotive radiators, solar heating panels, and communications cable. Stress relaxation which can be significant even at ambient temperature, can result in service failures. Data indicating the amount of relaxation that can be expected is, therefore, useful to product designers.

Because of the wide variations in composition and processing among commercial copper alloys, resistance to stress relaxation varies considerably. Of course, selection of an alloy for a given application is based not only on stress-time-temperature response but also on such factors as cost, basic mechanical and physical properties, operating temperature, service environment, and formability. For many applications, electrical conductivity is a primary consideration.

Stress-Relaxation Data

Standard practices for performing stress-relaxation test are described in ASTM E 328. Testing can be performed in either tension, compression, torsion, or bending. It is advisable to use data generated for the stress state that most closely approximates the application being considered. Since the lifetime of a part is often very long, it is common practice to extrapolate short-time data to longer periods. Methods used include plots like those shown in Fig. 11 (where the dotted portion of the line is an extrapolation), and the Larson-Miller parameter (Ref 2). Use of accelerated tests at temperature in excess of the service temperature can be misleading (Ref 1).

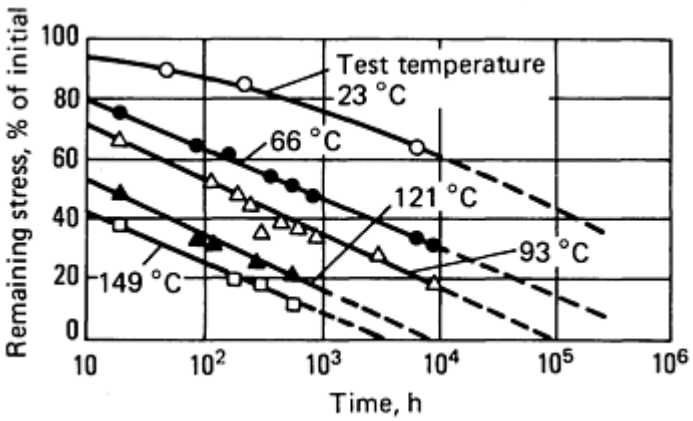

Fig. 11 Tensile-stress-relaxation characteristics of C11000. Data are for tinned 30 AWG (0.25 mm diam) annealed ETP copper wire; initial elastic stress, 89 MPa (13 ksi).

Unalloyed copper C11000 (electrolytic tough pitch) is probably the most inexpensive high-conductivity copper and is used extensively because of its ease of fabrication. The stress-relaxation behavior of this material is rather poor, as demonstrated in Fig. 11, in which relaxed stress is plotted as a function of time and temperature for 0.25 mm (0.10 in.) C11000 wire initially stressed in tension to 89 MPa (13 ksi). Comparison of stress values at a given time for different temperatures illustrated the very sharp dependence of stress relaxation on temperature for this copper. At 93 °C (200 °F), for example, no tension remains after 10^5 h (11.4 years), whereas 40% of the initial stress remains after 40 years at room temperature. For C11000 and for many other copper metals, stress relaxation in a given time period is inversely proportional to absolute temperature (Ref 3).

The stress-relaxation behavior of C10200 (oxygen-free copper) is somewhat better than that of C11000, as shown in Table 14, which also presents stress-relaxation data for many other high-conductivity copper metals. (For compositions of these metals, see Table 15; basic mechanical properties are given in Table 16). A more extensive comparison of the mechanical behavior of C10200 and C11000 has been presented in Ref 4.

Table 14 Tensile-stress-relaxation data for selected types of copper wire

Among the high-conductivity coppers, relaxation is greatest in very-high-purity copper (99.999+%)-- a material used mainly in research. Improvement in the stress-relaxation behavior of high-conductivity copper can be achieved by adding alloying elements that cause solid-solution strengthening, age hardening, or dispersion hardening (Ref 5). For example, minute additions of silver significantly reduce stress relaxation in copper (Ref 6, 7).

Besides the strengthened high-conductivity coppers for which stress-relaxation data are given in Table 14, proprietary coppers strengthened with small amounts of cadmium, chromium, zirconium, or a combination of one or more of these elements have been found to have good to superior stress-relaxation resistance (Ref 3). Processing variations that strengthen copper metals, even including internal oxidation, are almost always beneficial.

Lower-conductivity alloys, which are strengthened by alloy additions or precipitation hardening, exhibit improved resistance to stress relaxation, compared to pure copper. The performance of any particular material will be dependent on its chemical composition, condition, and temperature at which it is tested. For materials that are strengthened by cold rolling, several general comments can be made. First, the amount of relaxation that will occur during a given time at a certain temperature will increase with increasing amounts of prior cold work. Second, the performance of these materials may vary depending on the orientation of the test sample to the rolling direction. Finally, the performance of heavily cold-rolled materials can be improved by stress-relief annealing (Ref 8 and 9). Figures 12 and 13 illustrate these effects for alloys C51000 and C72500.

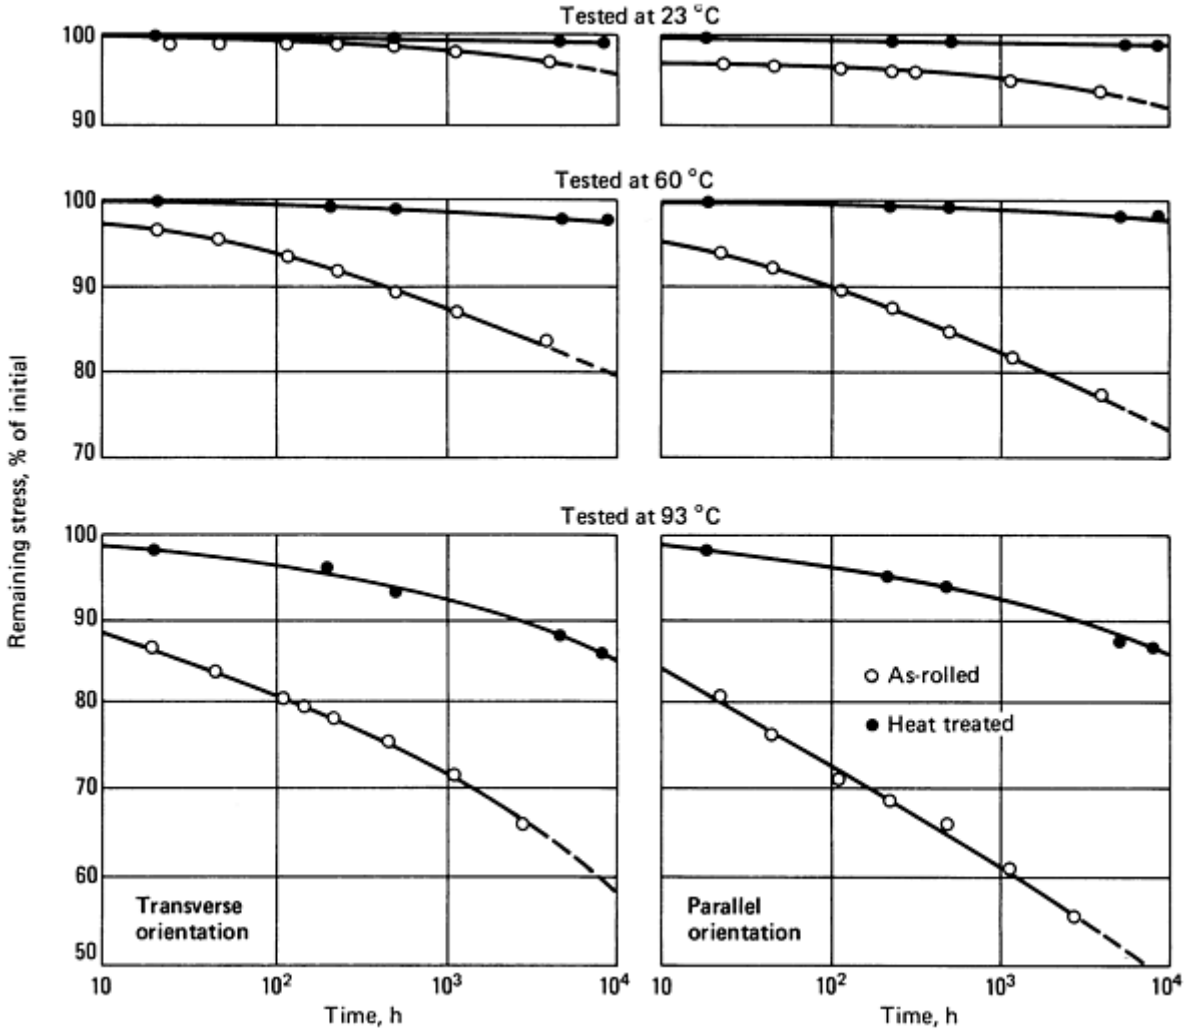

Fig. 12 Anisotropic stress-relaxation behavior in bending for highly cold-worked C51000 strip. Data are for 5% Sn phosphor bronze cold rolled 93% (reduction in area) to 0.25 mm (0.01 in.) and heat treated 2 h at 260 °C (500 °F). Graphs at left are for stress relaxation transverse to the rolling direction; graphs at right, for stress relaxation parallel to the rolling direction. Initial stresses: as rolled, parallel orientation, 607 MPa (88 ksi); as rolled, transverse orientation, 634 MPA (92 ksi); heat treated, orientation, 641 MPa (93 ksi); heat treated, transverse orientation, 738 MPa (107 ksi)

Fig. 13 Anisotropic stress-relaxation behavior in bending for highly cold-worked C72500 strip. Data are for 89Cu-9Ni-2Sn alloy cold rolled 98.7% (reduction in area) to 0.25 mm (0.01 in.) and heat treated 2 h at 375 °C (675 °F). Points represented by circles are for stress relaxation parallel to the rolling direction; triangles, for relaxation at 45° to the rolling direction; squares, for relaxation transverse to the rolling direction. Open points are for as-rolled stock. Initial stresses: as-rolled, parallel orientation, 524 MPa (76 ksi); as-rolled, 45° orientation, 510 MPa (74 ksi), as-rolled, transverse orientation, 586 MPa (85 ksi); heat treated, parallel orientation, 669 MPa (97 ksi); heat treated, 45° orientation, 552 MPa (80 ksi); heat treated, transverse orientation, 710 MPa (103 ksi)

Since copper alloys are commonly used in electrical and electronic connectors, some manufacturers have published data to assist in the design of these items (see Ref 1 and 10). A compilation of stress-relaxation data from these sources for some of the more common alloys is given in Table 17. It is important to realize that the data from relaxation tests, such as in Table 17, serves as only a comparative ranking of alloy performance because these tests are usually performed on flat samples cut from strip, rather than on finished parts. Other factors that might influence part performance include part geometry, deformation introduced during fabrication, and performance of other materials used in the part (for example, plastic housings used in electrical connectors). Testing of prototype parts is the best way to assess overall performance.

Table 17 Typical stress-relaxation values for selected copper alloys

Stress Relaxation in Mechanical Components

A solderless wrapped connection such as the one shown in Fig. 14, in which electrical contact is made by wrapping a wire around a terminal, is a typical application for high-conductivity copper metals where stress relaxation is of concern. Typical operating temperatures can be as high as 85 °C (185 °F); generally, conductivities higher than 98% IACS at 20 °C (68 °F) are desirable. After the connection is made, it is maintained by elastic stresses in the two members. If the wire undergoes stress relaxation, electrical contact between the wire and the terminal may be lost.

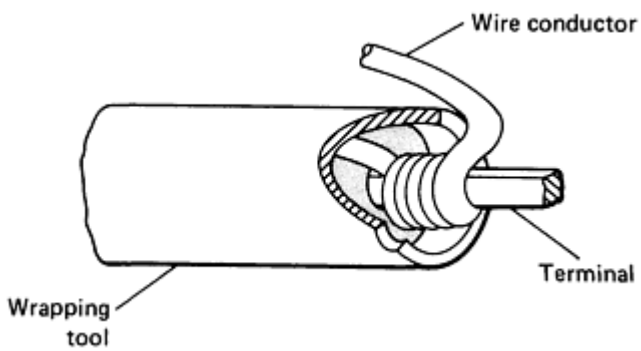

Fig. 14 Typical solderless wrapped connection. Wrapping tool is removed after connection is made.

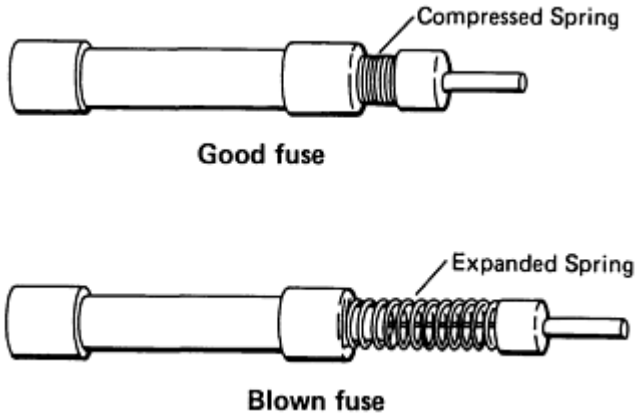
The spring in the alarm fuse shown in Fig. 15 is a typical application for copper alloys with room-temperature conductivities of 55 to 85% IACS. This spring conducts relatively high electrical currents and also triggers an alarm circuit if the fuse blows. To perform the latter function reliably, the spring must retain spring force for extended periods of time. But if the spring material undergoes stress relaxation, the device may fail to trigger the alarm when the fuse blows. C16200 (Cu-1Cd) has been used successfully in spring-loaded alarm fuses operating at temperatures below 95 °C (200 °F). (This alloy has an electrical conductivity of 80 to 85% IACS at 20 °C, or 68 °F.) For higher operating temperatures up to 165 °C (330 °F), C19000 (Cu-Ni-P alloy) springs have performed adequately, provided the ratio of nickel to phosphorus is at least 5 to 1 (Ref 12). (The nominal ratio for this alloy is about 3.5 to 1.) For applications where lower electrical conductivity can be

tolerated, C17500 (Cu-2.5Co-0.6Be) conductivity, 45% IACS at 20 °C (68 °F), is a satisfactory alternative for temperatures up to 165 °C (330 °F). Both C19000 and C17500 must be age hardened after forming.



A typical application of the lower-conductivity, high-strength copper alloys is the pressure-type, split-beam connector shown in Fig. 16. The knife edges of the connector first cut through the insulation on the conductor and then must maintain electrical contact with it. Materials used for connectors of this type, depending on operating stress and temperature, include some of the phosphor bronzes, nickel silvers, copper-nickels, beryllium-coppers, and some of the newer copper-nickel-tin alloys (Ref 13) strengthened by spinodal decomposition.

Fig. 15 Typical spring-type alarm fuse

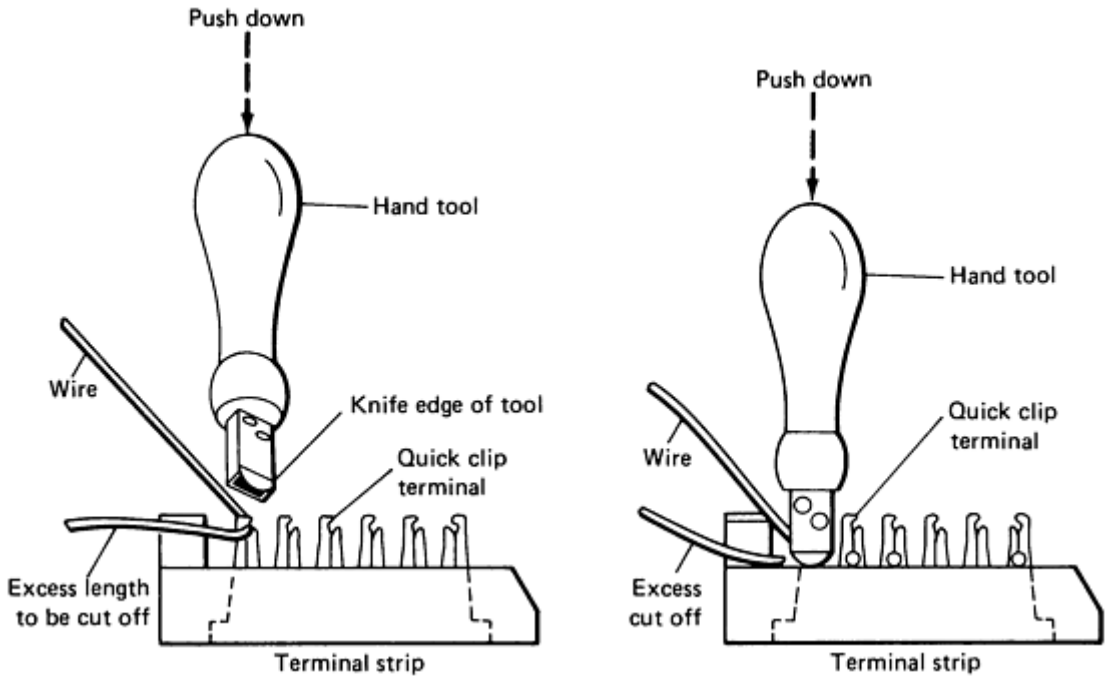


Fig. 16 Typical quick clip connection

Stress relaxation can produce mechanical or thermal ratcheting, which sometimes occurs in multilayer circuit boards such as the one illustrated in Fig. 17. A multilayer board usually consists of an epoxy-glass composite substrate with several lands of electroplated copper and including a plated-through hole. When a leadwire is soldered into the plated-through hole, differential thermal expansion causes the hole to expand more than the substrate, and a tensile stress is applied to the copper barrel. While at temperature, the stressed electroplated copper relaxes according to behavior that varies with the plating system and bath used (Ref 14). If the board is repeatedly heated and cooled, the electroplated copper alternatively expands and relaxes during each heating cycle, and permanent strain accumulates in the copper barrel until the assembly fails by buckling or by low-cycle fatigue.

Chemical Composition

Composition limits. C10100: 99.99 Cu min (there are specific limits in ppm for 17 named elements; refer to ASTM B 170 or the Copper Development Association *Standards Handbook*). C10200: 99.95 Cu + Ag min

Consequence of exceeding impurity limits. C10100 and C10200 are high-conductivity electrolytic coppers produced without use of metal or metalloid deoxidizers. Excessive amounts of impurities reduce conductivity. Excessive oxygen causes the metal to fail the ASTM B

170 bend test after being heated 30 min at 850 °C (1560 °F) in pure hydrogen.

Applications

Typical uses. Busbars, waveguides, lead-in-wire, anodes, vacuum seals, transistor components, glass-to-metal seals, coaxial cables, klystrons, microwave tubes

Precautions in use. Avoid heating in oxidizing atmospheres.

Mechanical Properties

Tensile properties. See Table 1, Fig. 1, and Fig. 2.

(b) Tensile strength, 238 MPa (34.5 ksi) at 21 °C (70 °F).

(c) Tensile strength, 352 MPa (51.1 ksi) at 21 °C (70 °F).

(d) Tensile strength, 426 MPa (61.8 ksi) at 21 °C (70 °F)

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Melting point. 1083 °C (1981 °F)

Coefficient of linear thermal expansion. 17.0 μm/m · K (9.4 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 17.3 μm/m · K (9.6 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 17.7 μm/m · K) (9.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 391 W/m · K (226 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Annealed: volumetric, 101% IACS min at 20 °C (68 °F)

Electrical resistivity. 17.1 nΩ · m at 20 °C (68 °F)

Chemical Properties

General corrosion behavior. Copper is cathodic to hydrogen in the electromotive series and therefore is the cathode in galvanic couples with other base metals such as iron, aluminum, magnesium, lead, tin, and zinc. C10100 and C10200 have excellent resistance to atmospheric corrosion and to corrosion by most waters, including brackish water and seawater. They have good resistance to nonoxidizing acids but poor resistance to oxidizing acids, moist ammonia, moist halogens, sulfides, and solutions containing ammonium ions.

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Forgeability. 65% of C37700 (forging brass)

Formability. Readily formed by a wide variety of hot and cold methods. Can be easily stamped, bent, coined, sheared, spun, upset, swaged, forged, roll threaded, and knurled

Weldability. Can be readily soldered, brazed, gas tungsten arc welded, gas metal arc welded, or upset welded. its capacity for being oxyfuel gas welded is fair. Shielded metal arc welding and most resistance welding methods are not recommended.

Annealing temperature. 375 to 650 °C (700 to 1200 °F)

Hot-working temperature. 750 to 875 °C (1400 to 1600 °F)

Properties of Wrought Coppers and Copper Alloys

Revised by Peter Robinson, Olin Corporation

C10300

Commercial Names

Common name. Oxygen-free extra-low-phosphorus copper

Designation. OFXLP

Specifications

ASTM. Flat products: B 133, B 152, B 187, B 272, B 432. Pipe: B 42, B 188, B 302. Rod: B 12, B 133, B 187. Shapes: B 133, B 187. Tubing: B 68, B 75, B 88, B 111, B 188, B 251, B 280, B 306, B 359, B 372, B 395, B 447

Chemical Composition

Composition limits. 99.95 Cu + Ag + P min, 0.001 to 0.005 P, 0.05 max other (total)

Applications

Typical uses. Busbars, electrical conductors and terminals, commutators, tubular busbars, clad products, waveguide tubing, thermostatic control tubing

Mechanical Properties

Tensile properties. See Table 4.

Table 4 Typical mechanical properties of C10300

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness			Shear strength

(a) At 0.5% extension under load

Shear strength. See Table 4.

Hardness. See Table 4.

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Fatigue strength. 1 mm (0.04 in.) thick strip: OS025 temper, 76 MPa (11 ksi); H02 or H04 temper, 90 MPa (13 ksi)

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1083 °C (1981 °F)

Solidus temperature. 1083 °C (1981 °F)

Coefficient of linear thermal expansion. 17.0 μm/m · K (9.4 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 17.3 μm/m · K (9.6 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 17.7 μm/m · K (9.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 386 W/m · K (223 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. O61 temper: volumetric, 99% IACS at 20 °C (68 °F)

Electrical resistivity. 17.4 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Annealing temperature. 375 to 650 °C (700 to 1200 °F)

Hot-working temperature. 750 to 875 °C (1400 to 1600 °F)

C10400, C10500, C10700

Commercial Names

Trade name. AMSIL copper

Common name. Oxygen-free silver-copper

Specifications

ASTM. See Table 5.

Wire	QQ-W-343, MIL-W-3318	QQ-W-343, MIL-W-3318	QQ-W-343, MIL-W-3318

Chemical Composition

Composition limits. C10400: 99.95 Cu + Ag min, 0.027 Ag min. C10500: 99.95 Cu + Ag min, 0.034 Ag min. C10700: 99.95 Cu + Ag min, 0.085 Ag min

Applications

Typical uses. Busbars, conductivity wire, contacts, radio parts, windings, switches, commutator segments, automotive gaskets and radiators, chemical plant equipment, printing rolls, printed-circuit foil. Many uses are based on the good creep strength at elevated temperatures and the high softening temperature of these alloys.

Mechanical Properties

Tensile properties. See Table 6 and Fig. 3

Table 6 Typical mechanical properties of C10400, C10500, and C10700

C10800

Commercial Names

Trade name. AMAX-LP copper

Common name. Oxygen-free low-phosphorus copper

Specifications

ASTM. Flat products: B 113, B 152, B 187, B 432. Pipe: B42, B 302. Rod: B 12, B 133. Shapes: B 133. Tubing: B 68, B 75, B 88, B 111, B 188, B 251, B 280, B 306, B 357, B 360, B 372, B 395, B 447, B 543

Chemical Composition

Composition limits. 99.95 Cu + Ag + P min, 0.005 to 0.012 P

Applications

Typical uses. Refrigerator and air conditioner tubing and terminals, commutators, clad products, gas and burner lines and units, oil burner tubes, condenser and heat exchanger tubes, pulp and paper lines, steam and water lines, tank gage lines, plumbing pipe and tubing, thermostatic control tubing, plate for welded continuous casting molds, tanks, kettles, rotating bands, and similar uses

Mechanical Properties

Tensile properties. See Table 7.

Table 7 Typical mechanical properties of C10800

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness			Shear strength		Fatigue strength[(b)]

Government. Federal specifications: See Table 8. Military specifications: Rod, MIL-C-12166; wire, MIL-W-3318, MIL-W-6712

Chemical Composition

Composition limits. 99.90 Cu min (silver counted as copper)

Silver has little effect on mechanical and electrical properties, but does raise the recrystallization temperature and tends to produce a fine-grain copper.

Iron , as present in commercial copper, has no effect on mechanical properties, but even traces of iron can cause C11000 to be slightly ferromagnetic.

Sulfur causes spewing and unsoundness, and is kept below 0.003% in ordinary refinery practice.

Selenium and tellurium are usually considered undesirable impurities but may be added to improved machinability.

Bismuth creates brittleness in amounts greater than 0.001%.

Lead should not be present in amounts greater than 0.005% if the copper is to be hot rolled.

Cadmium is rarely present; its effect is to toughen copper without much loss in conductivity.

Arsenic decreases the conductivity of copper noticeably, although it is often added intentionally to copper not used in electrical service because it increases the toughness and heat resistance of the metal.

Antimony is sometimes added to the copper when a high recrystallization temperature is desired.

Applications

Typical uses. Produced in all forms except pipe, and used for building fronts, down-spouts, flashing, gutters, roofing, screening, spouting, gaskets, radiators, busbars, electrical wire, stranded conductors, contacts, radio parts, switches, terminals, ball floats, butts, cotter pins, nails, rivets, soldering copper, tacks, chemical process equipment, kettles, pans, printing rolls, rotating bands, roadbed expansion plates, vats

Precautions in use. C11000 is subject to embrittlement when heated to 370 °C (700 °F) or above in a reducing atmosphere, as in annealing, brazing, or welding. If hydrogen or carbon monoxide is present in the reducing atmosphere, embrittlement can be rapid.

Mechanical Properties

Tensile properties. See Table 9 and Fig. 4, 5, 6, 7, and 8.

	12[b]	9[b]

(a) Parallel to rolling direction.

(b) Transverse to rolling direction

Fatigue strength. See Table 9; values shown there are typical of all tough pitch, oxygen-free, phosphorus-deoxidized and arsenical coppers. Copper does not exhibit an endurance limit under fatigue loading and, on the average, will fracture in fatigue at the stated number of cycles when subjected to an alternating stress equal to the corresponding fatigue strength (see Fig. 10).

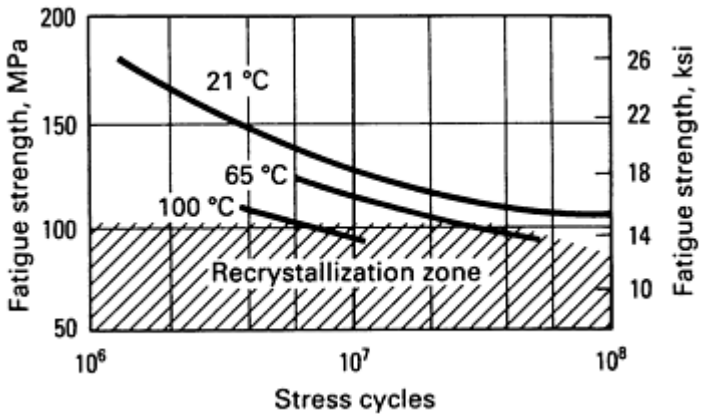

Fig. 10 Rotating-beam fatigue strength of C11000 wire, 2 mm (0.08 in.) in diameter, H80 temper

Creep-rupture characteristics. See Table 11.

Table 11 Creep properties of copper

Temper	Testing temperature		Stress		Duration of test, h	Total extension, %[a]	Intercept, %	Minimum creep rate, % per 1000 h

			100	14.5	8700	7.31	0.16	0.055
			140	20	4030	11[b]	0.24	0.17

Rod, 3.2 mm (0.13 in.) diameter								
OS025	260	500	2.5	0.36	6000	0.08	0.016	0.011
			4.1	0.60	6000	0.19	0.010	0.030
			7.2	1.05	6500	0.64	0.113	0.080
			13.8	2.0	6500	2.88	0.87	0.306
H08	205	400	7.2	1.05	6500	0.06	0.045	0.011
			14.5	2.1	6500	0.20	0.112	0.012
			28	4.05	6500	1.08	0.41	0.097
			50	7.25	6500	5.42	2.47	0.44

Note: Values shown are typical for the tough pitch grades of copper. Oxygen-free, phosphorus-deoxidized, and arsenical coppers have marginally greater resistance to creep deformation.

(a) Total extension is initial extension (not given in table) plus intercept (column 8) plus the product of minimum creep rate (column 9) and duration (column 6).

(b) Rupture test

Specific damping capacity. The damping capacity of coppers and brasses depends on the amplitude and, in some instances, on the frequency of vibration; it is also affected by the condition of the metal. Up to a point, damping capacity increases with increasing cold work; for example, the damping capacity of 70-30 brass has been reported to increase for reductions up to 60%. When subjected to the same conditions, coppers have about three times the damping capacity of C21000 or C22000. A specific damping capacity of 5×10^{-5} has been recorded for single-crystal annealed copper. Log decrement: O60 temper, 3.2; cold rolled (H) tempers, 5.0

Coefficient of friction. Values given below apply to any of the unalloyed coppers in contact with the indicated materials without lubrication of any kind between the contacting surfaces:

Opposing material	Coefficient of friction	
	Static	Sliding
Carbon steel	0.53	0.36

Cast iron	1.05	0.29
Glass	0.68	0.53

Mass Characteristics

Density. Solid: 8.89 g/cm^3 (0.321 lb/in.^{3}) at 20 °C (68 °F); 8.32 g/cm^3 (0.301 lb/in.^{3}) at 1083 °C (1981 °F); see also Fig. 11. Liquid: 7.93 g/cm^3 (0.286 lb/in.^{3}) at 1083 °C (1981 °F)

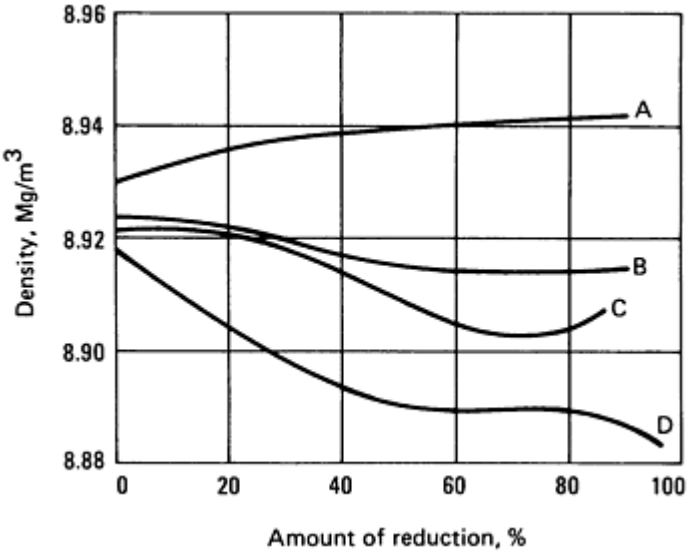

Fig. 11 Variation of density with amount of cold reduction by rolling for C11000 and similar coppers. A, vacuum annealed 12 h at 880 °C (1615 °F) and cold drawn. B, vacuum annealed 12 h at 970 °C (1780 °F) and flat rolled. C, vacuum annealed 12 h at 995 °C (1825 °F) and cold drawn. D, hot rolled, vacuum annealed 4 h at 600 °C (1110 °F), and drawn

Thermal Properties

Liquidus temperature. 1083 °C (1981 °F)

Solidus temperature. Eutectic point, 1065 °C (1950 °F)

Coefficient of linear thermal expansion. 17 μm/m · K (9.4 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 17.3 μm/m · K (9.6 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 17.7 μm/m · K (9.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F). See also Fig. 12.

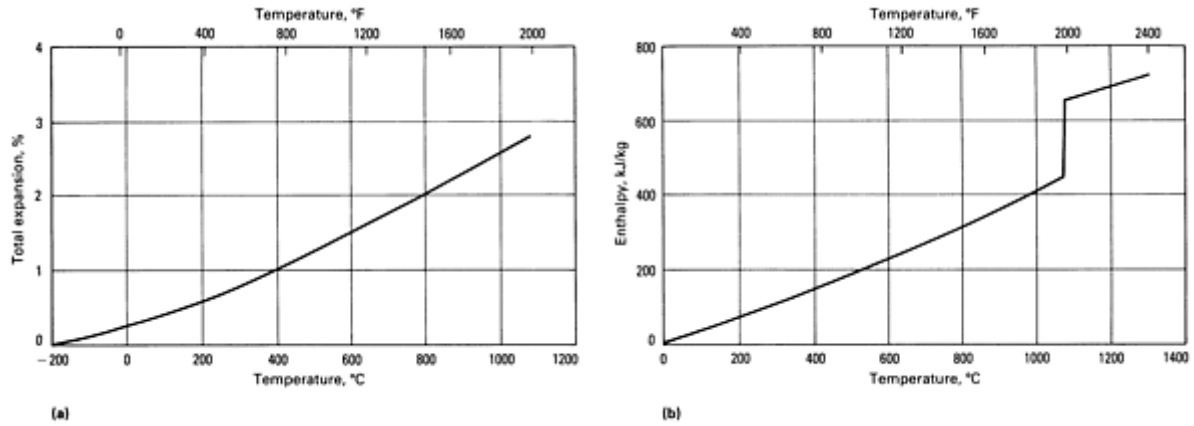

Fig. 12 Thermal expansion and enthalpy of C11000. (a) Total thermal expansion from -190 °C (-310 °F). (b) Enthalpy (heat content) above 0 °C (32 °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Enthalpy. See Fig. 12.

Latent heat of fusion. 205 kJ/kg

Thermal conductivity. 388 W/m · K (224 Btu/ft · h · °F) at 20 °C (68 °F). For high conductivity coppers, a values of 387 W/m · K (223 Btu/ft · h · °F) is an adjusted value corresponding to an electrical conductivity of 101% IACS:

Temperature		**Thermal conductivity**	
K	**°C**	**W/m · K**	**Btu/ft · h · °F**
4.2	-268.8	300	170
20	-253	1300	750
77	-196	550	318
194	-79	400	230
273	0	390	225
373	100	380	220
573	300	370	215

973	700	300	170

Electrical Properties

Electrical conductivity. Volumetric: O60 temper: 100 to 101.5% IACS; H14 temper, 97% IACS. See also Fig. 13.

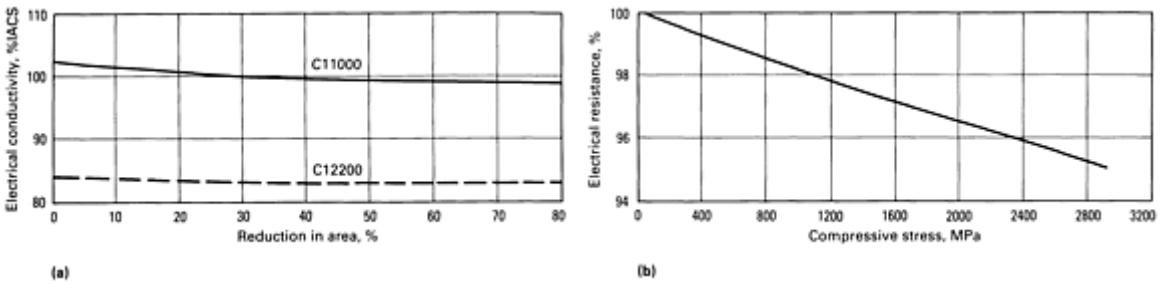

Fig. 13 Electrical properties of copper. (a) Electrical conductivity as a function of amount of cold reduction by drawing. (b) Variation of electrical resistance with applied compressive stress at 30 and 75 °C (86 and 167 °F). Resistance expressed as percent of no load value.

Electrical resistivity. O60 temper: 17.00 to 17.24 nΩ · m; temperature coefficient, 0.00393/K at -100 to 200 °C (-148 to 392 °F) for 100% IACS material, 0.00397/K at -100 to 200 °C for 101% IACS material. H14 temper: 1.78 nΩ · m; temperature coefficient, 0.00381/K at 0 to 100 °C (32 to 212 °F) for 97% IACS material. See also Fig. 13.

Thermoelectrical potential. See Fig. 14.

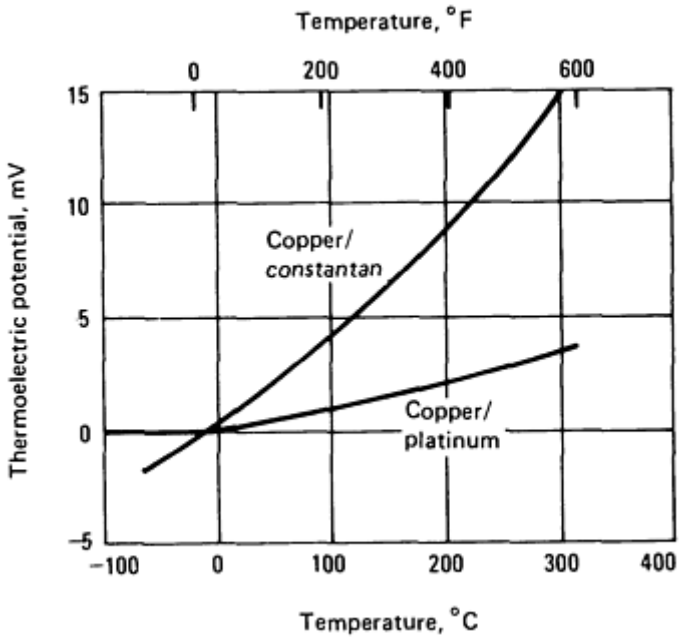

Fig. 14 Thermoelectric properties of copper with cold junctions at 0 °C (32 °F)

Electrochemical equivalent. Cu^{2+}, 0.329 mg/C; Cu^{+}, 0.659 mg/C

Electrolytic solution potential. Cu^{2+}, -0.344 V versus standard hydrogen electrode; Cu^{+}, -0.470 V versus standard hydrogen electrode; temperature coefficient, -0.01 mV/K at 20 to 50 °C (68 to 122 °F)

Hydrogen overvoltage. Approximately 0.23 V in dilute sulfuric acid; specific value varies with current density.

Hall effect. Hall coefficient, -52pV · m/A · T

Color. Reddish metallic

Optical Properties

Spectral reflectivity. 32.7% for λof 420 nm; 43.7% for λof 500 nm; 71.8% for λof 600 nm; 83.4% for λof 700 nm. See also Fig. 15 and 16.

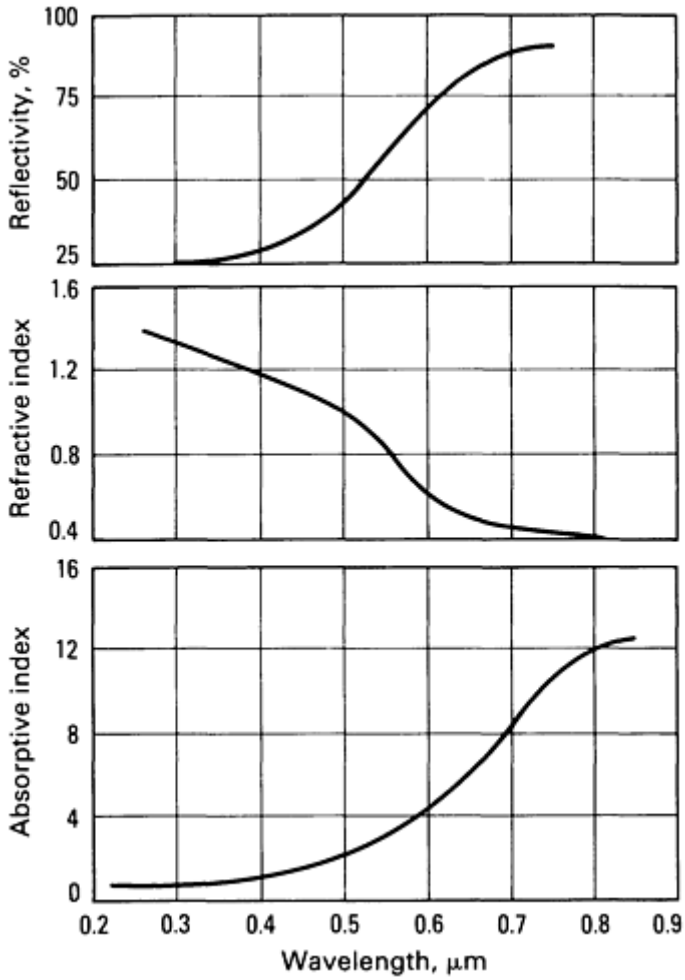

Fig. 15 Optical properties of C11000 and similar coppers at 21 °C (70 °F)

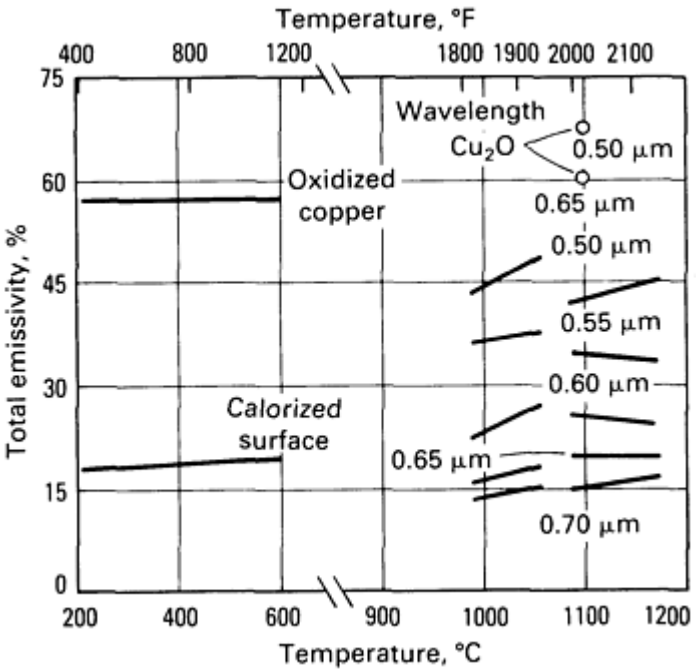

Fig. 16 Emissivity of commercial coppers

Chemical Properties

General corrosion behavior. Although many factors influence the corrosion resistance of copper under specific conditions of service, copper is generally less subject to corrosion than other engineering metals. Copper often is used where resistance to corrosion is of prime importance. Sometimes, it is better to use a copper alloy rather than an unalloyed copper.

In general, copper resists nonoxidizing mineral and organic acids, caustic solutions, saline solutions, and various natural waters or process waters. It is suitable for underground service because it resist soil corrosion. Copper is not suitable for service in oxidizing acids such as nitric acid, and it is not recommended for use with, ammonia, nitric acid, acid chromate solutions, ferric chloride, mercury salts, perchlorates, or persulfates. Also, copper may corrode in aerated nonoxidizing acids such as sulfuric or acetic acids, even though it is practically immune to these acids in the complete absence of air.

Tough pitch copper is considered to be immune to stress-corrosion cracking in ammonia and the other agents that induce season cracking of brasses. However, tough pitch copper is susceptible to embrittlement in reducing atmosphere, especially those containing hydrogen.

Resistance to specific corroding agents. Depending on concentration and specific conditions of exposure, copper generally resists the following agents.

Acids: mineral acids such as hydrochloric and sulfuric acids; organic acids such as acetic acid (including vinegar and acetates), carbolic acid, citric acid, formic acid, oxalic acid, and tartaric acid; fatty acids; and acidic solutions containing sulfur, such as the sulfurous acid and sulfite solutions used in pulp mills

Alkalies: fused sodium or potassium hydroxide; concentrated or dilute caustic solutions

Salt solutions: aluminum chloride, aluminum sulfate, calcium chloride, copper sulfate, sodium carbonate, sodium nitrate, sodium sulfate, and zinc sulfate

Waters: all types of potable water, many industrial and mine waters, seawater, and brackish water

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Forgeability. 65% of C37700 (forging brass)

Formability. Excellent for cold working and hot forming

Weldability. Soldering: excellent. Brazing and resistance butt welding: good. Gas-shielded arc welding: fair. Oxyfuel gas, shielded metal-arc, resistance spot, and resistance seam welding: not recommended

Annealing temperature. 475 to 750 °C (900 to 1400 °F). See also Fig. 4 and 17.

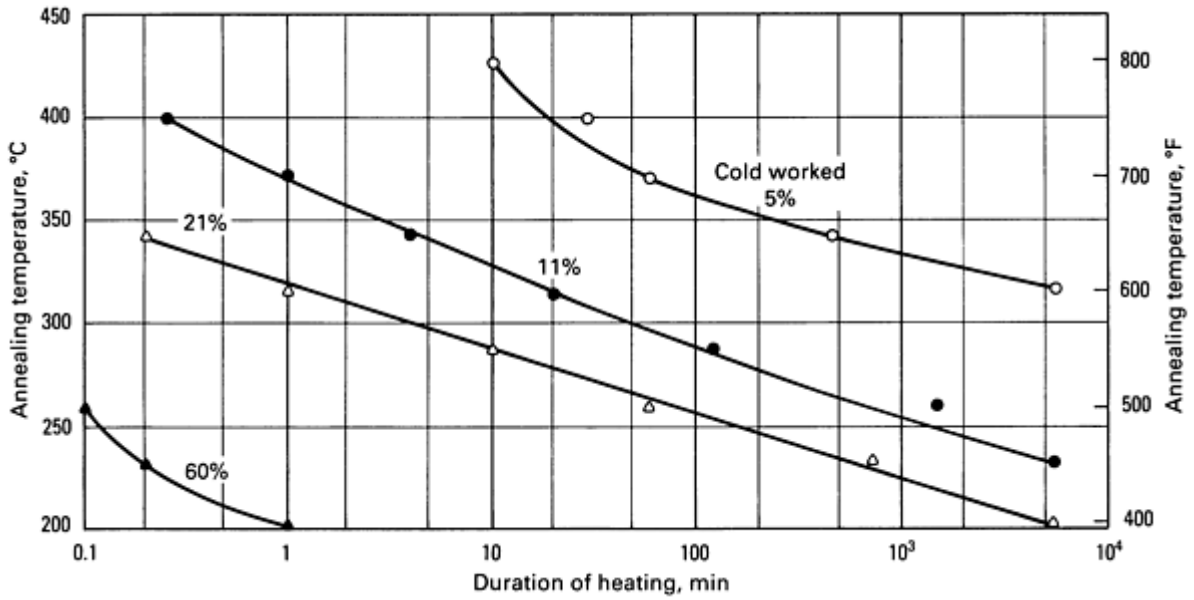

Fig. 17 Time-temperature relationships for annealing C11000 and similar coppers

Hot-working temperature. 750 to 875 °C (1400 to 1600 °F)

Typical softening temperature. 360 °C (675 °F)

C11100
99.95Cu-0.04O-0.01Cd

Commercial Names

Previous trade name. Electrolytic tough pitch copper, anneal resistant

Common name. Anneal-resistant electrolytic copper

Specifications

Chemical Composition

Composition limits. 99.90 Cu min. Limits on O and Cd or other elements present to make this copper anneal resistant are established by conductivity tests and/or stress relaxation tests rather than by chemical analysis.

Applications

Typical uses. Produced mainly as wire for electrical power transmission where resistance to softening under overloads is desired

Mechanical Properties

Typical tensile properties. Tensile strength, 455 MPa (66 ksi); elongation, 1.5% in 150 cm (60 in.)

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Mass Characteristics

Density. 8.89 to 8.94 g/cm^3 (0.321 to 0.323 lb/in.^{3} at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1085 °C (1980 °F)

Solidus temperature. 1065 °C (1950 °F)

Coefficient of linear thermal expansion. 17.0 μm/m · K (9.4 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 17.3 μm/m · K (9.6 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 17.7 μm/m · K (9.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 388 W/m · K (224 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric: 100% IACS at 20 °C (68 °F)

Electrical resistivity. 17.2 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Forgeability. 65% of C37700 (forging brass)

Formability. Excellent for cold working and hot forming. Common processes include drawing, stranding, and stamping.

Weldability. Soldering: excellent. Brazing and resistance butt welding: good. Gas-shielded arc welding: fair. Oxyacetylene coated metal-arc and resistance spot and seam welding: not recommended

Annealing temperature. 475 to 750 °C (900 to 1400 °F)

Hot-working temperature. 750 to 875 °C (1400 to 1600 °F)

Typical softening temperature. 355 °C (675 °F)

C11300, C11400, C11500, C11600
99.96Cu + Ag-0.4O

Commercial Names

Previous trade name. Tough pitch copper with silver

Common name. Silver-bearing tough pitch copper

Designation. STP

Mass Characteristics

Density. 8.89 to 8.94 g/cm^3 (0.321 to 0.323 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1080 °C (1980 °F)

Coefficient of linear thermal expansion. 17.7 μm/m · K (9.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 388 W/m · K (224 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric: 100% IACS at 20 °C (68 °F)

Electrical resistivity. 17.2 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Forgeability. 65% of C37700 (forging brass)

Formability. Excellent for cold working and hot forming

Weldability. Soldering: excellent. Brazing and resistance butt welding: good. Gas-shielded arc welding: fair. Oxyacetylene coated metal-arc and resistance spot and seam welding: not recommended

Annealing temperature. 475 to 750 °C (900 to 1400 °F)

Hot-working temperature. 750 to 875 °C (1400 to 1600 °F)

C12500, C12700, C12800, C12900, C13000

Commercial Names

Previous trade name. Fire-refined tough pitch copper (C12500); fire-refined tough pitch copper with silver (C12700, C12800, C12900, C13000)

Common name. Fire-refined copper

Designation. C12500; FRTP. Others: FRTSP

Specifications

ASTM. Flat products: B 11, B 124, B 133, B 152, B 272. Rod: B 12, B 124, B 133. Shapes: B 124, B 133, B 216. Lake copper wirebar, cake, slab, billet, and ingot: B 4

Government. MIL-W-3318

Chemical Composition

Composition limits in ASTM B 216: 99.88 Cu + Ag min (minimum Ag content may be specified by agreement), 0.012 As max, 0.003 Sb max, 0.025 Se + Te max, 0.05 Ni max, 0.003 Bi max, 0.004 Pb max

Consequence of exceeding impurity limits. Bi and Pb can cause hot workability problems if composition limits are exceeded. Se and Te greatly affect recrystallization and grain growth.

Applications

Typical uses. Architectural: Building fronts, downspouts, flashing, gutters, roofing, screening, spouting. Automotive: gaskets, radiators. Electrical: busbars, contacts, radio parts, commutator segments, switches, terminals. Miscellaneous: anodes, chemical process equipment, kettles, pans, printing rolls, rotating bands, roadbed expansion plates, vats. This copper is suitable for use where the high conductivity and low annealing temperature of electrolytic tough pitch copper are not required.

Precautions in use. This copper is subject to embrittlement when heated in a reducing atmosphere, as in annealing, brazing, or welding at temperatures of 370 °C (700 °F) or above. If hydrogen or carbon monoxide is present, embrittlement can be rapid.

Mechanical Properties

Tensile properties. See Table 15.

Table 15 Typical mechanical properties of C12500, C12700, C12800, C12900, and C13000

(b) Elongation in 1500 mm (60 in.)

Shear strength. See Table 15.

Hardness. See Table 15.

Fatigue strength. Strip, OS025 temper, 76 MPa (11 ksi)

Mass Characteristics

Density. 8.89 g/cm^3 (0.321 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1085 °C (1980 °F)

Coefficient of linear thermal expansion. 16.8 μm/m · K (9.3 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 17.4 μm/m · K (9.7 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 17.7 μm/m · K (9.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 377 W/m · K (218 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 98% IACS at 20 °C (68 °F), annealed

Electrical resistivity. 17.6 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent for hot or cold forming but should not be heated for forming or annealed in a reducing atmosphere

Joining. Riveting: use copper rivets. Pressure welding: use Koldweld proprietary method. Soft solder with all grades of solder, commercial solder fluxes, or rosin. Silver braze with all types of flame using copper-phosphorus, silver, or copper-zinc (see ASTM B 260). Satisfactory fluxes are commercially available. Use gas-shieldedarc welding processes with recommended filler metals, depending on application. Other welding methods generally are not recommended.

Annealing temperature. 400 to 650 °C (750 to 1200 °F)

Hot-working temperature. 750 to 950 °C (1400 to 1750 °F)

C14300, C14310
99.9Cu-0.1Cd; 99.8Cu-0.2Cd

Commercial Names

Previous trade names. C14300: cadmium-copper, deoxidized

Chemical Composition

Copper. 99.8 to 99.9 Cu

Cadmium. C14300, 0.05 to 0.15 Cd; C14310, 0.1 to 0.3 Cd

Applications

Typical uses. Rolled strip for anneal-resistant electrical applications: applications requiring thermal softening and embrittlement resistance, such as lead frames, contacts, terminals, solder-coated and solder-fabricated parts. Furnace brazed assemblies and welded components such as tube or cable wrap

Mechanical Properties

Tensile properties. See Table 16.

Table 16 Typical mechanical properties of C14300 and C14310

Temper	Tensile strength		Yield strength at 0.2% offset		Elongation in 50 mm (2 in.), %
	MPa	ksi	MPa	ksi	
OS025	220	32	75	11	42
H04	310	45	275	40	14
H08	350	51	330	48	7
H10	400	58	385	56	3

Shear strength. See Table 16.

Hardness. See Table 16.

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1080 °C (1976 °F)

Solidus temperature. 1052 °C (1926 °F)

Coefficient of linear thermal expansion. 17.0 μm/m · K (9.4 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 17.3 μm/m · K (9.6 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 17.7 μm/m · K (9.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. C14300, 377 W/m · K (218 Btu/ft · h · °F) at 20 °C (68 °F); C14310, 343 W/m · K (198 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric: C14300, 96% IACS at 20 °C (68 °F); C14310, 85% IACS at 20 °C (68 °F)

Electrical resistivity. C14300, 18 nΩ · m at 20 °C (68 °F); C14310, 20.3 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Forgeability. 65% of C37700 (forging brass)

Formability. Excellent capacity for cold working and hot forming

Weldability. Soldering, brazing, and gas-shielded arc welding: excellent, Oxyacetylene welding and resistance butt welding: good. Coated metal arc and resistance seam and spot welding: not recommended

Annealing temperature. 535 to 750 °C (1000 to 1400 °F)

Hot-working temperature. 750 to 875 °C (1400 to 1600°F)

C14500
99.5Cu-0.5Te

Commercial Names

Previous trade name. Phosphorus-deoxidized tellurium-bearing copper

Common name. Free-machining copper

Designation. DPTE

Specifications

ASTM. Flat products and rod: B 124, B 301, Shapes: B 124, B 283

Chemical Composition

Composition limits. 99.90 Cu + Ag + Te min, 0.004 to 0.012 P, 0.40 to 0.60 Te

Applications

Typical uses. Forgings and screw machine products requiring high conductivity, extensive machining, corrosion resistance, copper color, or a combination of these qualities; typical parts include electrical connectors, motor parts, switch parts, plumbing fixtures, soldering tips, welding-torch tips, transistor bases, and parts that are assembled by furnace brazing

Precautions in use. Carbide-tipped tools should be used for machining C14500.

Mechanical Properties

Tensile properties. See Table 17.

Table 17 Typical mechanical properties of C14500, C14700, and C18700 rod

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness, HRB	Shear strength

50 mm (2 in.) diameter								
H02	290	42	270	39	35	42	170	25

(a) At 0.5% extension under load

Shear strength. See Table 17.

Hardness. See Table 17.

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1075 °C (1967 °F)

Solidus temperature. 1051 °C (1924 °F)

Coefficient of linear thermal expansion. 17.1 μm/m · K (9.5 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 17.4 μm/m · K (9.7 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 17.8 μm/m · K (9.9 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 355 W/m · K (205 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric: 93% IACS at 20 °C (68 °F)

Electrical resistivity. 18.6 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 85% of C36000 (free-cutting brass)

Formability. Good capacity for being cold worked, usually by drawing, rolling, or swaging. Excellent capacity for being hot formed, most often by extrusion, forging, or rolling

Weldability. Soldering or brazing: excellent. Arc welding, oxyfuel gas welding, and most resistance welding processes are not recommended.

Annealing temperature. 425 to 650 °C (800 to 1200 °F)

Hot-working temperature. 750 to 875 °C (1400 to 1600 °F)

C14700
99.6Cu-0.4S

Commercial Names

Previous trade name. Sulfur-bearing copper

Common name. Free-machining copper, sulfur copper

Specifications

ASTM. Flat products and rod: B 301

Chemical Composition

Composition limits. 0.20 to 0.50 S, 0.10 max other (total), bal Cu + Ag

Applications

Typical uses. Screw machine products and parts requiring high conductivity, extensive machining, corrosion resistance, copper color, or a combination of these

properties; electrical connectors, motors, and switch components; plumbing fittings; furnace-brazedbrazed articles; screws; soldering coppers; rivets; and welding-torch tips

Mechanical Properties

Tensile properties. See Table 17, C14500.

Hardness. See Table 17, C14500.

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1076 °C (1969 °F)

Solidus temperature. 1067 °C (1953 °F)

Coefficient of linear thermal expansion. 17.0 μm/m · K (9.4 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 17.3 μm/m · K (9.6 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 17.7 μm/m · K (9.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 374 W/m · K (216 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric: O61 temper, 95% IACS at 20 °C (68 °F)

Electrical resistivity. 18.1 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 85% of C36000 (free-cutting brass)

Annealing temperature. 425 to 650 °C (800 to 1200 °F)

Hot-working temperature. 750 to 875 °C (1400 to 1600 °F)

C15000
99.85Cu-0.15Zr

Commercial Names

Trade name. Amzirc Brand copper; N-4 alloy

Common name. Zirconium-copper

Chemical Composition

Composition limits. 99.95 Cu + Ag + Zr min, 0.13 to 0.20 Zr

Applications

Typical uses. Stud bases for power transmitters and rectifiers, switches and circuit breakers for high-temperature service, commutators, resistance welding tips and wheels, solderless wrapped connectors. Zirconium-copper is heat treatable and retains much of its room-temperature strength up to 450 °C (840 °F).

Precautions in use. During hot working, forging should be discontinued if the temperature falls below 800 °C (1470 °F). The part must be reheated to at least 900 °C (1650 °F) before forging can be resumed.

Mechanical Properties

Tensile properties. See Tables 18 and 19, and Fig. 18.

Table 18 Typical mechanical properties of C15000

Note: Data are for materials solution treated, cold worked the indicated amount, then aged 1 h at 425 °C (795 °F).

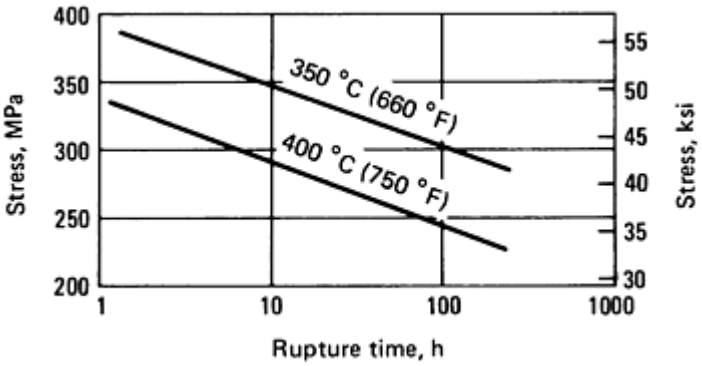

Fig. 19 Stress-rupture properties of C15000, TH08 temper. Material was solution treated 1 h at 950 °C (1740 °F), quenched, cold worked 85%, and aged 1 h at 425 °C (795 °F).

Mass Characteristics

Density. 8.89 g/cm^3 (0.321 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1080 °C (1976 °F)

Solidus temperature. 980 °C (1796 °F)

Coefficient of linear thermal expansion. 16.9 μm/m · K (9.4 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 17.6 μm/m · K (9.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F); 20.2 μm/m · K (11.2 μin./in. · °F) at 20 to 650 °C (68 to 1200 °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. Solution-treated, cold-worked 84%, and aged material, 367 W/m · K (212 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric: 93% IACS at 20 °C (68 °F)

Electrical resistivity. Solution-treated, cold-worked 84%, and aged material, 18.6 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent capacity for being cold worked or hot formed. Most often fabricated by swaging, bending, heading, or forging

Weldability. Soldering: excellent. Brazing or resistance butt welding: good. Other welding processes are not recommended.

Heat treating. Solution treat 5 to 30 min at temperature, then age 1 to 4 h. Aging time and temperature depend on section size and amount of previous cold work.

Annealing temperature. 600 to 700 °C (1110 to 1300 °F)

Solution temperature. 900 to 925 °C (1650 to 1700 °F)

Aging temperature. Aged only, 500 to 550 °C (930 to 1020 °F); cold worked and aged, 375 to 475 °C (705 to 885 °F)

Hot-working temperature. 900 to 950 °C (1650 to 1740 °F)

C15100
99.9Cu-0.1Zr

Commercial Names

Trade name. ZHC Copper

Chemical Composition

Composition limits. 0.05 to 0.15 Zr, 0.005 Al max, 0.005 Mn max, 0.005 Fe max, 0.01 Al + Mn + Fe max, bal Cu

Applications

Typical uses. Lead frames for high-power electronic circuits, connectors, and switchblade jaws. Applications requiring high conductivity, moderate strength, good bend formability, and good stress relaxation resistance

Mechanical Properties

Tensile properties. See Table 21.

Table 21 Nominal mechanical properties of C15100 rolled strip

Temper	Tensile strength		Yield strength		Elongation in 50 mm (2 in.), %	Hardness, HRB	Fatigue strength[(a)]	
	MPa	ksi	MPa	ksi			MPa	ksi

H06	430	62	415	60	2	60	. . .	. . .

(a) At 10^8 cycles

Hardness. See Table 21.

Elastic modulus. 121 GPa (17.5×10^6 psi)

Fatigue strength. See Table 21.

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1080 °C (1976 °F)

Solidus temperature. 1065 °C (1949 °F) at 0.05 Zr; 966 °C (1771 °F) at 0.15 Zr

Coefficient of linear thermal expansion. 17.7 μm/m · K (9.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Thermal conductivity. 360 W/m · K (208 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric at 20 °C (68 °F); annealed, 95% IACS; rolled, 90% IACS

Electrical resistivity. At 20 °C (68 °F): annealed, 18.1 nΩ · m; rolled, 19.2 nΩ · m

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent capacity for both cold and hot forming.

Weldability. Solderability: excellent. Brazing or resistance butt welding: good. All other welding processes are not recommended.

Annealing temperature. 450 to 550 °C (840 to 1025 °F)

Hot-working temperature. 750 to 875 °C (1400 to 1600 °F)

Chemical Composition

Composition limits. 99.75 Cu min, 0.027-0.10 Ag, 0.04-0.080 P, 0.08-0.13 Mg

Applications

Typical uses. High-conductivity light-duty springs, electrical contacts, resistance welding electrodes, electrical fittings, clamps, connectors, diaphragms, electronic components

Mechanical Properties

Tensile properties. See Table 22.

Table 22 Mechanical properties of C15500 flat products

Temper	Tensile strength		Yield strength				Elongation in 50 mm (2 in.), %	Hardness		Fatigue strength

Modulus of rigidity. 44 GPa (6.4×10^6 psi)

Fatigue strength. See Table 22.

Mass Characteristics

Density. 8.9 g/cm^6 (0.322 lb/in.^{3})

Thermal Properties

Liquidus temperature. 1080 °C (1980 °F)

Solidus temperature. 1078 °C (1972 °F)

Coefficient of linear thermal expansion. 17.7 μm/m · K (9.8 μin./in. · °F) from 20 to 300 °C (68 to 570 °F)

Thermal conductivity. 345 W/m · K (200 Btu/ft · h · °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Annealed condition: 90% IACS at 20 °C (68 °F)

Electrical resistivity. Annealed condition after precipitation heat treatment: 1.92 μΩ· cm at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent capacity for cold working and hot forming

Hot forgeability. 65% of C37700 (forging brass)

Annealing temperature. 485 to 540 °C (900 to 1000 °F)

Hot-working temperature. 750 to 875 °C (1400 to 1600 °F)

Joining

Weldability. Welding not recommended except for resistance spot welding

Solderability. Excellent

Brazing. Excellent

C15710
99.8Cu-0.2Al_2O_3

Chemical Composition

Composition limits. 99.69 to 99.85 Cu, 0.15 to 0.25 Al_2O_3, 0.01 Fe max, 0.01 Pb max, 0.04 O max

Applications

Typical uses. Rolled strip, rolled flat wire, rod and wire for electrical connectors, light-duty current-carrying springs, inorganic insulated wire, thermocouple wire, lead wire, resistance welding electrodes for aluminum, heat sinks

Mechanical Properties

Tensile properties. See Table 23.

Table 23 Typical mechanical properties of C15710

Diameter		Amount of cold working or temper designation	Tensile strength[a]		Yield strength at 0.2% offset[a]		Elongation in 50 mm (2 in.), %	Hardness, HRB

		O61	345	50	290	42	. . .	. . .

(a) Properties will vary, depending on extrusion ratio and temperature.

Hardness. See Table 23.

Elastic modulus. Tension, 105 GPa (15×10^6 psi)

Mass Characteristics

Density. 8.82 g/cm^3 (0.319 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1080 °C (1980 °F)

Coefficient of linear thermal expansion. 19.5 μm/m · K (10.8 μin/in. · °F) from 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 360 W/m · K (208 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, 90% IACS at 20 °C (68 °F)

Electrical resistivity. 19.2 nΩ · m at 20 °C (68 °F); temperature coefficient, 5.22 nΩ · m per K at 20 °C (68 °F)

Fabrication Characteristics

Formability. Excellent for cold working; poor for hot forming

Weldability. Soldering: excellent. Brazing: good. Resistance butt welding: fair. Resistance spot and seam

welding: poor. Oxyacetylene, gas shielded arc, and coated metal arc welding are not recommended.

Annealing temperature. 650 to 875 °C (1200 to 1600 °F)

C15720
99.6Cu-0.4Al_2O_3

Chemical Composition

Composition limits. 99.49 to 99.6 Cu, 0.35 to 0.45 Al_2O_3, 0.01 Pb max, 0.01 Fe max, 0.04 O max

Applications

Typical uses. Rolled and drawn strip, rolled flat wire, drawn bar, rod, wire, and shapes for relay and switch springs, lead frames, contact supports, heat sinks, circuit breaker parts, rotor bars, resistance welding electrodes and wheels, and connectors. Parts requiring a combination of high strength and conductivity, particularly after exposure to high manufacturing or operating temperatures

Mechanical Properties

Tensile properties. See Table 24.

Table 24 Typical mechanical properties of C15720

Size	Amount of cold working or temper designation	Tensile strength[(a)]		Yield strength at 0.2% offset[(a)]		Elongation in 50 mm (2 in.), %	Hardness, HRB

102 mm (4.0 in.) diameter	M30	460	67	395	57	20	68

(a) Properties will vary, depending on extrusion ratio and temperature.

Hardness. See Table 24.

Elastic modulus. Tension, 113 GPa (16.4×10^6 psi)

Mass Characteristics

Density. 8.81 g/cm^3 (0.319 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1080 °C (1980 °F)

Coefficient of linear thermal expansion. 19.6 μm/m · K (10.9 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 353 W/m · K (204 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, 89% IACS at 20 °C (68 °F)

Electrical resistivity. 19.4 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Formability. Excellent for cold working; poor for hot forming

Weldability. Soldering: excellent. Brazing: good. Resistance butt welding: fair. Resistance spot and seam welding: poor. Oxyacetylene, gas-shielded arc, and coated metal arc welding are not recommended.

Annealing temperature. 650 to 925 °C (1200 to 1700 °F)

C15735
99.3Cu-0.7Al_2O_3

Chemical Composition

Composition limits. 99.19 to 99.35 Cu, 0.65 to 0.72 Al_2O_3, 0.01 Fe max, 0.01 Pb max, 0.04 O max

Applications

Typical uses. Rod for resistance welding electrodes, circuit breakers, feed-through conductors, heat sinks, motor parts; parts requiring retention of high strength and conductivity after high-temperature exposure

Mechanical Properties

Tensile properties. See Table 25.

Table 25 Typical mechanical properties of C15735 rod

Diameter		Amount of cold working or temper designation	Tensile strength[(a)]		Yield strength at 0.2% offset[(a)]		Elongation in 50 mm (2 in.), %	Hardness, HRB
mm	in.		MPa	ksi	MPa	ksi		

24	0.94	0%	485	70	420	61	16	77
19	0.75	39%	550	80	540	78	13	80
16	0.63	56%	585	85	565	82	10	83
64	2.5	M30	490	71	415	60	16	76
76	3.0	M30	565	82	540	78	11	78
102	4.0	M30	515	75	485	70	13	75

(a) Properties will vary, depending on extrusion ratio and temperature.

Hardness. See Table 25.

Elastic modulus. Tension, 123 GPa (17.8×10^6 psi)

Mass Characteristics

Density. 8.80 g/cm^3 (0.318 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1080 °C (1980 °F)

Coefficient of linear thermal expansion. 20 μm/m · K (11.1 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 420 J/kg · K (0.10 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 339 W/m · K (196 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, 85% IACS at 20 °C (68 °F)

Electrical resistivity. 20.3 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Formability. Excellent for cold working; poor for hot forming

Weldability. Soldering: excellent. Brazing: good. Resistance butt welding: fair. Resistance spot and seam welding: poor. Oxyacetylene, gas-shielded arc, and coated metal arc welding are not recommended.

Annealing temperature. 650 to 925 °C (1200 to 1700 °F)

C16200
99Cu-1Cd

Commercial Names

Previous trade name. Cadmium-copper

Specifications

ASTM. Wire: B 9, B 105

SAE. J463

Chemical Composition

Composition limits. 98.78 to 99.3 Cu, 0.7 to 1.2 Cd, 0.02 Fe max

Applications

Typical uses. Rolled strip, rod, and wire for trolley wire, heating pad and electric blanket elements, spring contacts, rail bands, high-strength transmission lines, connectors, cable wrap, switch gear components, waveguide cavities

Mechanical Properties

Tensile properties. See Table 26.

Table 26 Typical mechanical properties of C16200

Temper	Tensile strength		Yield strength[a]		Elongation in 50 mm (2 in.), %	Hardness
	MPa	ksi	MPa	ksi		
Flat products, 1 mm (0.04 in.) thick						
OS025 anneal (0.025 mm grain size)	240	35	76	11	52	54 HRF
Hard	415	60	310	45	5	64 HRB
Spring	440	64	. . .	. . .	3	73 HRB
Extra spring	495	72	405	59	1	75 HRB
Rod, 13 mm (0.50 in.) diameter						
OS050 anneal (0.050 mm grain size)	240	35	48	7	56	46 HRF
OS025 anneal (0.025 mm grain size)	250	36	83	12	57	46 HRF
Half hard (25%)	400	58	310	45	12	65 HRB
Hard	505	73	474	68.7	9	73 HRB
Wire, 0.25 mm (0.01 in.) diameter						
Drawn (>99%)	690	100	. . .	. . .	1.0[b]	. . .
Wire, 2 mm (0.08 in.) diameter						
OS025 anneal (0.025 mm grain size)	260	38	83	12	50	. . .
Hard	485	70	380	55	6	. . .
Spring	550	80	455	66	2	. . .

(a) At 0.5% extension under load.

(b) In 1.5 m (60 in.)

Shear strength. Rod, 13 mm (0.50 in.) in diameter: OS050 temper, 185 MPa (27 ksi); H04 temper, 385 MPa (56 ksi)

Hardness. See Table 26.

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Fatigue strength. At 10^8 cycles for rod 13 mm (0.50 in.) in diameter: OS050 temper, 100 MPa (14.5 ksi); H04 temper, 205 MPa (30 ksi)

Mass Characteristics

Density. 8.89 g/cm^3 (0.321 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1076 °C (1969 °F)

Solidus temperature. 1030 °C (1886 °F)

Coefficient of linear thermal expansion. 17.0 μm/m · K (9.4 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 17.3 μm/m · K (9.6 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 17.7 μm/m · K (9.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 360 W/m · K (208 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, 90% IACS at 20 °C (68 °F)

Electrical resistivity. 19.2 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent for cold working; good for hot forming

Weldability. Soldering and brazing: excellent. Oxyfuel gas, gas shielded arc, and resistance butt welding: good. Shielded metal arc, resistance spot, and resistance seam welding are not recommended.

Annealing temperature. 425 to 750 °C (800 to 1400 °F)

Hot-working temperature. 750 to 875 °C (1400 to 1600 °F)

C17000
98Cu-1.7Be-0.3Co

Commercial Names

Trade name. Berylco 165

Common name. Beryllium-copper; 165 alloy

Specifications

ASTM. Flat products: B 194. Rod, bars: B 196. Forgings and extrusions: B 570

SAE: J463

Government: QQ-C-533

Resistance Welding Manufacturer's Association. Class IV

Chemical Composition

Composition limits. 1.60 to 1.79 Be, 0.20 Ni + Co min, 0.6 Ni + Fe + Co max, bal Cu

Applications

Typical uses. Bellows, Bourdon tubing; diaphragms, fuse clips, fasteners, lock washers, springs, switch and relay parts, electrical and electronic components, retaining rings, roll pins, valves, pumps, spline shafts, rolling mill parts, welding equipment, nonsparking safety tools

Precautions in use. This material is a potential health hazard. Because it contains beryllium, ventilation must be provided for dry sectioning and grinding, machining,

melting, welding, and any other process that produces metal dust or fumes.

Mechanical Properties

Tensile properties. See Tables 27 and 28.

Table 27 Typical mechanical properties and electrical conductivity of C17000 strip

Temper	Tensile strength		Proportional limit at 0.002% offset		Yield strength at 0.2% offset		Elongation in 50 mm (2 in.), %	Electrical conductivity, %IACS	Fatigue strength[a]

TM06	320-350	31-37 HRC	52-56 HR30N
TM08	434-375	32-38 HRC	55-58 HR30N

Poisson's ratio. 0.30

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 50 GPa (7.3×10^6 psi)

Fatigue strength. See Table 27.

Mass Characteristics

Density. 8.26 g/cm^3 (0.298 lb/in.^{3}) at 20 °C (68 °F)

Volume change on phase transformation. During age hardening: 0.2% maximum decrease in length; 0.6% maximum increase in density

Thermal Properties

Liquidus temperature. 980 °C (1800 °F)

Solidus temperature. 865 °C (1590 °F)

Coefficient of linear thermal expansion. 16.7 μm/m · K (9.3 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 17.0 μm/m · K (9.4 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 17.8 μm/m · K (9.9 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 420 J/kg · K (0.10 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 118 W/m · K (69 Btu/ft · h · °F) at 20 °C (68 °F); 145 W/m · K (84 Btu/ft · h · °F) at 200 °C (392 °F)

Electrical Properties

Electrical conductivity. Volumetric, 15 to 33% IACS at 20 °C (68 °F), depending on heat treatment. See also Tables 27 and 28.

Electrical resistivity. Typical, 76.8 nΩ · m at 20 °C (68 °F), but varies with heat treatment

Chemical Properties

General corrosion behavior. Similar to that of other high-copper alloys and basically the same as that of pure copper

Resistance to specific corroding agents. Essentially the same as that of C17200. See also Table 30.

Table 30 Approximate corrosion resistance of C17000

Good resistance[a]	**Fair resistance[b]**	**Poor resistance[c]**
Acetate solvents	Acetic acid, cold aerated	Acetic acid, hot
Acetic acid, cold, unaerated	Acetic anhydride	Ammonia, moist
Alcohols	Acetylene	Ammonium hydroxide
Ammonia, dry	Ammonium chloride	Ammonium nitrate
Atmosphere, rural, industrial, marine	Ammonium sulfate	Bromine, aerated or hot

marine	Aniline	Chlorine, moist or warm
Benzene	Bromine, dry	Chromic acid
Borax	Carbonic acid	Ferric chloride
Boric acid	Copper nitrate	Ferric sulfate
Brine	Ferrous chloride	Fluorine, moist or warm
Butane	Ferrous sulfate	Hydrochloric acid, over 0.1%
Carbon dioxide	Fluorine, dry	Hydrocyanic acid
Carbon tetrachloride	Hydrochloric acid, up to 0.1%	Hydrofluoric acid, concentrate
Chlorine, dry	Hydrofluoric acid, dilute	Hydrogen sulfide, moist
Freon	Hydrofluosilicic acid	Lactic acid, hot or aerated
Gasoline	Hydrogen peroxide	Mercuric chloride
Hydrogen	Nitric acid, up to 0.1%	Mercury
Nitrogen	Phenol	Mercury salts
Oxalic acid	Phosphoric acid, unaerated	Nitric acid, over 0.1%
Potassium chloride	Potassium hydroxide	Phosphoric acid, aerated
Potassium sulfate	Sodium hydroxide	Picric acid
Propane	Sodium hypochlorite	Potassium cyanide
Rosin	Sodium peroxide	Silver chloride
Sodium bicarbonate	Sodium sulfide	Sodium cyanide
Sodium chloride	Sulfur	Stannic chloride
Sodium sulfate	Sulfur chloride	Sulfuric acid, aerated

Sulfur dioxide	Sulfuric acid, unaerated	Sulfurous acid
Sulfur trioxide	Zinc chloride	Tartaric acid, hot or aerated
Water, fresh or salt		

(a) <0.25 mm/year (0.01 in./year) penetration.

(b) 0.025-2.5 mm/year (0.001-0.10 in./year) penetration.

(c) >0.25 mm/year (0.01 in./year) penetration

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. This alloy can be formed, drawn, blanked, pierced, and machined on the unhardened condition.

Weldability. Soldering, brazing, gas-shielded arc welding, shielded metal arc welding, and resistance spot welding: good. Resistance seam and resistance butt welding: fair. Oxyfuel gas welding is not recommended.

Recrystallization temperature. 730 °C (1350 °F)

Annealing temperature. Strip, thin rod, wire: 775 to 800 °C (1425 to 1475 °F) for 10 min, water quench. Larger sections: 1 h for each 25 mm (1 in.) of thickness

Solution temperature. 760 to 790 °C (1400 to 1450 °F). All annealing of this material is a solution treatment.

Aging temperature. 260 to 425 °C (500 to 800 °F). Maximum strength is obtained by aging 1 to 3 h at 315 to 345 °C (600 to 650 °F), depending on amount of cold work preceding the aging treatment.

Hot-working temperature. 650 to 825 °C (1200 to 1500 °F)

Hot-shortness temperature. 845 °C (1550 °F)

C17200, C17300

Commercial Names

Previous trade names. C17200: 25 alloy, alloy 25. C17300: alloy M25

Common name. Beryllium-copper

Specifications

AMS. Flat products: 4530, 4532, Rod, bar, and forgings: 4650. Wire: 4725

ASTM. Flat products: B 194 (C17200 only), B 196. Rod and bar: B 196. Wire: B 197 (C17200 only). Forgings and extrusions: B 570 (C17200 only)

SAE. J463 (C17200)

Government. Strip: QQ-C-533 (C17200 only). Rod and bar: MIL-C-21657, QQ-C-530. Wire: QQ-C-530

Resistance Welding Manufacturers' Association. Class IV

Chemical Composition

Composition limits. 1.80 to 2.00 Be, 0.20 Ni + Co min, 0.6 Ni + Co + Fe max, 0.10 Pb max (C17200) or 0.20 to 0.6 Pb (C17300), 0.5 max other (total), bal Cu

Consequences of exceeding impurity limits. Excessive P and Si decrease electrical conductivity. Excessive Sn and Pb cause hot shortness.

Applications

Typical uses. C17200 and C17300 are used in parts that are subject to severe forming conditions but require high strength, anelasticity, and fatigue and creep resistance (a wide variety of springs, flexible metal hose, Bourdon tubing, bellows, clips, washers, retaining rings); in parts that require highstrength or wear resistance along with good electrical conductivity and/or magnetic

characteristics (navigational instruments, nonsparking safety tools, firing pins, bushings, valves, pumps, shafts, rolling mill parts); and in parts requiring high strength and good corrosion resistance and electrical conductivity (electrochemical springs, diaphragms, contact bridges, bolts, screws).

Precautions in use. Because this alloy contains beryllium, it is a potential health hazard. Adequate ventilation should be provided for dry sectioning, melting, grinding, machining, welding, and any other fabrication or testing process that produces dust or fumes.

Mechanical Properties

Tensile properties. See Tables 31 and 32.

Table 31 Tensile property ranges for C17200 and C17300 strip of various tempers

(a) (a) In reversed bending at 10^8 cycles.

(b) Proprietary mill heat treatment to produce tensile strength of 1030-1100 MPa (150 to 160 ksi)

Structure

Crystal structure. Alpha copper solid solution is face-centered cubic, disordered. At 20 °C (68 °F), the lattice parameter of the parent phase with about 1.8% Be, homogenized at 815 °C (1500 °F), and quenched in water, is 0.3570 nm. The lattice parameter decreases sharply with increasing beryllium content. Age hardening begins with the formation of coherent Guinier-Preston (G-P) zones on {100} planes. The intermediate precipitate γ' may be nucleated either from the G-P zones or discontinuously at the grain boundaries. In either case, it has a B2 superlattice structure, a lattice parameter of 0.270 nm, and the orientation $(\bar{1}13)\alpha \parallel (130)\gamma'$, $[110]\alpha \parallel [001]\gamma'$. The equilibrium precipitate γ', which requires longer aging times than are normally used commercially, is body-centered cubic of the CsCl type with a B2 superlattice structure, a lattice parameter of 0.270 nm, and the orientation $(\bar{1}11)\alpha \parallel (110)\gamma$, $[110]\alpha \parallel [001]\gamma$.

Microstructure. Small, mainly spheroidal, uniformly dispersed (Cu,Co)Be beryllides (bluish gray) in a matrix of equiaxed α-copper. (Typical grain size is 0.012 to 0.030 nm in wrought product.) There is a strong tendency to form mechanical and annealing twins. In the age-hardened condition, the matrix shows pronounced striations (the so-called tweed structure) caused by G-P zone formation on {110} planes. At long aging times (>8 h), or high aging temperatures (>315 °C, or >600 °F), there is a strong tendency to form continuous bands of cellular precipitate at the grain boundaries and along twin boundaries.

Conventional metallographic techniques may be used. Dry sectioning and grinding should be done in a ventilated area.

One of the common etchants for immersion etching is ammonium persulfate: 3 parts concentrated NH_4OH, 1 part 3% H_2O_2, 2 parts 10% $(NH_4)_2S_2O_3$, and 7 to 10 parts H_2O. This etchant reveals general details of the microstructure. The matrix is stained blue to deep lavender, depending on the state of heat treatment, etchant concentration, and etching time. The etchant should be freshly made.

A common etchant for swabbing is potassium dichromate: $K_2Cr_2O_7$, 1.5 g NaCl, 8 ml H_2SO_4, and 100 ml H_2O. This etchant emphasizes grain boundaries, particularly when heavily decorated with discontinuous precipitate. A very effective procedure for studying grain boundaries and discontinuous precipitation is to first etch with ammonium persulfate, then remove the stain with a single wipe of the dichromate etchant.

Mass Characteristics

Density. 8.25 g/cm^3 (0.298 lb/in.^{3}) at 20 °C (68 °F)

Volume change on phase transformation. During age hardening, there is a maximum decrease in length of 0.2% and a maximum increase in density of 0.6%.

Thermal Properties

Liquidus temperature. 980 °C (1800 °F)

Solidus temperature. 865 °C (1590 °F)

Coefficient of linear thermal expansion. 16.7 μm/m · K (9.3 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 17.0 μm/m · K (9.4 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 17.8 μm/m · K (9.9 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 420 J/kg · K (0.10 Btu/lb · °F) at 20 to 100 °C (68 to 212 °F)

Thermal conductivity. 105 to 130 W/m · K (60 to 75 Btu/ft · h · °F) at 20 °C (68 °F); 130 to 133 W/m · K (75 to 77 Btu/ft · h · °F) at 200 °C (392 °F)

Electrical Properties

Electrical conductivity. Volumetric, 15 to 30% IACS at 20 °C (68 °F), depending on heat treatment. See also Tables 32 and 33.

Electrical resistivity. 57 to 115 nΩ · m at 20 °C (68 °F), depending on heat treatment

Chemical Properties

General corrosion behavior. Similar to that of other high-copper alloys; basically the same as that of pure copper

Resistance to specific corroding agents. See Table 34.

Table 34 Approximate corrosion resistance of C17200 and C17300

Good resistance[a]	Fair resistance[b]	Poor resistance[c]
Acetate solvents	Acetic acid, cold, aerated	Acetic acid, hot
Acetic acid, cold, unaerated	Acetic anhydride	Ammonia, moist
Alcohols	Acetylene	Ammonium hydroxide
Ammonia, dry	Ammonium chloride	Ammonium nitrate
Atmosphere, rural, industrial, marine	Ammonium sulfate	Bromine, aerated or hot
Benzene	Aniline	Chlorine, moist or warm
Borax	Bromine, dry	Chromic acid
Boric acid	Carbonic acid	Ferric chloride
Brine	Copper nitrate	Ferric sulfate
Butane	Ferrous chloride	Fluorine, moist or warm
Carbon dioxide	Ferrous sulfate	Hydrochloric acid, over 0.1%
Carbon tetrachloride	Fluorine, dry	Hydrocyanic acid
Chlorine, dry	Hydrochloric acid, up to 0.1%	Hydrofluoric acid, concentrated
Freon	Hydrofluoric acid, dilute	Hydrogen sulfide, moist
Gasoline	Hydrofluosilicic acid	Lactic acid, hot or aerated
Hydrogen	Hydrogen peroxide	Mercuric chloride
Nitrogen	Nitric acid, up to 0.1%	Mercury
Oxalic acid	Phenol	Mercury salts

Water, fresh or salt	Zinc chloride	

(a) <0.25 mm/year (0.01 in./year) attack.

(b) 0.025-2.54 mm/year (0.001-0.10 in./year) attack.

(c) >0.25 mm/year (0.01 in./year) attack

Fabrication Characteristics

Machinability. C17200: 20% of C36000 (free-cutting brass). C17300: 50% of C36000. Both alloys can be readily machined by all conventional methods. Specific machining parameters depend on shapes, machining method, and temper or condition of the metal. The leaded version of this alloy, C17300, is especially intended for machined parts. Other properties are unchanged by the addition of lead to enhance machinability.

Recrystallization temperature. Approximately 730 °C (1350 °F)

Annealing temperature. Strip, thin rod, and wire: 760 to 790 °C (1400 to 1450 °F)/10 min/water quench. Larger sections: 1 h per inch or fraction of an inch of cross section

Solution temperature. 760 to 790 °C (1400 to 1450 °F). All annealing of this material is a solution treatment.

Aging temperature. 260 to 425 °C (500 to 800 °F). Maximum strength is obtained by aging material 1 to 3 h at 315 to 345 °C (600 to 650 °F), depending on the amount of cold work.

Hot-working temperature. 650 to 800 °C (1200 to 1475 °F). C17300 cannot be hot rolled or forged, but it can be hot extruded.

Hot-shortness temperature. 845 °C (1550 °F)

C17410
99.2Cu-0.3Be-0.5Co

Chemical Composition

Composition limits. 0.15 to 0.5 Be, 0.35 to 0.6 Co, 0.2 Al max, 0.2 Si max, 0.2 Fe max, 99.5 min Cu + Ag + named elements

Applications

Typical uses. Strip and wire: fuse clips, fasteners, springs, diaphragms, lead frames, switch parts, and electrical connectors. Rod and plate: resistance spot welding tips, die casting plunger tips, tooling for plastic molding

Precautions in use. Because this alloy contains beryllium, it is a potential health hazard. Adequate safety precautions are mandatory for all melting, welding, grinding, and machining operations.

Mechanical Properties

Tensile properties. See Table 35.

Table 35 Nominal mechanical properties of mill-hardened C17410 strip

Temper	Tensile strength		Yield strength		Elongation in 50 mm (2 in.), %	Hardness, HRB	Fatigue strength	
	MPa	ksi	MPa	ksi			MPa	ksi
$\frac{1}{2}$ HT	725	105	620	90	15	95	. . .	. . .

Hardness. See Table 35.

Elastic modulus. 138 GPa (20.0×10^6 psi)

Fatigue strength. See Table 35.

Mass Characteristics

Density. 8.80 g/cm^3 (0.318 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1065 °C (1950 °F)

Solidus temperature. 1025 °C (1875 °F)

Thermal conductivity. 233 W/m · K (135 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 45% IACS at 20 °C (68 °F)

Electrical resistivity. 38.2 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 25% of C36000 (free-cutting brass)

Formability. Excellent capacity for both cold and hot forming

Weldability. Solderability, brazing, or resistance spot welding: good. Oxyacetylene welding is not recommended. Other welding processes: fair

Heat-treating temperature. 450 to 550 °C (840 to 1025 °F)

Hot-working temperature. 650 to 925 °C (1200 to 1700 °F)

C17500

SAE. J463

Government. Rod, bar: MIL-C-46087. Strip: MIL-C-81021

Resistance Welding Manufacturers' Association. Class III

Chemical Composition

Composition limits. 0.40 to 0.7 Be, 2.4 to 2.7 Co, 0.10 Fe max, 0.5 max other (total), bal Cu

Applications

Typical uses. Strip, wire: fuse clips, fasteners, springs, switch parts, electrical connectors, and conductors. Rod, plate: resistance spot welding tips, seam welding discs, die casting plunger tips, tooling for plastic molding

Precautions in use. Because this alloy contains beryllium, it is a potential health hazard. Adequate safety precautions are mandatory for all melting, welding, grinding, and machining operations.

Mechanical Properties

Tensile properties. See Table 36 and Fig. 20.

Table 36 Typical mechanical properties and electrical conductivity of C17500

(a) Reversed bending at 10^8 cycles.

(b) Proprietary mill hardening for maximum strength.

(c) Proprietary mill hardening for maximum electrical conductivity

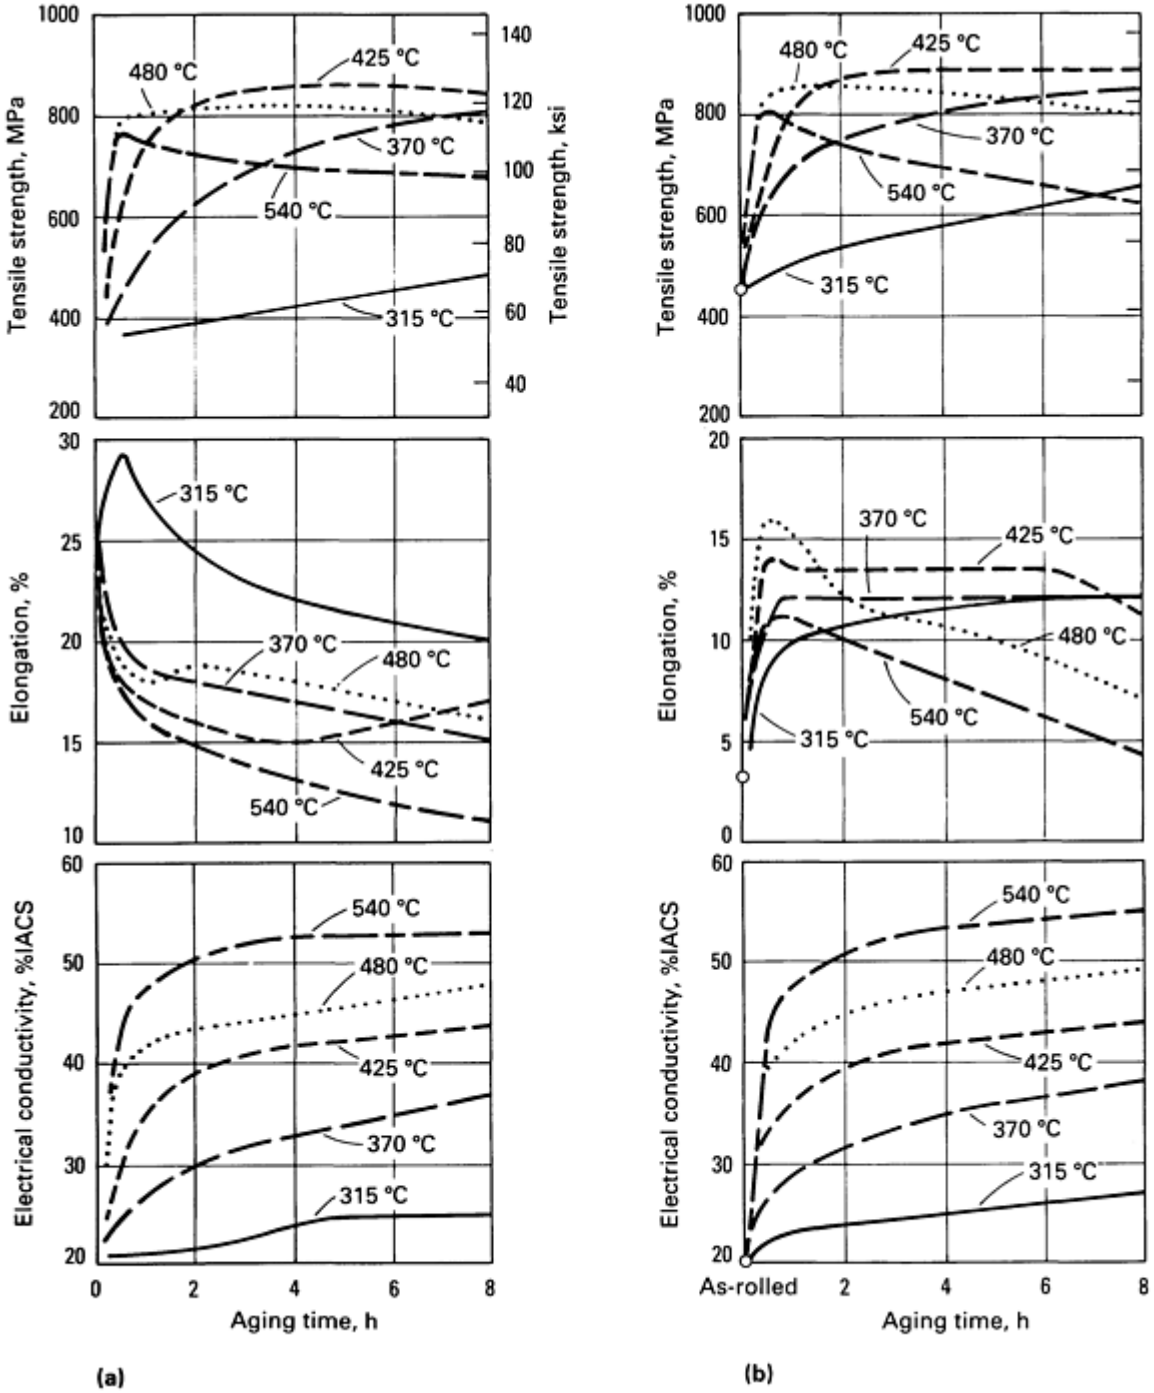

Fig. 20 Aging curves for C17500. (a) TB00 temper. (b) TD02 temper

Hardness. See Table 36.

Elastic modulus. Tension, 125 to 130 GPa (18 to 19 × 10^6 psi)

Fatigue strength. Rod, TF00 temper (rotating-beam tests): 275 to 310 MPa (40 to 45 ksi) at 10^7 cycles. Strip: see Table 36.

Structure

Crystal structure. The α-Cu solid solution is face-centered cubic. The beryllide, (Cu,Co)Be, is ordered body-centered cubic of the CsCl (B2) type.

Microstructure. Alpha copper with beryllium in solid solution and with (Cu,Co)Be beryllide inclusions. The appearance of the matrix of the beryllides depends on the extent of deformation and the state of heat treatment.

In the cast condition, the matrix is essentially like pure copper; the beryllides, which are blue-gray, are large and

sharply angular in the grain boundaries and small with Widmanstätten orientation within the grains. When such cast shapes are annealed the cored appearance is reduced slightly, and the matrix becomes slightly cleaner as small amounts of the beryllides are dissolved. As the cast product is reduced by either hot or cold working, the beryllides are broken up and uniformly distributed.

For such products as strip or rod, the microstructure is fine-grain equiaxed α-copper with small, mainly spherical, uniformly dispersed beryllides. For all products types, there is little difference in microstructure between the annealed and the aged conditions.

Metallography is by ordinary metallographic techniques, except that grinding must be performed in a vented area, and all other appropriate OSHA requirements should be strictly observed.

Mass Characteristics

Density. 8.75 g/cm^3 (0.316 lb/in.^{3}) at 20 °C (68 °F)

Volume change on phase transformation. Slight contraction during age hardening; exact amount depends on starting condition of material and on time and temperature of aging.

Thermal Properties

Liquidus temperature. 1070 °C (1955 °F)

Solidus temperature. 1030 °C (1885 °F)

Coefficient of linear thermal expansion. 17.6 μm/m · K (9.8 μin./in. · °F) at 20 to 200 °C (68 to 392 °F)

Specific heat. 420 J/kg · K (0.10 Btu/lb · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. See Table 36.

Electrical resistivity. 29 to 86 nΩ · m at 20 °C (68 °F), depending on heat treatment

Chemical Properties

General corrosion behavior. Comparable to that of other high-copper alloys. May tarnish in humid or sulfur-bearing atmospheres

Fabrication Characteristics

Machinability. Readily machinable by all common methods. Recommended machining conditions depend greatly on the shape of the part, on the heart treatment of material, and on the type of machining operation.

Because this alloy contains beryllium, OSHA requirements must be strictly observed. Normally, these requirements include flooding and/or special ventilation to prevent personnel from inhaling or ingesting metal dust.

Annealing temperature. All annealing of this alloy is a solution treatment.

Solution temperature. Strip, rod, bar, tubing, wire: 10 min at 900 to 955 °C (1650 to 1750 °F), water quench. Large sections: 1 h per inch or fraction of an inch at 900 to 925 °C (1650 to 1700 °F), water quench

Aging temperature. For maximum strength: 3 to 6 h at 425 °C (800 °F), depending on the degree of cold work. Commercial practice: 2 to 3 h at 470 to 495 °C (875 to 925 °F) to provide a combination of high strength and electrical conductivity. Cooling rate after aging is not critical. See also Fig. 20.

Hot-working temperature. 700 to 925 °C (1300 to 1700 °F)

Hot-shortness temperature. 980 °C (1800 °F)

C17600

Commercial Names

Previous trade name. 50 alloy, alloy 50

Common name. Beryllium-copper

Specifications

SAE. J463 (CA176)

Resistance Welding Manufacturer's Association. Class III

Chemical Composition

Composition limits. 99.5 Cu + Be + additives min, 0.25 to 0.50 Be, 1.40 to 1.70 Co, 0.90 to 1.10 Ag, 1.40 Co + Ni min, 1.90 Co + Ni + Fe max

Applications

Typical uses. A high-conductivity alloy designed especially for resistance welding electrodes for spot, seam, flash, and projection welding methods; electrical connectors, clips

Precautions in use. Ventilation should be used during melting, welding, grinding, and all machining operations.

Mechanical Properties

Tensile properties. See Table 37.

Table 37 Typical mechanical properties and electrical conductivity of C17600 heat treated to various tempers

Temper[(a)]	Tensile strength		Yield strength at 0.2% offset		Elongation in 50 mm (2 in.), %	Hardness, HRB	Electrical conductivity, %IACS

TF00	655-760	95-110	515-550	75-80	3-15	92-100	50-60
Forged products							
TB00	240-380	35-55	140-205	20-30	20-35	25-45	20-30

(a) For TB00 temper: solution treat strip, bar, rod, and tubing 10 min at 900 to 955 °C (1650 to 1750 °F) and water quench; solution treat thicker products such as billet 1 h for each 25 mm (1 in.) of thickness or fraction thereof at 900 to 925 °C (1650 to 1700 °F) and water quench. For aging cast billets or producing TF00 temper, age 3 h at 470 to 500 °C (875 to 925 °F). For producing TH04 temper, age 2 h at 470 to 500 °C (875 to 925 °F).

Hardness. See Table 37.

Elastic modulus. Tension, 125 to 130 GPa (18 to 19 × 10^6 psi); shear, 44 GPa (6.4 × 10^6 psi)

Structure

Crystal structure. Alpha copper solid solution is face-centered cubic; the beryllide, (Cu,Co)Be, is ordered body-centered cubic of the CsCl (B2) type.

Microstructure. Matrix of α-copper; large and sharply angular blue-gray beryllide inclusions in grain boundaries of cast product, smaller Widmanstätten beryllides within the grain. In wrought products with large amounts of deformation, the beryllides are small, mainly spherical, and uniformly distributed.

Metallography is by conventional techniques. For dry grinding, ventilationshould be provided. Some common etchants for immersion etching are 3 parts concentrated NH_4OH, 1 part 3% H_2O_2, 2 parts 10% $(NH_4)_2S_2O_3$, and 7 to 10 parts H_2O. Common etchants for swabbing are 3 g $K_2Cr_2O_7$, 1.5 g NaCl, 8 ml H_2SO_4, and 100 ml H_2O.

Mass Characteristics

Density. 8.75 g/cm^3 (0.316 lb/$in.^3$) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1068 °C (1955 °F)

Solidus temperature. 1031 °C (1855 °F)

Coefficient of linear thermal expansion. 16.7 μm/m · K (9.3 μin./in. · °F) at 20 to 200 °C (68 to 392 °F)

Specific heat. 420 J/kg · K (0.10 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 215 to 245 W/m · K (125 to 140 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical properties

Electrical conductivity. See Table 37.

Electrical resistivity. 28.7 to 86.2 nΩ · m at 20 °C (68 °F), depending strongly on heat treatment

Fabrication Characteristics

Machinability. Readily machinable by all conventional methods

Annealing temperature. For strip, wire, rod, and bar, 900 to 950 °C (1650 to 1750 °F)/10 min/water quench. For larger sections, anneal 1 h per inch or fraction of an inch at 900 to 925 °C (1650 to 1700 °F) and water quench.

Solution temperature. All annealing for this alloy is solution treatment.

Aging temperature. Maximum strength is obtained by 3 to 6 h at 425 °C (800 °F). Commercial practice is to age material 2 to 3 h at 480 °C (900 °F) to obtain a combination of high strength and electrical conductivity.

Hot-working temperature. 750 to 925 °C (1400 to 1700 °F)

Hot-shortness temperature. 975 °C (1800 °F)

C18100
99Cu-0.8Cr-0.16Zr-0.04Mg

Chemical Composition

Composition limits. 0.4 to 1.2 Cr, 0.05 to 0.3 Zr, 0.03 to 0.6 Mg

Applications

Typical uses. Resistance welding electrodes and wheels, switches, circuit breakers, high-temperature wire, semiconductor bases, heat sinks, and continuous castings molds

Mechanical Properties

Tensile properties. See Table 38.

Table 38 Nominal mechanical properties of C18100 strip and wire

Temper	Tensile strength		Yield strength		Elongation in 50 mm (2 in.), %	Hardness, HRB
	MPa	ksi	MPa	ksi

Cold worked (90% reduction)	500	73	455	66	4	. . .
Cold worked (90% reduction), aged	585	85	515	75	13	. . .

Hardness. See Table 38.

Elastic modulus. 125 GPa (18.2×10^6 psi)

Mass Characteristics

Density. 8.88 g/cm^3 (0.319 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1075 °C (1967 °F)

Thermal conductivity. 324 W/m · K (187 Btu/ft · h · °F) at 20 °C (68 °F)

Coefficient of linear thermal expansion. 16.7 μm/m · K (9.3 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 18.4 μm/m · K (10.2 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 19.3 μm/m · K (10.7 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Electrical Properties

Electrical conductivity. Volumetric, 80% IACS at 20 °C (68 °F), annealed

Electrical resistivity. 21.7 nΩ · m at 20 °C (68 °F), annealed

Fabrication Characteristics

Formability. Excellent capacity for both cold and hot forming

Weldability. Solderability, excellent; brazing and gas-shielded arc welding, good; butt resistance welding, fair. Oxyacetylene, spot, and seam resistance welding are not recommended.

Annealing temperature. 600 to 700 °C (1110 to 1300 °F)

Heat-treating temperatures. Solution treatment: 900 to 975 °C (1650 to 1790 °F) for 1 h. Aging treatment: 400 to 500 °C (750 to 930 °F) for 1 h

Hot-working temperature. 790 to 925 °C (1450 to 1700 °F)

Commercial Names

Previous trade name. CA182, CA184, CA185; Chrome Copper 999 (C18200)

Common name. Chromium-copper

Specifications

ASTM. Wire: F 9

SAE. J463 (C18400 only)

Government. Bar, forgings, rod, strip: MIL-C-19311 (C18400, C18500)

Chemical Composition

Composition limits of C18200. 0.6 to 1.2 Cr, 0.10 Fe max, 0.10 Si max, 0.05 Pb max, 0.5 max other (total), bal Cu + Ag

Composition limits of C18400. 0.40 to 1.2 Cr, 0.7 Zn max, 0.15 Fe max, 0.10 Si max, 0.05 P max, 0.05 Li max, 0.005 As max, 0.005 Ca max, 0.2 max other (total), bal Cu + Ag

Composition limits of C18500. 0.40 to 1.0 Cr, 0.08 to 0.12 Ag, 0.04 P max, 0.04 Li max, 0.015 Pb max, bal Cu + Ag

Applications

Typical uses. Applications requiring excellent cold workability and good hot workability coupled with medium-to-high conductivity. Uses include resistance welding electrodes, seam welding wheels, switch gears, electrode holder jaws, cable connectors, current-carrying arms and shafts, circuit breaker parts, molds, spot welding tips, flash welding electrodes, electrical and thermal conductors requiring more strength than that provided by unalloyed coppers, and switch contacts

Mechanical Properties

Tensile properties. See Table 39.

Table 39 Typical mechanical properties of C18200, C18400, and C18500

(c) Aged 3 h at 450 °C (840 °F).

Hardness. See Table 39.

Elastic modulus. Tension, 130 GPa (19×10^6 psi); shear, 50 GPa (7.2×10^6 psi)

Mass Characteristics

Density. 8.89 g/cm^3 (0.321 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1075 °C (1965 °F)

Solidus temperature. 1070 °C (1960 °F)

Coefficient of linear thermal expansion. 17.6 μm/m · K (9.8 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. TB00 temper: 171 W/m · K (99 Btu/ft · h · °F) at 20 °C (68 °F). TH04 temper: 324 W/m · K (187 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric. TB00 temper: 40% IACS at 20 °C (68 °F). TH04 temper: 80% IACS at 20 °C (68 °F)

Electrical resistivity. TH04 temper: 21.6 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Suited for hot working by extrusion, rolling, and forging (subsequent solution treatment required) and for cold working (in soft, solution-annealed, or suitable drawn temper) by drawing, rolling, impacting, heading, bending, or swaging

Weldability. Welding and brazing temperatures lower the properties developed by heat treatment; such processes normally are applied to material in the soft condition, followed by necessary heat treatment. Soldering: good. Oxyfuel gas, shielded metal arc, resistance spot, and resistance seam welding are not recommended.

Solution treatment. 980 to 1000 °C (1800 to 1850 °F) for 10 to 30 min, water quench

Aging temperature. 425 to 500 °C (800 to 930 °F) for 2 to 4 h

Hot-working temperature. 800 to 925 °C (1500 to 1700 °F)

C18700
99Cu-1Pb

Commercial Names

Previous trade name. Leaded copper

Common name. Free-machining copper

Specifications

ASTM. Flat products, rod: B 301

SAE. Rod: J463

Chemical Composition

Composition limits. 0.8 to 1.5 Pb, 0.10 max other (total), bal Cu. Oxygen-free grades or grades containing deoxidizers such as P, B, or Li may be specified.

Applications

Typical uses. Electrical connectors, motor parts, switch parts, and screw machine parts requiring high conductivity

Precautions in use. Unless specifically deoxidized, this copper is subject to embrittlement when heated in a reducing atmosphere (as in annealing or brazing) at temperatures of 350 °C (660 °F) or higher. If hydrogen or carbon monoxide is present, embrittlement can be rapid.

Mechanical Properties

Tensile properties. See Tables 17 and 40.

Table 40 Typical mechanical properties of C18700 rod, H04 temper

Diameter		Tensile strength		Yield strength		Elongation in 50 mm (2 in.), %	Hardness, HRB	Shear strength	
mm	in.	MPa	ksi	MPa	ksi			MPa	ksi
6	0.25	415	60	380	55	10	55	200	32
13	0.50	380	55	345	50	11	50	205	30
19	0.75	365	53	330	48	12	50	200	29

Shear strength. See Tables 17 and 40.

Hardness. See Tables 17 and 40.

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1080 °C (1975 °F)

Solidus temperature. 950 °C (1750 °F)

Coefficient of linear thermal expansion. 17.6 μm/m · K (9.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 377 W/m · K (218 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 96% IACS at 20 °C (68 °F)

Electrical resistivity. 17.9 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 85% of C36000 (free-cutting brass)

Formability. Good for cold working; poor for hot forming

Weldability. Soldering: excellent. Brazing: good. Most arc, gas, and resistance welding processes are not recommended.

Annealing temperature. 425 to 650 °C (800 to 1200 °F)

Hot-working temperature. 750 to 875 °C (1400 to 1600 °F)

C19200
98.97Cu-1.0Fe-0.03P

Specifications

ASTM. Tubing: B 111, B 359, B 395, B 469

Chemical Composition

Composition limits. 98.7 to 99.19 Cu, 0.8 to 1.2 Fe, 0.01 to 0.04 P

Applications

Typical uses. Rolled strip and tubing for air conditioning and heat exchanger tubing, applications requiring resistance to softening and stress corrosion, automotive hydraulic brake lines, cable wrap, circuit breaker components, contact springs, electrical connectors and terminals, eyelets, flexible hose, fuse clips, gaskets, gift hollowware, lead frames

Mechanical Properties

Tensile properties. See Table 41.

Table 41 Typical mechanical properties of C19200

Temper	Tensile strength		Yield strength				Elongation in 50 mm (2 in.), %	Hardness, HRB
			At 0.5% extension under load		At 0.2% offset			
	MPa	ksi	MPa	ksi	MPa	ksi		
Strip, 1 mm (0.04 in.) diameter

H08	510	74	. . .	. . .	490	71	2 min	76
H10	530	77	. . .	. . .	510	74	2 min	77
Tubing, 48 mm (1.88 in.) outside diameter × 3 mm (0.12 in.) wall thickness								
O50	290	42	160	23	150	22	30	. . .
O60	255	37	83	12	76	11	40	. . .

H80 (40%)	385	56	360	52	360	52	7	. . .
Tubing, 5 mm (0.19 in.) outside diameter × 0.8 mm (0.03 in.) wall thickness								
H55	290	42	215	31	205	30	35	. . .

Hardness. See Table 41.

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Mass Characteristics

Density. 8.87 g/cm^3 (0.320 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1084 °C (1983 °F)

Solidus temperature. 1078 °C (1973 °F)

Coefficient of linear thermal expansion. 16.2 μm/m · K (9.0 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. Strip, 251 W/m · K (145 Btu/ft · h · °F) at 20 °C (68 °F); tubing, 216 W/m · K (125 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Strip, 60% IACS at 20 °C (68 °F); tubing, 50% IACS at 20 °C (68 °F)

Electrical resistivity. Strip, 28.8 nΩ · m at 20 °C (68 °F); tubing, 34.5 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Forgeability. 65% of C37700 (forging brass)

Weldability. Soldering, brazing, and gas-shielded arc welding: excellent. Oxyacetylene welding: good. Coated metal arc and resistance seam, spot, and butt welding are not recommended.

Annealing temperature. 700 to 815 °C (1300 to 1500 °F)

Hot-working temperature. 825 to 950 °C (1500 to 1750 °F)

C19210
99.87Cu-0.1Fe-0.03P

Chemical Composition

Composition limits. 0.05 to 0.15 Fe, 0.025 to 0.04 P, bal Cu

Applications

Typical uses. Air conditioner and heat exchanger tubing, lead frames, electrical connectors and terminals

Mechanical Properties

Tensile properties. See Table 42.

Table 42 Nominal tensile properties of C19210 sheet

Temper	Tensile strength		Yield strength		Elongation in 50 mm (2 in.), %
	MPa	ksi	MPa	ksi	
H01	345	50	330	48	13

H02	390	57	385	56	6
H04	440	64	435	63	4
H08	490	71	480	70	2

Elastic modulus. 125 GPa (18.2 × 10^6 psi)

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/$in.^3$) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1082 °C (1980 °F)

Coefficient of linear thermal expansion. 16.9 μm/m · K (9.4 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Electrical Properties

Electrical conductivity. Volumetric, 80% IACS at 20 °C (68 °F), annealed

Electrical resistivity. 21.6 nΩ · m at 20 °C (68 °F), annealed

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent capacity for both cold and hot forming

Weldability. Soldering, brazing, and coated metal arc welding: excellent. Butt, resistance and oxyacetylene welding: good. Gas-shielded arc, spot, and seam resistance welding are not recommended.

Annealing temperature. 450 to 550 °C (840 to 1020 °F)

Hot-working temperature. 700 to 900 °C (1300 to 1650 °F)

Hot forgeability rating. 65% of C37700 (forging brass)

C19400
Cu-2.35Fe-0.03P-0.12Zn

Commercial Names

Previous trade name. High-strength modified copper, HSM copper

Specifications

ASME. Welded tubing: SB543

ASTM. Flat products: B 465. Welded tubing: B 543, B 586

Chemical Composition

Composition limits. 2.1 to 2.6 Fe, 0.05 to 0.20 Zn, 0.015 to 0.15 P, 0.03 Pb max, 0.03 Sn max, 0.15 max other (total), bal Cu

Applications

Typical uses. Applications requiring excellent hot and cold workability as well as high strength and conductivity. Specific uses include circuit breaker components; contact springs; electrical clamps, springs, and terminals; flexible hose; fuse clips; gaskets; gift hollowware; plug contacts; rivets; welded condenser tubes; semiconductor lead frames, and cable shielding

Mechanical Properties

Tensile properties. See Tables 43, 44, 45, and 46.

Table 43 Typical mechanical properties of C19400

Temper	Tensile strength	Yield strength	Elongation in	Hardness	Fatigue strength[(a)]

815	1500	285	41	105	15	35	48

(a) Conductivity may be restored to about 70% IACS by holding at 500 °C (925 °F) for 1 h.

Hardness. See Table 43.

Elastic modulus. Tension, 121 GPa (17.5×10^6 psi); shear, 45.5 GPa (6.6×10^6 psi)

Charpy impact strength. Plate, O61 temper: longitudinal, 144 J (106 ft · lbf) at -196 °C (-320 °F); transverse, 99 J (73 ft · lbf) at -196 °C (-320 °F)

Fatigue strength. See Table 43.

Creep and stress-rupture properties. See Table 45.

Mass Characteristics

Density. 8.78 g/cm^3 (0.317 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1090 °C (1990 °F)

Solidus temperature. 1080 °C (1980 °F)

Coefficient of linear thermal expansion. 16.3 μm/m · K (9.0 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 385 J/kg · K (0.092 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 260 W/m · K (150 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, at 20 °C (68 °F). O60 temper: 40% IACS nominal. H14 temper: 50% IACS min. All other tempers: 65% IACS nominal, 60% IACS min. In O50, O80, and H02 tempers, 75% IACS min conductivity may be available depending on mill processing restrictions.

Electrical resistivity. At 20 °C (68 °F). O60 temper: 43.1 nΩ · m nominal. H14 temper: 34.5 nΩ · m max. All other tempers: 26.6 nΩ · m nominal; may be only 23.0 nΩ · m max under certain circumstances

Magnetic Properties

Magnetic permeability. 1.1

Chemical Properties

General corrosion behavior. Very corrosion resistant and essentially immune to stress-corrosion cracking

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Suited to forming by blanking, coining, coppersmithing, drawing, bending, heading and upsetting, hot forging and pressing, piercing and punching, roll threading and knurling, shearing, spinning, squeezing, and stamping

Weldability. Joining by soldering, brazing, and gas tungsten arc welding: excellent

Annealing temperature. See Table 46.

C19500
97Cu-1.5Fe-0.1P-0.8Co-0.6Sn

Commercial Names

Trade name. Strescon

Chemical Composition

Composition limits. 1.3 to 1.7 Fe, 0.6 to 1.0 Co, 0.08 to 0.12 P, 0.40 to 0.7 Sn, 0.20 Zn max, 0.02 Al max, 0.02 Pb max, 0.05 max other (each), 0.10 max other (total), bal Cu

Applications

Typical uses. Electrical springs, sockets, terminals, connectors, clips, and other current-carrying parts requiring strength and exceptional softening resistance. Applications requiring excellent hot and cold workability, high strength, and high conductivity

Mechanical Properties

Tensile properties. See Table 47.

Table 47 Typical mechanical properties of C19500

Temper	Tensile strength		Yield strength at 0.2% offset		Elongation in 50 mm (2 in.), %	Hardness, HRB
	MPa	ksi	MPa	ksi		
O61	360 min	52 min	170 min	25 min	25 min	. . .
O50	520-590	75-85	395-530	57-77	11-17	81-89
H02	565-620	82-90	505-605	73-88	3-13	85-88
H08	605-670	88-97	585-650	85-94	2-5	87-90

Hardness. See Table 47.

Elastic modulus. Tension, 119 GPa (17.3×10^6 psi)

Mass Characteristics

Density. 8.92 g/cm^3 (0.322 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1090 °C (1995 °F)

Solidus temperature. 1085 °C (1985 °F)

Coefficient of linear thermal expansion. 16.9 μm/m · K (9.4 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Thermal conductivity. 199 W/m · K (115 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 50% IACS at 20 °C (68 °F), annealed

Electrical resistivity. 34.4 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Suited to forming by bending, coining, drawing, and stamping

---

C19520
97.97Cu-0.75Fe-1.25Sn-0.03P

Chemical Composition

Composition limits. 0.5 to 1.5 Fe, 0.5 to 1.5 Sn, 0.01 to 0.35 P, 96.6 Cu min

Applications

Typical uses. Lead frames

Mechanical Properties

Tensile properties. See Table 48.

Table 48 Nominal mechanical properties of C19520 strip

Elastic Modulus. 121 GPa (17.5×10^6 psi)

Mass Characteristics

Density. 8.83 g/cm^3 (0.319 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1086 °C (1987 °F)

Solidus temperature. 1069 °C (1956 °F)

Coefficient of linear thermal expansion. 15.8 μm/m · K (8.8 μin./in. · °F) at 20 to 100 °C (68 to 212 °F); 16.8 μm/m · K (9.3 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 17.3 μm/m · K (9.6 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Thermal conductivity. 320 W/m · K (185 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 80% IACS at 20 °C (68 °F)

Electrical resistivity. 21.6 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent capacity for both cold and hot forming

Weldability. Soldering and brazing: excellent

Annealing temperature. 450 to 600 °C (840 to 1110 °F)

Hot-working temperature. 750 to 950 °C (1400 to 1740 °F)

C21000
95Cu-5Zn

Commercial Names

Previous trade name. Gilding metal, 95%; CA210

Specifications

ASTM. Rolled bar, plate, sheet, and strip: B 36. Wire: B 134

SAE. J463

Government. Wire: QQ-W-321. Sheet and strip: MIL-C-21768

Chemical Composition

Composition limits. 94.0 to 96.0 Cu, 0.05 Pb max, 0.05 Fe max, bal Zn

Effect of zinc content on properties. See Fig. 21.

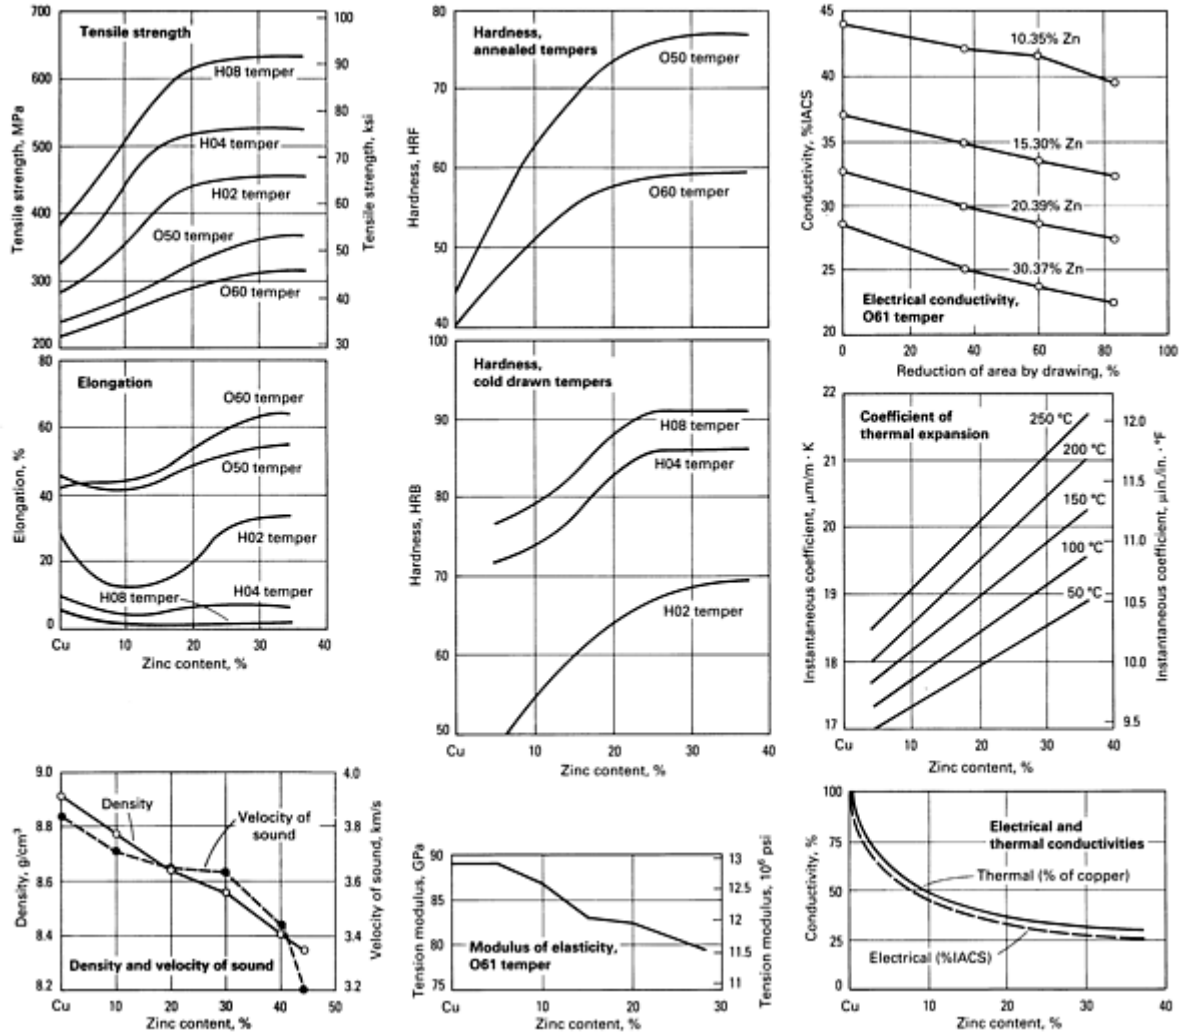

Fig. 21 Variation of properties with zinc content for wrought copper-zinc alloys

Applications

Typical uses. Coins, medals, tokens, bullet jackets, firing-pin supports, shells, fuse caps and primers, emblems, jewelry plaques, base for gold plate, base for vitreous enamel

Mechanical Properties

Tensile properties. See Table 50 and Fig. 22.

Table 50 Typical mechanical properties of C21000

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness		Shear strength	
	MPa	ksi	MPa	ksi		HRB	HR30T	MPa	ksi

Note: Values for flat products. 1 mm (0.04 in.) thick.

(a) At 0.5% extension under load

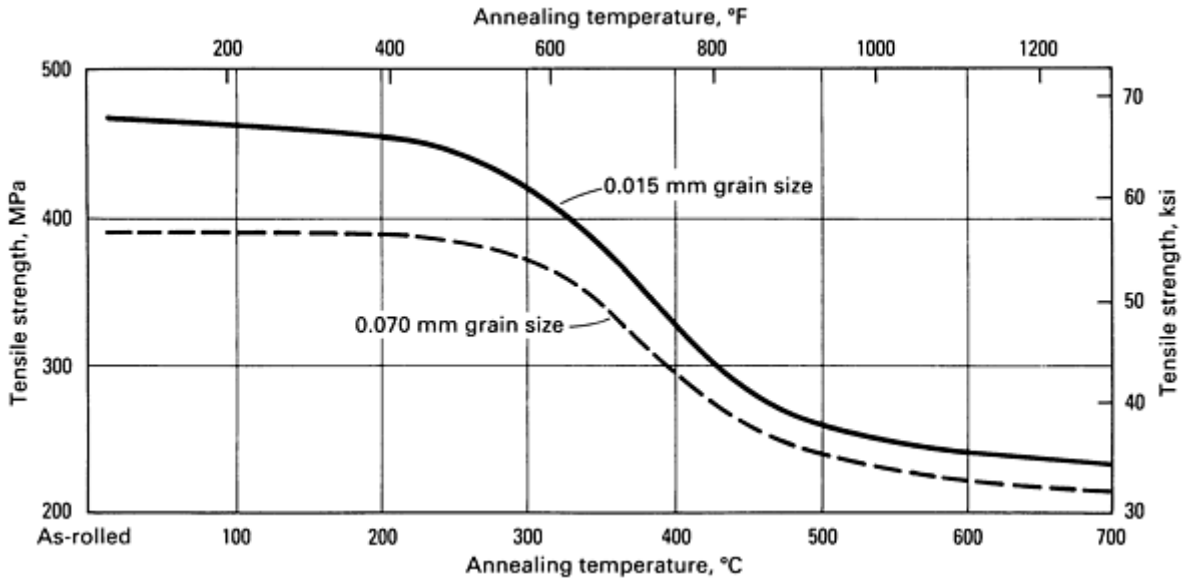

Fig. 22 Variation of tensile strength with annealing temperature for C21000. Data are for 1 mm (0.04 in.) thick ready-to-finish strip that was cold rolled 50% then annealed 1 h at the indicated temperature. Recrystallization temperature, 370 °C (700 °F) for initial grain sizes of 0.015 to 0.070 mm

Shear strength. See Table 50.

Hardness. See Table 50.

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Velocity of sound. 3.78 km/s at 20 °C (68 °F)

Structure

Crystal structure. Face-centered cubic alpha; lattice parameter, 0.3627 nm

Minimum interatomic distance. 0.2564 nm

Mass Characteristics

Density. 8.86 g/cm^3 (0.320 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1065 °C (1950 °F)

Solidus temperature. 1050 °C (1920 °F)

Coefficient of linear thermal expansion. 18 μm/m · K (10μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 234 W/m · K (135 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 56% IACS at 20 °C (68 °F), annealed

Electrical resistivity. 31 nΩ · m at 20 °C (68 °F), annealed; temperature coefficient, 0.0231 nΩ · m per K at 20 °C (68 °F). Liquid phase: 244 nΩ · m at 1100 °C (2010 °F), 266 nΩ · m at 1300 °C (2370 °F)

Magnetic Properties

Magnetic susceptibility. -1.0×10^{-6} to -12.5×10^{-6} (SI units)

Optical Properties

Spectral reflectance. 90% for λ= 578 nm

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Recrystallization temperature. 370 °C (700 °F) for 50% reduction and 0.015 to 0.070 mm initial grain size. See Fig. 22.

Annealing temperature. 425 to 800 °C (800 to 1450 °F)

Hot-working temperature. 750 to 875 °C (1400 to 1600 °F)

C22000
90Cu-10Zn

Commercial Names

Previous trade name. Commercial bronze, 90%; CA220

Specifications

ASTM. Rolled bar, plate, and sheet: B 36. Strip: B 36 and B 130. Cups, bullet jacket: B 131. Tube, rectangular waveguide: B 372. Seamless tube: B 135. Wire: B 134

SAE. Rolled bar, plate, sheet, strip, and seamless tube: J463 (CA220)

Government. Wire: QQ-W-321; MIL-W-6712. Bands, projectile rotating: MIL-B-18907. Blanks, rotating band for projectiles: MIL-B-20292. Cups, bullet jacket: MIL-C-3383. Sheet and strip: MIL-C-21768. Tube, rectangular waveguide: MIL-W-85. Seamless tube for microwave use: MIL-T-52069

Chemical Composition

Composition limits. 89.0 to 91.0 Cu, 0.05 Pb max, 0.05 Fe max, bal Zn

Consequence of exceeding impurity limits. See general statement for brasses under C26000.

Effect of zinc content on properties. See Fig. 21.

Applications

Typical uses. Architectural: etching bronze, grillwork, screen cloth, weather stripping. Hardware: escutcheons, kickplates, line clamps, marine hardware, rivets, screws, screw shells. Munitions: primer caps, rotating bands. Miscellaneous: compacts, lipstick cases, costume jewelry, ornamental trim, screen wire, base for vitreous enamel, waveguides

Mechanical Properties

Tensile properties. See Table 51 and Fig. 23

Table 51 Typical mechanical properties of C22000

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness		Shear strength

(a) At 0.5% extension under load.

(b) Drawn 35%

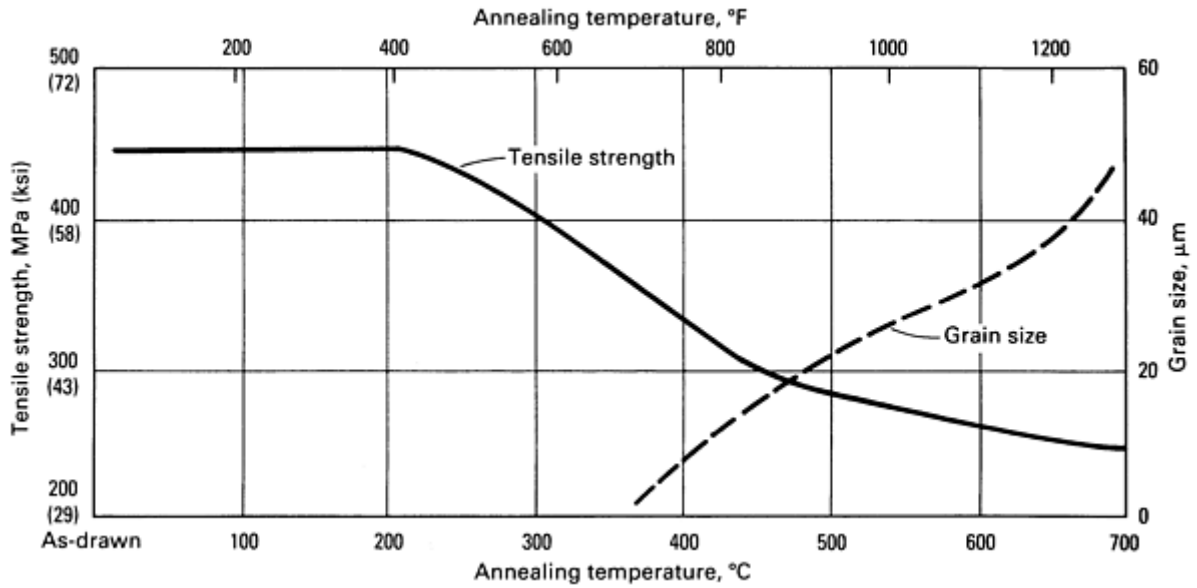

Fig. 23 Variation of tensile strength and grain size with annealing temperature for C22000. Data are for rod less than 25 mm (1 in.) in diameter that was cold drawn to a 37% reduction in area and then annealed 1 h at the indicated temperature. Grain size before annealing was 0.050 mm.

Shear strength. See Table 51.

Hardness. See Table 51.

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Fatigue strength. Spring temper flat product 1.0 mm (0.40 in.) thick: 145 MPa (21 ksi) at 15×10^6 cycles; hard wire

2.0 mm (0.080 in.) in diameter: 160 MPa (23 ksi) at 10^8 cycles

Velocity of sound. 3720 m/s (12,200 ft/s) at 20 °C (68 °F)

Structure

Crystal structure. Face-centered cubic α; lattice parameter, 0.364 nm

Minimum interatomic distance. 0.257 nm

Mass Characteristics

Density. 8.80 g/cm^3 (0.318 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1045 °C (1910 °F)

Solidus temperature. 1020 °C (1870 °F)

Boiling point. About 1400 °C (2550 °F) at 101 kPa (1 atm)

Coefficient of linear thermal expansion. 18.4 μm/m · K (10.2 μin./in. · °F) at 20 to 300 °C (68 to 572 °F), cold rolled

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 189 W/m · K (109 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 44% IACS at 20 °C (68 °F), annealed

Electrical resistivity. 39.1 nΩ · m at 20 °C (68 °F). Liquid phase, 272 nΩ · at 1100 °C (2012 °F). Temperature coefficient, 0.00186 nΩ · m per K at 20 °C (68 °F)

Magnetic Properties

Magnetic susceptibility. -0.086×10^{-6} to -1.00×10^{-6} (cgs units)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Recrystallization temperature. 370 °C (700 °F) for 37% reduction and 0.050 mm (0.002 in.) initial grain size. See Fig. 23.

Annealing temperature. 425 to 800 °C (800 to 1450 °F)

Hot-working temperature. 750 to 875 °C (1400 to 1600 °F)

C22600
87.5Cu-12.5Zn

Commercial Names

Previous trade name. Jewelry bronze, $87\frac{1}{2}$%; CA226

Common name. Jewelry bronze

Chemical Composition

Composition limits. 86.0 to 89.0 Cu, 0.05 Pb max, 0.005 Fe max, bal Zn

Applications

Typical uses. Architectural: angles, channels. Hardware: chain, eyelets, fasteners, slide fasteners. Novelties: compacts, costume jewelry, emblems, etched articles, lipstick containers, plaques, base for gold plate

Mechanical Properties

Tensile properties. See Table 52 and Fig. 24.

Table 52 Typical mechanical properties of C22600

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness	Shear strength

(a) At 0.5% extension under load

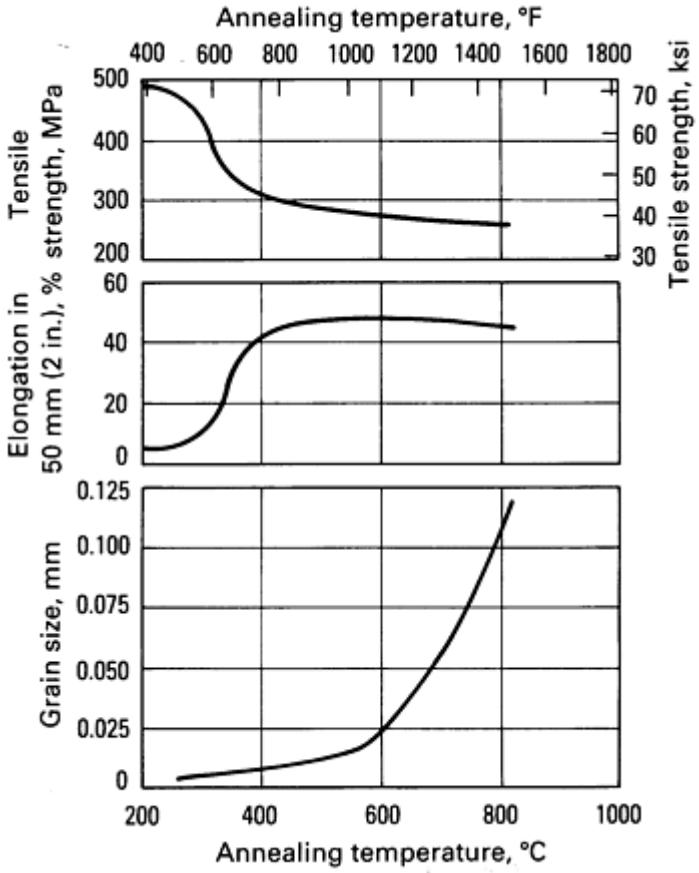

Fig. 24 Annealing characteristics of C22600. Data are for jewelry bronze strip with an initial grain size of 0.035 mm that was cold rolled 50% to a thickness of 1 mm (0.04 in.) and annealed 1 h at various temperatures.

Machinability. 30% of C36000 (free-cutting brass)

Recrystallization temperature. About 330 °C (625 °F) for 1 mm (0.04 in.) strip rolled six Brown and Sharpe numbers hard from a 0.035 mm (0.001 in.) grain size. See also Fig. 24.

Shear strength. See Table 52.

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Mass Characteristics

Density. 8.78 g/cm^3 (0.317 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1035 °C (1895 °F)

Solidus temperature. 1005 °C (1840 °F)

Coefficient of linear thermal expansion. 18.6 μm/m · K (10.3 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 173 W/m · K (100 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 40% IACS at 20 °C (68 °F), annealed

Electrical resistivity. 43 nΩ · m at 20 °C (68 °F), annealed

Fabrication Characteristics

Annealing temperature. 425 to 750 °C (800 to 1400 °F)

Hot-working temperature. 750 to 900 °C (1400 to 1650 °F)

C23000
85Cu-15Zn

Commercial Names

Previous trade name. Red brass, 85%; CA230

Common name. Red brass

Specifications

ASME. Pipe: SB43. Condenser tubing: SB111. Finned tubing: SB359. U-bend tubing: SB395

ASTM. Plate, sheet, strip, hot-rolled bar: B 36. Pipe: B 43. Condenser tubing: B 111. Finned tubing: B 359. Seamless tubing: B 135. U-bend tubing: B 395. Wire: B 134

SAE. Sheet, strip, seamless tube: J463 (CA230)

Government. Bar, forgings, rod, shapes, strip: QQ-B-626. Plate, sheet, strip, hot-rolled bar: QQ-B-613. Pipe: WW-P-351. Seamless tubing: WW-T-791; MIL-T-20168. Wire: QQ-W-321

Chemical Composition

Composition limits. 84.0 to 86.0 Cu, 0.06 Pb max, 0.05 Fe max, bal Zn

Consequence of exceeding impurity limits. See general statement for cartridge brass (C26000).

Effect of zinc on properties. See Fig. 21.

Applications

Typical uses. Architectural: etching parts, trim, weather strip. Electrical: conduit, screw shells, sockets. Hardware: eyelets, fasteners, fire extinguishers. Industrial: condenser and heat exchanger tubes, flexible hose, pickling crates, pump lines, radiator cores. Plumbing: plumbing pipe, J-bends, service lines, traps. Miscellaneous: badges, compacts, costume jewelry, dials, etched articles, lipstick containers, nameplates, tags

Mechanical Properties

Tensile properties. See Table 53 and Fig. 25.

(a) At 0.5% extension under load

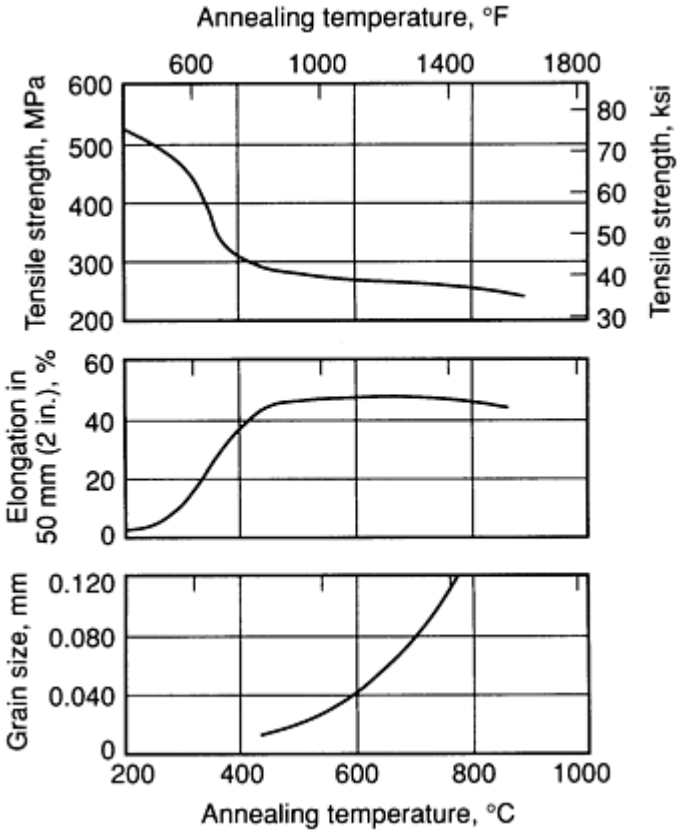

Fig. 25 Annealing characteristics of C23000. Data are for 1 mm (0.04 in.) thick red brass sheet, H06 temper, annealed 1 h at various temperatures.

Shear strength. See Table 53.

Hardness. See Table 53.

Impact strength. Izod: cast, 45 J (33 ft · lbf); cast and annealed, 43 J (32 ft · lbf). Charpy keyhole: annealed rod, 69 J (51 ft · lbf). See also Fig. 26.

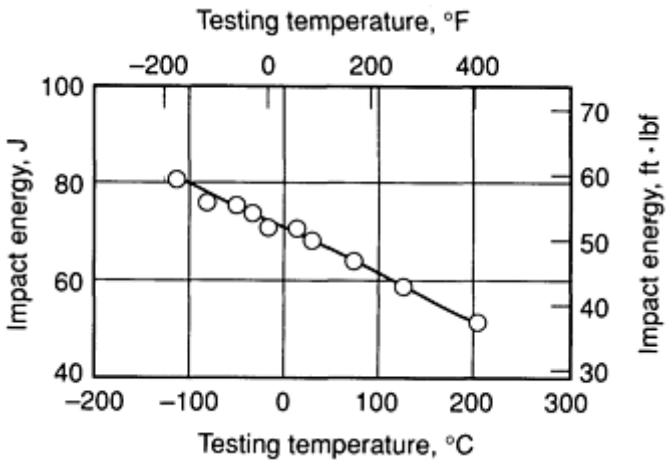

Fig. 26 Impact strength of C23000. Charpy keyhole specimens were machined from O61 temper material, then tested at the indicated temperatures. Impact strengths represent energy absorbed without fracture.

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Fatigue strength. Rod, H00 temper, 140 MPa (20 ksi) at 300×10^6 cycles

Creep-rupture characteristics. See Fig. 27.

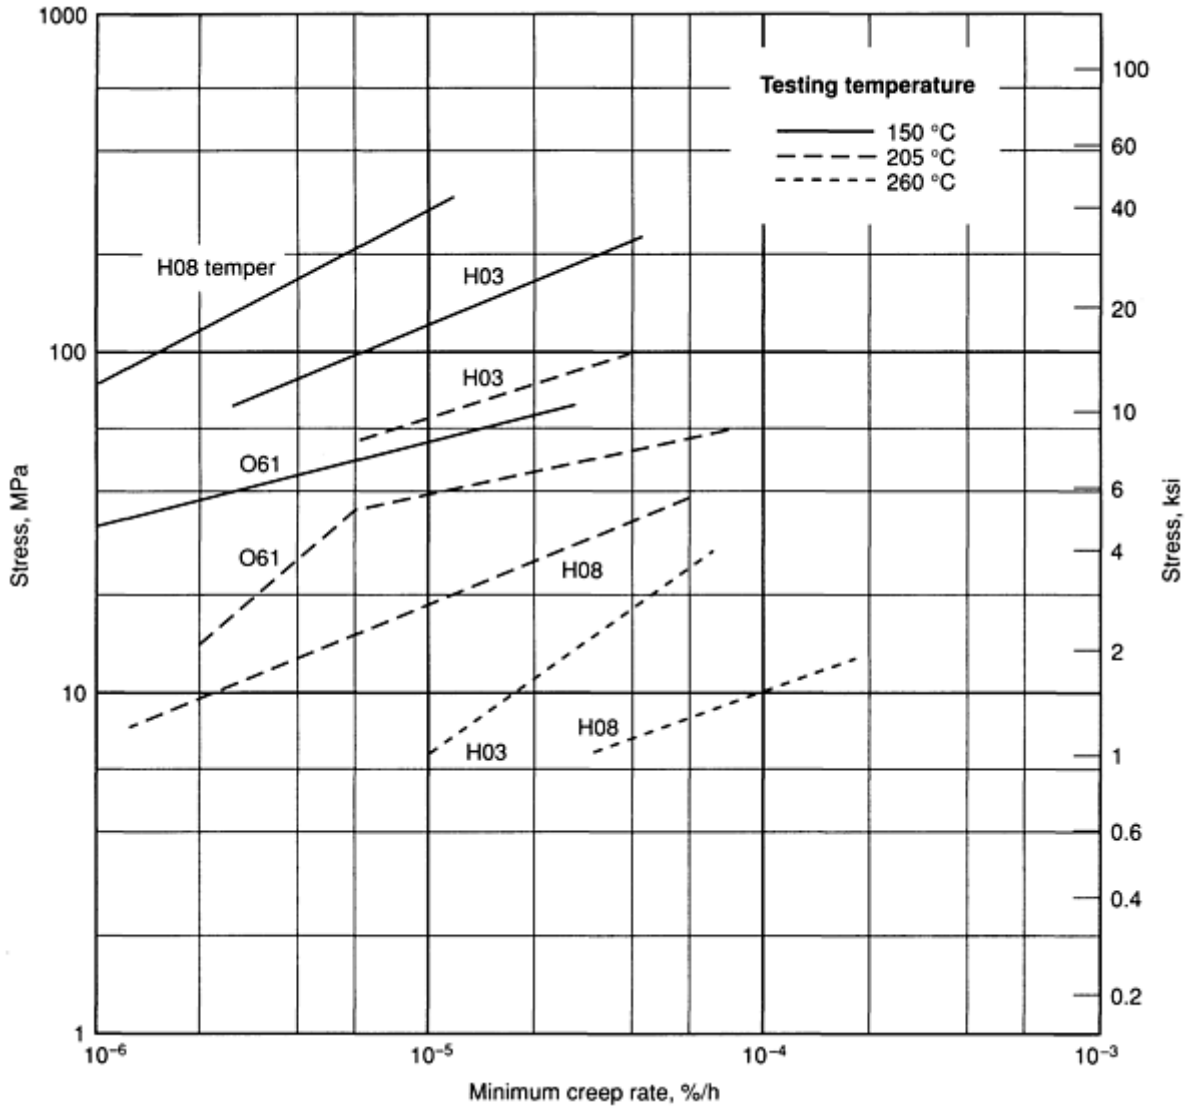

Fig. 27 Minimum creep rates for C23000 wire. Data are for red brass wire, 3.2 mm (0.125 in.) in diameter, that was cold drawn to size, then tested in the as-drawn or annealed condition.

Velocity of sound. 3660 m/s (12,000 ft/s) at 20 °C (68 °F)

Mass Characteristics

Density. 8.75 g/cm^3 (0.316 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1025 °C (1880 °F)

Solidus temperature. 990 °C (1810 °F)

Coefficient of linear thermal expansion. 18.7 μm/m · K (10.4 μin./in. · °F) at 20 to 300 °C (68 to 572 °F), cold rolled

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 159 W/m · K (92 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 37% IACS at 20 °C (68 °F), annealed

Electrical resistivity. 47 nΩ · m at 20 °C (68 °F), annealed. Liquid: 299 nΩ · m at 1100 °C (2012 °F); 304 nΩ · m at 1200 °C (2192 °F). Temperature coefficient, 0.0016/°C at 20 °C (68 °F)

Magnetic Properties

Magnetic susceptibility. Approximately -1.00 × 10^{-6} (cgs units)

Fabrication Characteristics

Machinability. 30% of C26000 (free-cutting brass)

Recrystallization temperature. About 350 °C (660 °F) for 1 mm (0.04 in.) sheet rolled six Brown and Sharpe numbers hard with a 50% reduction and 0.035 mm (0.001 in.) initial grain size

Annealing temperature. 425 to 725 °C (800 to 1350 °F). See also Fig. 25.

Hot-working temperature. 800 to 900 °C (1450 to 1650 °F)

C24000
80Cu-20Zn

Commercial Names

Trade name. Low brass, 80%; CA240

Common name. Low brass

Specifications

ASTM. Flat products: B 36. Wire: B 134

SAE. Sheet, strip: J463 (CA240)

Government. Finished-edge bar and strip, forgings, rod, shapes: QQ-B-626. Rolled bar, plate, sheet, strip: QQ-B-613. Wire: QQ-W-321. Brazing alloy wire: QQ-B-650

Chemical Composition

Composition limits. 78.5 to 81.5 Cu, 0.05 Pb max, 0.05 Fe max, bal Zn

Effect of zinc content on properties. See Fig. 21.

Applications

Typical uses. Ornamental metal work, medallions, spandrels, electrical battery caps, bellows and musical instruments, clock dials, flexible hose, pump lines, tokens

Mechanical Properties

Tensile properties. See Table 54 and Fig. 28.

Table 54 Typical mechanical properties of C24000

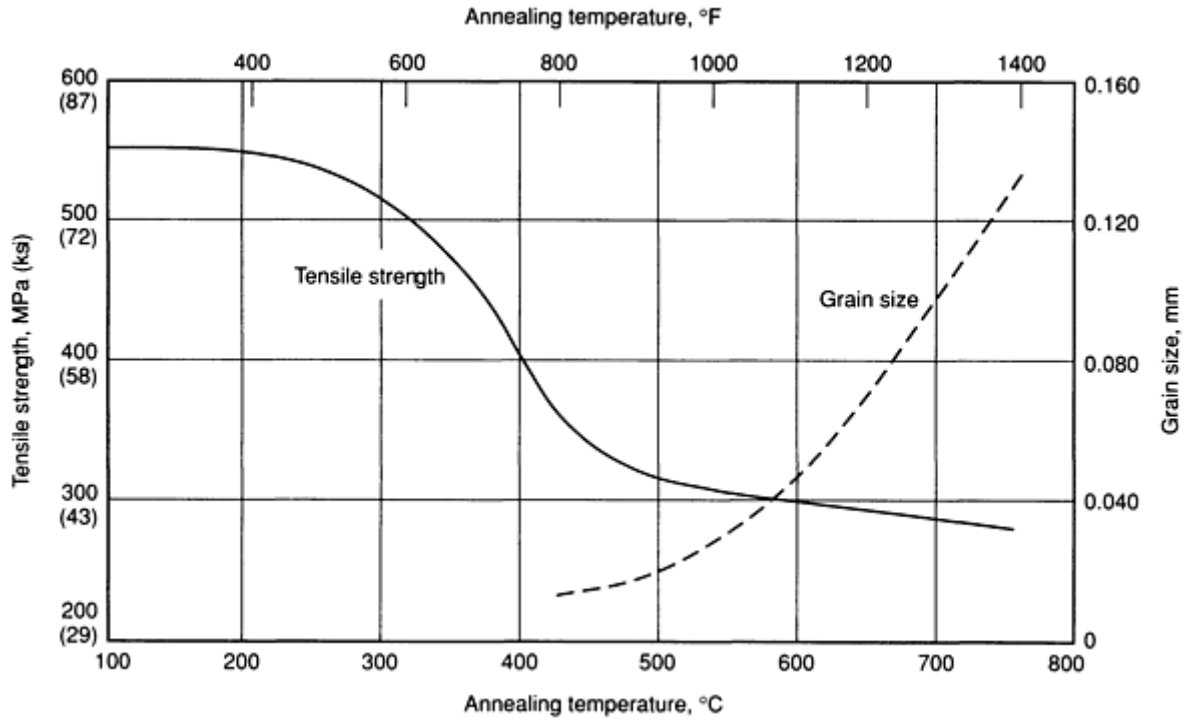

Fig. 28 Tensile strength and grain size versus annealing temperature for C24000, annealed from H02 temper. Data are for low brass with an initial grain size of 0.060 mm that was cold drawn 37% to a diameter of less than 25 mm (1 in.) and annealed 1 h at the indicated temperature.

Shear strength. See Table 54.

Hardness. See Table 54.

Elastic modulus. Tension, 110 GPa (16×10^6 psi); shear, 40 GPa (6×10^6 psi)

Fatigue strength. 1 mm (0.04 in.) thick strip, H08 temper: 165 MPa (24 ksi) at 20×10^6 cycles

Structure

Crystal structure. Face-centered cubic α; lattice parameter, 0.366 nm

Minimum interatomic distance. 0.259 nm

Mass Characteristics

Density. 8.67 g/cm^3 (0.313 lb/in.^{3}) at 20 °C (68 °F)

Solidification shrinkage. 5 to 6%

Thermal Properties

Liquidus temperature. 1000 °C (1830 °F)

Solidus temperature. 965 °C (1770 °F)

Coefficient of linear thermal expansion. 19.1 μm/m · K (10.6 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 140 W/m · K (81 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O61 temper: 32% IACS at 20 °C (68 °F)

Electrical resistivity. O61 temper: 54 nΩ · m at 20 °C (68 °F). Liquid: 330 nΩ · m at 1000 °C (1830 °F); 338 nΩ · m at 1200 °C (2190 °F). Temperature coefficient, 0.00154/°C at 20 °C (68 °F)

Magnetic Properties

Magnetic susceptibility. Approximately -1.00×10^{-6} (cgs units)

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

Recrystallization temperature. About 400 °C (750 °F) for 37% reduction and 0.060 mm initial grain size

Annealing temperature. 425 to 700 °C (800 to 1300 °F). See also Fig. 28.

Hot-working temperature. 825 to 900 °C (1500 to 1650 °F)

C26000
70Cu-30Zn

Commercial Names

Previous trade name. Cartridge brass, 70%; CA260

Common name. Cartridge brass, 70-30 brass, spinning brass, spring brass, extra-quality brass

Specifications

AMS. Flat products: 4505, 4507. Tube: 4555

ASTM. Flat products: B 19, B 36, B 569. Cups for cartridge cases: B 129. Tube: B 135, B 587. Wire: B 134

SAE. J463

Government. Flat products: QQ-B-613, QQ-B-626, MIL-C-50. Rod, bar, shapes, forgings: QQ-B-626. Tube: MIL-T-6945, MIL-T-20219. Wire: QQ-W-321, QQ-B-650. Shim stock, laminated: MIL-S-22499. Cups for cartridge cases: MIL-C-10375

Chemical Composition

Composition limits. 68.5 to 71.5 Cu, 0.07 Pb max, 0.05 Fe max, 0.15 max other (total), bal Zn

Effect of zinc on properties. See Fig. 21.

Lead should be kept under 0.01% for hot rolling, although additions of lead up to 4% improve machinability in material processed by extrusion and cold working. Lead lowers room-temperature ductility in brass and leads to hot shortness at temperatures above 315 °C (600 °F).

Aluminum at levels as high as 2% has no adverse effect on hot or cold working. However, annealing and grain size are affected.

Arsenic does not affect hot or cold working, but it tends to refine the grain size, thereby lowering ductility.

Cadmium. The effects of cadmium are not universally agreed upon; some claim as much as 0.10% has little effect, others maintain that it should be kept below 0.05%.

Chromium affects temperature of anneal and grain size. This condition is aggravated when iron is present.

Iron chiefly affects annealing and magnetic properties.

Nickel restrains grain growth.

Phosphorus has no adverse effect up to 0.04%; it does, however, restrain grain growth, increase tensile strength, and lower ductility to some extent.

Applications

Typical uses. Architectural: grillwork. Automotive: radiator cores and tanks. Electrical: bead chain. flashlight shells, reflectors, lamp fixtures, socket shells, screw shells. Hardware: eyelets, fasteners, pins, hinges, kickplates, locks, rivets, springs, stampings, tubes, etched articles. Munitions: ammunition components, particularly cartridge cases. Plumbing: accessories, fittings. Industrial: pump and power cylinders, cylinder liners

Precautions in use. Highly susceptible season cracking in ammoniacal environments

Mechanical Properties

Tensile properties. See Tables 55 and 56 and Fig. 29, 30, and 31.

Table 55 Typical mechanical properties of C26000

Temper	Tensile strength		Yield strength[a]		Elongation in 50 mm (2 in.), %	Hardness		Shear strength		Fatigue strength[b]

Table 56 Typical tensile properties of cold-rolled and annealed C26000 sheet

Direction in sheet	**Tensile strength**		**Elongation, %**
	MPa	**ksi**	
Parallel to RD	330	48	59
40° to RD	305	44	66
90° to RD	325	47	61

Note: Approximate values for material given a ready-to-finish anneal at 400 °C (750 °F), then cold rolled 70% and annealed 1 h at

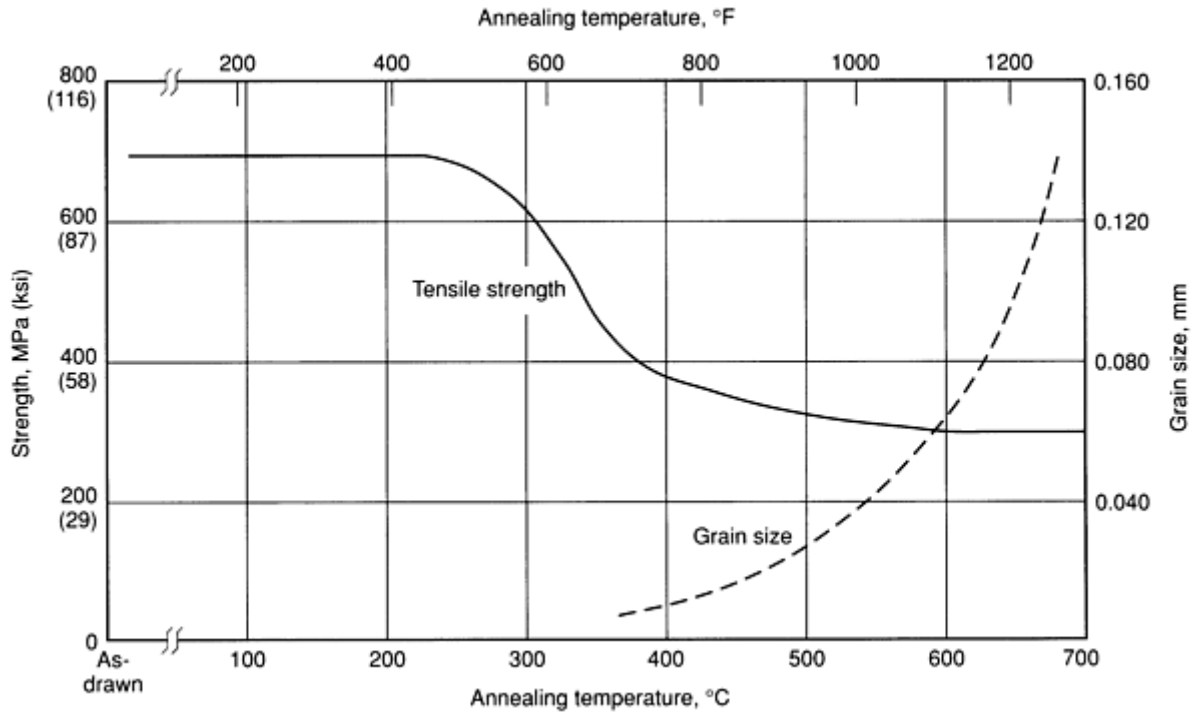

Fig. 29 Tensile strength and grain size as a function of annealing temperature for C26000 rod. Data are for cartridge brass rod less than 25 mm (1 in.) in diameter that was cold drawn 50% (from starting material having a grain size of 0.045 mm), then annealed 1 h at the indicated temperature.

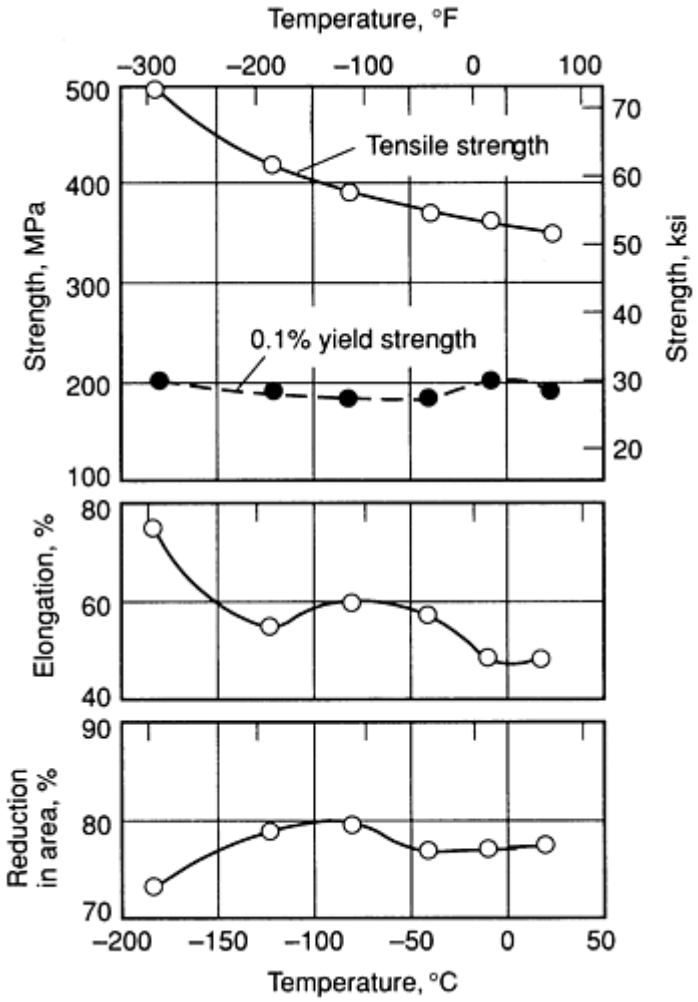

Fig. 30 Low-temperature tensile properties of C26000 rod, O61 temper

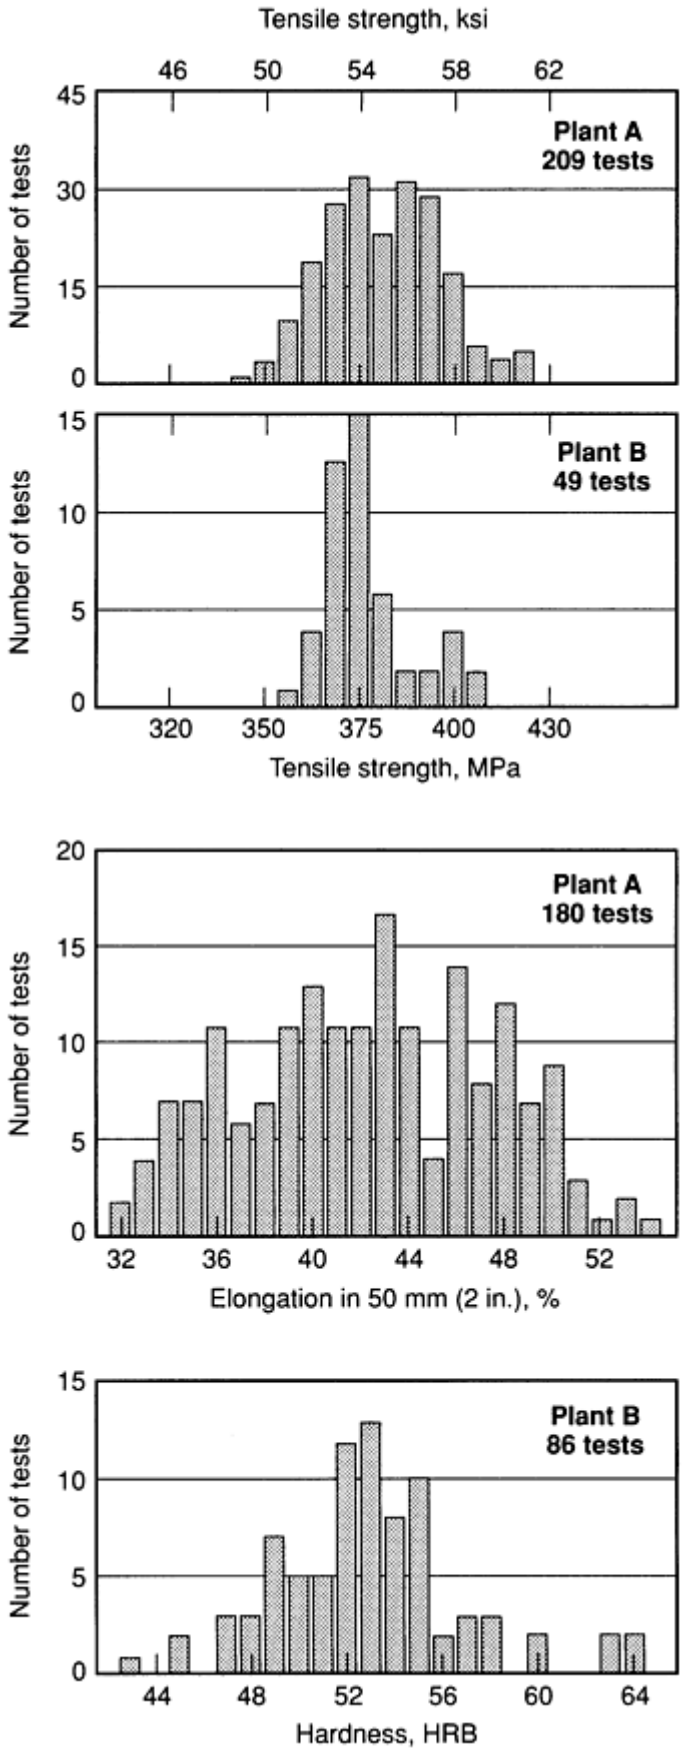

Fig. 31 Typical distribution of tensile properties and hardness for C26000 strip, H01 temper. Data are for cartridge brass strip 0.5 to 1 mm (0.020 to 0.040 in.) thick.

Hardness. See Table 55 and Fig. 31.

Elastic modulus. Tension, 110 GPa (16×10^6 psi); shear, 40 GPa (6×10^6 psi)

Fatigue strength. See Table 55.

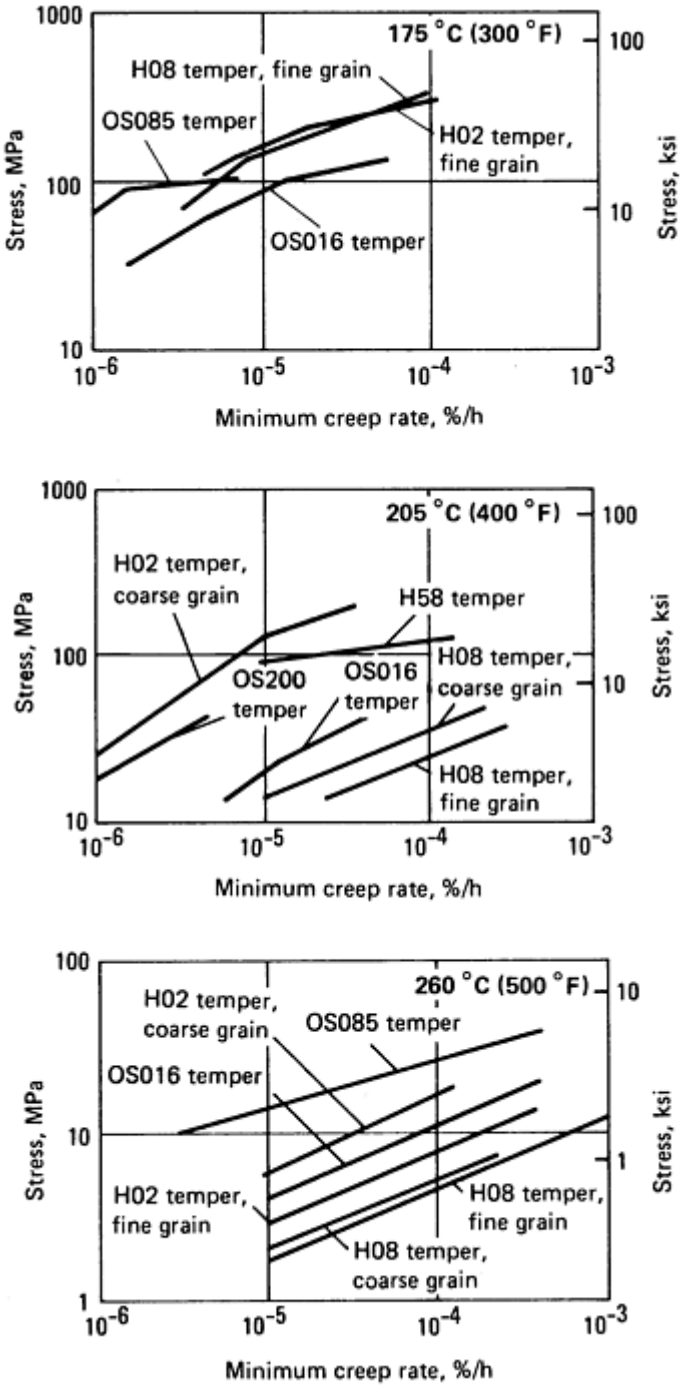

Fig. 32 Minimum creep rates for C26000

Impact strength. Charpy V-notch: O61 temper 60 J (44 ft · lbf); M20 temper, 19 J (14 ft · lbf); Izod: O61 temper, 89 J (66 ft · lbf) for notched round specimen

Creep-rupture properties. See Fig. 32.

Velocity of sound. 3660 m/s (12,000 ft/s) at 20 °C (68 °F)

Structure

Crystal structure. Face-centered cubic; lattice parameter, 0.3684 nm

Minimum interatomic distance. 0.2605 nm

Microstructure. Single-phase α usually with extensive patter of annealing twins

Damping capacity. See Fig. 33.

Mass Characteristics

Density. 8.53 g/cm^3 (0.308 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 955 °C (1750 °F)

Solidus temperature. 915 °C (1680 °F)

Coefficient of linear thermal expansion. Cold-rolled stock: 19.9 μm/in · K (11.1 μin./in. · °F) at 20 to 300 °C (68 to 572 °F). Equation for 20 to 300 °C: $L_t = L_0[1 + (17.75t + 0.00653t^2) \times 10^{-6}]$, where t is temperature difference from 20 °C

Specific heat. 375 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 120 W/m · K (70 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O61 temper, 28% IACS at 20 °C (68 °F)

Electrical resistivity. O61 temper, 62 nΩ · m at 20 °C (68 °F), temperature coefficient, 0.092 nΩ · m per K at 20 °C (68 °F)

Hall coefficient. 25 pV · m/A · T

Magnetic Properties

Iron in excess of 0.03% can precipitate from C26000 during suitable low-temperature anneals. Precipitation is slow and occurs chiefly in a nonmagnetic form, which is converted to a ferromagnetic structure on subsequent cold working.

Magnetic susceptibility. -8×10^{-8} to -16×10^{-8} (mks units); susceptibility in α brasses decreases with increasing zinc content.

Chemical Properties

General corrosion behavior. Resists corrosion in a wide variety of waters and chemical solutions; may undergo dezincification in stagnant or slowly moving slat solutions, brackish water, or mildly acidic solutions. Susceptible to stress-corrosion cracking (season cracking), especially in ammoniacal environments

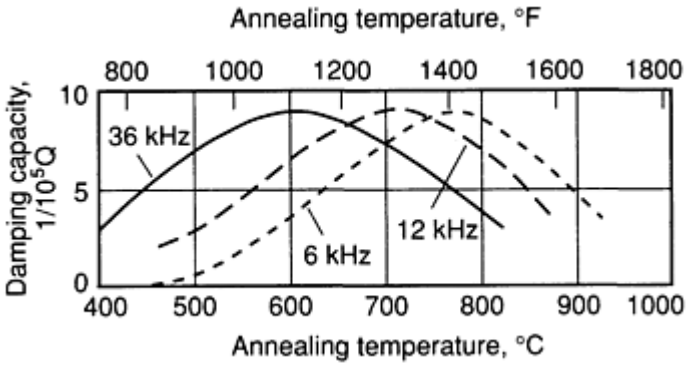

Fig. 33 Damping capacity of annealed C26000

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

Formability. Excellent for cold working and forming; fair for hot forming. Directionality in brass is more readily developed with high zinc content, such as in C26000 and higher-zinc brasses. Earing usually occurs 45° to the direction of rolling and is aggravated by heavy final reductions, low ready-to-finish annealing temperatures, and high finish annealing temperatures.

Weldability. Soldering and brazing: excellent. Oxyfuel gas, resistance spot, and resistance butt welding: good. Gas metal arc welding: fair. Other welding processes are not recommended.

Recrystallization temperature. About 300 °C (575 °F) for 0.045 mm initial grain size and a cold reduction of 50%

Annealing temperature. 425 to 750 °C (800 to 1400 °F)

Hot-working temperature. 725 to 850 °C (1350 to 1550 °F)

C26800, C27000
65Cu-35Zn

Commercial Names

Previous trade name. C26800: Yellow brass, 66%. C27000: Yellow brass, 65%

Common name. Yellow brass

Specifications

AMS. Wire: 4710, 4712

ASTM. Flat products: B 36 (C26800). Tube: B 135 (C27000), B 587 (C26800 and C27000). Wire: B 134

SAE. J463

Government. Flat products: QQ-B-613, Bar, rod, forgings, shapes: QQ-B-626. Wire: QQ-W-321, MIL-W-6712

Chemical Composition

Composition limits of C26800. 64.0 to 68.5 Cu, 0.15 Pb max, 0.05 Fe max, bal Zn

Composition limits of C27000. 63.0 to 68.5 Cu, 0.10 Pb max, 0.07 Fe max, bal Zn

Effect of zinc on properties. See Fig. 21.

Applications

Typical uses. Architectural grillwork, radiator cores and tanks, reflectors, flashlight shells, lamp fixtures, screw shells, socket shells, bead chain, chain, eyelets, fasteners, grommets, kickplates, push plates, stencils, plumbing accessories, sink strainers, wire, pins, rivets, screws, springs

Mechanical Properties

Tensile properties. See Table 57.

Table 57 Typical mechanical properties of C26800 and C27000

(a) At 0.5% extension under load.

(b) 75% reduction in area.

(c) 70% reduction in area

Shear strength. See Table 57.

Hardness. See Table 57.

Elastic modulus. Tension, 105 GPa (15×10^6 psi); shear, 35 GPa (5×10^6 psi)

Fatigue strength. Rotating beam tests. At 10^8 cycles, for strip 1 mm (0.04 in.) thick: OS070 temper, 83 MPa (12 ksi); H04 temper, 97 MPa (14 ksi); H08 temper, 140 MPa (20 ksi)

Mass Characteristics

Density. 8.47 g/cm^3 (0.306 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 930 °C (1710 °F)

Solidus temperature. 905 °C (1660 °F)

Coefficient of linear thermal expansion. 20.3 μm/m · K (11.3 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 116 W/m · K (67 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 27% IACS at 20 °C (68 °F), annealed

Electrical resistivity. 64 nΩ · m at 20 °C (68 °F), annealed

Structure

Crystal structure. Face-centered cubic α

Microstructure. Single-phase α

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

Recrystallization temperature. About 290 °C (550 °F) for strip cold rolled 50% to 1 mm (0.04 in.) thickness and having an initial grain size of 0.035 mm

Maximum cold reduction between anneals. 90%

Annealing temperature. 425 to 700 °C (800 to 1300 °F)

Hot-working temperature. 700 to 820 °C (1300 to 1500 °F)

C28000
60Cu-40Zn

Commercial Names

Previous trade name. Muntz metal, 60%; CA280

Common name. Muntz metal

Specifications

ASME. Condenser tubing: SB111

ASTM. Tubing: B 111, B 135

Government. Flat products: QQ-B-613. Bar, rod, forgings, shapes: QQ-B-626. Seamless tubing: WW-T-791

Chemical Composition

Composition limits. 59.0 to 63.0 Cu, 0.30 Pb max, 0.07 Fe max, bal Zn

Effect of zinc on properties. See Fig. 21.

Applications

Typical uses. Decoration, as architectural panel sheets; structural, as heavy plates; bolting and valve stems; tubing for heat exchangers; brazing rod (for copper alloys and cast iron); hot forgings

Precautions in use. C28000 has poor cold-drawing and forming properties in comparison with those of higher-copper alloys, but it has excellent hot-working properties. It is the strongest of the copper-zinc alloys but is less ductile than higher-copper alloys. It is subject to dezincification and stress-corrosion cracking under certain conditions.

Mechanical Properties

Tensile properties. See Table 58 and Fig. 34 and 35.

Table 58 Typical mechanical properties of C28000

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness, HRF	Shear strength	
	MPa	ksi	MPa	ksi			MPa	ksi
Flat products, 1 mm (0.04 in.) thick

(a) 0.5% extension under load

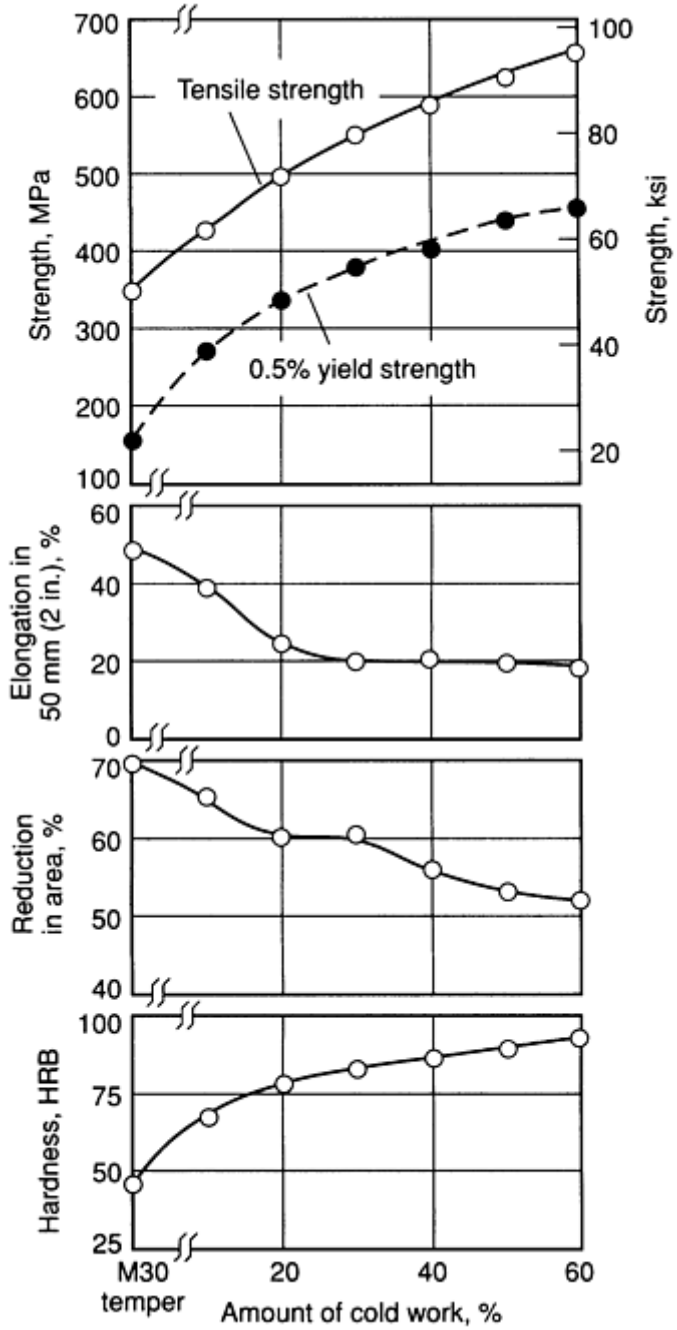

Fig. 34 Typical mechanical properties of extruded and drawn C28000. Data are for Muntz metal rod less than 25 mm (1 in.) in diameter that was extruded and then cold drawn to various percentages of reduction in area.

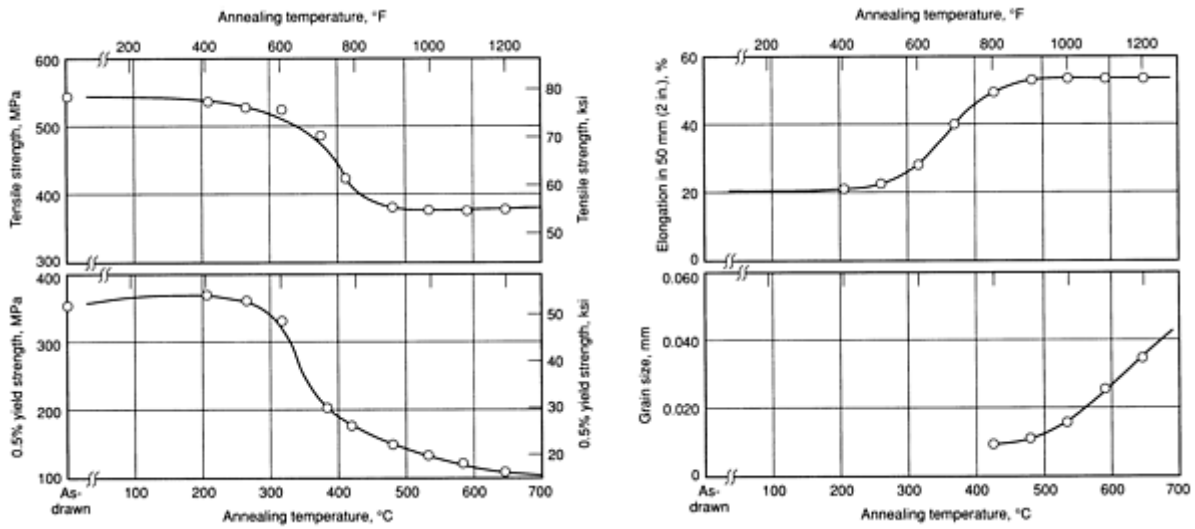

Fig. 35 Annealing curves for C28000. Data are for Muntz metal rod less than 25 mm (1 in.) in diameter that was extruded, cold drawn 30%, and annealed 1 h at various temperatures.

Shear strength. See Table 58.

Hardness. See Table 58.

Elastic modulus. Tension, 105 GPa (15×10^6 psi); shear, 39 GPa (5.6×10^6 psi)

Mass Characteristics

Density. 8.39 g/cm^3 (0.303 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 905 °C (1660 °F)

Solidus temperature. 900 °C (1650 °F)

Coefficient of linear thermal expansion. 20.8 μm/m · K (11.6 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 375 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 123 W/m · K (71 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 28% IACS at 20 °C (68 °F)

Electrical resistivity. 61.6 nΩ · m at 20 °C (68 °F)

Structure

Microstructure. Two phase: face-centered cubic α plus body-centered cubic β. Beta phase appears lemon yellow when etched with ammonia peroxide; it is dark when etched with ferric chloride. In grain size determination, the beta phase should be ignored.

Optical Properties

Color. Reddish compared to C26000 (70-30 cartridge brass). C28000 is used as a good match to the color of C23000 (85-15 red brass).

Chemical Properties

General corrosion behavior. Generally good; similar to copper except as noted below

Resistance to specific corroding agents. Better resistance to sulfur-bearing compounds than that of higher-copper alloys

Fabrication Characteristics

Machinability. 40% of C36000 (free-cutting brass)

Forgeability. 90% of C37700 (forging brass)

Formability. Fair capacity for cold working; excellent capacity for hot forming

Weldability. Soldering or brazing: excellent. Oxyfuel gas welding, resistance spot welding, or resistance butt welding: good. Gas-shielded arc welding: fair

Annealing temperature. 425 to 600 °C (800 to 1100 °F). See also Fig. 35.

Hot-working temperature. 625 to 800 °C (1150 to 1450 °F)

C31400
89Cu-9.1Zn-1.9Pb

Commercial Names

Previous trade name. Leaded commercial bronze; CA314

Specifications

ASTM. B 140

Chemical Composition

Composition limits. 87.5 to 90.5 Cu, 1.3 to 2.5 Pb, 0.10 Fe max, 0.7 Ni max, 0.5 max other (total), bal Zn

Applications

Typical uses. Screws, screw machine parts, pickling racks and fixtures, electrical plug-type connectors, builders' hardware

Mechanical Properties

Tensile properties. Rod, typical. O61 temper: tensile strength, 255 MPa (37 ksi); yield strength, 83 MPa (12 ksi) at 0.5% extension under load; elongation, 45% in 50 mm (2 in.); reduction in area, 70%. H02 temper: tensile strength, 360 MPa (52 ksi); yield strength, 310 MPa (45 ksi); elongation, 18%; reduction in area, 60%

Shear strength. Rod, typical: O61 temper, 165 MPa (24 ksi); H02 temper, 205 MPa (30 ksi)

Hardness. O61 temper, 55 HRF; H02 temper, 58 HRB; H04 temper, 61 to 65 HRB

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 45 GPa (6.4×10^6 psi)

Mass Characteristics

Density. 8.83 g/cm^3 (0.319 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1040 °C (1900 °F)

Solidus temperature. 1010 °C (1850 °F)

Coefficient of linear thermal expansion. 18.4 μm/m · K (10.2 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 375 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 180 W/m · K (104 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 42% IACS at 20 °C (68 °F)

Electrical resistivity. 41 nΩ · m at 20 °C (68 °F)

Optical Properties

Color. Rich bronze

Fabrication Characteristics

Machinability. 80% of C36000 (free-cutting brass)

Formability. Cold working, good; hot forming, poor

Weldability. Soldering: excellent. Brazing: good. Resistance butt welding: fair. All other welding processes are not recommended.

Annealing temperature. 425 to 650 °C (800 to 1200 °F)

C31600
89Cu-8.1Zn-1.9Pb-1Ni

Commercial Names

Previous trade name. Leaded commercial bronze-nickel bearing; CA316

Specifications

ASTM. B 140

Chemical Composition

Composition limits. 87.5 to 90.5 Cu, 1.3 to 2.5 Pb, 0.7 to 1.2 Ni, 0.1 Fe max, 0.04 to 0.10 P, 0.5 max other (total), bal Zn

Applications

Typical uses. Electrical connectors, fasteners, hardware, nuts, screws, screw machine parts. Most commonly used as rod or drawn bar

Mechanical Properties

Tensile properties. See Table 59.

Table 59 Typical mechanical properties of C31600

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness, HRB	Shear strength	
	MPa	ksi	MPa	ksi			MPa	ksi
Drawn bar, 6 mm (0.25 in.) diameter								
H04	435	63	385	56	12	70	. . .	. . .
Rod, 13 mm (0.50 in.) diameter								
H04	460	67	405	59	13	72	275	40
Rod, 25 mm (1 in.) diameter								
OS050	255	37	83	12	45	55 HRF	165	24

(a) 0.5% extension under load

Hardness. See Table 59.

Elastic modulus. Tension, 115 GPa (17×10^6 psi)

Mass Characteristics

Density. 8.86 g/cm^3 (0.320 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1040 °C (1900 °F)

Solidus temperature. 1010 °C (1850 °F)

Coefficient of linear thermal expansion. 18.4 μm/m · K (10.2 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 140 W/m · K (81 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 32% IACS at 20 °C (68 °F)

Electrical resistivity. 54 nΩ · m at 20 °C (68 °F)

Optical Properties

Color. Rich bronze

Fabrication Characteristics

Machinability. 80% of C36000 (free-cutting brass)

Formability. Cold working: good. Hot forming, poor

Weldability. Soldering: excellent. Brazing: good. Resistance butt welding: fair. All other welding processes are not recommended.

Annealing temperature. 425 to 650 °C (800 to 1200 °F)

C33000
66Cu-33.5Zn-0.5Pb

Commercial Names

Previous trade name. Low-leaded brass (tube)

Common name. High brass; yellow brass

Specifications

AMS. 4555

ASTM. B 135

SAE. J463

Government. WW-T-791, MIL-T-46072

Chemical Composition

Composition limits. 65 to 68 Cu, 0.2 to 0.8 Pb, 0.07 Fe max, 0.5 max other (total), bal Zn. For tubing with an outside diameter greater than 125 mm (5 in.), Pb content may be less than 0.2%.

Applications

Typical uses. General-purpose use where some degree of machinability is required together with moderate cold-working properties; for example, primers for munitions. Plumbing: J-bends, pump lines, trap lines

Mechanical Properties

Tensile properties. See Table 60.

Table 60 Typical mechanical properties of C33000 tubing

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness		
	MPa	ksi	MPa	ksi		HRF	HRB	HR30T
OS050	325	47	105	15	60	64	. . .	26

H58	450	65	345	50	32	100	70	66
H80	515	75	415	60	7	. . .	85	76

(a) 0.5% extension under load

Hardness. See Table 60.

Elastic modulus. Tension, 105 GPa (15×10^6 psi); shear, 39 GPa (5.6×10^6 psi)

Mass Characteristics

Density. 8.50 g/cm^3 (0.31 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 940 °C (1720 °F)

Solidus temperature. 905 °C (1660 °F)

Coefficient of linear thermal expansion. 20.2 μm/m · K (11.2 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 115 W/m · K (67 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O61 temper, 26% IACS at 20 °C (68 °F)

Electrical resistivity. 66 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 60% of C36000 (free-cutting brass)

Formability. Cold working, excellent; hot forming, poor

Weldability. Soldering: excellent. Brazing: good. Oxyfuel gas, gas-shielded arc, resistance spot, and resistance butt welding; fair. All other welding processes are not recommended.

Recrystallization temperature. 290 °C (550 °F)

Annealing temperature. 425 to 650 °C (800 to 1200 °F)

C33200
66Cu-32.4Zn-1.6Pb

Commercial Names

Previous trade name. High-leaded brass (tube)

Common name. Free-cutting tube brass

Specifications

AMS. 4558

ASTM. B 135

Government. MIL-T-46072

Chemical Composition

Composition limits. 65.0 to 68.0 Cu, 1.3 to 2.0 Pb, 0.07 Fe max, 0.5 max other (total), bal Zn

Applications

Typical uses. General-purpose screw machine products

Mechanical Properties

Tensile properties. See Table 61 and Fig. 36

Table 61 Typical mechanical properties of C33200 tubing

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness		
	MPa	ksi	MPa	ksi		HRF	HRB	HR30T

(a) 0.5% extension under load

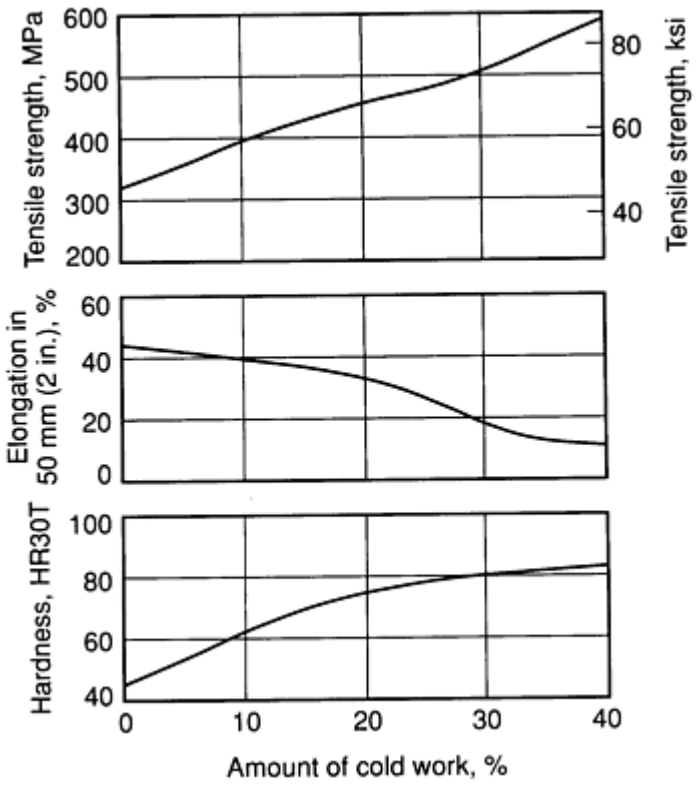

Fig. 36 Typical mechanical properties of cold drawn C33200 copper alloy tubing

Electrical resistivity. 66 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 80% of C36000 (free-cutting brass)

Formability. Cold working, fair; hot forming, poor

Hardness. See Table 61 and Fig. 36.

Elastic modulus. Tension, 105 GPa (15×10^6 psi); shear, 39 GPa (5.6×10^6 psi)

Mass Characteristics

Density. 8.53 g/cm^3 (0.31 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 930 °C (1710 °F)

Solidus temperature. 900 °C (1650 °F)

Coefficient of linear thermal expansion. 20.3 μm/m · K (11.3 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 115 W/m · K (67 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric. O61 temper, 26% IACS at 20 °C (68 °F)

Weldability. Soldering: excellent. Brazing: good. Resistance butt welding: fair. All other welding processes are not recommended.

Recrystallization temperature. 288 °C (550 °F)

Annealing temperature. 425 to 650 °C (800 to 1200 °F)

C33500
65Cu-34.5Zn-0.5Pb

Commercial Names

Previous trade name. Low-leaded brass

Specifications

ASTM. Flat products: B 121. Rod: B 453

Government. Flat products: QQ-B-613. Bar, forgings, rod, shapes, strip: QQ-B-626

Chemical Composition

Composition limits. 62.5 to 66.5 Cu, 0.3 to 0.8 Pb, 0.1 Fe max, 0.5 max other (total), bal Zn

Applications

Typical uses. Hardware such as butts and hinges; watch backs

Mechanical Properties

Tensile properties. See Table 62.

Table 62 Typical mechanical properties of C33500

Temper	Tensile	Yield	Elongation in 50 mm	Hardness	Shear strength

	MPa	ksi	MPa	ksi	(2 in.), %	HRF	HR30T	MPa	ksi
OS070	315	46	97	14	65	58	15	220	32

H06	580	84	. . .	. . .	. . .	86 HRB	74	. . .	. . .

Note: Values for flat products, 1 mm (0.04 in.) thick.

(a) 0.5% extension under load

Shear strength. See Table 62.

Hardness. See Table 62.

Elastic modulus. Tension, 105 GPa (15×10^6 psi); shear, 39 GPa (5.6×10^6 psi)

Mass Characteristics

Density. 8.47 g/cm^3 (0.306 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 925 °C (1700 °F)

Solidus temperature. 900 °C (1650 °F)

Coefficient of linear thermal expansion. 20.3 μm/m · K (11.3 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 115 W/m · K (67 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 26% IACS at 20 °C (68 °F)

Electrical resistivity. 66 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 60% of C36000 (free-cutting brass)

Formability. Cold working, good; hot forming, poor. Commonly fabricated by blanking, drawing, machining, piercing, punching, and stamping

Weldability. Soldering: excellent. Brazing: good. Oxyfuel gas, gas-shielded arc, resistance spot, and resistance butt welding: fair. Shielded metal arc and resistance seam welding are not recommended.

Annealing temperature. 425 to 700 °C (800 to 1300 °F)

C34000
65Cu-34Zn-1Pb

Commercial Names

Previous trade name. Medium-leaded brass, 64.5%

Specifications

ASTM. Flat products: B 121. Rod: B 453

Government. Flat products: QQ-B-613. Bar, forgings, rod, shapes, strip: QQ-B-626

Chemical Composition

Composition limits. 62.5 to 66.5 Cu, 0.8 to 1.4 Pb, 0.10 Fe max, 0.5 max other (total), bal Zn

Applications

Typical uses. Flat products: butts, dials, engravings, gears, instrument plates, nuts, or drawn shells, all involving piercing, threading, or machining. Rod, bar, and wire: couplings, free-machining screws and rivets, gears, nuts, tire valve stems, screw machine products involving severe knurling and roll threading or moderate cold heading, flaring, spinning, or swaging

Mechanical Properties

Tensile properties. See Table 63.

Table 63 Typical mechanical properties of C34000

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness		Shear strength

(a) 0.5% extension under load

Annealing temperature. 425 to 650 °C (800 to 1200 °F)

Shear strength. See Table 63.

Hardness. See Table 63.

Elastic modulus. Tension, 105 GPa (15 × 10^6 psi); shear, 39 GPa (5.6 × 10^6 psi)

Mass Characteristics

Density. 8.47 g/cm^3 (0.306 lb/$in.^3$) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 925 °C (1700 °F)

Solidus temperature. 885 °C (1630 °F)

Coefficient of linear thermal expansion. 20.3 μm/m · K (11.3 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 115 W/m · K (67 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric. O61 temper, 26% IACS at 20 °C (68 °F)

Electrical resistivity. 66 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 60% of C36000 (free-cutting brass)

Formability. Cold working, good; hot forming, poor

Weldability. Soldering: excellent. Brazing: good. Resistance butt welding: fair. All other welding processes are not recommended.

Recrystallization temperature. 288 °C (550 °F)

C34200
64.5Cu-33.5Zn-2Pb
C35300
62Cu-36.2Zn-1.8Pb

Commercial Names

Previous trade name. High-leaded brass

Common name. Clock brass, engraver's brass, heavy-leaded brass

Specifications

ASTM. Flat products: B 121. Rod: B 453

SAE. J463

UNS number. C34200, C35300

Government. Flat products: QQ-B-613. Bar, forgings, rod, shapes, strip: QQ-B-626

Chemical Composition

Composition limits of C34200. 62.5 to 66.5 Cu, 1.5 to 2.5 Pb, 0.1 Fe max, 0.5 max other (total), bal Zn

Composition limits of C35300. 59.0 to 64.5 Cu, 1.3 to 2.3 Pb, 0.1 Fe max, 0.5 max other (total), bal Zn

Applications

Typical uses. Flat products: gears, wheels, nuts, plates for clocks, keys, bearing cages, engraver's plates. Rod: gears, pinions, valve stems, automatic screw machine parts that need more severe cold working than can be tolerated with free-cutting brass (for example, processes such as knurling and moderate staking)

Mechanical Properties

Tensile properties. See Table 64.

Table 64 Typical mechanical properties of C34200

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness		Shear strength	
	MPa	ksi	MPa	ksi		HRB	HR30T	MPa	ksi
Flat products, 1 mm (0.04 in.) thick

(a) 0.5% extension under load.

(b) Reduction in area 65%.

(c) Reduction in area 50%.

(d) Reduction in area 35%

Hardness. See Table 64.

Elastic modulus. Tension, 105 GPa (15×10^6 psi); shear, 39 GPa (5.6×10^6 psi)

Structure

Crystal structure. Face-centered cubic α

Microstructure. Two phase, α and lead

Mass Characteristics

Density. 8.5 g/cm^3 (0.307 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 910 °C (1670 °F)

Solidus temperature. 885 °C (1630 °F)

Coefficient of linear thermal expansion. 20.3 μm/m · K (11.3 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 115 W/m · K (67 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O61 temper, 26% IACS at 20 °C (68 °F)

Electrical resistivity. 66 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 90% of C36000 (free-cutting brass)

Formability. Cold working, fair; hot forming, poor

Weldability. Soldering: excellent. Brazing: good. Resistance butt welding: fair. All other welding processes are not recommended.

Recrystallization temperature. 320 °C (600 °F)

Annealing temperature. 425 to 600 °C (800 to 1100 °F). See also Fig. 37.

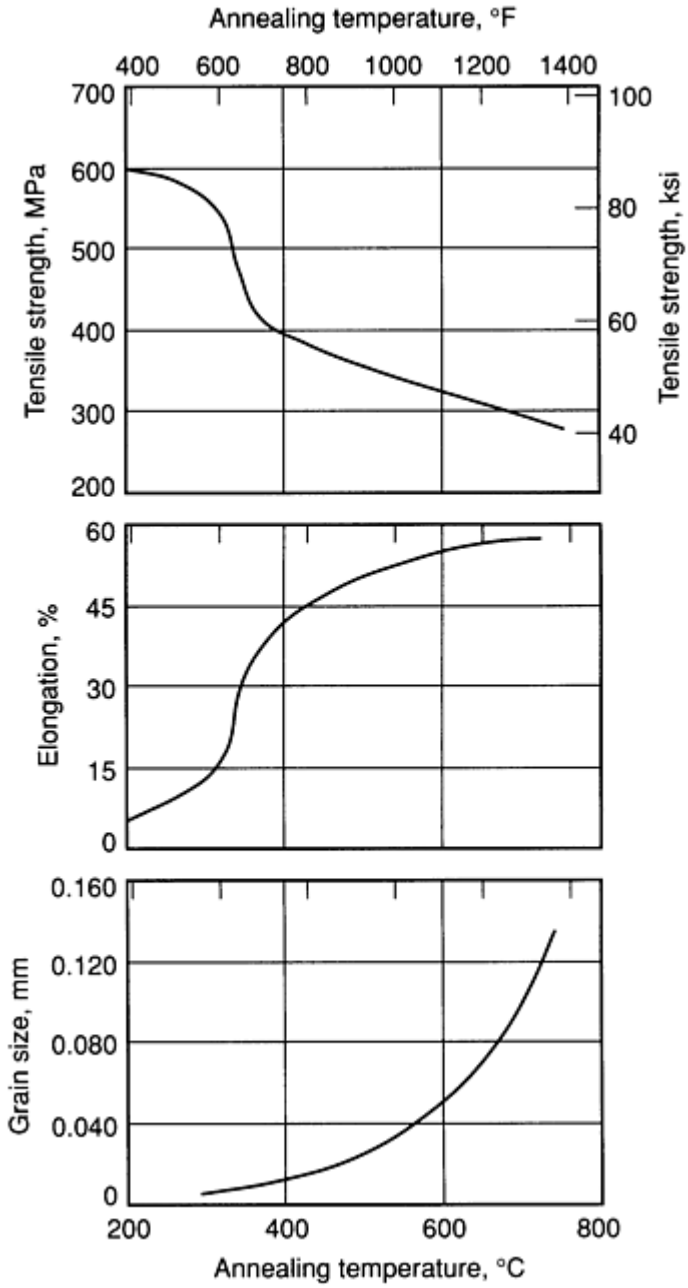

Fig. 37 Annealing behavior of C34200. Curves are for 1 mm (0.04 in.) thick strip cold rolled from OS035 temper starting stock.

Hot-working temperature. 785 to 815 °C (1445 to 1500 °F)

C34900
62Cu-37.5Zn-0.3Pb

Chemical Composition

Composition limits. 61.0 to 64.0 Cu, 0.1 to 0.5 Pb, 0.1 Fe max, 0.5 max other (total), bal Zn

Applications

Typical uses. Building hardware, drilled and tapped rivets, plumbing goods, saw nuts, and parts requiring moderate cold working combined with some machining

Mechanical Properties

Tensile properties. See Table 65.

Table 65 Typical mechanical properties of C34900

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness	Shear strength	
	MPa	ksi	MPa	ksi			MPa	ksi

(a) At 0.5% extension under load

Shear strength. See Table 65.

Hardness. See Table 65.

Elastic modulus. Tension, 105 GPa (15×10^6 psi); shear, 39 GPa (5.6×10^6 psi)

Mass Characteristics

Density. 8.44 g/cm^3 (0.305 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 910 °C (1670 °F)

Solidus temperature. 895 °C (1640 °F)

Coefficient of linear thermal expansion. 20.3 μm/m · K (11.3 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 115 W/m · K (67 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 26% IACS at 20 °C (68 °F)

Electrical resistivity. 66 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 50% of C36000 (free-cutting brass)

Formability. Cold working, good; hot forming, poor

Weldability. Soldering: excellent. Brazing: good. Oxyfuel gas, gas-shielded arc, and resistance spot and butt

welding: fair. Shielded metal arc and resistance seam welding are not recommended.

Hot-working temperature. 675 to 800 °C (1250 to 1450 °F)

Annealing temperature. 425 to 650 °C (800 to 1200 °F)

C35000
62.5Cu-36.4Zn-1.1Pb

Commercial Names

Previous trade name. Medium-leaded brass, 62%

Specifications

ASTM. Flat products: B 121. Rod: B 453

SAE. J463

Government. Flat products: QQ-B-613. Bar, forgings, rod, shapes, strip: QQ-B-626

Chemical Composition

Composition limits. 59.0 to 64.0 Cu, 0.8 to 1.4 Pb, 0.1 Fe max, 0.5 max other (total), bal Zn

Applications

Typical uses. Bearing cages, book dies, clock plates, engraving plates, gears, hinges, hose couplings, keys, lock parts, lock tumblers, meter parts, sink strainers, strike plates, templates, nuts, type characters, washers, wear plates

Mechanical Properties

Tensile properties. See Table 66.

Table 66 Typical mechanical properties of C35000

Shear strength. See Table 66.

Hardness. See Table 66.

Elastic modulus. Tension, 105 GPa (15×10^6 psi); shear, 39 GPa (5.6×10^6 psi)

Mass Characteristics

Density. 8.47 g/cm^3 (0.306 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 915 °C (1680 °F)

Solidus temperature. 895 °C (1640 °F)

Coefficient of linear thermal expansion. 20.3 μm/m · K (11.3 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 115 W/m · K (67 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 26% IACS at 20 °C (68 °F)

Electrical resistivity. 66 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 70% of C36000 (free-cutting brass)

Forgeability. 50% of C37700 (forging brass)

Formability. Fair for cold working and hot forming

Weldability. Soldering: excellent. Brazing: good. Resistance butt welding: fair. All other welding processes are not recommended.

Annealing temperature. 425 to 600 °C (800 to 1100 °F)

Hot-working temperature. 760 to 800 °C (1400 to 1500 °F)

C35600
62Cu-35.5Zn-2.5Pb

Commercial Names

Previous trade name. Extra-high-leaded brass

Specifications

ASTM. Flat products: B 121. Rod: B 453

Government. Flat products: QQ-B-613. Bar, rod, shapes, strip: QQ-B-626

Chemical Composition

Composition limits. 59.0 to 64.5 Cu, 2.0 to 3.0 Pb, 0.1 Fe max, 0.5 max other (total), bal Zn

Applications

Typical uses. Hardware: clock plates and nuts, clock and watch backs, clock gears and wheels. Industrial: channel plate

Mechanical Properties

Tensile properties. See Table 67.

Table 67 Typical mechanical properties of 1 mm (0.04 in.) thick C35600 sheet and strip

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness	
	MPa	ksi	MPa	ksi		HRB	HR30T
OS035	340	49	115	17	50	68 HRF	31
H01	370	54	275	40	35	55	54
H02	420	61	345	50	20	70	65

(a) At 0.5% extension under load

Hardness. See Table 67.

Elastic modulus. Tension, 97 GPa (14×10^6 psi); shear, 37 GPa (5.3×10^6 psi)

Mass Characteristics

Density. 8.5 g/cm^3 (0.307 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 905 °C (1660 °F)

Solidus temperature. 885 °C (1630 °F)

Coefficient of linear thermal expansion. 20.5 μm/m · K (11.4 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 115 W/m · K (67 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O61 temper, 26% IACS at 20 °C (68 °F)

Electrical resistivity. 66 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 100% of C36000 (free-cutting brass)

Formability. Cold working, poor; hot forming, fair

Weldability. Soldering: excellent. Brazing: good. Resistance butt welding: fair. All other welding processes are not recommended.

Annealing temperature. 425 to 600 °C (800 to 1100 °F)

Hot-working temperature. 700 to 800 °C (1300 to 1450 °F)

C36000
61.5Cu-35.5Zn-3Pb

Commercial Names

Previous trade name. Free-cutting brass

Common name. Free-turning brass, free-cutting yellow brass, high-leaded brass

Specifications

AMS. 4610

ASTM. B 16

SAE. J463

Government. Flat products: QQ-B-613. Bar, forgings, rod, shapes, strip: QQ-B-626

Chemical Composition

Composition limits. 60.0 to 63.0 Cu, 2.5 to 3.7 Pb, 0.35 Fe max, 0.5 max other (total), bal Zn

Applications

Typical uses. Hardware: gears, pinions. Industrial: automatic high-speed screw machine parts

Mechanical Properties

Tensile properties. See Table 68 and Fig. 38.

Table 68 Typical mechanical properties of C36000

Temper	Tensile strength		Yield strength[a]		Elongation in 50 mm (2 in.), %	Reduction in area, %	Hardness, HRB	Shear strength	
	MPa	ksi	MPa	ksi				MPa	ksi
Rod, 6 mm, (0.25 in.) diameter									
H02[b]	400	58	310	45	25	50	78	235	34
Rod, 25 mm (1 in.) diameter									
O61	340	49	125	18	53	58	68 HRF	205	30
H02[c]	340	49	125	18	53	58	68 HRF	205	30
Rod, 50 mm (2 in.) diameter									
H02[d]	380	55	305	44	32	52	75	220	32
Shapes									
M30	340	49	125	18	50	. . .	68 HRF	205	30

(a) 0.5% extension under load.

(b) Cold drawn 25%.

(c) Cold drawn 20%.

(d) Cold drawn 18%.

(e) Cold drawn 15%

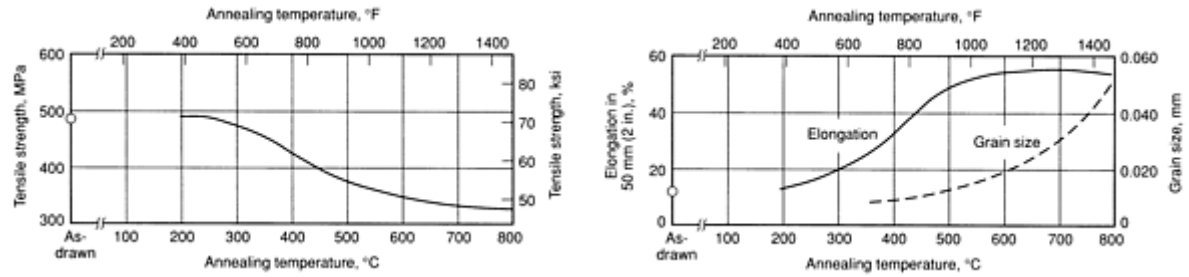

Fig. 38 Annealing curves for C36000. Data are for free-cutting brass rod, cold drawn 30% to 19 mm (0.75 in.) in diameter from M30 temper (as-extruded) starting stock, then annealed 1 h at temperature

Hardness. See Table 68.

Elastic modulus. Tension, 97 GPa (14×10^6 psi); shear, 37 GPa (5.3×10^6 psi)

Fatigue strength. Rotating-beam tests on 90 mm (0.350 in.) diam specimens taken from 50 mm (2 in.) diam rod. H02 temper (cold drawn 15%): 140 MPa (20 ksi) at 10^8 cycles; 97 MPa (14 ksi) at 3×10^8 cycles

Structure

Microstructure. Generally three phase: α, β, and lead

Mass Characteristics

Density. 8.5 g/cm^3 (0.307 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 900 °C (1660 °F)

Solidus temperature. 885 °C (1630 °F)

Coefficient of linear thermal expansion. 20.5 μm/m · K (11.4 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 115 W/m · K (67 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O61 temper, 26% IACS at 20 °C (68 °F)

Electrical resistivity. 66 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 100%. This is the standard material against which the machining qualities of all other copper alloys are judged.

Formability. Cold working, poor; hot forming, fair

Weldability. Soldering: excellent, Brazing: good. Resistance butt welding: fair. All other welding processes are not recommended.

Recrystallization temperature. 330 °C (625 °F)

Annealing temperature. 425 to 600 °C (800 to 1100 °F). See also Fig. 38.

Hot-working temperature. 700 to 800 °C (1300 to 1450 °F)

C36500, C36600, C36700, C36800
60Cu-39.4Zn-0.6Pb

Commercial Names

Previous trade name. C36500, uninhibited leaded Muntz metal; C36600, arsenical leaded Muntz metal; C36700, antimonial leaded Muntz metal; C36800, phosphorized leaded Muntz metal

Common name. Leaded Muntz metal; inhibited leaded Muntz metal

Specifications

ASME. Plate, condenser tube: SB171

ASTM. Plate, condenser tube: B 171. Plate, clad: B 432

Chemical Composition

Composition limits. 58.0 to 61.0 Cu, 0.4 to 0.9 Pb, 0.15 Fe max, 0.25 Sn max; As Sb, or P (see below); 0.1 max other (total), bal Zn

Antimony or phosphorus limits. C36500, none specified; C36600, 0.02 to 0.1 As; C36700, 0.02 to 0.1 Sb; C36800, 0.02 to 0.1 P

Applications

Typical uses. Main tube sheets for condensers and heat exchangers; support sheets; baffles

Mechanical Properties

Tensile properties. 25 mm (1 in.) plate, M20 temper: tensile strength, 370 MPa (54 ksi); yield strength (0.5% extension), 140 MPa (20 ksi); elongation, 45% in 50 mm (2 in.)

Shear strength. M20 temper: 275 MPa (40 ksi)

Hardness. M20 temper: 80 HRF

Elastic modulus. Tension, 105 GPa (15×10^6 psi); shear, 39 GPa (5.6×10^6 psi)

Structure

Crystal structure. Face-centered cubic

Microstructure. Alpha and βwith undissolved lead. Beta phase appears lemon yellow with ammonia peroxide etch; it may be darkened with ferric chloride etch. Lead appears as insoluble gray particles randomly distributed throughout the structure.

Mass Characteristics

Density. 8.41 g/cm^3 (0.304 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 900 °C (1650 °F)

Solidus temperature. 885 °C (1630 °F)

Coefficient of linear thermal expansion. 20.8 μm/m · K (11.6 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 123 W/m · K (71 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O61 temper: 28% IACS at 20 °C (68 °F)

Electrical resistivity. 62 nΩ · m at 20 °C (68 °F)

Chemical Properties

General corrosion behavior. Good resistance to corrosion in both fresh and salt water. C36500 is the uninhibited alloy and is subject to dezincification: the inhibited alloys each contain 0.02 to 0.10% of an inhibitor element (As, Sb, or P), which imparts high resistance to dezincification.

Fabrication Characteristics

Machinability. 60% of C36000 (free-cutting brass)

Formability. Cold working, fair; hot working, excellent

Weldability. Soldering: excellent. Brazing: good. Oxyfuel gas, gas-shielded arc, and resistance butt welding: fair. All other welding processes are not recommended.

Annealing temperature. 425 to 600 °C (800 to 1100 °F)

Hot-working temperature. 625 to 800 °C (1150 to 1450 °F)

C37000
60Cu-39Zn-1Pb

Commercial Names

Previous trade name. Free-cutting Muntz metal

Specifications

ASTM. Tube: B 135

Government. Flat products: QQ-B-613. Bar, forgings, rod, strip: QQ-B-626. tube: MIL-T-46072

Chemical Composition

Composition limits. 59.0 to 62.0 Cu, 0.9 to 1.4 Pb, 0.15 Fe max, 0.5 max other (total), bal Zn

Applications

Typical uses. Automatic screw machine parts

Mechanical Properties

Tensile properties. See Table 69.

Table 69 Typical mechanical properties of C37000

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness	
	MPa	ksi	MPa	ksi		HRB	HR30T
Tube, 38 mm (1.5 in.) outside diameter × 3 mm (0.125 in.) wall thickness							
O50	370	54	140	20	40	80 HRF	43
H80[(b)]	550	80	415	60	6	85	74
Tube, 50 mm (2 in.) outside diameter × 6 mm (0.25 in.) wall thickness							

(a) At 0.5% extension under load.

(b) Cold drawn 35%.

(c) Cold drawn 25%

Hardness. See Table 69.

Elastic modulus. Tension, 105 GPa (15×10^6 psi); shear, 39 GPa (5.6×10^6 psi)

Mass Characteristics

Density. 8.41 g/cm^3 (0.304 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 900 °C (1650 °F)

Solidus temperature. 885 °C (1630 °F)

Coefficient of linear thermal expansion. 20.8 μm/m · K (11.6 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 375 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 120 W/m · K (69 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O61 temper; 27% IACS at 20 °C (68 °F)

Electrical resistivity. 63.9 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 70% of C36000 (free-cutting brass)

Weldability. Soldering: excellent. Brazing: good. Resistance butt welding: fair. All other welding processes are not recommended.

Annealing temperature. 425 to 600 °C (800 to 1100 °F)

Hot-working temperature. 625 to 800 °C (1150 to 1450 °F)

C37700
60Cu-38Zn-2Pb

Commercial Names

Previous trade name. Forging brass

Specifications

AMS. Die forgings, forging rod: 4614

ASME. Die forgings: SB283

ASTM. Bar, forging, rod, shapes: B 124. Die forgings: B 283

SAE. Die forgings: J463

Government. QQ-B-626. Die Forgings: MIL-C-13351

Chemical Composition

Composition limits. 58.0 to 62.0 Cu, 1.5 to 2.5 Pb, 0.3 Fe max, 0.5 max other (total), bal Zn

Applications

Typical uses. Forgings and pressings of all kinds

Mechanical Properties

Tensile properties. M30 temper: tensile strength, 360 MPa (52 ksi); yield strength (0.5% extension), 140 MPa (20 ksi); elongation, 45% in 50 mm (2 in.). See Fig. 39 and 40.

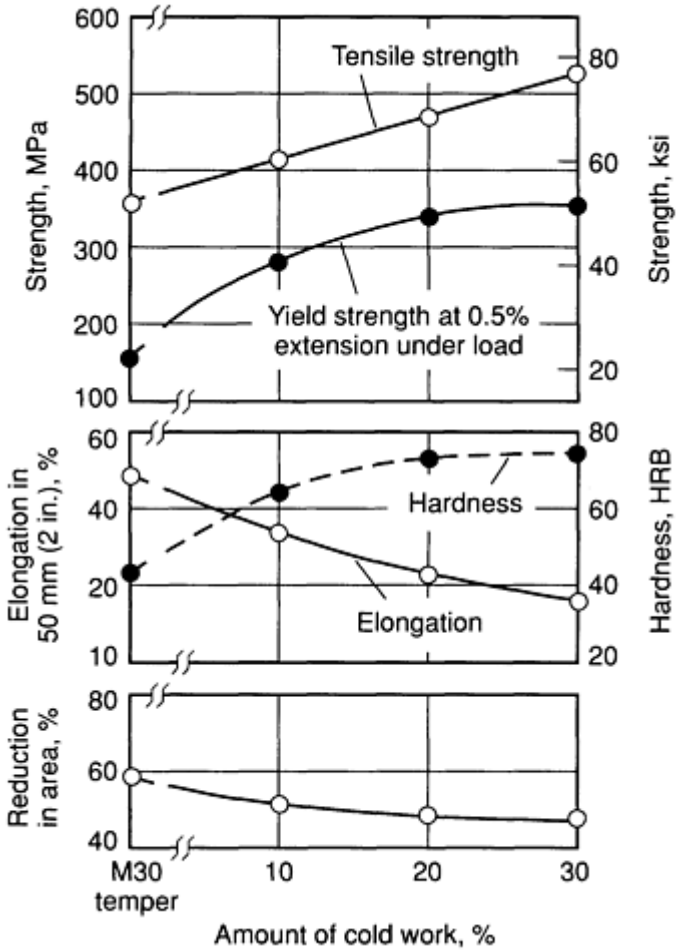

Fig. 39 Typical mechanical properties of extruded and drawn C37700. Data are for forging brass rod less than 25 mm (1 in.) diameter that was extruded, then cold drawn to various percentages of reduction in area.

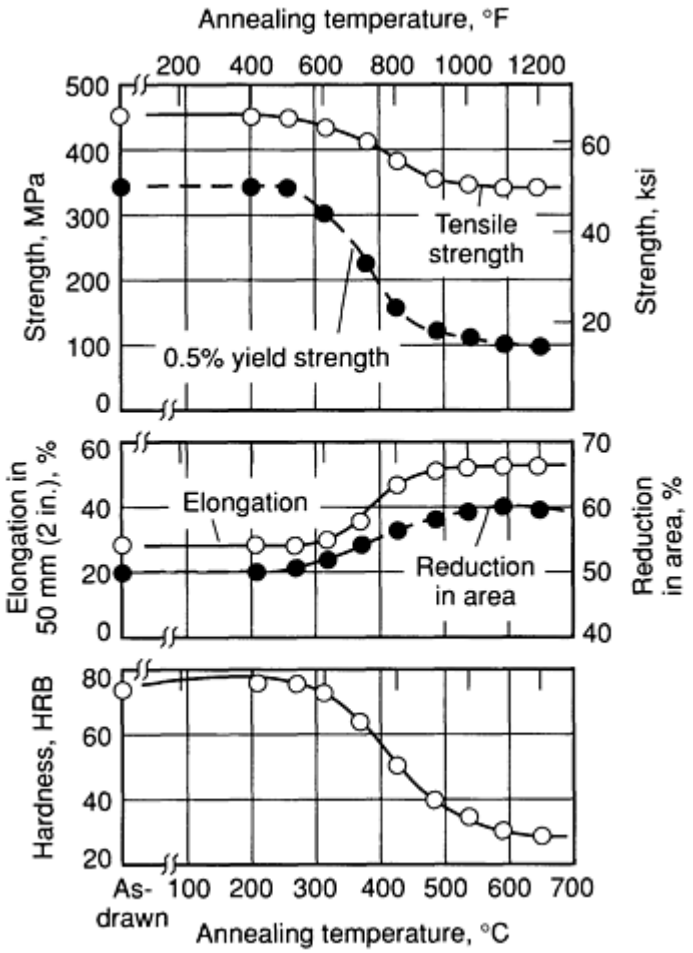

Fig. 40 Annealing curves for C37700. Typical data are for forging brass rod less than 25 mm (1 in.) in diameter that was extruded, cold drawn 18%, and annealed 1 h at various temperatures.

Hardness. M30 temper: 78 HRF. See also Fig. 39 and 40.

Elastic modulus. Tension, 105 GPa (15×10^6 psi); shear, 39 GPa (5.6×10^6psi)

Structure

Crystal structure. Face-centered cubic

Microstructure. Two phase: α and β, with undissolved lead. Beta phase appears lemon yellow with ammonia peroxide etch. Ferric chloride darkens β-phase. Lead appears as gray particles.

Mass Characteristics

Density. 8.44 g/cm^3 (0.305 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 895 °C (1640 °F)

Solidus temperature. 880 °C (1620 °F)

Coefficient of linear thermal expansion. 20.7 μm/m · K (11.5 μin./in · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 120 W/m · K (69 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 27% IACS at 20 °C (68 °F)

Electrical resistivity. 64 nΩ · m at 20 °C (68 °F)

Magnetic Properties

Magnetic susceptibility. Nonmagnetic

Optical Properties

Color. Golden hue compared to yellow of C26000 (cartridge brass)

Fabrication Characteristics

Machinability. 80% of C36000 (free-cutting brass)

Forgeability. 100%. This is the standard material against which the forging qualities of all other copper alloys are judged.

Formability. Cold working, poor; hot forming, excellent

Weldability. Soldering: excellent. Brazing: good. Resistance butt welding: fair. All other welding processes are not recommended.

Annealing temperature. 425 to 600 °C (800 to 1100 °F). See also Fig. 40.

Hot-working temperature. 650 to 825 °C (1200 to 1500 °F)

C38500
57Cu-40Zn-3Pb

Commercial Names

Previous trade name. Architectural bronze

Specifications

ASTM. Shapes: B 455

Chemical Composition

Composition limits. 55.0 to 60.0 Cu, 2.0 to 3.8 Pb, 0.35 Fe max, 0.5 max other (total), bal Zn

Applications

Typical uses. Architectural: extrusions, storefronts, threshold, and trim. Hardware: butts, hinges, and lock bodies. Industrial: forgings

Mechanical Properties

Tensile properties. M30 temper: tensile strength, 415 MPa (60 ksi); yield strength (0.5% extension), 140 MPa (20 ksi); elongation, 30% in 50 mm (2 in.)

Shear strength. M30 temper: 240 MPa (35 ksi)

Hardness. M30 temper: 65 HRB

Elastic modulus. Tension, 97 GPa (14×10^6 psi); shear, 37 GPa (5.3×10^6 psi)

Mass Characteristics

Density. 8.47 g/cm^3 (0.306 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 890 °C (1630 °F)

Solidus temperature. 875 °C (1610 °F)

Coefficient of linear thermal expansion. 20.9 μm/m · K (11.6 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 123 W/m · K (71 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O61 temper: 28% IACS at 20 °C (68 °F)

Electric resistivity. 62 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 90% of C36000 (free-cutting brass)

Formability. Cold working, poor; hot forming, excellent

Weldability. Soldering: excellent. Brazing: good. Resistance butt welding: fair. All other welding processes are not recommended.

Annealing temperature. 425 to 600 °C (800 to 1100 °F)

Hot-working temperature. 625 to 725 °C (1150 to 1350 °F)

C40500
95Cu-4Zn-1Sn

Commercial Names

Trade name. High-conductivity bronze

Common name. Penny bronze

Specifications

ASTM. B 591

Chemical Composition

Table 70 Typical mechanical properties of C40500

Composition limits. 94 to 96 Cu, 0.7 to 1.3 Sn, 0.05 Pb max, 0.05 Fe max, bal Zn

Applications

Typical uses. Meter clips, terminals, fuse clips, contact springs, relay springs, washers from rolled strip, rolled bar, sheet

Mechanical Properties

Tensile properties. See Table 70.

Temper	Tensile strength		Yield strength				Elongation in 50 mm (2 in.), %	Hardness		Shear strength	
			At 0.5% extension under load		At 0.2% offset

Shear strength. See Table 70.

Hardness. See Table 70.

Elastic modulus. Tension: hard, 110 GPa (16×10^6 psi); annealed, 125 GPa (18×10^6 psi)

Mass Characteristics

Density. 8.83 g/cm^3 (0.319 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1060 °C (1940 °F)

Solidus temperature. 1025 °C (1875 °F)

Thermal conductivity. 165 W/m · K (95 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 41% IACS at 20 °C (68 °F)

Electrical resistivity. 42 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent for cold working; good for hot forming

Weldability. Soldering and brazing: excellent. Gas-shielded arc and resistance spot and butt welding: good. Oxyacetylene and resistance seam welding: fair. Coated metal arc welding is not recommended.

Annealing temperature. 510 to 670 °C (950 to 1240 °F)

Hot-working temperature. 830 to 890 °C (1525 to 1635 °F)

C40800
95Cu-2Sn-3Zn

Specifications

ASTM. Flat products: B 591

Chemical Composition

Composition limits. 94 to 96 Cu, 1.8 to 2.2 Sn, 0.05 Pb max, 0.05 Fe max, bal Zn

Applications

Typical uses. Rolled strip for electrical connectors

Mechanical Properties

Tensile properties. See Table 71.

Table 71 Typical mechanical properties of C40800

Elastic modulus. Tension: hard, 110 GPa (16×10^6 psi); shear, 41 GPa (6×10^6 psi)

Mass Characteristics

Density. 8.86 g/cm^3 (0.320 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1054 °C (1930 °F)

Solidus temperature. 1038 °C (1900 °F)

Coefficient of linear thermal expansion. 18.2 μm/m · K (10.1 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 160 W/m · K (92 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 37% IACS at 20 °C (68 °F)

Electrical resistivity. 46.6 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent for cold working; fair for hot forming

Weldability. Soldering and brazing: excellent. Oxyacetylene, gas-shielded arc, and resistance butt welding: good. Resistance spot and seam welding are not recommended.

Annealing temperature. 450 to 675 °C (850 to 1250 °F)

Hot-working temperature. 830 to 890 °C (1525 to 1635 °F)

C41100
91Cu-8.5Zn-0.5Sn

Commercial Names

Previous trade name. Lubaloy

Specifications

ASTM. Flat products: B 508, B 591. Wire: B 105

Chemical Composition

Composition limits. 89 to 93 Cu, 0.3 to 0.7 Sn, 0.1 Pb max, 0.05 Fe max, bal Zn

Applications

Typical uses. Rolled strip; rolled bar, rod, and sheet for bushings, bearing sleeves, thrust washers, terminals, connectors, flexible metal hose, and electrical conductors

Mechanical Properties

Tensile properties. See Table 72.

Table 72 Typical mechanical properties of C41100

Temper	Tensile strength		Yield strength				Elongation in 50 mm (2 in.), %	Hardness		Shear strength

(a) Elongation in 254 mm (10 in.).

(b) Elongation in 1500 mm (60 in.)

Hardness. See Table 72.

Elastic modulus. Tension: hard, 115 GPa ($16.7 \cdot 10^6$ psi); annealed, 125 GPa (18×10^6 psi). Shear, 46 GPa (6.7×10^6 psi)

Mass Characteristics

Density. 8.80 g/cm^3 (0.318 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1040 °C (1905 °F)

Solidus temperature. 1020 °C (1870 °F)

Coefficient of linear thermal expansion. 18 μm/m · K (10 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Thermal conductivity. 130 W/m · K (75 Btu/ft · h · °F) at 20 °C (68 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 32% IACS at 20 °C (68 °F)

Electrical resistivity. 54 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent for cold working; good for hot forming

Weldability. Soldering: excellent. Gas-shielded arc welding and resistance buttwelding: good. Brazing, oxyacetylene, and resistance spot welding: fair. Coated metal arc and resistance seam welding are not recommended.

Annealing temperature. 500 to 700 °C (930 to 1290 °F)

Hot-working temperature. 830 to 890 °C (1525 to 1635 °F)

C41500
91Cu-7.2Zn-1.8Sn

Specifications

ASTM. B 591

Chemical Composition

Composition limits. 89 to 93 Cu, 1.5 to 2.2 Sn, 0.1 Pb max, 0.05 Fe max, bal Zn

Applications

Typical uses. Rolled strip for spring applications for electrical switches

Mechanical Properties

Tensile properties. See Table 73

Table 73 Typical mechanical properties of C41500

Temper	Tensile strength		Yield strength				Elongation in 50 mm (2 in.), %	Hardness		Fatigue strength	
			At 0.5% extension under load		At 0.2% offset

Note: Values for flat products, 1 mm (0.04 in.) thick

Hardness. See Table 73.

Elastic modulus. Tension: hard, 110 GPa (16×10^6 psi); annealed, 125 GPa (18×10^6 psi). Shear, 46 GPa (6.7×10^6 psi)

Mass Characteristics

Density. 8.80 g/cm^3 (0.318 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1032 °C (1890 °F)

Solidus temperature. 1010 °C (1850 °F)

Coefficient of linear thermal expansion. 18.6 μm/m · K (10.3 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 123 W/m · K (71 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 28% IACS at 20 °C (68 °F)

Electrical resistivity. 62 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

Formability. Excellent for cold working; fair for hot forming

Weldability. Soldering and brazing: excellent. Oxyacetylene, gas-shielded arc, and resistance butt welding: good. Resistance spot welding: fair. Coated metal arc and resistance seam welding are not recommended.

Annealing temperature. 400 to 705 °C (750 to 1300 °F)

Hot-working temperature. 730 to 845 °C (1350 to 1550 °F)

C41900
90.5Cu-4.35Zn-5.15Sn

Commercial Names

Previous trade name. CA419

Common name. Tin brass

Chemical Composition

Composition limits. 89 to 92 Cu, 4.8 to 5.5 Sn, 0.10 Pb max, 0.05 Fe max, bal Zn

Applications

Typical uses. Electrical connectors

Mechanical Properties

Tensile properties. See Table 74.

Table 74 Typical mechanical properties of C41900 strip

Temper	Tensile strength		Yield strength at 0.2% offset		Elongation in 50 mm (2 in.), %	Hardness, HRB
	MPa	ksi	MPa	ksi

H08	705	102	550	80	2	95

Fabrication Characteristics

Annealing temperature. 480 to 680 °C (900 to 1250 °F)

Hardness. See Table 74.

Elastic modulus. Tension, 125 GPa (18×10^6 psi)

Mass Characteristics

Density. 8.80 g/cm^3 at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1025 °C (1880 °F)

Solidus temperature. 1000 °C (1830 °F)

Coefficient of linear thermal expansion. 18.7 μm/m · K (10.4 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Thermal conductivity. 100 W/m · K (58 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 22% IACS at 20 °C (68 °F)

Electrical resistivity. 78 nΩ · m at 20 °C (68 °F)

C42200
87.5Cu-11.4Zn-1.1Sn

Commercial Names

Previous trade name. Lubronze

Specifications

ASTM. B 591

Chemical Composition

Composition limits. 86.0 to 89.0 Cu, 0.8 to 1.4 Sn, 0.35 P max, 0.05 Pb max, 0.05 Fe max, bal Zn

Applications

Typical uses. Rolled strip, rolled bar and sheet for sash chains, terminals, fuse clips, spring washers, contact springs, and electrical connectors

Mechanical Properties

Tensile properties. See Table 75.

Table 75 Typical mechanical properties of C42200

(a) At 0.5% extension under load

Hardness. See Table 77.

Elastic modulus. Tension, 110 GPa (16×10^6 psi); shear, 119 GPa (17.3×10^6 psi)

Mass Characteristics

Density. 8.75 g/cm^3 (0.316 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1025 °C (1877 °F)

Solidus temperature. 1000 °C (1832 °F)

Coefficient of linear thermal expansion. 18.4 μm/m · K (10.2 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 119 W/m · K (69 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, 27% IACS at 20 °C (68 °F)

Electrical resistivity. 64 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

Formability. Excellent for cold working; good for hot forming

Weldability. Soldering and brazing: excellent. Oxyacetylene, gas-shielded arc, and resistance butt welding: good. Resistance spot welding: fair. Coated metal arc and resistance seam welding are not recommended.

Annealing temperature. 425 to 700 °C (800 to 1300 °F)

Hot-working temperature. 790 to 840 °C (1455 to 1545 °F)

C43400
85Cu-14.3Zn-0.7Sn

Specifications

ASTM. Flat products: B 591

Chemical Composition

Composition limits. 84 to 87 Cu, 0.4 to 1.0 Sn, 0.05 Pb max, 0.05 Fe max, bal Zn

Applications

Typical uses. Rolled strip for electrical uses: switch parts, blades, relay springs, contacts

Mechanical Properties

Tensile properties. See Table 78.

Table 78 Typical mechanical properties of C43400

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness		Shear strength

Shear strength. See Table 78.

Hardness. See Table 78.

Elastic modulus. Tension: hard, 110 GPa (16×10^6 psi); annealed, 40 GPa (6×10^6 psi)

Mass Characteristics

Density. 8.75 g/cm^3 (0.316 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1020 °C (1870 °F)

Solidus temperature. 990 °C (1810 °F)

Coefficient of linear thermal expansion. 18.9 μm/m · K (10.5 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · h · °F) at 20 °C (68 °F)

Thermal conductivity. 137 W/m · K (79 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 31% IACS at 20 °C (68 °F)

Electrical resistivity. 56 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

Formability. Excellent for cold working; fair for hot forming

Weldability. Soldering and brazing: excellent. Oxyacetylene, gas-shielded arc, and resistance spot and butt welding: good. Resistance seam welding is not recommended.

Annealing temperature. 425 to 675 °C (800 to 1250 °F)

Hot-working temperature. 815 to 870 °C (1500 to 1600 °F)

C43500
81Cu-18.1Zn-0.9Sn

Chemical Composition

Composition limits. 79 to 83 Cu, 0.6 to 1.2 Sn, 0.1 Pb max, 0.05 Fe max, 0.15 max other (total), bal Zn

Applications

Typical uses. Rolled strip and tubing for Bourdon tubing and musical instruments

Mechanical Properties

Tensile properties. See Table 79.

Table 79 Typical mechanical properties of C43500

(a) At 0.5% extension under load

Shear strength. See Table 79.

Elastic modulus. Tension, 110 GPa (16×10^6 psi); shear, 40 GPa (6×10^6 psi)

Mass Characteristics

Density. 8.66 g/cm^3 (0.313 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1005 °C (1840 °F)

Solidus temperature. 965 °C (1770 °F)

Coefficient of linear thermal expansion. 19.4 μm/m · K (10.8 μin./in. · °F) at 20 °C (68 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 28% IACS at 20 °C (68 °F)

Electrical resistivity. 62 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

Formability. Excellent for cold working; good for hot forming

Weldability. Soldering and brazing: excellent. Oxyacetylene and resistance spot and butt welding: good. Gas-shielded metal arc welding: fair. Coated metal arc and resistance seam welding are not recommended.

C44300, C44400, C44500
71Cu-28Zn-1Sn

Commercial Names

Previous trade names. C44300, arsenical admiralty metal; C44400, antimonial admiralty metal; C44500, phosphorized admiralty metal

Common names. Inhibited admiralty metal; admiralty brass

Specifications

ASME. Condenser plate: SB171. Tubing: SB111, SB359, SB395, SB543

ASTM. Condenser plate: B 171. Tubing: B 111, B 359, B 395, B 543

Chemical Composition

Composition limits. 70.0 to 73.0 Cu, 0.07 Pb max, 0.06 Fe max, 0.9 to 1.2 Sn (or 0.8 to 1.2 Sn for flat-rolled products); As, Sb, or P (see below); bal Zn

Arsenic, antimony, or phosphorus limits. C44300, 0.02 to 0.10 As; C44400, 0.02 to 0.10 Sb, C44500, 0.02 to 0.10 P

Applications

Typical uses. Condenser, distiller, and heat exchanger tubes, ferrules, strainers, condenser tube plates

Precautions in use. These three alloys are susceptible to stress-corrosion cracking. Whenever possible, they

should be used in the annealed condition. Where fabrication results in residual stresses, a suitable stress-relieving heat treatment should be applied.

Mechanical Properties

Tensile properties. See Table 80 and Fig. 41.

Table 80 Typical mechanical properties of C44300, C44400, and C44500

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness

O60 (0.015 mm)	330	48	97	14	62	60	9	20

(a) At 0.5% extension under load. Apparent elastic limit (tubing), 125 MPa (18 ksi)

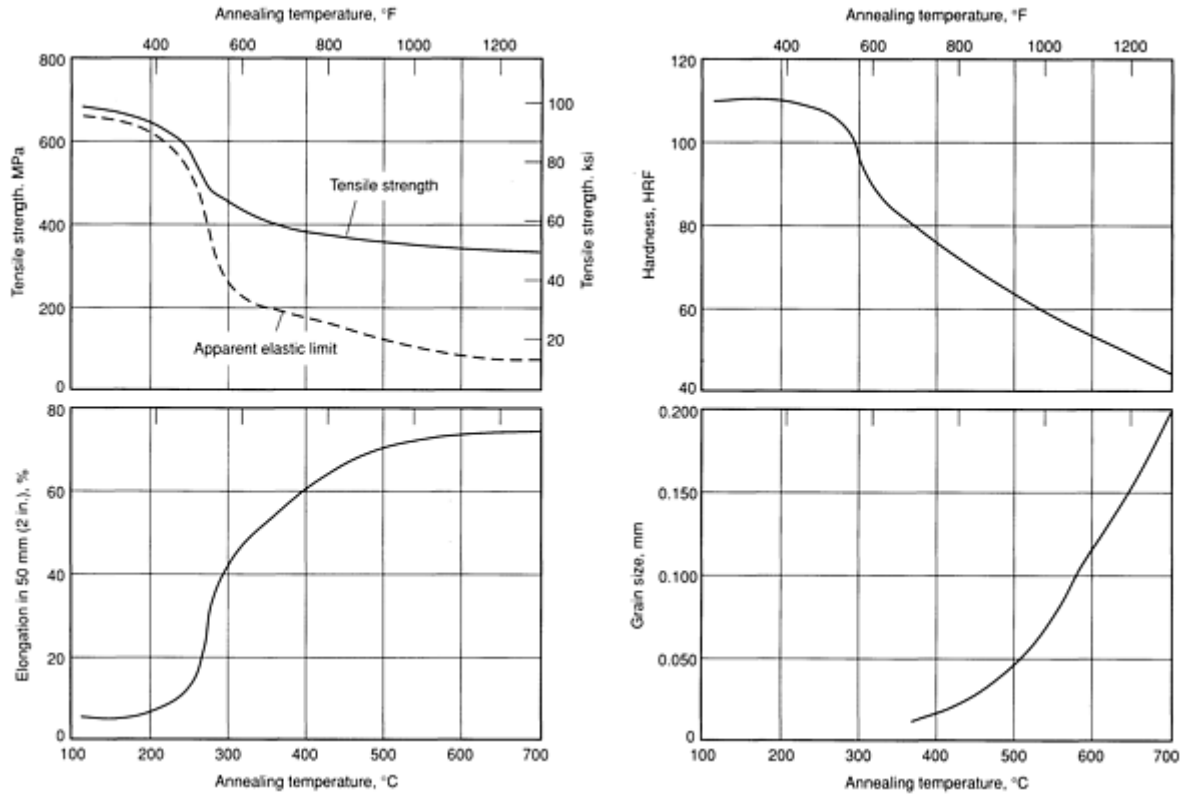

Fig. 41 Variation of properties and grain size with annealing temperature for C44300, C44400, or C44500. Data for inhibited admiralty metal tubing (71Cu-28Zn-1Sn), cold drawn 50% and annealed 1 h at temperature

Hardness. See Table 80.

Impact strength. See Table 81.

Elastic modulus. Tension, 110 GPa (16×10^6 psi); shear, 40 GPa (6×10^6 psi)

Table 81 Typical Charpy impact strength data for C44300, C44400, or C44500

Test temperature		Impact strength	
°C	°F	J	ft · lbf
20	68	82.4	60.8
3	38	82.2	60.6
-18	0	79.7	58.8
-30	-25	82.4	60.8
-50	-60	79.9	58.9
-80	-110	83.4	61.5

-115	-175	80.3	59.2

Note: Annealed specimens, cut from 19 mm (0.75 in.) diam rod into keyhole-notch bars. Values are averages of data from three tests (specimens did not fracture). Tensile strength at 20 °C (68 °F), 320 MPa (46.5 ksi); yield strength, 92 MPa (13.3 ksi); elongation. 83.5%; hardness, 64 HRF

Fatigue strength. 115 to 125 MPa (17 to 18 ksi) at 10^7 cycles

Creep-rupture characteristics. See Table 82.

Table 82 Typical creep data for C44300, C44400, or C44500

Temperature		Stress required to produce designated creep in 1000 h							
		Nil[(a)]		0.01%		0.10%		1.00%	
°C	°F	MPa	ksi	MPa	ksi	MPa	ksi	MPa	ksi
205	400	69	10	90	13	117	17	130	19
315	600	(b)	(b)	6.9	1.0	13.4	1.95	26	3.8
425	800	(b)	(b)	0.37	0.054	1.1	0.16	3.4	0.5

(a) No measurable flow.

(b) Nearly zero

Mass Characteristics

Density. 8.53 g/cm^3 (0.308 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 935 °C (1720 °F)

Solidus temperature. 900 °C (1650 °F)

Coefficient of linear thermal expansion. 20.2 μm/m · K (11.2 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/ft · °F) at 20 °C (68 °F)

Thermal conductivity. 110 W/m · K (64 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 25% IACS at 20 °C (68 °F)

Electrical resistivity. 69 nΩ · m at 20 °C (68 °F)

Chemical Properties

General corrosion behavior. Good resistance to salt and fresh waters at low velocities. Water velocities above 1.8 m/s (6 ft/s) give rise to impingement attack. A different inhibitor is added to each alloy to protect against dezincification.

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

Formability Excellent for cold working; fair for hot forming

Weldability. Soft soldering: excellent. Silver alloy brazing, oxyfuel gas welding, resistance spot welding, and flash welding: good. Gas-shielded arc welding: fair. Shielded metal arc welding and resistance seam welding are not recommended.

Recrystallization temperature. 300 °C (575 °F) for 1 mm (0.04 in.) strip cold rolled hard (50% reduction) from a grain size of 0.015 mm. See also Fig. 41.

Annealing temperature. 425 to 600 °C (800 to 1100 °F)

Hot-working temperature. 650 to 800 °C (1200 to 1450 °F)

C46400, C46500, C46600, C46700
60Cu-39.2Zn-0.8Sn

Commercial Names

Previous trade names. C46400, uninhibited naval brass; C46500, arsenical naval brass; C46600, antimonial naval brass; C46700, phosphorized naval brass

Common names. Naval brass; inhibited naval brass

Specifications

AMS. Bar and rod (C46400 only): 4611, 4612

ASME. Condenser plate: SB171

ASTM. Bar, rod, and shapes (C46400 only): B 21, B 124, Forgings (C46400 only): B 283. Condenser plate: B 171

SAE. Bar, rod, and shapes (C46400 only): J461, J463

Government. QQ-B-626. Bar, rod, shapes, forgings, and wire (C46400 only): QQ-B-637. Bar and flat products (C46400 only): QQ-B-639. Tubing (C46400 only): MIL-T-6945

Chemical Composition

Composition limits. 59.0 to 62.0 Cu; 0.50 to 1.0 Sn; 0.20 Pb max; 0.10 Fe max; As, Sb, or P (see below); bal Zn

Arsenic, antimony, or phosphorus limits. C46400, none specified; C46500, 0.02 to 0.10 As; C46600, 0.02 to 0.10 Sb; C46700, 0.2 to 0.10 P

Applications

Typical uses. Condenser plates, welding rod, marine hardware, propeller shafts, valve stems, airplane turnbuckle barrels, balls, nuts, bolts, rivets, fittings

Mechanical Properties

Tensile properties. See Table 83 and Fig. 42.

Table 83 Typical mechanical properties of C46400, C46500, C46600, or C46700

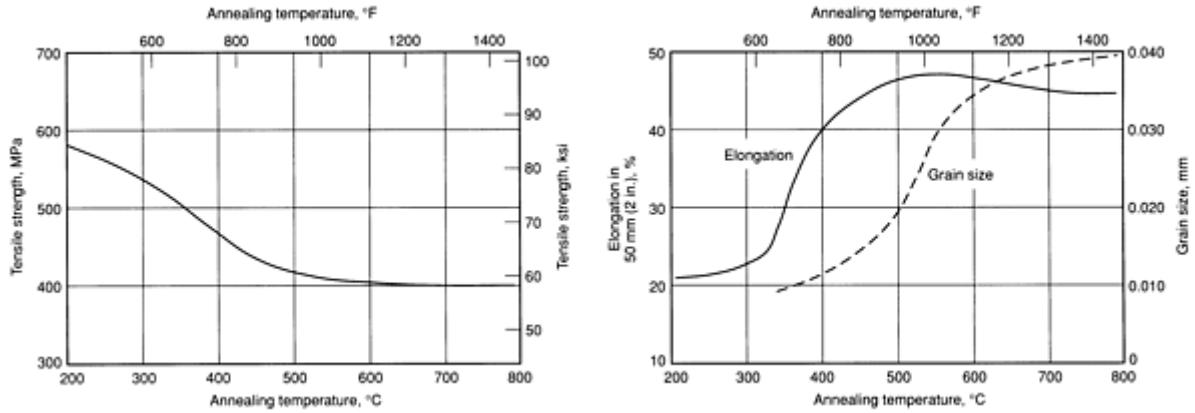

Fig. 42 Variation of strength, ductility, and grain size with annealing temperature for C46400, C46500, C46600, or C46700. Data for 19 mm (0.75 in.) diam naval brass rod (60Cu-39.2Zn-0.8Sn), cold drawn 30% and annealed 1 h at temperature. Grain size before cold drawing, 0.025 mm

Shear strength. See Table 83.

Hardness. See Table 83.

Elastic modulus. Tension, 100 GPa (15×10^6 psi); shear, 39 GPa (5.6×10^6 psi)

Impact strength. 43 J (32 ft · lbf) at 21 °C (70 °F) for Charpy keyhole specimens 10 mm (0.4 in.) square machined from annealed plate 13 mm (0.5 in.) thick; plate hardness, 96 HRF

Fatigue strength. 100 MPa (15 ksi) at 3×10^8 cycles

Structure

Crystal structure. Face-centered-cubic α and body-centered-cubic β

Microstructure. Generally two phases: α and β

Mass Characteristics

Density. 8.41 g/cm^3 (0.304 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 900 °C (1650 °F)

Solidus temperature. 885 °C (1630 °F)

Coefficient of linear thermal expansion. 21.2 μm/m · K (11.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 116 W/m · K (67 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 26% IACS at 20 °C (68 °F), annealed

Electrical resistivity. 66.3 nΩ · m at 20 °C (68 °F), annealed

Chemical Properties

General corrosion behavior. Good resistance to corrosion in both fresh and salt water; different inhibitor elements are added to C46500, C46600, and C46700 to protect against dezincification.

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

Forgeability. 90% of C37700 (forging brass)

Formability. Excellent for hot forming; fair for cold forming

Weldability. Soft soldering and silver alloy brazing: excellent. Oxyfuel gas welding, resistance spot welding, and flash welding: good. Gas-shielded arc welding and resistance seam welding: fair. Shielded arc welding is not recommended.

Recrystallization temperature. About 350 °C (660 °F) for 19 mm (0.75 in.) diam rod cold drawn 30%. See also Fig. 42.

Annealing temperature. 425 to 600 °C (800 to 1100 °F)

Maximum cold reduction between anneals. 30%

Hot-working temperature. 650 to 825 °C (1200 to 1500 °F)

C48200
60.5Cu-38Zn-0.8Sn-0.7Pb

Commercial Names

Previous trade names. Naval brass, medium leaded; CA482

Common name. Leaded naval brass

Specifications

ASTM. Rod, bar, and shapes: B 21 (CA482), B 124 (C48200)

Government. QQ-B-626. Bar, rod, shapes, forgings, and wire: QQ-B-637. Bar and plate: QQ-B-639

Chemical Composition

Composition limits. 59.0 to 62.0 Cu, 0.40 to 1.0 Pb; 0.10 Fe max, 0.50 to 1.0 Sn, bal Zn

Applications

Typical uses. Marine hardware, screw machine products, valve stems

Mechanical Properties

Tensile properties. See Table 84.

Table 84 Typical mechanical properties of C48200

(a) At 0.5% extension under load

Shear strength. See Table 84.

Hardness. See Table 84.

Elastic modulus. Tension, 100 GPa (15×10^6 psi); shear, 39 GPa (5.6×10^6 psi)

Structure

Microstructure. Generally three phases: α , β, and lead

Mass Characteristics

Density. 8.44 g/cm^3 (0.305 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 900 °C (1650 °F)

Solidus temperature. 885 °C (1625 °F)

Coefficient of linear thermal expansion. 21.2 μm/m · K (11.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 116 W/m · K (67 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, 26% IACS at 20 °C (68 °F)

Electrical resistivity. 66.3 nΩ · m at 20 °C (68 °F), annealed

Chemical Properties

General corrosion behavior. Good resistance to seawater and marine atmospheres

Fabrication Characteristics

Machinability. 50% of C36000 (free-cutting brass)

Forgeability. 90% of C37700 (forging brass)

Formability. Good for hot working; poor for cold working

Weldability. Soft soldering: excellent. Silver alloy brazing: good. Flash welding: fair. Oxyfuel gas welding, arc welding, and most resistance welding processes are not recommended.

Recrystallization temperature. About 360 °C (680 °F) for 19 mm (0.75 in.) diam rod cold drawn 30%

Annealing temperature. 425 to 600 °C (800 to 1100 °F)

Hot-working temperature. 650 to 760 °C (1200 to 1400 °F)

C48500
60Cu-37.5Zn-1.8Pb-0.7Sn

Commercial Names

Previous trade names. High-leaded naval brass; CA485

Common name. Leaded naval brass

Specifications

ASTM. Rod, bar, and shapes: B 21 (CA482), B 124 (C48500). Forgings: B 283 (CA485)

Government. QQ-B-626. Bar, rod, shapes, forgings, and wire: QQ-B-637. Bar and plate products: QQ-B-639

Chemical Composition

Composition limits. 59.0 to 62.0 Cu, 1.3 to 2.2 Pb; 0.10 Fe max, 0.50 to 1.0 Sn, bal Zn

Applications

Typical uses. Marine hardware, screw-machine products, valve stems

Mechanical Properties

Tensile properties. See Table 85.

Table 85 Typical mechanical properties of C48500

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness, HRB	Shear strength

Liquidus temperature. 900 °C (1650 °F)

Solidus temperature. 885 °C (1625 °F)

Coefficient of linear thermal expansion. 21.2 μm/m · K (11.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 116 W/m · K (67 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, 26% IACS at 20 °C (68 °F)

Electrical resistivity. 66.3 nΩ · m at 20 °C (68 °F)

Chemical Properties

General corrosion behavior. Good resistance to seawater and marine atmospheres

Fabrication Characteristics

Machinability. 70% of C36000 (free-cutting brass)

Forgeability. 90% of C37700 (forging brass)

Formability. Good for hot working; poor for cold working

Weldability. Soft soldering: excellent. Silver alloy brazing: good. Flash welding: fair. Oxyfuel gas welding, arc welding, and most resistance welding processes are not recommended.

Recrystallization temperature. About 360 °C (680 °F) for 19 mm (0.75 in.) diam rod cold drawn 30%. See also Fig. 43.

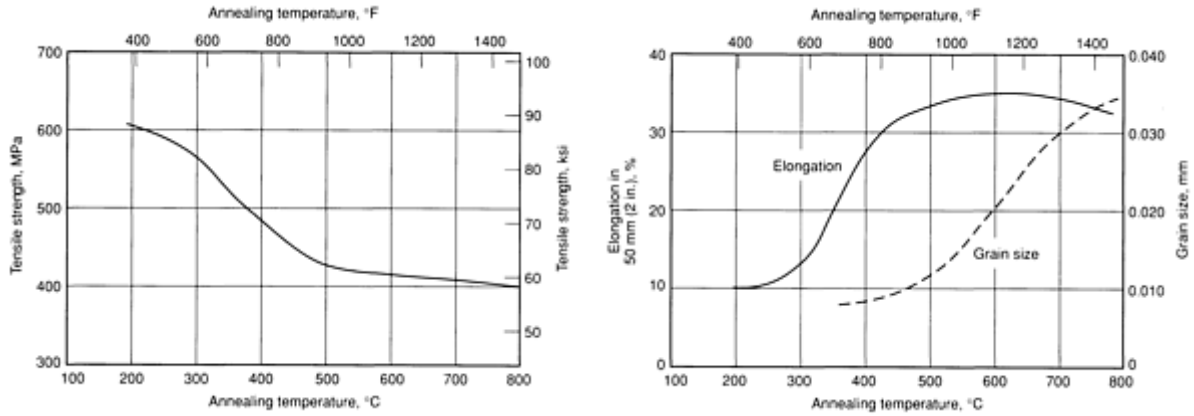

Fig. 43 Variation of strength, ductility, and grain size with annealing temperature for C48500. Data for 19 mm (0.75 in.) diam high-leaded naval brass (60Cu-37.5Zn-1.8Pb-0.7Sn) rod that was cold drawn 30% and annealed 1 h at temperature. Grain size before cold drawing, 0.025 mm

Annealing temperature. 425 to 600 °C (800 to 1100 °F)

Maximum cold reduction between anneals. 20%

Hot working temperature. 650 to 760 °C (1200 to 1400 °F)

C50500
98.7Cu-1.3Sn

Commercial Names

Previous names. Phosphor bronze, 1.25% E; CA505

Common name. Phosphor bronze (1.25% Sn)

Specifications

ASTM. Strip: B 105. Wire: B 105

Chemical Composition

Composition limits. 1.0 to 1.7 Sn; 0.05 Pb max; 0.10 Fe max; 0.30 Zn max; 0.35 P max; bal Cu; 99.5 Cu + Sn + P min

Applications

Typical uses. Electrical contacts, flexible hose, pole line hardware

Mechanical Properties

Tensile properties. See Table 86.

Note: Values for flat products 1 mm (0.040 in.) thick. Data in this table were interpolated from ASTM STP 1.

(a) At 0.2% offset.

(b) At 10^8 cycles of fully reversed stress

Hardness. See Table 86.

Elastic modulus. Tension, 117 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Fatigue strength. See Table 86.

Mass Characteristics

Density. 8.89 g/cm^3 (0.321 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1075 °C (1970 °F)

Solidus temperature. 1035 °C (1900 °F)

Coefficient of linear thermal expansion. 17.8 μm/m · K (9.9 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 208 W/m · K (120 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 48% IACS at 20 °C (68 °F)

Electrical resistivity. 36 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Cold: excellent. Hot: good. Commonly fabricated by blanking, forming, bending, heading, upsetting, shearing, squeezing, and swaging

Weldability. Flash welding, soldering, and brazing: excellent. Gas metal are welding: good. Oxyfuel gas welding and shielded metal arc welding: fair. Other processes are not recommended.

Annealing temperature. 475 to 650 °C (900 to 1200 °F)

Hot-working temperature. 800 to 875 °C (1450 to 1600 °F)

C50710
97.7Cu-2.0Sn-0.3Ni

Chemical Composition

Composition limits. 1.7 to 2.3 Sn, 0.1 to 0.4 Ni, 0.35 P max

Applications

Typical uses. Lead frames

Mechanical Properties

Tensile properties. See Table 87.

Table 87 Nominal mechanical properties of C50710 strip

Temper	Tensile strength		Elongation in 50 mm (2 in.), %	Hardness, HV
	MPa	ksi		
H02	455	66	25	150
H04	540	78	11	168

Hardness. See Table 87.

Elastic modulus. 113 GPa (16.4×10^6 psi)

Mass Characteristics

Density. 8.88 g/cm^3 (0.321 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1065 °C (1950 °F)

Solidus temperature. 995 °C (1820 °F)

Coefficient of linear thermal expansion. 17.0 μm/m · K (9.4 μin./in. · °F) from 20 to 550 °C (68 to 1025 °F)

Thermal conductivity. 154 W/m · K (89 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 30% IACS at 20 °C (68 °F)

Electrical resistivity. 57.4 nΩ · m at 20 °C (68 °F)

C51000
94.8Cu-5Sn-0.2P

Commercial Names

Previous trade names. Phosphor bronze, 5% A

Specifications

AMS. Flat products: 4510. Bar, rod, tubing: 4625. Wire: 4720

ASTM. Flat products: B 100, B 103. Bar: B 103, B 139. Rod, shapes: B 139. Wire: B 159

(a) At 0.5% extension under load

Hardness. See Table 88.

Elastic modulus. Tension, 110 GPa (16×10^6 psi); shear, 41 GPa (6×10^6 psi)

Fatigue structure. At 10^8 cycles. Flat products: H04 temper, 170 MPa (25 ksi); H08 temper, 150 MPa (22 ksi). Wire: H04 temper, 185 MPa (27 ksi); H06 temper, 205 MPa (30 ksi)

Mass Characteristics

Density. 8.86 g/cm^3 (0.320 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1060 °C (1945 °F)

Solidus temperature. 975 °C (1785 °F)

Coefficient of linear thermal expansion. 17.8 μm/m · K (9.9 μin./in. °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F)

Thermal conductivity. 84 W/m · K (48.4 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 20% IACS at 20 °C (68 °F)

Electrical resistivity. 87 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent capacity for cold working by blanking, drawing, forming, bending, roll threading, knurling, shearing, and stamping. Poor capacity for hot forming

Weldability. Soldering, brazing, and resistance butt welding: excellent. Gas metal arc and resistance spot

welding: good. Oxyfuel gas, shielded metal arc, and resistance seam welding: fair

Annealing temperature. 475 to 675 °C (900 to 1250 °F)

C51100
95.6Cu-4.2Sn-0.2P

Specifications

ASTM. Flat products: B 100, B 103

Chemical Composition

Composition limits. 94.5 to 96.3 Cu, 3.5 to 4.9 Sn, 0.003 to 0.35 P, 0.05 Pb max, 0.1 Fe max, 0.3 Zn max

Applications

Typical uses. Architectural: bridge bearing plates. Hardware: beater bars, bellows, clutch disks, connectors, diaphragms, fuse clips, fasteners, lock washers, sleeve bushings, springs, switch parts, terminals. Industrial: chemical hardware, perforated sheets, textile machinery

Mechanical Properties

Tensile properties. See Table 89.

Table 89 Typical mechanical properties of 1 mm (0.04 in.) thick C51100 strip

Mass Characteristics

Density. 8.86 g/cm^3 (0.32 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1060 °C (1945 °F)

Solidus temperature. 975 °C (1785 °F)

Coefficient of linear thermal expansion. 17.8 μm/m · K (9.9 μin./in °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 84 W/m · K (48.4 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 20% IACS at 20 °C (68 °F)

Electrical resistivity. 87 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent capacity for cold working by blanking, drawing, forming, bending, roll threading, knurling, shearing, and stamping. Poor capacity for hot forming

Weldability. Soldering, brazing, and resistance butt welding: excellent. Gas metal arc and resistance spot welding: good. Oxyfuel gas, shielded metal arc, and resistance seam welding: fair

Annealing temperature. 475 to 675 °C (900 to 1250 °F)

C52100
92Cu-8Sn

Commercial Names

Previous trade names. Phosphor bronze, 8% C

Specifications

ASTM. Flat products: B 103. Bar: B 103, B 139. Rod, shapes: B 139. Wire: B 159

SAE. J463

Government. MIL-E-23765

Chemical Composition

Composition limits. 90.5 to 92.8 Cu, 7.0 to 9.0 Sn, 0.03 to 0.35 P, 0.05 Pb max, 0.1 Fe max, 0.2 Zn max

Applications

Typical uses. For more severe service conditions than C51000. Architectural: bridge bearing plates. Hardware: beater bars, belows. Bourdon tubing, clutch disks, cotter pins, diaphragms, fuse clips, fasteners, lock washers, sleeve bushings, springs, switch parts, truss wire, wire brushes. Industrial: chemical hardware, perforated sheets, textile machinery, welding rods

Mechanical Properties

Tensile properties. See Table 90.

Table 90 Typical mechanical properties of C52100

(a) At 0.5% extension under load.

Hardness. See Table 90.

Elastic modulus. Tension, 110 GPa (16×10^6 psi); shear, 41 GPa (6×10^6 psi)

Fatigue strength. Strip, 1 mm (0.04 in.) thick, H04 temper: 150 MPa (22 ksi) at 10^8 cycles

Mass Characteristics

Density. 8.8 g/cm^3 (0.318 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1025 °C (1880 °F)

Solidus temperature. 880 °C (1620 °F)

Coefficient of linear thermal expansion. 18.2 μm/m · K (10.1 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/b · °F) at 20 °C (68 °F)

Thermal conductivity. 62 W/m · K (36 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 13% IACS at 20 °C (68 °F)

Electrical resistivity. 133 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Good capacity for cold working blanking, drawing, forming, bending, shearing, and stamping. Poor capacity for hot forming

Weldability. Soldering, brazing, and resistance butt welding: excellent. Gas metal arc and resistance spot welding: good. Oxyfuel gas, shielded metal arc, and resistance seam welding: fair

Annealing temperature. 475 to 675 °C (900 to 1250 °F)

C52400
90Cu-10Sn

Commercial Names

Previous trade name. Phosphor bronze, 10% D

Specifications

ASTM. Flat products: B 103. Bar: B 103, B 139. Rod, shapes: B 139. Wire: B 159

Government. Flat products, wire: QQ-B-750

Chemical Composition

Composition limits. 88.3 to 90.07 Cu, 9.0 to 11.0 Sn, 0.03 to 0.35 P, 0.05 Pb max, 0.1 Fe max, 0.2 Zn max

Table 91 Typical mechanical properties of C52400

Temper	Tensile strength		Elongation in 50 mm (2 in.), %	Hardness, HRB

Elastic modulus. Tension, 110 GPa (16×10^6 psi); shear, 41 GPa (6×10^6 psi)

Mass Characteristics

Density. 8.78 g/cm^3 (0.317 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1000 °C (1830 °F)

Solidus temperature. 845 °C (1550 °F)

Coefficient of linear thermal expansion. 18.4 μm/m · K (10.2 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 50 W/m · K (29 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 11% IACS at 20 °C (68 °F)

Electrical resistivity. 157 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Good capacity for cold working by blanking, forming, bending, and shearing. Poor capacity for hot forming

Weldability. Soldering, brazing, and resistance butt welding: excellent. Gas metal arc and resistance spot welding: good. Oxyfuel gas, shielded metal arc, and resistance seam welding: fair

Annealing temperature. 475 to 675 °C (900 to 1250 °F)

C54400
88Cu-4Pb-4Sn-4Zn

Commercial Names

Previous trade name. Phosphor bronze B-2

Common names. Free-cutting phosphor bronze; 444 bronze; bearing bronze

Specifications

AMS. Strip 4520

ASTM. B 103, B 139

SAE. J463. Bearing alloy: J460 (791)

Government. Bar and rod: QQ-B-750

Chemical Composition

Composition limits. 3.5 to 4.5 Pb, 3.5 to 4.5 Sn, 1.5 to 4.5 Zn, 0.10 Fe max, 0.01 to 0.50 P, bal Cu; 99.5 Cu + Pb + Sn + Zn + P min

Applications

Typical uses. Bearings (sleeve and thrust), bushings, gears, pinions, screw machine products, shafts, thrust washers, valve parts

Mechanical Properties

Tensile properties. See Table 92.

Table 92 Typical mechanical properties of C54400

Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness, HRB

Rod, 25 mm (1.0 in.) diameter						
H04	470	68	395	57	20	80

(a) At 0.5% extension under load

Hardness. See Table 92.

Elastic modulus. Tension, 103 GPa (15×10^6 psi); shear, 39 GPa (5.6×10^6 psi)

Mass Characteristics

Density. 8.89 g/cm^3 (0.321 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1000 °C (1830 °F)

Solidus temperature. 930 °C (1700 °F)

Coefficient of linear thermal expansion. 17.3 μm/m · K (9.6 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 87 W/m · K (50 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical properties

Electrical conductivity. Volumetric, 19% IACS at 20 °C (68 °F)

Electrical resistivity. 91 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 80% of C36000 (free-cutting brass)

Formability. Good cold working characteristics; commonly fabricated by machining, shearing, blanking, drawing, forming, bending. Hot working and hot forming are not recommended.

Weldability. Soldering: excellent. Brazing: good. Flash welding: fair. Other welding processes are not recommended.

C60600
95Cu-5Al

Commercial Names

Previous trade name. Aluminum bronze A; CA606

Common names. Aluminum bronze, 5%

Specifications

ASTM. Flat products: B 169

Government. Bar, rod, forgings, shapes: QQ-C-645. Sheet and plate: QQ-C-450. Strip: QQ-C-450, QQ-C-465

Chemical Composition

Composition limits. 92.0 to 96.0 Cu, 4.0 to 7.0 Al, 0.50 Fe max, 0.50 max other (total)

Consequence of exceeding impurity limits. Excessive amounts of Pb, Zn, and P will cause hot shortness and difficulties in welding.

Applications

Typical uses. Produced as sheet, strip, and rolled bar; used to make fasteners, deep drawn "gold" decoration, and parts requiring corrosion resistance

Precautions in use. Not suitable for use in oxidizing acids

Mechanical Properties

Tensile properties. Typical data for 13 mm (0.5 in.) thick plate. Tensile strength: O61 temper, 310 MPa (45 ksi); H04 temper, 415 MPa (60 ksi). Yield strength: O60 temper, 115 MPa (17 ksi); H04 temper, 165 MPa (24 ksi). Elongation: O60 temper, 40% in 50 mm (2 in.); H04 temper, 25% in 50 mm (2 in.)

Hardness. O60 temper, 42 HRB; H04 temper, 55 HRB

Poisson's ratio. 0.326

Elastic modulus. Tension, 121 GPa (17.5×10^6 psi); shear, 46 GPa (6.6×10^6 psi)

Fatigue strength. Rotating beam, 169 MPa (24.5 ksi) at 10^8 cycles

Structure

Microstructure. Alpha structure, face-centered cubic

Mass Characteristics

Density. 8.17 g/cm^3 (0.295 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. Approximately 1.6% contraction

Thermal Properties

Liquidus temperature. 1065 °C (1945 °F)

Solidus temperature. 1050 °C (1920 °F)

Coefficient of linear thermal expansion. 18 μm/m · K (10 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 375 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 79.5 W/m · K (45.9 Btu/ft · h · F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 17% IACS at 20 °C (68 °F)

Electrical resistivity. 100 nΩ · m at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.01

Chemical Properties

General corrosion resistance. See C61400.

Resistance to specific agents. Has been used in sulfuric acid pickling applications where oxygen content is low. Has been used for anhydrous NH_4OH, but the presence of moisture leads to season cracking. Not suitable for use with nitric acid. Oxidizing salts such as chromates and metal salts such as ferric chloride are generally corrosive to C60600.

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass). Tends to form tough, stringy chips. Good lubrication and cooling essential for good finish. Carbide or tool steel cutters may be used.

Recrystallization temperature. 350 °C (660 °F) at 44% reduction and 0.075 mm (0.003 in.) initial grain size

Annealing temperature. 550 to 650 °C (1020 to 1200 °F)

Hot-working temperature. 815 to 870 °C (1500 to 1600 °F)

C60800
95Cu-5Al

Commercial Names

Previous trade name. 5% aluminum bronze

Common name. Aluminum bronze, 5%

Specifications

ASME. Tubing: SB111, SB359, SB395

ASTM. Tubing: B 111, B 359, B 395

Chemical Composition

Composition limits. 92.5 to 94.8 Cu, 5.0 to 6.5 Al, 0.02 to 0.35 As, 0.10 Pb max, 0.10 Fe max

Consequence of exceeding impurity limits. Excessive amounts of Pb, Zn, and P will cause difficulties in welding and hot working.

Applications

Typical uses. Produced as seamless tubing and ferrule stock for heat exchanger tubes, condenser tubes, and other applications requiring corrosion-resistant seamless tubing

Precautions in use. Not suitable for use in oxidizing acids.

Mechanical Properties

Tensile properties. Typical for OS025 temper tubing, 25 mm (1.0 in.) outside diameter × 1.65 mm (0.065 in.) wall thickness: tensile strength, 415 MPa (60 ksi); yield strength (0.5% extension under load), 185 MPa (27 ksi); elongation, 55% in 50 mm (2 in.)

Hardness. OS025 temper: 77 HRF

Poisson's ratio. 0.325

Elastic modulus. Tension, 121 GPa (17.5×10^6 psi); shear, 46 GPa (6.6×10^6 psi)

Structure

Microstructure. Alpha structure, face-centered cubic

Mass Characteristics

Density. 8.17 g/cm^3 (0.295 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. Approximately 1.6% contraction

Thermal Properties

Liquidus temperature. 1065 °C (1945 °F)

Solidus temperature. 1050 °C (1920 °F)

Coefficient of linear thermal expansion. 18 μm/m · K (10 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 79.5 W/m · K (45.9 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 17% IACS at 20 °C (68 °F)

Electrical resistivity. 100 nΩ · m at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.01

Chemical Properties

General corrosion resistance. See C61400.

Resistance to specific agents. Has been used in sulfuric acid pickling applications where oxygen content is low. Has been used for anhydrous NH^4OH, but the presence of moisture leads to season cracking. Not suitable for use with nitric acid. Oxidizing salts such as chromates and metal salts such as ferric chloride are generally corrosive to C60800.

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass). Tends to form tough, stringy chips. Good lubrication and cooling essential for good finishes. Carbide or tool steel cutters may be used.

Formability. Good for cold working; fair for hot forming.

Weldability. Arc and resistance welding: good. Brazing: fair. Soldering and oxyfuel gas welding are not recommended.

Recrystallization temperature. 350 °C (660 °F) at 44% reduction and 0.075 mm (0.003 in.) initial grain size

Annealing temperature. 550 to 650 °C (1020 to 1200 °F)

Hot-working temperature. 800 to 875 °C (1470 to 1610 °F)

C61000
92Cu-8Al

Commercial Names

Common name. 8% aluminum bronze

Specifications

ASME. SB169

ASTM. B 169

Government. QQ-C-450; MIL-E-23765

Chemical Composition

Composition limits. 6.0 to 8.5 Al, 0.50 Fe max, 0.02 Pb max, 0.20 Zn max, 0.10 Si max, 0.50 max other (total), bal Cu

Applications

Typical uses. Produced as rod or wire and used to make bolts, shafts, tire rods, and pump parts. Also used as a welded overlay on steel to improve surface wear resistance

Mechanical Properties

Tensile properties. Typical data for rod, 25 mm (1 in.) in diameter. O60 temper: tensile strength 480 MPa (70 ksi); yield strength (0.5% extension under load), 205 MPa (30 ksi); elongation, 65% in 50 mm (2 in.). H04 temper: tensile strength, 550 MPa (80 ksi); yield strength, 380 MPa (55 ksi); elongation, 25%

Hardness. O60 temper: 60 HRB. H04 temper: 85 HRB

Elastic modulus. Tension, 117 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Mass Characteristics

Density. 7.78 g/cm^3 (0.281 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1040 °C (1905 °F)

Coefficient of linear thermal expansion. 17.9 μm/m · K (9.9 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 375 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 69 W/m · K (40 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 15% IACS at 20 °C (68 °F)

Electrical resistivity. 115 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Forgeability. 70% of C37700 (forging brass)

Formability. Good capacity for being hot formed or cold worked. Common fabrication processes include blanking, drawing, forming, bending, cold heading, and roll threading.

Weldability. Arc welding, resistance spot welding, and resistance butt welding: good. Soldering and resistance seam welding: fair. Brazing and oxyfuel gas welding are not recommended.

Annealing temperature. 600 to 675 °C (1100 to 1250 °F)

Hot-working temperature. 760 to 875 °C (1400 to 1600 °F)

C61300
90Cu-7Al-2.7Fe-0.3Sn

Commercial Names

Common name. Aluminum bronze, 7%

Specifications

Government. Flat products: QQ-C-450

Chemical Composition

Composition limits. 88.5 to 91.5 Cu, 6.0 to 7.5 Al, 0.02 to 0.50 Sn, 2.0 to 3.0 Fe, 0.10 Mn max, 0.15 Ni (+ Co) max, 0.01 Pb max, 0.05 Zn max, 0.05 max other

Consequence of exceeding impurity limits. Excessive amounts of Pb, Zn, P, or Si will cause hot shortness, which can lead to problems during hot working or welding.

Applications

Typical uses. Produced as rod, bar, sheet, plate, seamless tubing and pipe, welded pipe, fasteners, tube sheets, heat exchanger tubes, acid-resistant piping, columns, water boxes, and corrosion-resistant vessels

Precautions in use. Not suitable for use in oxidizing acids

Mechanical Properties

Tensile properties. Typical data for 13 mm (0.50 in.) thick plate. Tensile strength: O60 temper, 540 MPa (78 ksi); H04 temper, 585 MPa (85 ksi). Yield strength (0.5% extension): O60 temper, 240 MPa (35 ksi); H04 temper, 400 MPa (58 ksi). Elongation: O60 temper, 42% in 50 mm (2 in.); H04 temper, 35% in 50 mm (2 in.). Reduction in area: O60 temper, 32%; H04 temper, 25%. See also Table 93.

Density. 7.89 g/cm^3 (0.285 lb/$in.^3$) at 20 °C (68 °F)

Volume change on freezing. Approximately 1.8% contraction

Thermal Properties

Liquidus temperature. 1045 °C (1915 °F)

Solidus temperature. 1040 °C (1905 °F)

Coefficient of linear thermal expansion. 16.2 μm/m · K (9.0 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 375 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 56.5 W/m · K (32.7 Btu/ft · h · °F) at 20 °C (68 °F); temperature coefficient, 0.12 W/m · K per K at 20 °C

General corrosion resistance. See C61400.

Resistance to specific agents. C61300 is very resistant to neutral and nonoxidizing salts. It has given extended service in potash solutions of potassium chloride, sodium chloride, magnesium chloride, and calcium chloride. The alloy resists nonoxidizing mineral acids and has been used successfully for tanks containing hydrofluoric acid in glass-etching applications. In organic acid service, it has been used to make acetic acid distillation columns.

C61300 is highly resistant to dealloying and to season cracking in steam and in hot oxidizing aqueous solutions

and vapors. The presence of tin in 7% aluminum bronze (C61300 contains 0.3% Sn, C61400 does not contain Sn) evidently renders the alloy immune to stress-corrosion cracking in these environments. Like many copper alloys, C61300 is susceptible to season cracking in moist ammonia and mercurous nitrate solutions. However, it is highly resistant to season cracking in anhydrous ammonia, especially when the moisture content is below 500 ppm and the temperature is below 85 °C (180 °F).

Because of its high resistance to corrosion in salt water, C61300 has been specified for a wide variety of components for marine and desalting plant service. Typical uses of C61300 include tube sheets for condensers in both nuclear and fossil fuel power stations, cooling tower transfer piping, seawater piping for secondary cooling systems in nuclear power plants, and piping for geothermal heat transfer systems.

Fabrication Characteristics

Machinability. Fair to poor, with chips tending to be stringy and gummy. Good lubrication and cooling are essential. Tool steel cutters: roughing speed, 90 m/min (300 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev); finishing speed, 350 m/min (1150 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev)

Forgeability. 50% of C37700 (forging brass)

Formability. Good for cold working and hot forming

Weldability. Arc and resistance welding: good. Brazing: fair. Soldering and oxyfuel gas welding are not recommended.

Recrystallization temperature. 785 to 870 °C (1450 to 1600 °F)

Annealing temperature. 600 to 875 °C (1125 to 1600 °F)

Hot-working temperature. 800 to 925 °C (1450 to 1700 °F)

Hot-shortness temperature. 1010 °C (1850 °F)

Magnetic Properties

Magnetic permeability. 1.16

Chemical Properties

General corrosion behavior. The aluminum bronzes resist nonoxidizing mineral acids such as sulfuric, hydrochloric, and phosphoric acid. Resistance tends to decrease with increasing concentration of dissolved oxygen or oxidizing agents, particularly as temperatures increase above 55 °C (130 °F). Aluminum bronzes are generally suited for service in alkalies, neutral salts, nonoxidizing acid salts, and many organic acids and compounds. Oxidizing acids, oxidizing salts, and heavy-metal salts are corrosive. Aluminum bronzes resist waters, whether potable water, brackish water, or seawater. Softened water tends to be more corrosive than hard water. Aluminum bronzes resist dealloying, but to different degrees depending on alloy composition. In general, corrosion resistant is influenced most by solution concentration, aeration, temperature, velocity, and the type and amount of any impurities in the solution.

Like many other copper alloys, the aluminum bronzes are susceptible to stress-corrosion cracking in moist ammonia and mercury compounds. When stress levels are high, they may also be susceptible to stress-corrosion cracking in purified steam or in steam containing acidic or salt vapors.

Resistance to specific agents. C61400 has been used successfully to contain mineral acids, alkalies such as sodium or potassium hydroxide, neutral salts such as sodium chloride, and organic acids such as acetic, lactic, or oxalic acid. C61400 resists anhydrous ammonia, but precautions must be taken to exclude moisture and thus avoid season cracking. Similarly, this alloy resists anhydrous chlorinated hydrocarbons such as carbon tetrachloride, but the presence of moisture makes those chemicals corrosive.

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass). Tendency to form continuous, stringy chips. Good lubrication and cooling essential. Tool steel or carbide cutters may be used. Typical conditions, using tool steel cutters: roughing speed, 90 m/min (300 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev); finishing speed, 350 m/min (1150 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev)

Formability. Fair for cold working; good for hot forming

Weldability. Gas-shielded arc, coated metal arc, and resistance welding: good. Brazing: fair. Soldering, oxyacetylene, and carbon arc welding are not recommended.

Recrystallization temperature. 785 to 870 °C (1450 to 1600 °F)

Annealing temperature. 600 to 900 °C (1125 to 1650 °F)

Hot-working temperature. 800 to 925 °C (1450 to 1700 °F)

Hot-shortness temperature. 1010 °C (1850 °F)

Electrical conductivity. Volumetric, 12.6% IACS at 20 °C (68 °F)

Electrical resistivity. 137 nΩ · m at 20 °C (68 °F)

Optical Properties

Color. Gold

Chemical Properties

General corrosion behavior. Excellent; similar to that of other aluminum bronzes

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

Forgeability. 50% of C37700 (forging brass)
Formability. Suitable for forming by bending, drawing, deep drawing, forging, extrusion, blanking, and stamping; only slight directionality in bending. Good for cold working and hot forming

Weldability. Gas-shielded arc welding, shielded metal arc welding, and resistance welding: excellent. Soldering and brazing: easily done using mildly aggressive fluxes. Oxyfuel gas welding is not recommended.

Annealing temperature. 620 to 675 °C (1150 to 1250 °F)

Aging temperature. Order strengthening, 300 °C (575 °F) for 1 h

Hot-working temperature. 815 to 870 °C (1500 to 1600 °F).

C62300
87Cu-10Al-3Fe

Commercial Names

Common name. Aluminum bronze, 9%

Specifications

ASME. Bar, rod, shapes: SB150

ASTM. Bar, rod, shapes: B 150. Forgings: B 283

SAE. J463

Government. Forgings: MIL-B-16166

Chemical Composition

Composition limits. 82.2 to 89.5 Cu, 8.5 to 11.0 Al, 2.0 to 4.0 Fe, 1.0 Ni (+ Co) max, 0.6 Sn max, 0.50 Mn max, 0.25 Si max, 0.5 max other (total)

Consequence of exceeding impurity limits. An excessive amount of Pb will cause hot shortness, and excessive Si will cause the alloy to lose ductility. Excessive Al will reduce ductility and corrosion resistance.

Applications

Typical uses. Produced as rod and bar for bearings, bushings, bolts, nuts, gears, valve guides, pump rods, cams, and applications requiring corrosion resistance

Precautions in use. Not suitable for use in oxidizing acids

Mechanical Properties

Tensile properties. Typical. Tensile strength, 605 MPa (88 ksi); yield strength, 305 MPa (44 ksi); elongation, 15% in 50 mm (2 in.); reduction in area, 15%. See Table 96.

(a) At 0.5% extension under load.

(b) 3000 kg (6615 lb) load

Compressive properties. See Table 97.

Table 97 Typical compressive properties for C62300 rod, H50 temper

Rod diameter	Compressive strength at permanent set of							
	0.1%		1%		10%		20%	
	MPa	ksi	MPa	ksi	MPa	ksi	MPa	ksi
≤25 mm (≤1 in.)	360	52	485	70	825	120	965	140
25-50 mm (1-2 in.)	345	50	450	65	675	98	930	135

Hardness. 89 HRB. See Table 96.

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi). See also Table 96.

Poisson's ratio. 0.328

Impact strength. Charpy V-notch, 25 to 40 J (18 to 30 ft · lbf); Izod, 43 to 47 J (32 to 35 ft · lbf). See also Fig. 45.

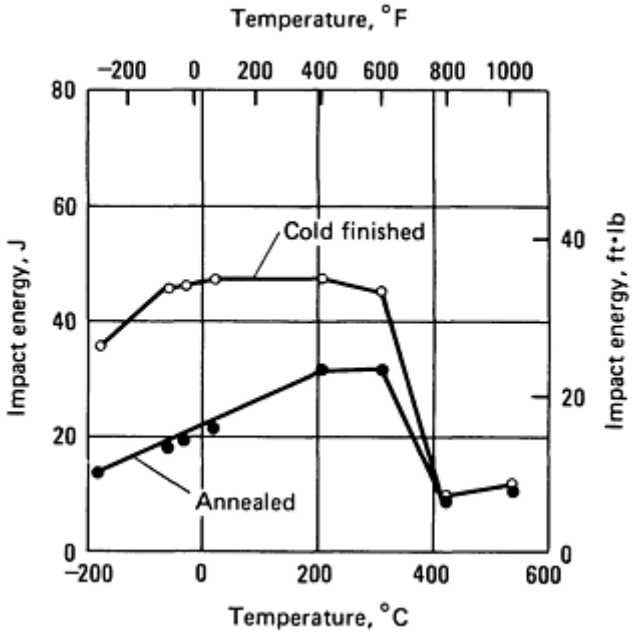

Fig. 45 Variation in Charpy V-notch impact strength with temperature for C62300

Fatigue strength. Reverse bending, 200 MPa (29 ksi) at 10^8 cycles

Structure

Microstructure. Duplex structure of face-centered-cubic α-plus metastable body-centered-cubic β with iron-rich precipitates

Mass Characteristics

Density. 7.65 g/cm^3 (0.276 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. Approximately 2% expansion

Thermal Properties

Liquidus temperature. 1045 °C (1915 °F)

Solidus temperature. 1040 °C (1905 °F)

Phase transformation temperature. Eutectoid transformation, 563 to 570 °C (1045 to 1055 °F)

Coefficient of linear thermal expansion. 16.2 μm/m · K (9.0 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 375 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 54.4 W/m · K (31.4 Btu/ft · h · °F) at 20 °C (68 °F); temperature coefficient, 0.12 W/m · K per K at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 12% IACS at 20 °C (68 °F)

Electrical resistivity. 144 nΩ · m at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.17

Chemical Properties

General corrosion behavior. See C61400.

Resistance to specific agents. C62300 resists nonoxidizing mineral acids, but hydrochloric acid is more corrosive than other nonoxidizing mineral acids. C62300 resists dealloying, but to a lesser extent than C61300 or C61400. Like other aluminum bronzes, C62300 is not suitable for use in an oxidizing acid such as nitric acid.

Fabrication Characteristics

Machinability. Fair, with good surface finish possible. Carbide or tool steel cutters may be used. Typical conditions using tool steel cutters: roughing speed, 107 m/min (350 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev); finishing speed, 350 m/min (1150 ft/min) with a feed of 0.15 mm/rev (0.006 in./rev)

Forgeability. 75% of C37700 (forging brass)

Formability. Good for cold working and hot forming

Weldability. Gas-shielded arc, shielded metal arc, and all types of resistance welding: good. Brazing: fair. Soldering and oxyfuel gas welding are not recommended.

Annealing temperature. 600 to 650 °C (1110 to 1200 °F)

Hot-working temperature. 700 to 875 °C (1290 to 1600 °F)

Hot shortness temperature. 1010 °C (1850 °F)

C62400
86Cu-11Al-3Fe

Commercial Names

Common name. Aluminum bronze, 11%

Specifications

SAE. J463

Chemical Composition

Composition limits. 82.8 to 88.0 Cu, 10.0 to 11.5 Al, 2.0 to 4.5 Fe, 0.30 Mn max, 0.25 Si max, 0.20 Sn max, 0.5 max other (total)

Consequence of exceeding impurity limits. Excessive amounts of Si and Al decrease ductility

Applications

Typical uses. Produced as rod and bar for gears, wear plates, cams, bushings, nuts, drift pins, and tie rods

Precautions in use. May lose ductility upon prolonged heating in range from 370 to 565 °C (700 to 1050 °F). Not suitable for use in oxidizing acids

Mechanical Properties

Tensile properties. Typical data for 50 mm (2 in.) diam round rod (half hard). Tensile strength, 655 MPa (95 ksi); yield strength (0.5% extension), 330 MPa (48 ksi); elongation, 14% in 50 mm (2 in.); reduction in area, 11%

Compressive properties. See Table 98.

Table 98 Typical compressive properties for C62400 rod, H50 temper

Rod diameter	Compressive strength at permanent set of						Ultimate compressive strength	
	0.1%		1%		10%			
	MPa	ksi	MPa	ksi	MPa	ksi	MPa	ksi
≤25 mm (≤1 in.)	290	42	470	68	885	128	1140	165
25-50 mm (1-2 in.)	220	32	400	58	825	120	1090	158

Hardness. 92 HRB

Poisson's ratio. 0.318

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, GPa (6.4×10^6 psi)

Impact strength. Charpy keyhole, 15 J (11 ft · lbf) at -23 to 27 °C (-10 to 80 °F); Izod, 23 J (17 ft · lbf) at -23 to 27 °C (-10 to 80 °F)

Fatigue strength. Reverse bending, 235 MPa (34 ksi) at 10^8 cycles

Structure

Microstructure. Duplex-structure α-plus metastable β-phases and iron-rich precipitates

Mass Characteristics

Density. 7.45 g/cm^3 (0.269 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. Approximately 2% contraction

Thermal Properties

Liquidus temperature. 1040 °C (1900 °F)

Solidus temperature. 1025 °C (1880 °F)

Phase transformation temperature. Eutectoid, 560 to 570 °C (1045 to 1055 °F)

Coefficient of linear thermal expansion. 16.5 μm/m · K (9.2 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 375 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 58.6 W/m · K (33.9 Btu/ft · h · °F) at 20 °C (68 °F); temperature coefficient, 0.12 W/m · K per K at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 12% IACS at 20 °C (68 °F)

Electrical resistivity. 144 nΩ · m at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.34

Chemical Properties

General corrosion behavior. See C61400.

Resistance to specific agents. C62400 resists nonoxidizing mineral acids, but hydrochloric acid is more corrosive than other nonoxidizing mineral acids. C62400 is susceptible to dealloying, but proper heat treatment increases resistance to this type of corrosion. Like other aluminum bronzes, C62400 is not suitable for use in an oxidizing acid such as nitric acid.

Fabrication Characteristics

Machinability. 50% of C36000 (free-cutting brass); chips break readily. Carbide or tool steel cutters may be used. Typical conditions using tool steel cutters: roughing speed, 90 m/min (300 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev); finishing speed, 290 m/min (950 ft/min) with a feed of 0.1 mm/rev (0.004 in./rev). Using carbide cutters with 2.3 to 6.4 mm (0.09 to 0.25 in.) cut: roughing speed, 53 m/min (175 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev); finishing speed, 38 to 45 m/min (125 to 150 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev)

Weldability. Similar to that of C62300

Annealing temperature. 600 to 700 °C (1110 to 1300 °F)

Hot-working temperature. 760 to 925 °C (1400 to 1700 °F).

C62500
82.7Cu-4.3Fe-13Al

Commercial Names

Trade name. Ampco 21, Wearite 4-13

Chemical Composition

Compositions limits. 12.5 to 13.5 Al, 3.5 to 5.0 Fe, 2.0 Mn max, 0.5 max other (total), bal Cu

Consequence of exceeding impurity limits. Possibility of hot shortness, reduced wear resistance, increased spalling tendency, and lower strength when elements such as Pb, Zn, P, and Si are present in more than trace quantities

Applications

Typical uses. Guide bushings, wear strips, cams, sheet metal forming dies, forming rolls

Precautions in use. Low ductility and impact resistance make it advisable to provide adequate structural support for components made of C62500 that will be subjected to shock loads or high stress. Corrosion resistance is inferior to that of aluminum bronzes containing less aluminum.

Mechanical Properties

Tensile properties. Typical M30 and O61 tempers: tensile strength, 690 MPa (100 ksi); yield strength (0.5% extension), 380 MPa (55 ksi); elongation, 1% in 50 mm (2 in.); reduction in area, 1%

Compressive properties. Compressive strength, 450 MPa (65 ksi) at a permanent set of 0.1%; 880 MPa (128 ksi) at a permanent set of 1%

Hardness. 27 HRC

Poisson's ratio. 0.312

Elastic modulus. Tension, 110 GPa (16×10^6 psi); shear, 42.3 GPa (6.13×10^6 psi)

Impact strength. Izod or Charpy keyhole, 3 J (2 ft · lbf) at -18 to 100 °C (0 to 212 °F)

Fatigue strength. Rod, M30 temper: 460 MPa (67 ksi) at 10^8 cycles

Structure

Microstructure. Primarily body-centered-cubic metastable β-phase with small crystals of ordered close-packed hexagonal γ-phase

Magnetic Properties

Magnetic permeability. 1.2

Mass Characteristics

Density. 7.21 g/cm^3 (0.260 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1052 °C (1925 °F)

Solidus temperature. 1047 °C (1917 °F)

Coefficient of linear thermal expansion. 16.2 μm/m · K (9.0 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 38.9 W/m · K (22.5 Btu/ft · h · °F) at 20 °C (68 °F); temperature coefficient, 0.093 W/m · K per K at -100 to 150 °C (-150 to 300 °F)

Electrical Properties

Electrical conductivity. Volumetric, 10% IACS at 20 °C (68 °F)

Electrical resistivity. 172 nΩ · m at 20 °C (68 °F)

Chemical Properties

General corrosion behavior. Adequate corrosion resistance to ambient moisture and industrial atmospheres. C62500 is rarely used for its corrosion characteristics in strongly corrosive environments. General corrosion characteristics are inferior to those of C62400 and C62300.

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Not recommended for cold working; excellent for hot forming

Weldability. Gas-shielded arc and shielded metal arc welding: good. Brazing and resistance welding: fair. Oxyfuel gas welding and soldering are not recommended.

Annealing temperature. 600 to 650 °C (1100 to 1200 °F)

Hot-working temperature. 745 to 850 °C (1375 to 1550 °F)

C63000
82Cu-10Al-5Ni-3Fe

Commercial Names

Previous trade name. Aluminum bronze E

Common name.

Nickel-aluminum bronze

Specifications

AMS. Bar, shapes: 4640

ASME. Bar, rod, shapes: SB150. Condenser tube plate: SB171

ASTM. Bar, rod, shapes: B 124, B 150. Condenser tube plate: B 171. Forgings: B 283

SAE. J463

Government. Flat products, rod, shapes: QQ-C-465. Forgings: QQ-C-465, MIL-B-16166

Chemical Composition

Composition limits. 78.0 to 85.0 Cu, 9.0 to 11.0 Al, 2.0 to 4.0 Fe, 4.0 to 5.5 Ni (+ Co), 1.5 Mn max, 0.30 Zn max, 0.25 Si max, 0.20 Sn max, 0.5 max other (total)

Consequence of exceeding impurity limits. Excessive amounts of Zn, Sn, and Pb will cause

cracking during hot working and joining. Excessive Si will result in machining difficulties.

Applications

Typical uses. Produced as rod, bar, and forgings for nuts, bolts, shafting, pump parts, valve seats, faucet balls, gears, cams, structural members, and tube sheets for condensers in power stations and desalting units

Precautions in use. Not suitable for use in oxidizing acids

Mechanical Properties

Tensile properties. Typical data for 25 mm (1 in.) diam round rod, HR50 temper: tensile strength, 760 MPa (110 ksi); yield strength, 470 MPa (68 ksi); elongation, 10% in 50 mm (2 in.); reduction in area, 10%. See also Table 99.

Compressive properties. HR50 temper. Compressive strength, ultimate: 1035 MPa (150 ksi)

Hardness. HR50 temper: 94 HRB. See also Table 99.

Poisson's ratio. 0.328

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi). See also Table 99.

Impact strength. Charpy V-notch, 16 to 21 J (12 to 15 ft · lbf) at 20 °C (68 °F). See also Fig. 46.

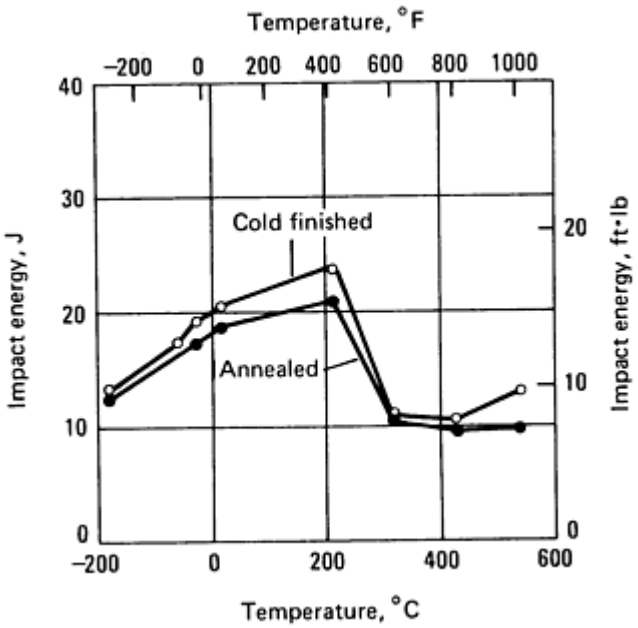

Fig. 46 Variation in Charpy V-notch impact strength with temperature for C63000

Fatigue strength. Reverse bending, 255 MPa (37 ksi) at 10^8 cycles

Structure

Microstructure. Features α, κ, and metastable βphases in various structures, depending on heat treatment and/or thermal history and composition. Normally, α plus α-κ lamellar structure with areas of β

Mass Characteristics

Density. 7.58 g/cm^3 (0.274 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. Approximately 2% contraction

Thermal Properties

Liquidus temperature. 1055 °C (1930 °F)

Solidus temperature. 1035 °C (1895 °F)

Coefficient of linear thermal expansion. 16.2 µm/m · K (9.0 µin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 375 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 37.7 W/m · K (21.8 Btu/ft · h · °F) at 20 °C (68 °F); temperature coefficient, 0.09 W/m · K per K at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 9% IACS at 20 °C (68 °F)

Electrical resistivity. 192 nΩ · m at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.05

Chemical Properties

General corrosion behavior. See C61400.

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass), with breaking to slightly stringy chips. Carbide or tool steel cutters may be used, and good lubrication and cooling are essential. Typical conditions using tool steel cutters: roughing speed, 75 m/min (250 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev); finishing speed, 290 m/min (950 ft/min) with a feed of 0.1 mm/rev (0.004 in./rev). Using carbide cutters: roughing speed, 53 m/min (175 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev); finishing speed, 38 m/min (125 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev)

Forgeability. 75% of C37700 (forging brass)

Formability. Poor for cold working; good for hot forming

Weldability. Gas-shielded arc, coated metal arc and spot, seam, and butt resistance welding: good. Brazing: fair. Soldering and oxyacetylene welding are not recommended

Annealing temperature. 600 to 700 °C (1100 to 1300 °F)

Hot-working temperature. 800 to 925 °C (1450 to 1700 °F)

C63200
82Cu-9Al-5Ni-4Fe

Commercial Names

Common name. Nickel-aluminum bronze

Chemical Composition

Composition limits. 75.9 to 84.5 Cu, 8.5 to 9.5 Al, 3.0 to 5.0 Fe, 4.0 to 5.5 Ni (+ Co), 3.5 Mn max, 0.10 Si max, 0.02 Pb max, 0.5 max other (total)

Iron content shall not exceed Ni content.

Consequence of exceeding impurity limits. Excessive Pb and Si will cause hot shortness in weld joints. Excessive Mn will reduce corrosion resistance.

Applications

Typical uses. Produced as rod, bar, and forgings for nuts, bolting, shafts, pump parts, propellers, and miscellaneous uses for corrosion- and spark-resistant parts for industrial, marine, and submarine applications

Precautions in use. Not suitable for use in oxidizing acids

Mechanical Properties

Tensile properties. Depending on amount of cold work or heat treatment. Tensile strength, 640 to 725 MPa (93 to 105 ksi); yield strength, 330 to 380 MPa (48 to 55 ksi); elongation, 18% in 50 mm (2 in.); reduction in area, 18%

Compressive properties. Compressive strength, ultimate: 760 MPa (110 ksi)

Hardness. 92 to 97 HRB

Poisson's ratio. 0.320

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Impact strength. Charpy V-notch, 23 to 27 J (17 to 20 ft · lbf) at -29 to 20 °C (-20 to 78 °F); Charpy keyhole, 13 to 16 J (10 to 12 ft · lbf) at -29 to 20 °C (-20 to 78 °F)

Structure

Microstructure. Features ακ, and metastable β-phases in various structures, depending on heat treatment and/or thermal history and composition. Normally, α-plus α-κ lamellar structure with or without areas of β-phase

Mass Characteristics

Density. 7.64 g/cm^3, (0.276 lb/in.^{3} at 20 °C (68 °F)

Volume change on freezing. Approximately 2% contraction

Thermal Properties

Liquidus temperature. 1060 °C (1940 °F)

Solidus temperature. 1040 °C (1905 °F)

Coefficient of linear thermal expansion. 16.2 μm/m · K (9.0 μin./in. · °F)) at 20 to 300 °C (68 to 572 °F)

Specific heat. 439 J/kg · K (0.105 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 36 W/m · K (21 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 7% IACS at 20 °C (68 °F)

Electrical resistivity. 246 nΩ · m at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.04

Fabrication Characteristics

Machinability. Fair. Tendency to form stringy chips and to gall makes good lubrication and cooling essential. Tool steel or carbide cutters may be used. Good finish and fine thread tapping possible. Typical conditions using tool steel cutters: roughing speed, 75 m/min (250 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev); finishing speed, 290 m/min (950 ft/min) with a feed of 0.1 mm/rev (0.004 in./rev). Using carbide cutters: roughing speed, 53 m/min (175 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev); finishing speed, 38 m/min (125 ft/min) with a feed of 0.3 mm/rev (0.011 in./rev)

Annealing temperature. 705 to 880 °C (1300 to 1615 °F)

Hot-working temperature. 705 to 925 °C (1300 to 1700 °F)

C63600
95.5Cu-3.5Al-1.0Si

Chemical Composition

Composition limits. 93.5 to 96.3 Cu, 3.0 to 4.0 Al, 0.7 to 1.3 Si, 0.50 Zn max, 0.20 Sn max, 0.15 Ni max, 0.15 Fe max, 0.05 Pb max

Applications

Typical uses. Rod and wire for components for pole line hardware; cold-headed nuts for wire and cable connectors; bolts; screw machine products

Mechanical Properties

Tensile properties. See Table 100.

Table 100 Typical mechanical properties of C63600

Diameter		Temper	Tensile strength		Elongation in 50 mm (2 in.), %	Hardness, HRB

Hardness. See Table 100.

Elastic modulus. Tension, 110 GPa (16×10^6 psi)

Mass Characteristics

Density. 8.33 g/cm^3 (0.301 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1035 °C (1890 °F)

Coefficient of linear thermal expansion. 17.2 μm/m · K (9.4 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Thermal conductivity. 57 W/m · K (33 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 12% IACS at 20 °C (68 °F)

Electrical resistivity. 143 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 40% of C36000 (free-cutting brass)

Formability. Excellent for cold working; fair for hot forming

Weldability. Gas-shielded arc, shielded metal arc, and resistance welding: fair. Soldering, brazing, and oxyfuel gas welding are not recommended.

Hot-working temperature. 760 to 875 °C (1400 to 1600 °F)

C63800
95Cu-2.8Al-1.8Si-0.40Co

Commercial Names

Trade name. Coronze

Chemical Composition

Composition limits. 2.5 to 3.1 Al, 1.5 to 2.1 Si, 0.25 to 0.55 Co, 0.80 Zn max, 0.10 Ni max, 0.05 Pb max, 0.10 Fe max, 0.10 Mn Max, bal Cu

Applications

Typical uses. Springs, switch parts, contacts, relay springs, glass sealing, and porcelain enameling

Mechanical Properties

Tensile properties. See Table 101 and Fig. 47 and 48.

Table 101 Typical mechanical properties of C63800 sheet and strip

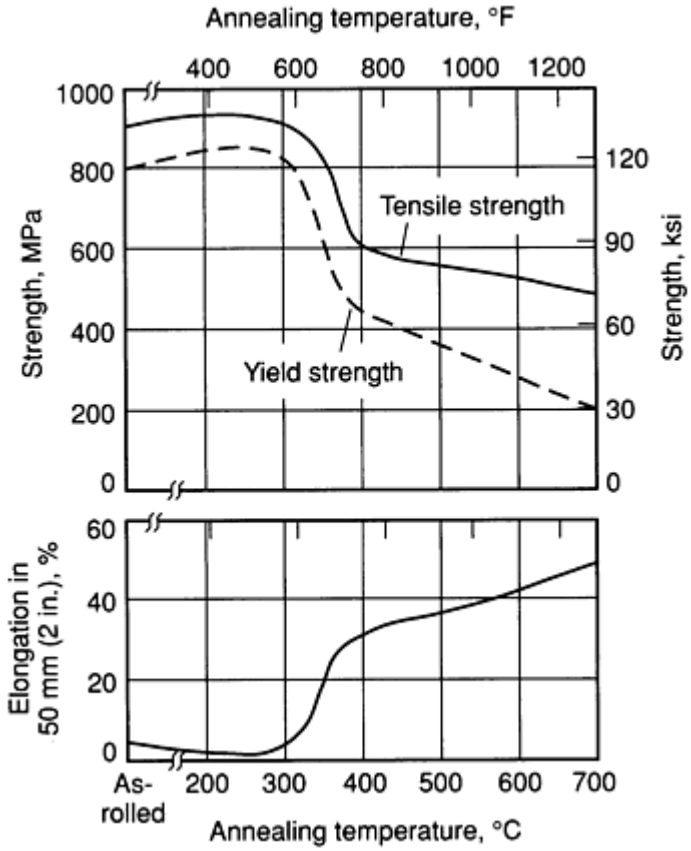

Fig. 48 Anneal resistance of C63800 strip, H08 temper. Typical room-temperature tensile properties for material annealed 1 h at various temperatures

Hardness. See Table 101.

Poisson's ratio. 0.312

Elastic modulus. Tension, 117 GPa (16.7×10^6 psi)

Mass Characteristics

Density. 8.28 g/cm^3 (0.299 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1030 °C (1885 °F)

Solidus temperature. 1000 °C (1830 °F)

Coefficient of linear thermal expansion. 17.1 μm/m · K (9.5 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 375 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 42 W/m · K (24 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 10% IACS at 20 °C (68 °F), annealed

Electrical resistivity. 174 nΩ · m at 20 °C (68 °F), annealed

Chemical Properties

General corrosion behavior. C63800 is more resistant to stress corrosion than the nickel silvers, approaching the performance of the highly resistant phosphor bronzes. This alloy is far superior to most other copper alloys in resistance to crevice corrosion. At elevated temperature, the oxidation resistance of C63800 is excellent. For example, after heating in air for 2 h, the film thickness on C83800 was 7 nm (0.26 μin.) at 450 °C (840 °F), 12 nm (0.47 μin.) at 600 °C (1100 °F), and 24 mm (0.94 μin.) at 700 °C (1300 °F). On the basis of weight gain after heating 2 to 24 h in air at temperatures of 600 to 800 °C (1100 to 1300 °F), C63800 was consistently superior to Nickel 270, Nichrome (80Ni-20Cr), type 301 stainless steel, Incoloy 800 (ASTM B 408), and C60600. The superiority of C63800 was especially evident at 800 °C (1300 °F).

Fabrication Characteristics

Formability. Suitable for blanking, drawing, bending, shearing, and stamping. Excellent for cold working and hot forming

Weldability. Soft soldering utilizing standard fluxes is normally employed. Brazing, gas-shielded arc welding, and all forms of resistance welding are also commonly used.

Annealing temperature. 400 to 600 °C (750 to 1100 °F). See also Fig. 48.

C65100
98.5Cu-1.5Si

Commercial Names

Previous trade name. Low-silicon bronze B

Common name. Low-silicon bronze

Specifications

ASME. Bar, rod, shapes: SB98. Tubular products: SB315

ASTM. Flat products: B 97. Bar, rod, shapes: B 98. Tubular products: B 315. Wire: B 99

Government. QQ-C-591

Chemical Composition

Composition limits. 0.8 to 2.0 Si, 0.05 Pb max, 0.8 Fe max, 1.5 Zn max, 0.7 Mn max, bal Cu

Applications

Typical uses. Aircraft: hydraulic pressure lines. Hardware: anchor screws, bolts, cable clamps, cap screws, machine screws, marine hardware, nuts, pole line hardware, rivets, U-bolts. Industrial: electrical conduits, heat exchanger tubes, welding rod

Mechanical Properties

Tensile properties. See Table 102.

Hardness. See Table 106.

Elastic modulus. Tension, 116 GPa (16.8 x 10^6 psi)

Mass Characteristics

Density. 8.20 g/cm^3 (0.296 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 965 °C (1765 °F)

Solidus temperature. 950 °C (1740 °F)

Coefficient of linear thermal expansion. 18 μm/m · K (10 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 375 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 69 W/m · K (40 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric: O61 temper: 18% IACS at 20 °C (68 °F); H08 temper, 16.6% IACS at 20 °C (68 °C)

Electrical resistivity. O61 temper, 96 nΩ · m at 20 °C (68 °F); H08 temper, 104 nΩ · m

Magnetic Properties

Magnetic permeability. 1.003

Chemical Properties

General corrosion behavior. C68800 is more resistant than C26000 to both corrosion and stress-corrosion cracking.

Fabrication Characteristics

Formability. Suitable for blanking, drawing, bending, shearing, and stamping. Bending characteristics are nearly nondirectional for all annealed and rolled tempers. Excellent for cold working and hot forming

Weldability. Can be joined by soft soldering when mildly activated commercial fluxes are used and exhibits substantially better tarnish resistance than most other copper alloys. Can also be joined by brazing and resistance welding

Annealing temperature. 400 to 600 °C (750 to 1100 °F)

Order strengthening. When heated to 220 °C (425 °F), temper-rolled C68800 undergoes an ordering reaction that increases strength (see Table 107) and decrease ductility. Because this decrease in ductility would adversely affect formability, parts should be order strengthened after forming. Specific times and temperatures for thermal treatment may vary, depending on cold-worked temper. Susceptibility to stress-corrosion cracking increases dramatically with an increase in the degree of ordering.

Stabilization treatment. Stabilization treatment is performed when enhanced stress relaxation is desired. This treatment causes little change in the 0.2% offset yield strength. Temperature and time of the treatment vary, depending on cold-worked temper; the ranges are 280 to 320 °C (535 to 610 °F) and 10 min to 2 h, respectively. To gain the maximum benefit from a stabilization treatment, parts should be stabilized after forming. There is no increase in stress-corrosion susceptibility as a result of this treatment.

C69000
73.3Cu-22.7Zn-3.4Al-0.6Ni

Chemical Composition

Composition limits. 72 to 74.5 Cu, 3.3 to 3.5 Al, 0.50 to 0.70 Ni, 0.05 Fe max, 0.025 Pb max, bal Zn

Applications

Typical uses. Electrical component parts, contacts, connectors, switches, relays, springs, high-strength shells

Mechanical Properties

Tensile properties. See Table 108.

Table 108 Typical mechanical properties of C69000

Temper	Tensile strength		Yield strength at 0.2% offset		Elongation in 50 mm (2 in.), %	Hardness	
	MPa	ksi	MPa	ksi		HRB	HR30T

OS025	565	82	360	52	35	. . .	69
H01	650	94	525	76	19.5	90.5	. . .
H02	715	105	635	92	9	95	. . .
H04	780	113	700	102	4.5	97	. . .
H06	825	120	750	109	2.5	98	. . .
H08	870	126	785	114	1.5	96	. . .

EHT[(a)]	930	135	875	127	1	. . .	84.5

(a) Cold rolled 50% and stress relief annealed 1 h at 220 °C (425 °F)

Hardness. See Table 108.

Elastic modulus. Tension, 115 GPa (16.7×10^6 psi)

Mass Characteristics

Density. 8.19 g/cm^3 (0.296 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 960 °C (1760 °F)

Solidus temperature. 950 °C (1745 °F)

Coefficient of linear thermal expansion. 18 μm/m · K (10 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 40 W/m · K (23 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O61 temper: 18% IACS at 20 °C (68 °F)

Electrical resistivity. O61 temper: 96 nμ · m

Chemical Properties

General corrosion behavior. Significantly better corrosion performance than C26000, both in uniform corrosion rate and stress-corrosion resistance

Fabrication Characteristics

Formability. Behavior in blanking, drawing, forming, bending, stamping, and other cold forming operations is similar to that of C26000, but with lower directionality in bending of cold-worked tempers. Excellent for cold working and hot forming

Weldability. Resistance welding: good. Soldering and brazing: fair, provided that active flux is used. Oxyfuel gas and arc welding are not recommended.

Annealing temperature. 400 to 600 °C (750 to 1100 °F); stress relief anneal, 225 °C (435 °F) for 1 h

Hot-working temperature. 790 to 840 °C (1450 to 1550 °F)

C69400
81.5Cu-14.5Zn-4Si

Commercial Names

Previous trade name. Silicon red brass, CA694

Specifications

ASTM. Rod B 371 (CA694)

Chemical Composition

Composition limits. 80.0 to 83.0 Cu, 0.30 Pb max, 0.20 Fe max, 3.5 to 4.5 Si, bal Zn

Applications

Typical uses. Valve stems requiring a combination of corrosion resistance and high strength; forged or screw-machined parts

Mechanical Properties

Tensile properties. See Table 109.

Table 109 Typical mechanical properties of copper alloy C69400 rod

Temper	Section size		Tensile strength		Yield strength (0.5% extension under load)		Elongation in 50 mm (2 in.), %	Hardness, HRB
	mm	in.	MPa	ksi	MPa	ksi		
O60	13	0.5	621	90	310	45	20	85
	25	1.0	586	85	296	43	25	85
	51	2.0	550	80	276	40	25	85

Hardness. See Table 109.

Elastic modulus. Tension, 110 GPa (16×10^6 psi)

Mass Characteristics

Density. 8.19 g/cm^3 (0.296 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 920 °C (1685 °F)

Solidus temperature. 820 °C (1510 °F)

Coefficient of linear thermal expansion. 20.2 μm/m · K (11.2 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 26 W/m · K (15 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 6.2% IACS at 20 °C (68 °F)

Electrical resistivity. 280 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

Forgeability. 80% of C37700 (forging brass)

Formability. Excellent capacity for being hot formed; poor for being cold formed

Weldability. Soft soldering and silver alloy brazing: excellent. Oxyfuel gas welding and resistance welding: good. Arc welding is not recommended.

Annealing temperature. 425 to 650 °C (800 to 1200 °F)

Hot-working temperature. 650 to 875 °C (1200 to 1600 °F)

C70250
95.4Cu-3.0Ni-0.6Si-0.1Mg

Chemical Composition

Composition limits. 2.2 to 4.2 Ni, 0.25 to 1.2 Si, 0.05 to 0.3 Mg, 1.0 Zn max, 0.05 Pb max, 0.1 Mn max, 0.2 Fe max, 99.5 Cu + named elements min

Applications

Typical uses. Applications where high strength and good formability combined with good stress relaxation resistance and moderate conductivity are required. Specific uses include contact springs, connectors, and lead frames.

Mechanical Properties

Tensile properties. See Table 110.

Table 110 Nominal tensile properties of C70250 strip

Temper	Tensile strength		Yield strength		Elongation in 50 mm (2 in.), %
	MPa	ksi	MPa	ksi	
TM00	585	85	655	95	6

Elastic modulus. 131 GPa (19.0×10^6 psi)

Mass Characteristics

Density. 8.80 g/cm^3 (0.318 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1095 °C (2003 °F)

Solidus temperature. 1075 °C (1967 °F)

Coefficient of linear thermal expansion. 17.6 μm/m · K (9.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Thermal conductivity. 147 to 190 W/m · K (85 to 110 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 35 to 40% IACS at 20 °C (68 °F)

Electrical resistivity. 43.1 to 49.3 nΩ · m at 20 °C (68 °F)

C70400
92.4Cu-5.5Ni-1.5Fe-0.6Mn

Specifications

ASTM. Pipe: B 466. Tubing: B 111, B 359, B 395, B 466, B 543

Chemical Composition

Composition limits. 91.2 Cu min, 4.8 to 6.2 Ni, 1.3 to 1.7 Fe, 0.3 to 0.8 Mn, 1.0 Zn max, 0.05 Pb max

Applications

Typical uses. Rolled strip, sheet, and tubing for industrial uses; condensers, condenser plates, evaporator and heat exchanger tubes, ferrules, saltwater piping, lithium bromide absorption system tubing, shipboard condenser intake systems

Mechanical Properties

Tensile properties. See Table 111.

Table 111 Typical mechanical properties of C70400

Temper	Tensile strength		Yield strength				Elongation in 50 mm (2 in.), %	Hardness	
			At 0.5% extension under load		At 0.2% offset

OS015	285	41	97	14	. . .	. . .	46	58 HRF	. . .

Hardness. See Table 111.

Elastic modulus. Tension, 115 GPa (17×10^6 psi); shear, 44 GPa (6.4×10^6 psi)

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1125 °C (2050 °F)

Coefficient of linear thermal expansion. 17.5 μm/m · K (9.7 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 64 W/m · K (37 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 14% IACS at 20 °C (68 °F)

Electrical resistivity. 120 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent for cold working; good for hot forming

Weldability. Soldering, brazing, and gas-shielded arc welding: excellent. Coated metal arc and resistance spot, seam, and butt welding: good. Oxyacetylene welding: fair

Annealing temperature. 565 to 815 °C (1050 to 1500 °F)

Hot-working temperature. 815 to 950 °C (1500 to 1750 °F)

C70600
90Cu-10Ni

Commercial Names

Previous trade names. Copper-nickel, 10%; CA706

Common name. 90-10 cupronickel

Specifications

ASME. Flat products: SB171, SB402. Pipe: SB466, SB467. Tubing: SB111, SB359, SB395, SB466, SB467, SB543

ASTM. Flat products: B 122, B 171, B 402, B 432. Pipe: B 466, B 467. Rod: B 151. Tubing: B 111, B 359, B 395, B 466, B 467, B 543, B 552

SAE. Plate and tubing: J463

Government. Bar, flat products, forgings, rod: MIL-C-15726 E(2). Tubing: MIL-T-16420 J(3), MIL-T-1368 C(2), MIL-T-23520 A(4). Condenser tubing: MIL-T-15005 F

Chemical Composition

Composition limits. 0.05 Pb max, 1 to 1.8 Fe, 1.0 Zn max, 9 to 11 Ni, 1.0 Mn max, 0.5 max other (total), bal Cu

Applications

Typical uses. Condensers, condenser plates, distiller tubes, evaporator and heat exchanger tubes, ferrules, saltwater piping, boat hulls

Mechanical Properties

Tensile properties. See Table 112 and Fig. 49.

Table 112 Typical mechanical properties of C70600 and C71000

Temper	Tensile strength		Yield strength				Elongation in 50 mm (2 in.), %	Hardness

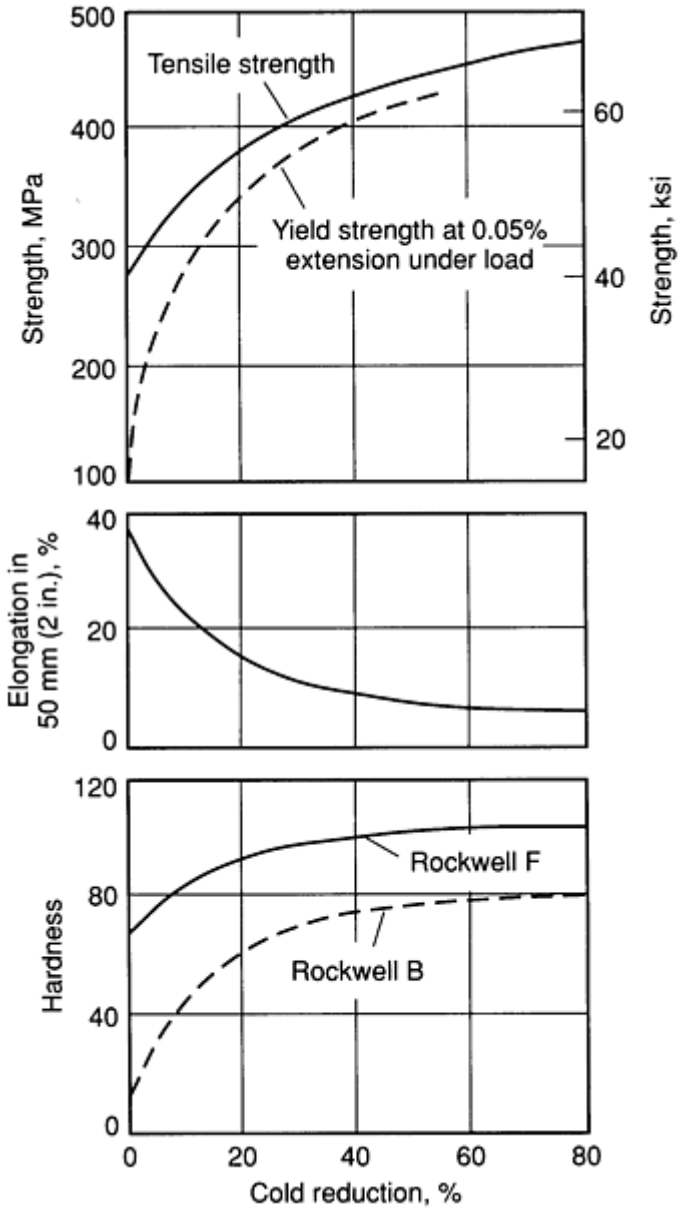

Fig. 49 Mechanical properties of cold drawn C70600 tubing. Data for variation in mechanical properties with amount of cold reduction for tubing with a diameter of 60 mm (2 $\frac{3}{8}$ in.) and a wall thickness of 4.8 mm ($\frac{3}{16}$) wall

Elastic modulus. Tension, 140 GPa (20 × 10^6 psi); shear, 52 GPa (7.5 × 10^6 psi)

Fatigue strength. Tubing, H55 temper: 138 MPa (20 ksi) at 10^8 cycles

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/$in.^3$) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1150 °C (2100 °F)

Solidus temperature. 1100 °C (2010 °F)

Coefficient of linear thermal expansion. 17.1 μm/m · K (9.5 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 40 W/m · K (23 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 9.1% IACS

Electrical resistivity. 190 nΩ · m at 20 °C (68 °F)

Optical Properties

Color. Pink-silver

Chemical Properties

Resistance to specific agents. Excellent resistance to seawater

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Good capacity for being both cold worked and hot formed

Weldability. Soldering, brazing, gas-shielded arc, and resistance butt welding: excellent. Shielded metal arc and resistance spot and seam welding: good. Oxyfuel gas welding: fair

Annealing temperature. 600 to 825 °C (1100 to 1500 °F)

Hot-working temperature. 850 to 950 °C (1550 to 1750 °F)

C71000
80Cu-20Ni

Commercial Names

Previous trade names. Copper-nickel, 20%; CA710

Common name. 80-20 cupronickel

Specifications

ASME. Pipe: SB466, SB467. Tubing: SB111, SB359, SB395, SB466, SB467

ASTM. Bar and flat products: B 122. Pipe: B 466, B 467. Tubing: B 111, B 359, B 395, B 466, B 467. Wire: B 206

SAE. Bar, flat products, and tubing: J463

Chemical Composition

Composition limits. 0.05 Pb max, 1.00 Fe max, 1.00 Zn max, 19 to 23 Ni, 1.00 Mn max, 0.5 max other (total), bal Cu

Applications

Typical uses. Communication relays, condensers, condenser plates, electrical springs, evaporator and heat exchanger tubes, ferules, resistors

Mechanical Properties

Tensile properties. See Table 112.

Fatigue strength. Tubing, H55 temper: 138 MPa (20 ksi) at 10^8 cycles

Elastic modulus. Tension, 140 GPa (20×10^6 psi); shear, 52 GPa (7.5×10^6 psi)

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1200 °C (2190 °F)

Solidus temperature. 1150 °C (2100 °F)

Coefficient of linear thermal expansion. 16.4 μm/m · K (9.1 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 36 W/m · K (21 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O61 temper: 6.5% IACS at 20 °C (68 °F)

Electrical resistivity. O61 temper: 265 nΩ · m at 20 °C (68 °F)

Optical Properties

Color. Pale silver

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Good capacity for being cold worked by blanking, forming, and bending; good capacity for being hot formed

Weldability. Soldering, brazing, gas-shielded arc welding and resistance welding (all forms): excellent. Shielded metal arc welding: good. Oxyfuel gas welding: fair

Annealing temperature. 650 to 825 °C (1200 to 1500 °F)

Hot-working temperature. 875 to 1050 °C (1600 to 1900 °F)

C71500
70Cu-30Ni

Commercial Names

Previous trade names. Copper-nickel, 30%; CA715

Common name. 70-30 cupronickel

Specifications

ASME. Flat products: SB171, SB402, Pipe: SB466, SB467. Tubing: SB111, SB359, SB395, SB466, SB467, SB543

ASTM. Flat products: B 122, B 151, B 171, B 402. Pipe: B 466, B 467. Rod: B 151. Tube: B 111, B 359, B 395, B 466, B 467, B 552

SAE. Bar, flat products, tubing: J463

Government. Bar, flat products, forgings, rod, wire: MIL-C-15726. Tubing: MIL-T-15005, MIL-T-16420, MIL-T-22214

Chemical Composition

Composition limits. 0.05 Pb max, 0.4 to 0.7 Fe, 1.0 Zn max, 29 to 33 Ni, 1.0 Mn max, 0.5 max other (total), bal Cu

Applications

Typical uses. Condensers, condenser plates, distiller tubes, evaporator and heat exchanger tubes, ferrules, saltwater piping

Precautions in use. Stress relieving or full annealing should precede exposure to solders of all kinds.

Mechanical Properties

Tensile properties. See Table 113 and Fig. 50.

Table 113 Typical mechanical properties of C71500

Size	Temper	Tensile strength		Yield strength[(a)]		Elongation in 50 mm (2 in.), %	Hardness, HRB

(a) 0.5% extension under load.

(b) Annealed at 705 °C (1300 °F).

(c) Annealed at 760 °C (1400 °F).

(d) Cold drawn 50%.

(e) Cold drawn 20%

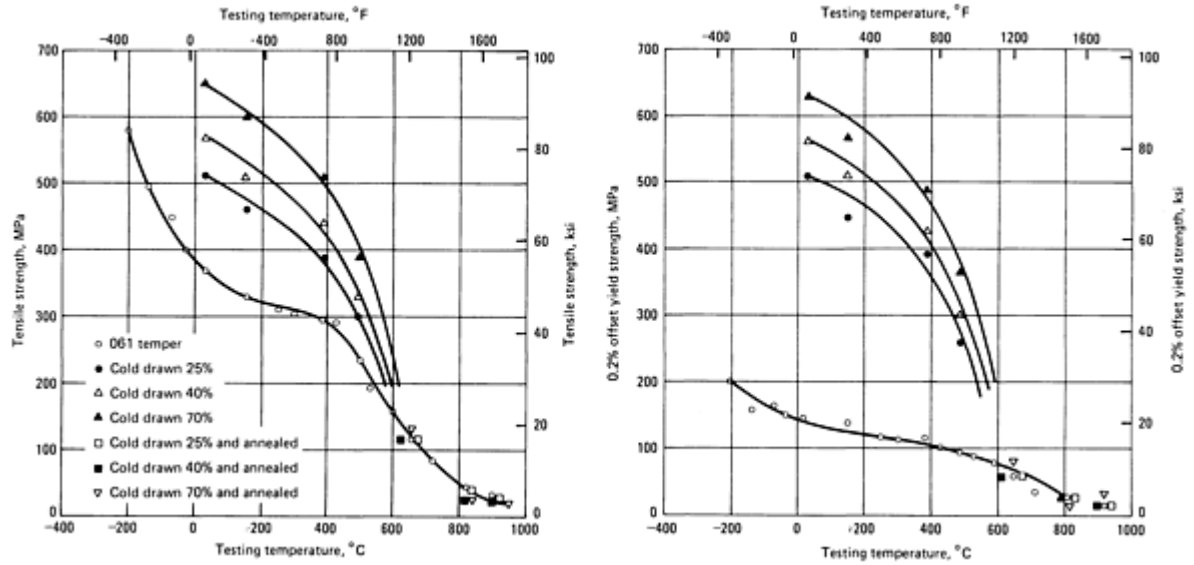

Fig. 50 Typical tensile and yield strengths of C71500 rod

Elastic modulus. Tension, 150 GPa (22 × 10^6 psi) at 20 °C (68 °F); shear, 57 GPa (8.3 × 10^6 psi) at 20 °C

Hardness. See Table 113.

Impact strength. Charpy keyhole data: 107 J (79 ft · lbf) at 21 °C (70 °F); 88 to 93 J (65 to 69 ft · lbf) at -73 °C (-100 °F) after holding 30 to 140 days at -87 °C (-125 °F). Data are for 10 mm (0.4 in.) square specimens machined from 25 mm (1 in.) thick plate having a room temperature hardness of 88 HRF. See Table 114 for additional impact data.

Table 114 Typical Charpy impact strengths for C71500

Testing temperature		Charpy impact strength[(a)]	
°C	°F	J	ft · lbf
-115	-175	81	60
-18	0	81	60
3	38	87	64
20	68	89	66
65	150	72	53
120	250	72	53
205	400	68	50

(a) For 10 mm (0.39 in.) square keyhole specimens machined from annealed rod

Fatigue strength. Rod, H80 temper, drawn 50% to 25 mm (1 in.) in diameter: 220 MPa (32 ksi) at 10^8 cycles. Rod, O61 temper, drawn 50% to 25 mm (1 in.) in diameter, then annealed at 760 °C (1400 °F): 150 MPa (22 ksi) at 10^8 cycles

Creep-rupture characteristics. Creep strength for 3.2 mm (0.125 in.) diam wire, OS020 temper: for a creep rate of 0.001% in 1000 h, 165 MPa (24 ksi) at 150 °C (300 °F) or 110 MPa (16 ksi) at 260 °C (500 °F); for a creep rate of 0.01% in 1000 h, 240 MPa (35 ksi) at 150 °C or 205 MPa (30 ksi) at 260 °C. Creep strength for 19 mm ($\frac{3}{4}$ in.) diam rod, O61 temper, drawn to size and annealed at 550 °C (1020 °F): 63 MPa (9.1 ksi) for a creep rate of 0.01% in 1000 h at 400 °C (750 °F); 130 MPa (18.8 ksi) for a creep rate of 0.1% in 1000 h at 400 °C (750 °F)

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1240 °C (2260 °F)

Solidus temperature. 1170 °C (2140 °F)

Coefficient of linear thermal expansion. 16.2 μm/m · K (9 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 29 W/m · K (17 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, O61 temper: 4.6% IACS at 20 °C (68 °F)

Electrical resistivity. O61 temper: 375 nΩ · m at 20 °C (68 °F); temperature coefficient, 4.8×10^{-5}/K (2.6×10^{-5}/ °F) at 20 to 200 °C (68 to 392 °F)

Optical Properties

Color. White

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Good capacity for being both cold worked and hot formed by bending and forming and welding processes

Weldability. Soldering, brazing, all forms of are welding, and all forms of resistance welding: excellent. Oxyfuel gas welding: good

Annealing temperature. 650 to 825 °C (1200 to 1500 °F)

Hot-working temperature. 925 to 1050 °C (1700 to 1900 °F)

C71900
67.2Cu-30Ni-2.8Cr

Commercial Names

Previous trade names. Copper-nickel, chromium-bearing; CA719

Common name. Cupronickel with Cr

Chemical Composition

Composition limits. 28 to 32 Ni, 2.4 to 3.2 Cr, 0.5 Fe max, 0.2 to 1.0 Mn, 0.01 to 0.20 Ti, 0.02 to 0.25 Zr, 0.04 C max, 0.25 Si max, 0.5 max other (total), bal Cu

Applications

Typical uses. Heat exchanger tubes, tube sheets, water boxes, ferrules, saltwater pipe

Mechanical Properties (Spinodally Decomposed Condition)

Tensile properties. Tensile strength, 540 MPa (78 ksi); yield strength, 330 MPa (47 ksi) at 0.2% offset, elongation, 25%. See Table 115.

Table 115 Typical mechanical properties of C71900 strip

Condition	Tensile strength		Yield strength at 0.2% offset		Elongation in 50 mm (2 in.), %	Hardness, HRB
	MPa	ksi	MPa	ksi		
Heat treated[(a)]	600	87	365	53	32	87
Half-hard temper[(b)]	730	106	685	99	14	100
Hard temper[(c)]	780	113	740	107	8	100
Spring temper[(d)]	835	121	800	116	6	101

(a) Spinodally decomposed by air cooling from 900 °C (1650 °F).

(b) Spinodally decomposed, then cold rolled 20%.

(c) Spinodally decomposed, then cold rolled 37%.

(d) Spinodally decomposed, then cold rolled 60%

Elastic modulus. Tension, 150 GPa (22 × 10^6 psi); shear, 59 GPa (8.5 × 10^6 psi)

Fatigue strength. Smooth bar, rotating beam: 275 MPa (40 ksi) at 10^8 cycles for both spinodally decomposed condition and half-hard temper (spinodally decomposed plus 44% cold work)

Mass Characteristics

Density. 8.85 g/cm^3 (0.319 lb/$in.^3$) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1220 °C (2225 °F)

Solidus temperature. 1170 °C (2140 °F)

Coefficient of linear thermal expansion. 16.8 μm/m · K (9.3 μin./in. · °F) at 20 to 200 °C (68 to 392 °F); 17.1 μm/m · K (9.5 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Thermal conductivity. 29 W/m · K (16.5 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties (Spinodally Decomposed Condition)

Electrical conductivity. Volumetric, 4.4% IACS at 20 °C (68 °F)

Electrical resistivity. 395 nΩ · m at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.0003 at magnetic field strength of 16 kA/m

Chemical Properties

Resistance to specific corroding agents. Seawater: C71900 resists both general and localized attack. The corrosion rate is very low (generally less than 0.1 mm/yr, or less than 4 mils/yr) in seawater flowing at velocities above about 1.8 m/s (6 ft/s). This level of corrosion resistance is comparable to or slightly less than the resistance of C71500 exposed to the same conditions. At low velocities or in stagnant seawater, C71900 exhibits slightly higher general weight loss than C71500, and corrosion is a broad, uniform type of attack. C71900 is not quite as resistant to crevice corrosion as C71500 at all velocities; for example, in a 3-month test in seawater flowing at intermediate

velocity, C71900 incurred 0.2 to 0.33 mm (8 to 13 mils) penetration compared to nil penetration for C71500. Welding does not have an adverse effect on corrosion resistance; corrosion in seawater is about the same for the weld zone, heat-affected zone, and unaffected base metal. C71900 appears to be immune to stress-corrosion cracking in seawater, even when the seawater is contaminated with 5 ppm H_2S. C71900 is cathodic to carbon steel and Ni-Resist type cast iron, slightly cathodic to C71500, and anodic to austenitic stainless steels.

Fabrication Characteristics

Formability. C71900 can be cold worked in a manner similar to C71500, although C71900 has higher tensile and yield strengths at any given reduction. Hot working is readily accomplished from a starting temperature of 1040 to 1065 °C (1900 to 1950 °F), but working should not be continued below 840 °C (1550 °F) because of reduced ductility. About 25% more extrusion pressure is required for C71900 than for C71500. Because of microsegregation, cast billets should be homogenized 3 to 4 h at 1040 to 1065 °C before being extruded.

Weldability. Soldering, brazing, and all forms of arc welding: excellent. Resistance welding is not normally used for this alloy. Oxyfuel gas welding is not recommended. Material thick enough to require multipass welds develops a minimum yield strength of 345 MPa (50 ksi) as-welded. Single-pass welds develop a minimum yield strength of 275 MPa (40 ksi) as-welded. The yield strength can be raised to 345 MPa (50 ksi) by a postweld heat treatment consisting of 1 h at 480 °C (900 °F).

Heat treatment. Full properties of the spinodally decomposed condition can be achieved by slow cooling (furnace cooling or still air cooling) through the temperature range 760 to 425 °C (1400 to 800 °F) from a soaking temperature of 900 to 1000 °C (1650 to 1850 °F)

Hot-working temperature. 900 to 1065 °C (1650 to 1950 °F)

C72200
83Cu-16.5Ni-0.5Cr

Commercial Names

Previous trade names. Copper-nickel, chromium-bearing; CA722

Common name. Cupronickel with Cr

Chemical Composition

Composition limits. 15 to 18 Ni, 0.3 to 0.7 Cr, 0.5 to 1.0 Fe, 0.4 to 0.9 Mn, 0.03 Si max, 0.03 Ti max, 0.03 C max, 0.5 max other (total), bal Cu

Applications

Typical uses. Condenser and heat exchanger tubing, saltwater pipe

Mechanical Properties

Tensile properties. O61 temper: tensile strength, 315 MPa (46 ksi); yield strength, 125 MPa (18 ksi) at 0.2% offset; elongation, 46%. H04 temper: tensile strength, 480 MPa (70 ksi); yield strength, 455 MPa (66 ksi) at 0.2% offset; elongation, 6%

Elastic modulus. Tension, 135 GPa (20×10^6 psi); shear; 55 GPa (8.2×10^6 psi)

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1176 °C (2148 °F)

Solidus temperature. 1122 °C (2052 °F)

Coefficient of linear thermal expansion. 15.8 μm/m · K (8.8 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 396 J/kg · K (0.094 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 34.5 W/m · K (19.9 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 6.53% IACS

Electrical resistivity. 264 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Formability. Good capacity for being cold worked or hot formed

Weldability. Gas-shielded arc welding: excellent. Soldering, brazing, shielding metal arc welding, and

resistance welding (all forms): good. Oxyfuel gas welding: fair

Annealing temperature. 730 to 815 °C (1350 to 1500 °F)

Hot-working temperature. 900 to 1040 °C (1650 to 1900 °F)

C72500
88.2Cu-9.5Ni-2.3Sn

Commercial Names

Previous trade names. Copper-nickel, tin-bearing; CA725

Common name. Cupronickel with Sn

Chemical Composition

Composition limits. 0.05 Pb max, 0.6 Fe max, 0.5 Zn max, 0.2 Mn max, 8.5 to 10.5 Ni, 1.8 to 2.8 Sn, 0.2 max other (total), bal Cu

Applications

Typical uses. Relay and switch springs, connectors, lead frames, control and sensing bellows, brazing alloy

Mechanical Properties

Tensile properties. See Table 116.

Table 116 Tensile properties of C72500

Temper	Tensile strength		Yield strength				Elongation in 50 mm (2 in.), %	Hardness, HRB
			0.5% extension under load		0.2% offset

(a) Grain size, 0.015 mm

Elastic modulus. Tension, 137 GPa (20×10^6 psi); shear, 52 GPa (7.5×10^6 psi)

Mass Characteristics

Density. 8.89 g/cm^3 (0.321 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1130 °C (2065 °F)

Solidus temperature. 1060 °C (1940 °F)

Coefficient of linear thermal expansion. 16.5 μm/m · K (9.2 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Thermal conductivity. 55 W/m · K (31 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 11% IACS at 20 °C (68 °F)

Electrical resistivity. O61 temper, 157 nΩ · m at 20 °C (68 °F)

Optical Properties

Color: Silver

Chemical Properties

Resistance to specific agents. Excellent resistance to seawater

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent capacity for being both cold worked and hot formed by blanking, coining, drawing, forming, bending, heading, upsetting, roll threading, knurling, shearing, spinning, squeezing, stamping, and swaging

Weldability. Soldering, brazing, and resistance spot and resistance butt welding: excellent. Gas-shielded arc, shielded metal arc, and resistance seam welding: good. Oxyfuel gas welding: fair

Annealing temperature. 650 to 800 °C (1200 to 1475 °F)

Hot-working temperature. 850 to 950 °C (1550 to 1750 °F)

C74500
65Cu-25Zn-10Ni

Commercial Names

Common name: Nickel silver, 65-10

Specifications

ASTM. Flat products: B 122. Bar: B 122, B 151. Rod: B 151. Wire: B 206

Government. Flat products: QQ-C-585. Bar: QQ-C-585, QQ-C-586. Rod, shapes, flat wire: QQ-C-586. Wire: QQ-W-321

Chemical Composition

Table 117 Typical mechanical properties of C74500

Composition limits. 63.5 to 68.5 Cu, 9.0 to 11.0 Ni, 0.10 Pb max, 0.25 Fe max, 0.5 Mn max, 0.5 max other, bal Zn

Applications

Typical uses. Hardware: rivets, screws, slide fasteners. Optical goods: optical parts. Miscellaneous: etching stock, hollowware, nameplates, platers' bars

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Formability. Excellent for cold working by blanking, drawing, etching, forming, bending, heading, upsetting, roll threading, knurling, shearing, spinning, squeezing, or swaging; poor for hot forming

Weldability. Soldering and brazing: excellent. Oxyfuel gas, resistance spot, and resistance butt welding: good. Gas metal arc and resistance seam welding: fair. Shielded metal arc welding is not recommended.

Annealing temperature. 600 to 825 °C (1100 to 1500 °F)

C77000
55Cu-27Zn-18Ni

Commercial Names

Common name. Nickel silver, 55-18

Specifications

ASTM. Flat products: B 122, Bar: B 122, B 151. Rod: B 151. Wire: B 206

SAE. J463

Government. Flat products: QQ-C-585. Bar: QQ-C-585, QQ-C-586. Rod, shapes, flat wire: QQ-C-586. Wire: QQ-W-321

Chemical Composition

Composition limits. 53.5 to 56.5 Cu, 16.5 to 19.5 Ni, 0.1 Pb max, 0.25 Fe max, 0.5 Mn max, 0.5 max other (total), bal Zn

Applications

Typical uses. Optical goods, springs, resistance wire

Mechanical Properties

Tensile properties. See Table 121.

Mass Characteristics

Density. 8.69 g/cm^3 (0.314 lb/in.^{3}) at 20 °C (68 °F)

Thermal Properties

Liquidus temperature. 1000 °C (1830 °F)

Solidus temperature. 970 °C (1780 °F)

Coefficient of linear thermal expansion. 18.5 μm/m · K (10.3 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 48 W/m · K (28 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 10.9% IACS at 20 °C (68 °F)

Electrical resistivity. 160 nΩ · m at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 60% of C36000 (free-cutting brass)

Formability. Cold working, good; hot forming, poor. Commonly fabricated by blanking, milling, and drilling

Weldability. Soldering: excellent. Brazing: good. Oxyfuel gas, arc, and resistance welding generally are not recommended.

Annealing temperature. 500 to 620 °C (930 to 1150 °F)

Selection and Application of Copper Alloy Castings

Revised by Robert F. Schmidt, Colonial Metals Co., and Donald G. Schmidt, R. Lavin & Sons, Inc.

Introduction

COPPER ALLOY CASTINGS are used in applications that require superior corrosion resistance, high thermal or electrical conductivity, good bearing surface qualities, or other special properties. Casting makes it possible to produce parts with shapes that cannot be easily obtained by fabrication methods such as forming or machining. Often, it is more economical to produce a part as a casting than to facilitate it by other means.

Types of Copper Alloys

Because pure copper is extremely difficult to cast and is prone to surface cracking, porosity problems, and the formation of internal cavities, small amounts of alloying elements (such as beryllium, silicon, nickel, tin, zinc, and chromium) are used to improve the casting characteristics of copper. Larger amounts of alloying elements are added for property improvement.

The copper-base castings are designated in the Unified Numbering System (UNS) with numbers ranging from C80000 to C99999. Also, copper alloys in the cast form are sometimes classified according to their freezing range (that is, the temperature range between the liquidus and solidus temperatures). The freezing range of various copper alloys is discussed in the section "Control of Solidification" in this article.

Compositions of copper casting alloys (Table 1) may differ from those of their wrought counterparts for various reasons. Generally, casting permits greater latitude in the use of alloying elements because the effects of composition on hot- or cold-working properties are not important. However, imbalances among certain elements, and trace amounts of certain impurities in some alloys, will diminish castability and can result in castings of lower quality.

Table 1 Nominal compositions of principal copper casting alloys

Certain cast alloys may also be unsuitable for wrought products. For example, several alloys listed in Table 1 have lead contents of 5% or more. Alloys containing such high percentages of lead are not suited to hot working, but they are ideal for low- or medium-speed bearings, where the lead prevents galling (and excessive wear if a lubricant is not present).

The tolerance for impurities is normally greater in castings than in their wrought counterparts because of the adverse effects certain impurities have on hot or cold workability. On the other hand, impurities that inhibit response to heat treatment must be avoided both in castings and in wrought products. The choice of an alloy for any casting usually depends on five factors: metal cost, castability, machinability, properties, and final cost.

Castability

Castability should not be confused with fluidity, which is only a measure of the distance to which a metal will flow before solidifying. Fluidity is thus one factor determining the ability of a molten alloy to completely fill a mold cavity in every detail. Castability, on the other hand, is a general term relating to the ability to reproduce fine detail on a surface. Colloquially, good castability refers to the ease with which an alloy responds to ordinary foundry practice without requiring special techniques for gating, risering, melting, sand conditioning, or any of the other factors involved in making good castings. High fluidity often ensures good castability, but it is not solely responsible for that quality in a casting alloy.

The castability of alloys is generally influenced by their shrinkage characteristics and their freezing range (which is not necessarily related directly to shrinkage). Classification of copper casting alloys according to a narrow or wide freezing

range is discussed in the article "Copper and Copper Alloys" in *Casting,*Volume 15 of *ASM Handbook*, formerly 9th Edition *Metals Handbook.* The effect of the freezing range on castability is discussed in the section "Control of Solidification" in this article.

Foundry alloys are also classified as high-shrinkage or low-shrinkage alloys. The former class includes the manganese bronzes, aluminum bronzes, silicon bronzes, silicon brasses, and some nickel-silvers. They are more fluid than the low-shrinkage red brasses, more easily poured, and give high-grade castings in the sand, permanent mold, plaster, die, and centrifugal casting processes. With high-shrinkage alloys, careful design is necessary to promote directional solidification, avoid abrupt changes in cross section, avoid notches (by using generous fillets), and properly place gates and risers; all of these design precautions help avoid internal shrinks and cracks. Turbulent pouring must be avoided to prevent the formation of dross becoming entrapped in the casting. Liberal use of risers or exothermic compounds ensures adequate molten metal to feed all sections of the casting. Table 2 presents foundry characteristics of selected standard alloys, including a comparative ranking of both fluidity and overall castability for sand casting; number 1 represents the highest castability or fluidity ranking.

Table 2 Foundry properties of the principal copper alloys for sand casting

(a) Relative rating for casting in sand molds. The alloys are ranked from 1 to 8 in both overall castability and fluidity; 1 is the highest or best possible rating.

All copper alloys can be successfully cast in sand. Sand casting allows the greatest flexibility in casting size and shape and is the most economical casting method if only a few castings are made (die casting is more economical above ~50,000 units). Permanent mold casting is best suited for tin, silicon, aluminum and manganese bronzes, and yellow brasses. Dies casting is well suited for yellow brasses, but increasing amounts of permanent mold alloys are also being die cast. Size is a definite limitation for both methods, although large slabs weighing as much as 4500 kg (10,000 lb) have been cast in permanent molds. Brass die castings generally weigh less than 0.2 kg (0.5 lb) and seldom exceed 0.9 kg (2 lb). The limitation of size is due to the reduced the life with larger castings.

Virtually all copper alloys can be cast successfully by the centrifugal casting process. Castings of almost every size from less than 100 g to more than 22,000 kg (<0.25 to >50,000 lb) have been made.

Because of their low lead contents, aluminum bronzes, yellow brasses, manganese bronzes, low-nickel bronzes, and silicon brasses and bronzes are best adapted to plaster mold casting. For most of these alloys, lead should be held to a minimum because it reacts with the calcium sulfate in the plaster, resulting in discoloration of the surface of the casting and increased cleaning and machining costs. Size is a limitation on plaster mold casting, although aluminum bronze castings that weigh as little as 100 g (0.25 lb) have been made by the lost-wax process, and castings that weigh more than 150 kg (330 lb) have been made by conventional plaster molding.

Control of Solidification. Production of consistently sound castings requires an understanding of the solidification characteristics of the alloys are as well as knowledge of relative magnitudes of shrinkage. The actual amount of contraction during solidification does not differ greatly from alloy to alloy. Its distribution, however, is a function of the freezing range and the temperature gradient in critical sections. Manganese and aluminum bronzes are similar to steel in that their freezing ranges are quite narrow--about 40 and 14 °C (70 and 25 °F), respectively. Large castings can be made by the same conventional methods used for steel, as long as proper attention is given to placement of gates and risers--both those for controlling directional solidification and those for feeding the primary central shrinkage cavity.

Tin bronzes have wider freezing ranges (~165 °C, or 300 °F, for C83600). Alloys with such wide freezing ranges form a mushy zone during solidification, resulting in interdendritic shrinkage or microshrinkage. Because feeding cannot take place properly under these conditions, porosity results in the affected sections. In overcoming this effect, design and riser placement, plus the use of chills, are important. Another means of overcoming interdendritic shrinkage is to maintain close temperature control of the metal during pouring and to provide for rapid solidification. These requirements limit section thickness and pouring temperatures, and this practice requires a gating system that will ensure directional solidification. Sections up to 25 mm (1 in.) in thickness are routinely cast. Sections up to 50 mm (2 in.) thick can be cast, but only with difficulty and under carefully controlled conditions. A bronze with a narrow solidification (freezing) range and good directional solidification characteristics is recommended for castings having section thicknesses greater than about 25 mm (1 in.).

It is difficult to achieve directional solidification in complex castings. The most effective and most easily used device is the chill. For irregular sections, chills must be shaped to fit the contour of the section of the mold in which they are

placed. Insulating pads and riser sleeves sometimes are effective in slowing down the solidification rate in certain areas to maintain directional solidification. Further information on the casting of copper alloys is given in *Casting,* Volume 15 of *ASM Handbook,* formerly 9th Edition *Metals Handbook.*

Mechanical Properties

Most copper-base casting alloys containing tin, lead, or zinc have only moderate tensile and yield strengths, low-to-medium hardness, and high elongation. When higher tensile or yield strength is required, the aluminum bronzes, manganese bronzes, silicon brasses, silicon bronzes, and some nickel-silvers are used instead. Most of the higher-strength alloys have better-than-average resistance to corrosion and wear. Mechanical and physical properties of copper-base casting alloys are presented in Table 3. (Throughout this discussion, as well as in Table 3, the mechanical properties quoted are for sand cast test bars. Properties of the castings themselves may be lower, depending on section size and process-design variables.)

Note: HT indicates alloy in heat-treated condition.

(a) At 0.5% extension under load.

(b) At a permanent set of 0.025 mm (0.001 in).

(c) 500 kgf (1100 lbf) load.

(d) 3000 kgf (6600 lbf) load.

(e) Heat treated at 900 °C (1650 °F), water quenched, tempered at 590 °C (1100 °F), water quenched.

(f) At 0.2% offset.

(g) Solution anneal of 760 °C (1400 °F) for 4 h, water quench, and then age at 315 °C (600 °F) for 5 h and air cool

Tensile strengths for cast test bars of aluminum bronzes and manganese bronzes range from 450 to 900 MPa (65 to 130 ksi), depending on composition; some aluminum bronzes attain maximum tensile strength only after heat treatment.

Although manganese and aluminum bronzes are often used for the same applications, the manganese bronzes are handled more easily in the foundry. As-cast tensile strengths as high as 800 MPa (115 ksi) and elongations of 15 to 20% can be obtained readily in sand castings; slightly higher values are possible in centrifugal castings. Stresses can be relieved at 175 to 200 °C (350 to 400 °F). Lead can be added to the lower-strength manganese bronzes to increase machinability, but at the expense of tensile strength and elongation. Lead content should not exceed 0.1% in high-strength manganese bronzes. Although manganese bronzes range in hardness from 125 to 250 HB, they are readily machined.

Tin is added to the low-strength manganese bronzes to enhance resistance to dezincification, but it should be limited to 0.1% in high-strength manganese bronzes unless sacrifices in strength and ductility can be accepted.

Manganese bronzes are specified for marine propellers and fittings, pinions, ball bearing races, worm wheels, gear shift forks, and architectural work. Manganese bronzes are also used for rolling mill screwdown nuts and slippers, bridge trunnions, gears, and bearings, all of which require high strength and hardness.

Various cast aluminum bronzes contain 9 to 14% Al and lesser amounts of iron, manganese, or nickel. They have a very narrow solidification range; therefore, they have a greater need for adequate gating and risering than do most other copper casting alloys and thus are more difficult to cast. A wide range of properties can be obtained with these alloys, especially after heat treatment, but close control of composition is necessary. Like the manganese bronzes, aluminum bronzes can developed tensile strengths well over 700 MPa (100 ksi).

Most aluminum bronzes contain from 0.75 to 4% Fe to refine grain structure and increase strength. Alloys containing from 8 to 9.5% Al cannot be heat treated unless other elements (such as nickel or manganese) in amounts over 2% are added as well. They have higher tensile strengths and greater ductility and toughness than any of the ordinary tin bronzes. Applications include valve nuts, cam bearings, impellers, hangers in pickling baths, agitators, crane gears, and connecting rods.

The heat-treatable aluminum bronzes contain from 9.5 to 11.5% Al; they also contain iron, with or without nickel or manganese. These castings are quenched in water or oil from temperatures between 760 and 925 °C (1400 and 1700 °F) and tempered at 425 to 650 °C (800 to 1200 °F), depending on the exact composition and the required properties.

From the range of properties shown in Table 3, it can be seen that all the maximum properties cannot be obtained in any one aluminum bronze. In general, alloys with higher tensile strengths, yield strengths, and hardnesses have lower values of elongation. Typical applications of the higher-hardness alloys are rolling mill screwdown nuts and slippers, worm gears, bushing, slides, impellers, nonsparking tools, valves, and dies.

Aluminum bronzes resist corrosion in many substances, including pickling solutions. When corrosion occurs, it often proceeds by preferential attack of the aluminum-rich phases. Duplex alpha-plus-beta aluminum bronzes are more susceptible to preferential attack of the aluminum-rich phases than are the all-alpha aluminum bronzes.

Aluminum bronzes have fatigue limits that are considerably greater than those of manganese bronze or any other cast copper alloy. Unlike Cu-Zn and Cu-Sn-Pb-Zn alloys, the mechanical properties of aluminum and manganese bronzes do not decrease with increases in casting cross section. This is because these alloys have narrow freezing ranges, which result in denser structures when castings are properly designed and properly fed.

Whereas manganese bronzes experience hot shortness above 230 °C (450 °F), aluminum bronzes can be used at temperatures as high as 400 °C (750 °F) for short periods of time without an appreciable loss in strength. For example, a room-temperature tensile strength of 540 MPa (78 ksi) declines to 529 MPa (76.7 ksi) at 260 °C (500 °F), 460 MPa (67 ksi) at 400 °C (750 °F), and 400 MPa (58 ksi) at 540 °C (1000 °F). Corresponding elongation values change from 28% to 32, 35, and 25%, respectively.

Unlike manganese bronzes, many aluminum bronzes increase in yield strength and hardness but decrease in tensile strength and elongation upon slow cooling in the mold. Whereas some manganese bronzes precipitate a relatively soft phase during slow cooling, aluminum bronzes precipitate a hard constituent rather rapidly within the narrow temperature range of 565 to 480 °C (1050 to 900 °F). Therefore, large castings, or smaller castings that are cooled slowly, will have properties different from those of small castings cooled relatively rapidly. The same phenomenon occurs upon heat treating the hardenable aluminum bronzes. Cooling slowly through the critical temperature range after quenching, or tempering at temperatures within this range, will decrease elongation. An addition of 2 to 5% Ni greatly diminishes this effect.

Nickel brasses, silicon brasses, and silicon bronzes, although generally higher in strength than red metal alloys, are used more for their corrosion resistance and are discussed in the section "Selection of Alloys for Corrosion Service" in this article. Distributions of hardness and tensile strength data for separately cast test bars of three different alloys are shown in Fig. 1.

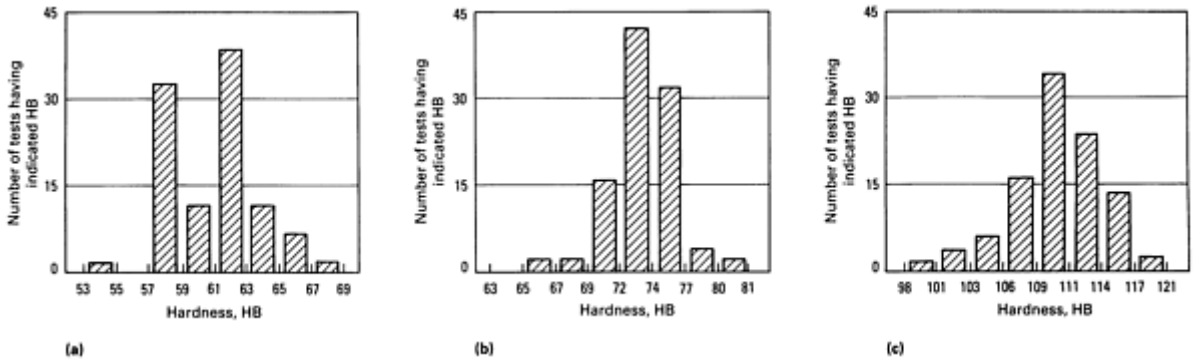

Fig. 1 Distribution of hardness over 100 tests for three copper casting alloys of different tensile strengths. (a) C83600. Tensile strength, 235 to 260 MPa (34 to 38 ksi); 500 kg (1100 lbf) load. (b) C90300. Tensile strength, 275 to 325 MPa (40 to 47 ksi); 500 kg (1100 lbf) load. (c) C87500. Tensile strength, 420 to 500 MPa (61 to 72 ksi); 1500 kg (3300 lbf) load

Properties of Test Bars. The mechanical properties of separately cast test bars often differ widely from those of production castings poured at the same time, particularly when the thickness of the casting differs markedly from that of the test bar.

The mechanical properties of tin bronzes are particularly affected by variations in casting section size. With increasing section sizes up to about 50 mm (2 in.), the mechanical properties--both strength and elongation--of the castings themselves are progressively lower than the corresponding properties of separately cast test bars. Elongation is particularly affected; for some tin bronzes, elongation of a 50 mm (2 in.) section may be as little as $\frac{1}{10}$ that of a 10 mm (0.4 in.) section or of a separately cast test bar.

The metallurgical behavior of many copper alloy systems is complex. The cooling rate (a function of casting section size) directly influences grain size, segregation, and interdendritic shrinkage; these factors, in turn, affect the mechanical

properties of the cast metal. Therefore, molding and casting techniques are based on metallurgical characteristics as well as on casting shape.

Dimensional Tolerances

Typical dimensional tolerances are different for castings produced by different molding methods. A molding process involving two or more mold parts requires greater tolerances for dimensions that cross the parting line than for dimensions wholly within one mold part. For castings made in green sand molds, tolerances across the parting line depend on the accuracy of pins and bushings that align the cope with the drag.

Figure 2 shows variations in two important dimensions for 50 production castings of red brass. The larger dimension presented the greatest difficulty: None of the 50 production castings had an actual dimension as large as the nominal design value. Figure 3 shows dimensional variations in two similar cored valve castings. For each design, both the cores and the corresponding cavities in the castings were measured for about 100 castings. For both designs, the castings had actual dimensions less than those of the cores. This indicates that cores may need to have a slightly larger nominal size than is desired in the finished casting in order to ensure proper as-cast hole sizes.

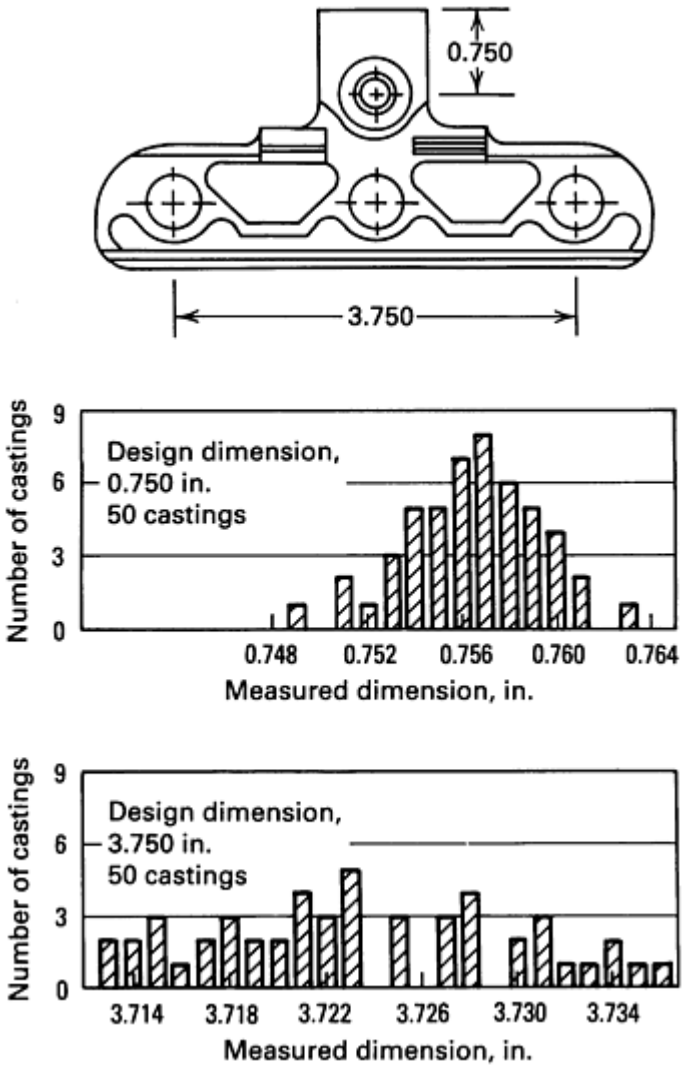

Fig. 2 Variations from design dimensions for a typical red brass casting. Parts were cast in green sand molds made using the same pattern. All dimensions in inches

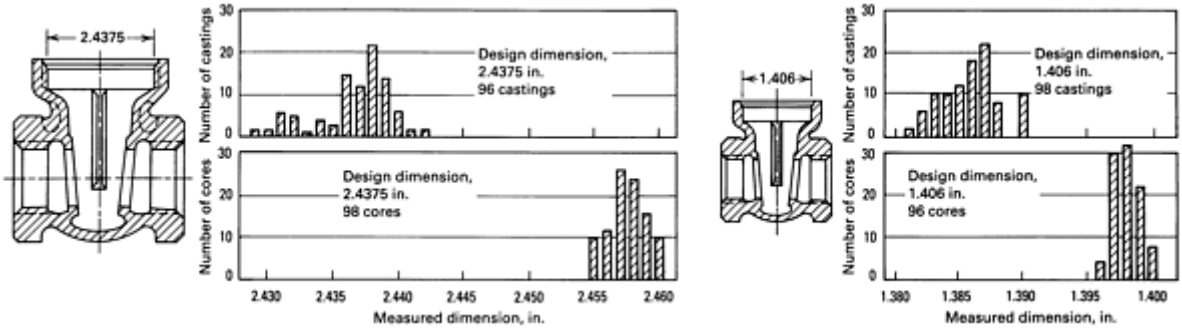

Fig. 3 Variations from design dimensions for two typical cast red brass valve bodies. Valve bodies, similar in design but of different sizes, were made using dry sand cores to shape the internal cavities. The upper histograms indicate dimensional variations for the castings; the lower histograms indicate variations for the corresponding cores. All dimensions in inches

Machinability

Machinability ratings of copper casting alloys are similar to those of their wrought counterparts. The cast alloys can be separated into three groups. The relative machinability of alloys belonging to the three groups is shown in Table 4.

Table 4 Machinability ratings of several copper casting alloys

UNS number	Common name	Machinability rating, %[(a)]
Group 1: free-cutting alloys		
C83600	Leaded red brass	90
C83800	Leaded red brass	90
C84400	Leaded semired brass	90
C84800	Leaded semired brass	90
C94300	High-lead tin bronze	90
C85200	Leaded yellow brass	80
C85400	Leaded yellow brass	80
C93700	High-lead tin bronze	80
C93800	High-lead tin bronze	80

C93200	High-lead tin bronze	70
C93500	High-lead tin bronze	70
C97300	Leaded nickel brass	70
Group 2: moderately machinable alloys		
C86400	Leaded high-strength manganese bronze	60
C92200	Leaded in bronze	60
C92300	Leaded tin bronze	60
C90300	Tin bronze	50
C90500	Tin bronze	50
C95600	Silicon-aluminum bronze	50
C95300	Aluminum bronze	35
C86500	High-strength manganese bronze	30
Group 3: hard-to-machine alloys		
C86300	High-strength manganese bronze	20
C95200	9% aluminum bronze	20
C95400	11% aluminum bronze	20
C95500	Nickel-aluminum bronze	20

(a) Expressed as a percentage of the machinability of C36000, free-cutting brass. The rating is based on relative speed for equivalent tool life. For example, a material having a rating of 50 should be machined at about half the speed that would be used to make a similar cut in C36000.

The first group includes only those containing a single copper-rich phase plus lead. Whether present merely to improve machinability or for some other purpose, lead facilitates chip breakage, thus allowing higher machining speeds with decreased tool wear and improved surface finishes.

Alloys of the second group contain two or more phases. Generally, the secondary phases are harder or more brittle than the matrix. Silicon bronzes, several aluminum bronzes, and the high-tin bronzes belong to this group. Hard and brittle secondary phases act as internal chip breakers, resulting in short chips and easier machining. Manganese bronzes produce a long spiral chip that is smooth on both sides and that does not break. Some aluminum bronzes, on the other hand, produce a long spiral chip that is rough on the underside and that breaks, thus acting like a short chip. Some of the alloys in the second group are classified as moderately machinable because tools wear more rapidly when these alloys are machined, even though chip formation is entirely adequate.

The third group, the most difficult to machine, is composed mainly in the high-strength manganese bronzes and aluminum bronzes that are high in iron or nickel content. Additional information on the machining of copper castings is available in *Machining,* Volume 16 of *ASM Handbook,* formerly 9th Edition *Metals Handbook.*

General-Purpose Alloys

General-purpose copper casting alloys are often classified as either red or yellow alloys. Nominal compositions and general properties of these alloys are given in Tables 1 and 3.

The leaded red and leaded semired brasses respond readily to ordinary foundry practice and are rated very high in castability. Alloy C83600 is the best known of this group and usually is referred to by one of its common names--85-5-5-5 or ounce metal. Alloy C83600 and its modification, C83800 (83-4-6-7), constitute the largest tonnage of copper-base foundry alloys. They are used where moderate corrosion resistance, good machinability, moderate strength and ductility, and good castability, are required. C83800 has lower machinability properties but better machinability and lower initial metal cost than C83600.

Both C83600 and C83800 are used for plumbing goods, flanges, feed pumps, meter casings and parts, general household and machinery hardware and fixtures, papermaking machinery, hydraulic and steam valves, valve disks and seats, impellers, injectors, memorial markers, plaques, statuary, and similar products.

Alloys C84400 and C84800 are higher in lead and zinc and lower in copper and tin than C83600 and C83800. They are lower in price, and they have lower tensile strengths and hardnesses. Their widest application is in the plumbing industry.

The leaded yellow brasses C85200 and C85700 are even lower in price and mechanical properties. Their main applications are die castings for plumbing goods and accessories, low-pressure valves, air and gas fittings, general hardware, and ornamental castings. In general, they are best suited for small parts; larger parts with thick sections should be avoided. Aluminum (0.15 to 0.25%) is added to yellow brasses to increase fluidity and to give a smoother surface.

All of the red and yellow general-purpose alloys, when properly made and cleaned, can be plated with nickel or chromium.

Alloys that do not contain lead, such as the tin bronzes C90500 (Navy G bronze) and C90300 (modified Navy G bronze), are considerably more difficult to machine than leaded alloys. Alloys containing 10 to 12% Sn, 1 to 2% Ni, and 0.1 to 0.3% P are known as gear bronzes. Up to 1.5% Pb frequently is added to increase machinability. The addition of lead to C90300 increases machinability, but a concurrent decrease in tin is needed to maintain elongation. The leaded tin bronzes include C92200 (known as steam bronze, valve bronze, or Navy M bronze) and C92300 (commercial G bronze).

All of the tin bronzes are suitable wherever corrosion resistance, leak tightness, or greater strength is required at higher operating temperatures than can be tolerated with leaded red or semired brasses. The limiting temperature for long-time operation of C92200 is 290 °C (550 °F); C90300, C90500, and C92300, it is 260 °C (500 °F) because of the embrittlement caused by the precipitation of a high-tin phase. This reaction does not occur in tin bronzes with tin contents less than about 8%. For elevated-temperature service in handling fluids and gases, Table UNF-23 of the ASME Boiler and Pressure Vessel Code defines allowable working stresses for C92200 (leaded tin bronze, ASTM B 61) and C83600 (leaded red brass, ASTM B 62) at different temperatures (Table 5).

Table 5 Allowable working stresses for C92200 and C83600 castings

Temperature		Working stress			
		ASTM B 61[(a)]		ASTM B 62[(b)]	
°C	°F	MPa	ksi	MPa	ksi
38	100	47	6.8	41	6.0

93	200	47	6.8	40	5.8
120	250	47	6.8	38	5.5
150	300	45	6.5	34	5.0
175	350	41	6.0	31	4.5
205	400	38	5.5	24	3.5
230	450	34	5.0	24	3.5

260	500	28	4.0	24	3.5
290	550	23	3.3	24	3.5

Source: ASME Boiler and Pressure Vessel Code, Table UNF-23

(a) A minimum tensile strength of 235 MPa (34 ksi) is specified for C92200 in ASTM B 61.

(b) A minimum tensile strength of 205 MPa (30 ksi) is specified for C83600 in ASTM B 62.

Nickel frequently is added to tin bronzes to increase density and leak tightness. Alloys containing more than 3% Ni are heat treatable, but they must contain less than 0.01% Pb for optimum properties; one example of such an alloy is C94700 (88Cu-5Sn-2Zn-5Ni).

Selection of Alloys for Corrosion Service

In Table 6, the relative corrosion resistance in a wide variety of liquids and gases is given for 14 different classes of copper casting alloys. Certain generalizations can be drawn from an examination of these data. In many liquids, the yellow brasses do not have corrosion resistance as high as that of the other copper alloys. However, the high strength of the yellow brasses may make them more desirable even though some corrosion may be encountered. Corrosion of these alloys often takes place by dezincification; if this is a problem, alloys with copper contents of 80% or more must be selected.

(a) Acetylene forms an explosive compound with copper when moist or when certain impurities are present and the gas is under pressure. Alloys containing less than 65% Cu are satisfactory under this use. When gas is not under pressure, other copper alloys are satisfactory.

(b) Copper and copper alloys resist corrosion by most food products. Traces of copper may be dissolved and affect taste or color. In such cases, copper metals often are tin coated.

Often, experience must be relied on for the proper selection of alloys. Laboratory tests are only guides because they fail to duplicate or approximate the conditions that will be encountered in service. When used in a "recommended" service application (see Table 6), copper metals generally give adequate service life. However, the table can only serve as a guide, and it should be used judiciously. Additional information on the corrosion of copper alloys is given in *Corrosion,* Volume 13 of *ASM Handbook,* formerly 9th Edition *Metals Handbook.*

Atmospheric Corrosion. Copper alloy castings have been used for centuries for their superior resistance to atmospheric corrosion. Resistance is afforded by the formation of a coating or patina of basic copper sulfate, which ultimately reacts further to form some basic copper carbonate. The sulfate is virtually insoluble in water and thus affords good protection.

Liquid Corrosion. Copper alloy castings are widely used for their superior corrosion resistance in many liquid media. Their resistance to corrosion in liquids, like their resistance to atmospheric corrosion, is increased by the formation of a stable, adherent reaction product. If the coating is removed by chemical or mechanical means, corrosion resistance is reduced, and this reduction often is severe. Thus, rapid corrosion takes place in aerated mineral acids or under conditions of severe agitation, impingement, or high-velocity flow.

Copper metals are attacked by strong organic and inorganic acids and, to some extent, by weak organic acids. Although a copper metal may not visibly corrode, even a minute quantity of copper ions in the solution is not acceptable in certain applications. This is particularly true for food products, in which adverse color or taste can develop.

Ammonium hydroxide attacks all copper alloys severely, and these alloys are not recommended where ammonium ions may be formed. Copper metals are generally satisfactory for applications involving neutral organic compounds, including petroleum products, solvents, and animal and vegetable products. However, in the presence of moisture, certain of these materials may form acids, which in turn may attack a copper metal.

In aqueous solutions, attack is accelerated by dissolved oxygen and carbon dioxide. Thus, although copper alloys are widely used for plumbing goods, they are attacked by many natural waters, especially the very soft waters with high oxygen and carbon dioxide contents. In these waters, carbonic acid is formed, which prevents the development of a resistant layer or dissolves any previously formed layer. Dezincification of high-zinc alloys frequently results if they are used indiscriminately in fresh-water service.

Bearing and Wear Properties

Copper alloys have long been used for bearings because of their combination of moderate-to-high strength, corrosion resistance, and self-lubrication properties. The choice of an alloy depends on the required corrosion resistance and fatigue strength, the rigidity of the backing material, lubrication, the thickness of bearing material, load, the speed of rotation, atmospheric conditions, and other factors. Copper alloys can be cast into plain bearings, cast on steel backs, cast on rolled strip, made into sintered powder metallurgy shapes, or pressed and sintered onto a backing material.

Three groups of alloys are used for bearing and wear-resistant applications: phosphor bronzes (Cu-Sn); copper-tin-lead (low-zinc) alloys; and manganese, aluminum, and silicon bronzes (see Table 1).

Phosphor bronzes (Cu-Sn-P or Cu-Sn-Pb-P alloys) have residual phosphorus ranging from a few hundredths of 1% (for deoxidation and slight hardening) to a maximum of 1%, a level which imparts great hardness. Nickel often is added to refine grain size and disperse the lead. Copper-tin bearings have high resistance to wear, high hardness, and moderately high strength. Alloy C90700 is so widely used for gears that it is commonly called gear bronze.

Phosphor bronzes of higher tin content, such as C91100 and C91300, are used in bridge turntables, where loads are high and rotational movements is slow. The maximum load permitted for C91100 (16% Sn) is 17 MPa (2500 psi); for C91300 (19% Sn) it is 24 MPa (3500 psi). These bronzes are high in phosphorus (1% max) to impart high hardness, and low in zinc (0.25% max) to present seizing. They are very brittle and because of this brittleness are sometimes replaced by manganese bronzes or aluminum bronzes.

High-lead tin bronzes are used where a softer metal is required at slow-to-moderate speeds and at loads not exceeding 5.5 MPa (800 psi). Alloys of this type include C93200 and C93700. The former, also known as 83-7-7-3, is an excellent general bearing alloy; it is especially well suited for applications where lubrication may be deficient. Alloy C93200 is widely used in machine tools, electrical and railroad equipment, steel mill machinery, and automotive applications. Alloy

C93200 is produced by the continuous casting process and has replaced sand castings for mass-produced bearings of high quality. Alloys C93800 (15% Pb) and C94300 (24% Pb) are used where high loads are encountered under conditions of poor or nonexistent lubrication; under corrosive conditions, such as in mining equipment (pumps and car bearings); or in dusty atmospheres, as in stonecrushing and cement plants. These alloys replace the tin bronzes or low-lead tin bronzes where operating conditions are unsuitable for alloys containing little or no lead. They also are produced by the continuous casting process.

High-strength manganese bronzes have high tensile strength, hardness, and resistance to shock. Large gears, bridge turntables (slow motion and high compression), roller tracks for antiaircraft guns, and recoil parts of cannons are typical applications.

Aluminum bronzes with 8 to 9% Al are widely used for bushings and bearings in light-duty or high-speed machinery. Aluminum bronzes containing 11% Al, either as-cast or heat treated, are suitable for heavy-duty service (such as valve guides, rolling mill bearings, screwdown nuts, and slippers) and precision machinery. As aluminum content increases above 11%, hardness increases and elongation decreases to low values. Such bronzes are well suited for guides and aligning plates, where wear would be excessive. Aluminum bronzes that contain more than 13% Al exceed 300 HB in hardness but are brittle. Such alloys are suitable for dies and other parts not subjected to impact loads.

Aluminum bronze generally has a considerably higher fatigue limit and freedom from galling than manganese bronze. On the other hand, manganese bronze has great toughness for equivalent tensile strength and does not need to be heat treated.

Electrical and Thermal Conductivity

Electrical and thermal conductivity of any casting will invariably be lower than for wrought metal of the same composition. Copper castings are used in the electrical industry for their current-carrying capacity, and they are used for water-cooled parts of melting and refining furnaces because of their high thermal conductivity: However, for a copper casting to be sound and have electrical or thermal conductivity of at least 85%, care must be taken in melting and casting. The ordinary deoxidizers (silicon, tin, zinc, aluminum, and phosphorus) cannot be used because small residual amounts lower electrical and thermal conductivity drastically. Calcium boride or lithium will help to produce sound castings with high conductivity.

Cast copper is soft and low in strength. Increased strength and hardness and good conductivity can be obtained with heat-treated alloys containing silicon, cobalt, chromium, nickel, and beryllium in various combinations. These alloys, however, are expensive and less readily available than the standardized alloys. Table 7 presents some of the properties of these alloys after heat treatment.

Table 7 Composition and typical properties of heat-treated copper casting alloys of high strength and conductivity

UNS number	Nominal composition	Tensile strength		Yield strength		Elongation, %	Hardness	Electrical conductivity, % IACS
		MPa	ksi	MPa	ksi			
C8140	99Cu-0.8Cr-0.06Be	365	53	250	36	11	69 HRB	70

C82200	98Cu-1.5Ni-0.5Be	655	95	515	75	7	96 HRB	48
C82500	97Cu-2Be-0.5Co-0.3Si	1105	160	1035	150	1	43 HRC	20
C82800	96.6Cu-2.6Be-0.5Co-0.3Si	1140	165	1070	155	1	46 HRC	18

Cost Considerations

During the design of a copper alloy casting, foundry personnel or the design engineer must choose a method of producing internal cavities. There is no general rule for choosing between cored and coreless designs. A cost analysis will determine which is the more economical method of producing the casting, although frequently the choice can be decided by experience.

For example, costs were compared for producing a small (13 mm, or $\frac{1}{2}$ in.) valve disk both as a cored casting and as a machined casting (internal cavities made without cores). The machined casting could be produced for about 78% of the cost of making the identical casting using dry sand cores--a savings of 22% in favor of the machined casting. In a similar instance, producing a larger (38 mm, or 1 $\frac{1}{2}$ in.) valve disk as a cored casting that required only a minimal amount of machining saved more than 8% in overall cost compared to producing the same valve disk without cores. Thus, for two closely related parts, a difference in manufacturing economy may exist when all cost factors are taken into account.

Properties of Cast Copper Alloys

Revised by Arthur Cohen, Copper Development Association, Inc.

C81100

Commercial Names

Previous trade name. CA811

Chemical Composition

Composition limits. 99.70 Cu + Ag min, 0.30 max other (total), 0.01 P + Si max to achieve a conductivity of 92% IACS

Applications

Typical uses. Electrical and thermal conductors, applications requiring resistance to corrosion and oxidation

Mechanical Properties

Tensile properties. Typical data for sand-cast test bars: tensile strength, 170 MPa (25 ksi); yield strength, 62 MPa (9 ksi) at 0.5% extension under load; elongation, 40% in 50 mm (2 in.)

Hardness. 44 HB

Elastic modulus. Tension, 115 GPa (17×10^6 psi)

Fatigue strength. 62 MPa (9 ksi) at 10^8 cycles

Mass Characteristics

Density. 8.94 g/cm^3 (0.323 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. 4.92% contraction

Patternmaker's shrinkage. 21 mm/m ($\frac{1}{4}$ in./ft)

Thermal Properties

Liquidus temperature. 1083 °C (1981 °F)

Solidus temperature. 1065 °C (1948 °F)

Coefficient of linear thermal expansion. 16.9 μm/m · K (9.4 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 346 W/m · K (200 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 92% IACS at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.0

Fabrication Characteristics

Machinability. 10% of C36000 (free-cutting brass)

C81300

Commercial Names

Previous trade name. CA813

Common name. Beryllium-copper

Chemical Composition

Composition limits. 98.5 Cu min, 0.20 to 0.10 Be, 0.6 to 1.0 Co. (Cu + sum of named elements shall be 99.5% minimum.)

Applications

Typical uses. Higher-hardness electrical and thermal conductors

Mechanical Properties

Tensile properties. Properties for separately cast heat-treated (TF00 temper) test bars; tensile strength, 365 MPa (53 ksi) min; yield strength, 250 MPa (36 ksi) min at 0.2% offset; elongation, 11% min in 50 min (2 in.)

Hardness. 89 HB (500 kg), typical

Elastic modulus. Tension, 110 GPa (16×10^6 psi) at 20 °C (68 °F)

Mass Characteristics

Density. 8.81 g/cm^3 (0.318 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. Patternmaker's shrinkage, 21 mm/m ($\frac{1}{4}$ in./ft)

Thermal Properties

Liquidus temperature. 1093 °C (2000 °F)

Solidus temperature. 1066 °C (1950 °F)

Coefficient of linear thermal expansion. 18 μm/m · K (10.0 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 390 J/kg · K (0.093 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 260 W/m · K (150 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 60% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. TF00 temper: 20% of C36000 (free-cutting brass)

Solution heat-treating temperature. 980 to 1010 °C (1800 to 1850 °F)

Aging temperature. 480 °C (900 °F)

Stress-relieving temperature. 260 °C (500 °F)

C81400
99Cu-0.8Cr-0.06Be

Commercial Names

Previous trade name. Beryllium-copper 70C, CA814

Common name. Be-modified chrome copper

Specifications

RWMA. Class II

Chemical Composition

Composition limits. 98.5 Cu min, 0.6 to 1.0 Cr, 0.02 to 0.10 Be

Applications

Typical uses. Electrical parts that meet RWMA Class II standards. The beryllium content of this alloy ensures that the chromium content will be kept under control during melting and casting, thus allowing the production of chrome copper castings of consistently high quality.

Precautions from health hazard. See C82500.

Mechanical Properties

Tensile properties. Typical as-cast: tensile strength, 205 MPa (30 ksi); yield strength, 83 MPa (12 ksi) at 0.2% offset; elongation, 35% in 50 mm (2 in.). TF00 temper: tensile strength, 365 MPa (53 ksi); yield strength, 250 MPa (36 ksi) at 0.2% offset; elongation, 11% in 50 mm (2 in.)

Hardness. As-cast: 62 HRB. TF00 temper: 69 HRB

Elastic modulus. Tension, 110 GPa (16×10^6 psi); shear, 41 GPa (5.9×10^6 psi)

Mass Characteristics

Density. 8.81 g/cm^3 (0.318 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 1.96%

Thermal Properties

Liquidus temperature. 1095 °C (2000 °F)

Solidus temperature. 1065 °C (1950 °F)

Coefficient of linear thermal expansion. 18 μm/m · K (10 μin./in. · F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 389 J/kg · K (0.093 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 259 W/m · K (150 Btu/ft · h · °F) at 20 °C (68 °F)

Fabrication Characteristics

Machinability. As-cast or TB00 temper: 30% of C36000 (free-cutting brass); TF00 temper: 40% of C36000

Melting temperature. 1065 to 1095 °C (1950 to 2000 °F)

Casting temperature. Light castings, 1200 to 1260 °C (2200 to 2300 °F); heavy castings, 1175 to 1230 °C (2150 to 2250 °F)

Solution temperature. 1000 to 1010 °C (1830 to 1850 °F)

Aging temperature. 480 °C (900 °F)

C81500
99Cu-1Cr

Commercial Names

Previous trade names. Chromium-copper; CA815

Common name. Chrome copper

Chemical Composition

Composition limits. 98.0 to 99.6 Cu, 0.40 to 1.50 Cr, 0.015 Pb max, 0.04 P max, 0.15 max other (total)

Consequence of exceeding impurity limits. Elements that contribute to hot shortness must be avoided. Because of the high solution temperatures necessary to develop the desired mechanical properties, elements that enter into solid solution must be held to close limits.

Applications

Typical uses. Electrical and/or thermal conductors used as structural members in applications requiring greater strength and hardness than that of cast coppers C80100 to C81100

Mechanical Properties

Tensile properties. Typical data for sand-cast test bars, heat treated: tensile strength, 350 MPa (51 ksi);

yield strength, 275 MPa (40 ksi) at 0.5% extension under load; elongation, 17% in 50 mm (2 in.)

Hardness. Heat treated, 105 HB

Poisson's ratio. 0.32

Elastic modulus. Tension, 115 GPa (17×10^6 psi)

Impact strength. Izod, 41 J (30 ft · lbf); Charpy V-notch, 27 J (20 ft · lbf)

Fatigue strength. 105 MPa (15 ksi) at 10^8 cycles

Mass Characteristics

Density. 8.82 g/cm^3 (0.319 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 21 mm/m ($\frac{1}{4}$ in./ft)

Liquidus temperature. 1085 °C (1985 °F)

Solidus temperature. 1075 °C (1967 °F)

Coefficient of linear thermal expansion. 17.1 μm/m · K (9.5 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 315 W/m · K (182 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric: solution heat treated, 40 to 50% IACS at 20 °C (68 °F); precipitation hardened, 80 to 90% IACS at 20 °C (68 °F)

Electrical resistivity. Solution heat treated, 38.3 nΩ · m at 20 °C (68 °F); precipitation hardened, 21 nΩ · m at 20 °C (68 °F). Temperature coefficient: solution heat treated, 0.08 nΩ · m per K at 20 °C (68 °F); precipitation hardened, 0.06 nΩ · m per K at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.0

Fabrication Characteristics

Machinability. 20% of C36000 (free-cutting brass)

Weldability. Chromium copper can be silver soldered, soft soldered, or brazed; it can be carbon arc welded with copper-chromium filler rod and fused-borax flux.

Solution temperature. 1000 to 1010 °C (1830 to 1850 °F)

Aging temperature. 480 °C (900 °F)

C81800
97Cu-1.5Co-1Ag-0.4Be

Commercial Names

Previous trade name. Beryllium-copper alloy 50C, CA818

Specifications

RWMA. Class III

Chemical Composition

Composition limits. 0.30 to 0.55 Be, 1.4 to 1.7 Co, 0.8 to 0.12 Ag, 0.15 Si max, 0.20 Ni max, 0.10 Fe max, 0.10 Al max, 0.10 Sn max, 0.002 Pb max, 0.10 Zn max, 0.10 Cr max, bal Cu

Table 1 Typical mechanical properties of C81800

Consequence of exceeding impurity limits. See C82500.

Applications

Typical uses. The silver content of C81800 provides an improved surface conductivity over other RWMA Class III alloys. Typical uses are resistance welding electrode tips and holders and arms.

Precautions as health hazard. See C82500.

Mechanical Properties

Tensile properties. See Table 1.

Temper	Tensile strength		Yield strength[a]		Elongation[b], %	Hardness, HRB

Commercial Names

Previous trade name. Beryllium-copper alloy 10C, CA820

Common name. Beryllium-copper casting alloy 10C

Specifications

Government. QQ-C-390 (CA820), MIL-C-19464 (Class I)

Chemical Composition

Composition limits. 0.45 to 0.8 Be, 2.4 to 2.7 Co, 0.15 Si max, 0.20 Ni max, 0.10 Fe max, 0.10 Al max, 0.10 Sn max, 0.02 Pb max, 0.10 Zn max, 0.10 Cr max, bal Cu

Consequence of exceeding impurity limits. See C82500.

Applications

Typical uses. C82000 castings are used when a combination of high conductivity and high strength is required. Applications include resistance welding tips, holders and arms, circuit-breaker parts, switch gear parts, plunger tips for die casting, concasting molds, for continuous casting installations, soldering-iron tips, brake drums, and whenever RWMA Class III properties are required.

Precautions as health hazard. See C82500.

Mechanical Properties

Tensile properties. See Table 2.

Density. 8.62 g/cm^3 (0.311 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 1.56%

Thermal Properties

Liquidus temperature. 1090 °C (1990 °F)

Solidus temperature. 970 °C (1780 °F)

Coefficient of linear thermal expansion. 17.8 μm/m · K (9.9 μin./in. · °F) at 20 to 300 °C (68 to 572 °F)

Specific heat. 420 J/kg · K (0.10 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 218 W/m · K (126 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 48% IACS at 20 °C (68 °F)

Electrical resistivity. 359 μΩ· m at 20 °C (68 °F)

Magnetic Properties

Magnetic susceptibility. Commercial beryllium-copper casting alloys containing 0.02 to 0.8% Be exhibit magnetic susceptibility of +0.001 cgs units or less. Magnetic susceptibility varies principally with iron content--on the high side of the commercial range of iron content (0.10%), magnetic susceptibility is approximately 0.001 cgs units; on the low side of the range (0.05%), the value will be much lower (0.0001 cgs units or less). A high-temperature solution treatment of 950 °C (1750 °F) and a low aging temperature of 425 to 450 °C (800 to 850 °F) will tend to keep iron in solution and keep the alloy nonmagnetic--that is, with a magnetic susceptibility less than 0.0001 cgs units.

Nuclear Properties

Effect of neutron irradiation. See C82500.

Chemical Properties

General corrosion behavior. At elevated temperatures, beryllium is an active oxide former. Beryllium in beryllium-copper alloys will preferably form BeO when low partial pressures of oxygen are present. This causes intergranular oxidation during solution treating in air, often resulting in surface deterioration up to 0.05 mm (0.002 in.) deep. For resistance to water, chemical solutions, organic chemicals and chemical gases, and for resistance to stress-corrosion cracking, see C82500.

Fabrication Characteristics

Machinability. As-cast or TB00 temper: 30% of C36000 (free-cutting brass). TF00 temper: 40% of C36000

C82400
98Cu-1.7Be-0.3Co

Commercial Names

Previous trade name. Beryllium-copper alloy 165C; CA824

Common name. Beryllium-copper casting alloy 165C

Specifications

Government. QQ-C-390 (CA824)

Chemical Composition

Composition limits. 1.65 to 1.75 Be, 0.20 to 0.40 Co, 0.10 Ni max, 0.20 Fe max, 0.15 Al max, 0.10 Sn max, 0.02 Pb max, 0.10 Zn max, 0.10 Cr max, bal Cu

Consequence of exceeding impurity limits. See C82500.

Applications

Typical uses. C82400 was developed for use in marine service as a corrosion-resistant, pressure-tight casting material. Its lower beryllium content compared to C82500 makes this alloy the least expensive of the commercial high-strength beryllium-copper alloys. When its hardness is relatively low, C82400 exhibits greater-than-normal toughness. Typical uses include various parts for the submarine telephone cable repeater system and hydrophone, molds for forming plastics, safety tools, plunger tips for die castings, cams, bushings, bearings, valves, pump parts, and gears.

Precautions as health hazard. See C82500.

C82500
97.2Cu-2Be-0.5Co-0.25Si

Commercial Names

Previous trade name. Beryllium-copper 20C, CA825

Common name. Standard beryllium-copper casting alloy

Specifications

AMS. Investment castings: 4890

Government. Sand castings: QQ-C-390, MIL-C-19464 (class 2); centrifugal castings: QQ-C-390; precision castings: MIL-C-11866 (composition 17), MIL-C-17324; investment castings: MIL-C-22087

Other. ICI-Cu-2-10780

Chemical Composition

Composition limits. 99.5 Cu min, 1.90 to 2.15 Be, 0.35 to 0.7 Co, 0.20 to 0.35 Si, 0.20 Ni max, 0.25 Fe max, 0.15 Al max, 0.10 Sn max, 0.02 Pb max, 0.10 Zn max, 0.10 Cr max. Available with or without 0.02 to 0.10% Ti added as a grain refiner.

Consequence of exceeding impurity limits. Generally, electrical conductivity is lowered. High Fe raises magnetic susceptibility. High Sn, Zn, or Pb causes hot shortness. High Cr diminishes response to precipitation hardening.

Applications

Typical uses. Molds for forming plastics, die casting plunger tips, safety tools, cams, bushings, bearings, gears, sleeves, valves, wear parts, structural parts, resistance welding electrodes and inserts, holders, and structural members. Exhibits low casting temperature, good castability, excellent ability to reproduce fine detail in the pattern, high strength, high electrical and thermal conductivity, and excellent resistance to corrosion and wear. Can be sand, shell, ceramic, investment, permanent, pressure, and die cast. Especially suited for investment castings and often replaces ferrous castings having similar mechanical properties. Investment castings are used for communication, textile, aerospace, business machine, firearm, instrument, and ordnance parts.

Precautions in use as health hazard. Melting, casting, abrasive-wheel operations, abrasive blasting, welding, arc cutting, flame cutting, grinding, polishing, and buffing under improper conditions may raise the concentration of beryllium in the air to levels above the limits prescribed by OSHA, thus creating a potential for personnel to contract berylliosis, a chronic lung disease. Exhaust ventilation, the principal means of achieving compliances with these limits, is a specific OSHA requirement for processes involving beryllium alloys. Careful attention to the exhaust-ventilation requirements of these and any other effluent-producing operations is essential. Actual exposure of workers should be continually monitored using prescribed air-sampling and calculation methods to determine compliance or noncompliance with OSHA limits.

Mechanical Properties

Tensile properties. See Table 5 and Fig. 5.

Solidus temperature. 855 °C (1575 °F)

Incipient melting temperature. 835 °C (1535 °F)

Coefficient of linear thermal expansion. 17 μm/m · K (9.4 μin./in. · °F) at 20 to 200 °C (68 to 392 °F)

Specific heat. 420 J/kg · K (0.10 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 105 W/m · K (61 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 20% IACS at 20 °C (68 °F)

Electrical resistivity. 862 μΩ· m at 20 °C (68 °F)

Magnetic Properties

Magnetic susceptibility. Commercial beryllium-copper casting alloys with 1.6 to 2.7% Be content exhibit magnetic susceptibility of approximately +0.002 cgs units. Magnetic susceptibility varies principally with iron content. On the high side of the range for iron content (0.25%), magnetic susceptibility is greater than 0.002 cgs units. On the low side of the commercial range (0.05%), the value is much less than 0.001 cgs units. A high-temperature solution treatment of 815 °C (1500 °F) and a low aging temperature of 315 to 345 °C (600 to 650 °F) will tend to keep iron in solution and keep magnetic susceptibility below 0.002 cgs units.

Nuclear Properties

Effect of neutron irradiation. Neutron irradiation causes precipitation hardening because of thermal spikes and induced vacancies. This will affect as-cast or solution-treated tempers but have little effect on material already peak aged or overaged.

Chemical Properties

General corrosion behavior. At elevated temperatures, beryllium is an active oxide former. Beryllium in beryllium-copper alloys will preferentially form BeO when low partial pressures of oxygen are present, especially when the environment is reducing with respect to copper. This leads to preferential formation of BeO films during hot processing of alloys containing 1.6% Be or more. BeO films may be abrasive to fabricating tools, and may be removed mechanically or by pickling. The general corrosion resistance of beryllium-copper alloys is similar to that of deoxidized copper, except as indicated above.

Resistance to specific agents. Beryllium-copper alloys possess excellent resistance to atmospheric corrosion in marine, industrial, and rural environments. They have excellent resistance to organic chemicals such as alcohols, aldehydes, esters, and ketones. They are slightly more resistant to seawater than tough pitch or deoxidized copper. Resistance is good with respect to: fresh water; most organic acids, hot or cold dilute sulfuric acid, cold concentrated sulfuric acid, and cold dilute hydrochloric acid; hot or cold dilute alkalis and cold concentrated alkalis; salts, including most sulfates and chlorides. Resistance is only fair towards sulfides, especially at elevated temperatures. Resistance is poor towards: mercury and mercury compounds; nitric acid; ferric chloride, ferric sulfate, and other heavy-metal salts with oxidizing cations and strong acid anions; acid chromates; and halogens (fluorine, chlorine, bromine, and iodine), particularly at elevated temperatures.

Stress-corrosion cracking. Beryllium-copper alloys resist stress-corrosion cracking in marine and most chemical environments, even when stressed up to 90% of their 0.2% offset yield strengths. They are susceptible to stress-corrosion cracking in ammonia and halogen gas environments, especially at elevated temperature.

Fabrication Characteristics

Machinability. As-cast or TB00 temper: 30% of C36000 (free-cutting brass). Cast and aged or TF00 temper: 10 to 20%

Melting temperature. 850 to 980 °C (1575 to 1800 °F)

Common name. Beryllium-copper casting alloy 245C

Specifications

Government. QQ-C-390

Chemical Composition

Composition limits. 2.25 to 2.45 Be, 0.35 to 0.7 Co, 0.20 to 0.35 Si, 0.20 Ni max, 0.25 Fe max, 0.15 Al max, 0.10 Sn max, 0.02 Pb max, 0.10 Zn max, 0.10 Cr max, bal Cu

Consequence of exceeding impurity limits. See C82500.

Applications

Typical uses. C82600 is a beryllium-copper casting alloy intermediate in beryllium content between C82500

and C82800. It exhibits better fluidity, castability, and hardness than C82500 and better toughness and lower cost than C82800. C82600 is used primarily to produce molds for plastic parts. In pressure castings, the lower pouring temperature results in longer tool life than for similar castings of C82500.

Table 6 Typical mechanical properties of C82600

Temper	Tensile strength		Yield strength[a]		Elongation[b], %	Hardness
	MPa	ksi	MPa	ksi		
As-cast	550	80	345	50	10	86 HRB
Cast and aged[b]	825	120	725	105	2	31 HRC
TB00[c]	485	70	205	30	12	75 HRB

(a) At 0.2% offset.

(b) In 50 mm (2 in.).

(c) Aged 3 h at 345 °C (650 °F).

(d) Solution treated at 790 to 800 °C (1450 to 1475 °F)

Hardness. See Table 6.

Poisson's ratio. 0.30

Elastic modulus. Tension, 130 GPa (19×10^6 psi); shear; 50 GPa (7.3×10^6 psi)

Structure

Crystal structure. Alpha phase, face-centered cubic

Mass Characteristics

Density. 8.16 g/cm^3 (0.295 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 1.56%

Dilation during aging. Linear, 0.2%

Change in density during aging. 0.6% increase

Precautions as health hazard. See C82500.

Mechanical Properties

Tensile properties. See Table 6.

Thermal Properties

Liquidus temperature. 955 °C (1750 °F)

Solidus temperature. 855 °C (1575 °F)

Incipient melting temperature. 835 °C (1535 °F)

Coefficient of linear thermal expansion. 17 μm/m · K (9.4 μin./in. · °F) at 20 to 200 °C (68 to 392 °F)

Specific heat. 420 J/kg · K (0.10 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 100 W/m · K (58 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 19% IACS at 20 °C (68 °F)

Electrical resistivity. 907 nΩ · m at 20 °C (68 °F)

Magnetic Properties

Magnetic susceptibility. See C82500.

Nuclear Properties

Effect of neutron irradiation. See C82500.

Chemical Properties

See C82500.

Fabrication Characteristics

Machinability. As-cast or TB00 temper: 30% of C36000 (free-cutting brass). Cast and aged or TF00 temper: 10 to 20% of C36000

Melting temperature. 855 to 955 °C (1575 to 1750 °F)

Casting temperature. Light castings, 1040 to 1150 °C (1900 to 2100 °F); heavy castings, 980 to 1040 °C (1800 to 1900 °F)

Solution temperature. 790 to 800 °C (1450 to 1475 °F)

Aging temperature 345 °C (650 °F)

C82800
96.6Cu-2.6Be-0.5Co-0.3Si

Commercial Names

Previous trade name. Beryllium-copper alloy 275C, CA828

Common name. Beryllium-copper casting alloy 275C

Specifications

Government. QQ-C-390, MIL-T-16243, MIL-C-19464 (Class IV)

Other. ICI-Cu-2-10785

Chemical Composition

Composition limits. 94.8 Cu min. 2.50 to 2.75 Be, 0.37 to 0.7 Co, 0.20 to 0.35 Si, 0.20 Ni max, 0.25 Fe max, 0.15 Al max, 0.10 Sn max, 0.02 Pb max, 0.10 Zn max, 0.10 Cr max

Consequence of exceeding impurity limits. See C82500.

Applications

Typical uses. C82800 is a special-purpose, high-fluidity casting alloy developed for molds for forming plastics and other applications where the casting process should replicate finest detail with maximum fidelity and the resultant part must exhibit maximum hardness and wear resistance for a cast beryllium-copper alloy. The relative slow pouring temperature results in increased tool life during pressure casting and permanent molding. Typical users are molds for forming plastics, cams bushings, bearings, valves, pump parts sleeves, and precision cast parts for the communications, textile, aerospace, business machine, firearm, instrument, ordnance, and other industries.

Precautions in use. See C82500.

Mechanical Properties

Tensile properties. See Table 7 and Fig. 8.

Table 7 Typical mechanical properties of C82800 sand cast test bars

Temper	Tensile strength		Yield strength[(a)]		Elongation[(b)], %	Hardness
	MPa	ksi	MPa	ksi		
As-cast	550	80	345	50	10	88 HRB

Cast and aged[(c)]	860	125	760	110	2	31 HRC
TB00[(d)]	550	80	240	35	10	85 HRB
TF00[(d)(c)]	1140	165	1070	155	1	46 HRC

(a) At 0.2% offset.

(b) In 50 mm (2 in.).

(c) Aged 3 h at 345 °C (650 °F).

(d) Solution treated at 790 to 800 °C (1450 to 1475 °F)

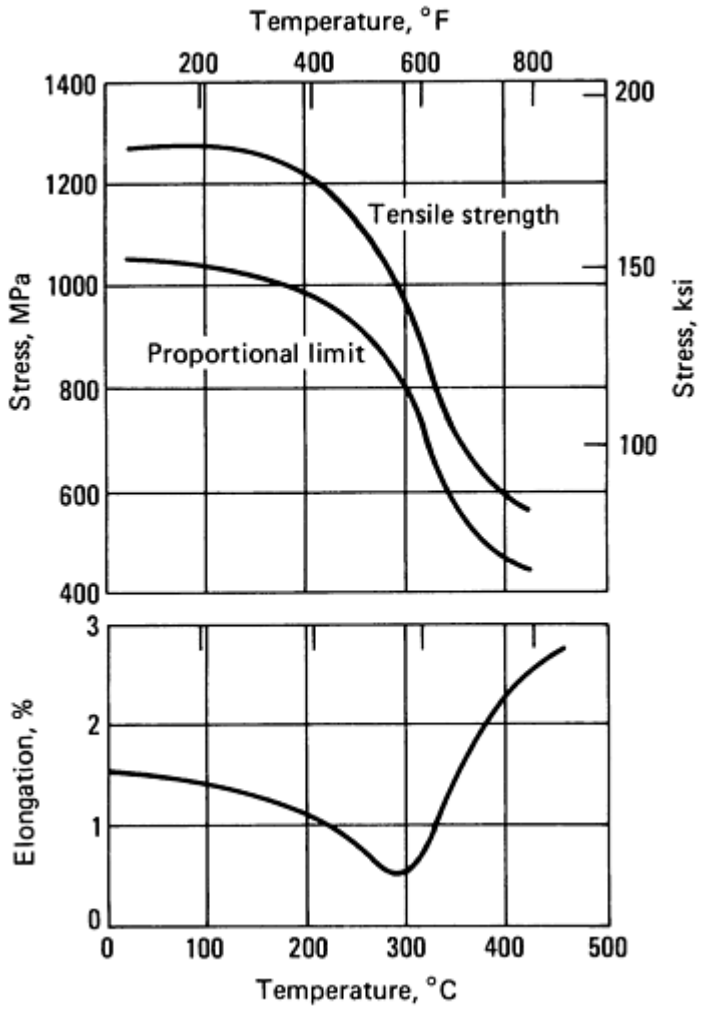

Fig. 8 Typical tensile properties of C82800, TF00 temper. Sand cast test bars were solution treated, then aged at 345 °C (650 °F).

Hardness. See Table 7 and Fig. 9 and 10.

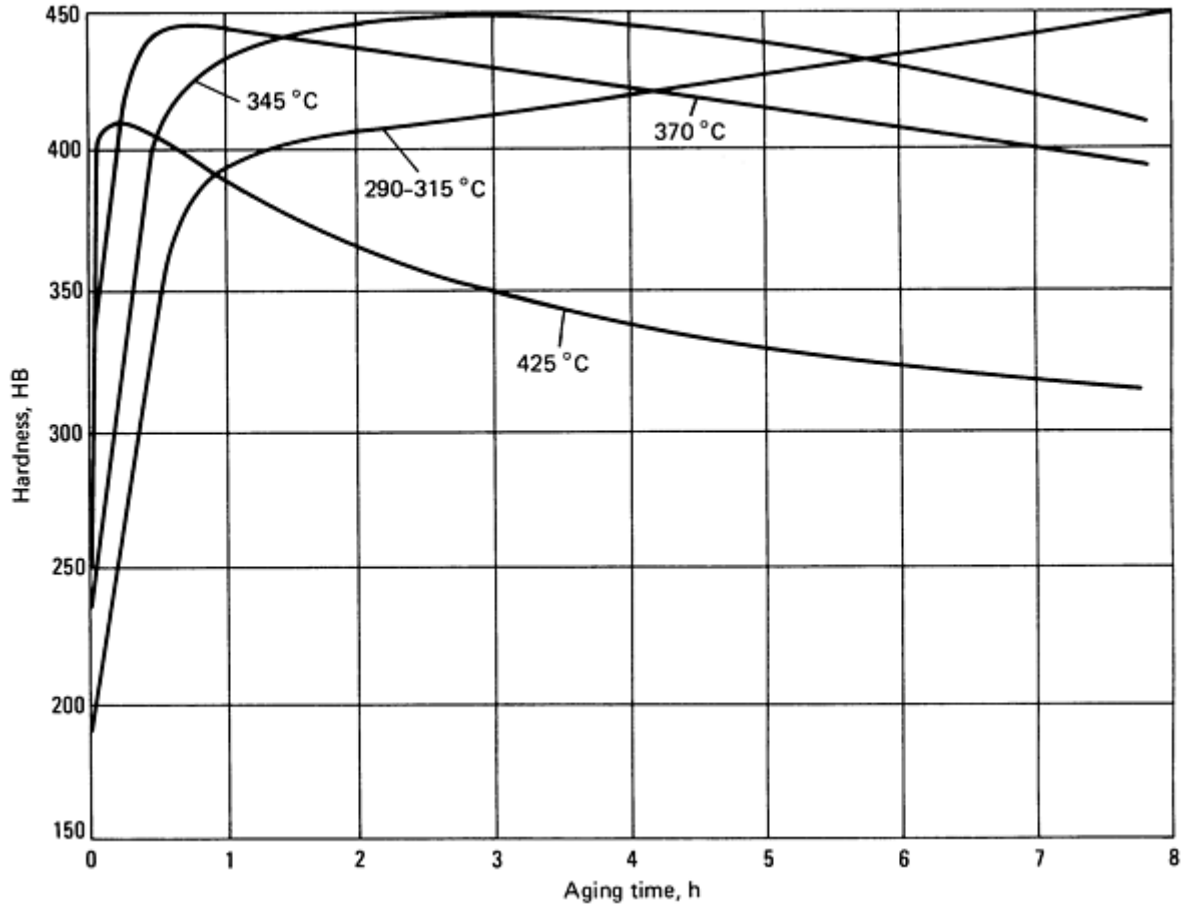

Fig. 9 Aging curves for solution-treated C82800

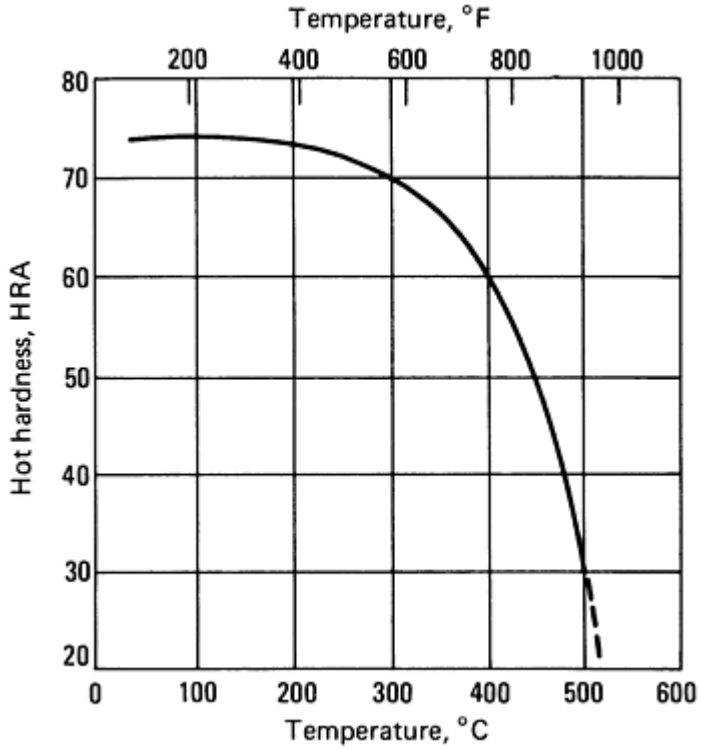

Fig. 10 Hot hardness of 82800, TF00 temper. Specimens were solution treated, then aged at 345 °C (650 °F).

Poisson's ratio. 0.30

Elastic modulus. Tension, 133 GPa (19.3×10^6 psi); shear, 51 GPa (7.4×10^6 psi)

Structure

Crystal structure. See C82500.

Mass Characteristics

Density. 8.09 g/cm^3 (0.292 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 1.56%

Linear dilation during aging. 0.2%

Change in density during aging. 0.6% increase

Thermal Properties

Liquidus temperature. 930 °C (1710 °F)

Solidus temperature. 835 °C (1535 °F)

Incipient melting temperature. 855 °C (1575 °F)

Coefficient of linear thermal expansion. 17 μm/m · K (9.4 μin./in. · °F) at 20 to 200 °C (68 to 392 °F)

Specific heat. 420 J/kg · K (0.10 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 95 W/m · K (55 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 18% IACS at 20 °C (68 °F)

Electrical resistivity. 958 μΩ· m at 20 °C (68 °F)

Magnetic Properties

Magnetic susceptibility. See C82500.

Nuclear Properties

Effect of neutron irradiation. See C82500.

Chemical Properties

See C82500.

Fabrication Characteristics

Machinability. As-cast or TB00 temper: 30% of C36000 (free-cutting brass). Cast and aged or TF00 temper: 10 to 20% of C36000

Melting temperature. 860 to 930 °C (1575 to 1710 °F)

Casting temperature. Light castings, 1040 to 1150 °C (1900 to 2100 °F); heavy castings. 965 to 1040 °C (1770 to 1900 °F)

Solution temperature. 790 to 800 °C (1450 to 1475 °F)

Aging temperature. 345 °C (650 °F). See also Fig. 9.

C83300

Commercial Names

Previous trade name. CA833

Common name. Contact metal

Specification

Ingot code number. 131

Chemical Composition

Composition limits. 92.0 to 94.0 Cu, 1.0 to 2.0 Pb, 1.0 to 2.0 Sn, 2.0 to 6.0 Zn

Copper Specification. In reporting chemical analyses by the use of instruments such as spectrograph, x-ray, and atomic absorption, copper may be indicated as balance. In reporting chemical analyses obtained by wet methods, zinc may be indicated as balance on those alloys with over 2% Zn.

Applications

Typical use. Terminal ends for electrical cables

Mechanical Properties

Tensile Properties. Typical data for as-sand-cast separately cast test bars (M01 temper); tensile strength, 220 MPa (32 ksi); yield strength, 70 MPa (10 ksi) at 0.5% extension under load; elongation, 35% in 50 mm (2 in.)

Hardness. 35 HB (500 kg), typical

Elastic modulus. Tension: 105 GPa (15×10^6 psi) at 20 °C (68 °F)

Mass Characteristics

Density. 8.8 g/cm^3 (0.318 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 16 to 21 mm/m ($\frac{3}{16}$ to $\frac{1}{4}$ in./ft)

Thermal Properties

Liquidus temperature. 1060 °C (1940 °F)

Solidus temperature. 1030 °C (1886 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 32% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. M01 temper, 35% of C36000 (free-cutting brass)

Stress-relieving temperature. 260 °C (500 °F)

C83600 85Cu-5Sn-5Pb-5Zn

Commercial Names

Common names. Ounce metal; 85-5-5-5; composition metal

Specifications

AMS. 4855

ASTM. B 30, B 62, B 271, B 505, B 584

SAE. J462 (CA836)

Ingot identification number. 115

Government. QQ-C-390 (CA836), MIL-C-15345 (Alloy 1)

Chemical Composition

Composition limits. 84.0 to 86.0 Cu, 4.0 to 6.0 Sn, 4.0 to 6.0 Pb, 4.0 to 6.0 Zn, 0.30 Fe max, 0.25 Sb max, 1.0 Ni max, 0.05 P max (1.5 max for continuous castings), 0.08 S max, 0.005 Al max, 0.005 Si max. In determining Cu min, Cu may be calculated as Cu + Ni.

Consequence of exceeding impurity limits. Aluminum and/or silicon in excess of 0.005% will adversely affect mechanical properties and pressure tightness.

Applications

Typical uses. Good general-purpose casting alloy. For castings requiring moderate strength, soundness, and good machinability, such as low-pressure valves, pipe fittings, gasoline- and oil-line fittings, fire-equipment fittings, small gears, small pump parts, general plumbing hardware

Mechanical Properties

Tensile properties. Typical data for separately cast test bars; tensile strength, 255 MPa (37 ksi); yield strength, 117 MPa (17 ksi) at 0.5% extension under load; elongation, 30% in 50 mm (2 in).

Compressive properties. Compressive strength at room temperature: 97 MPa (14 ksi) at permanent set of 0.1%; 120 MPa (17.4 ksi) at permanent set of 1%; 258 MPa (37.5 ksi) at permanent set of 10%. See also Fig. 11.

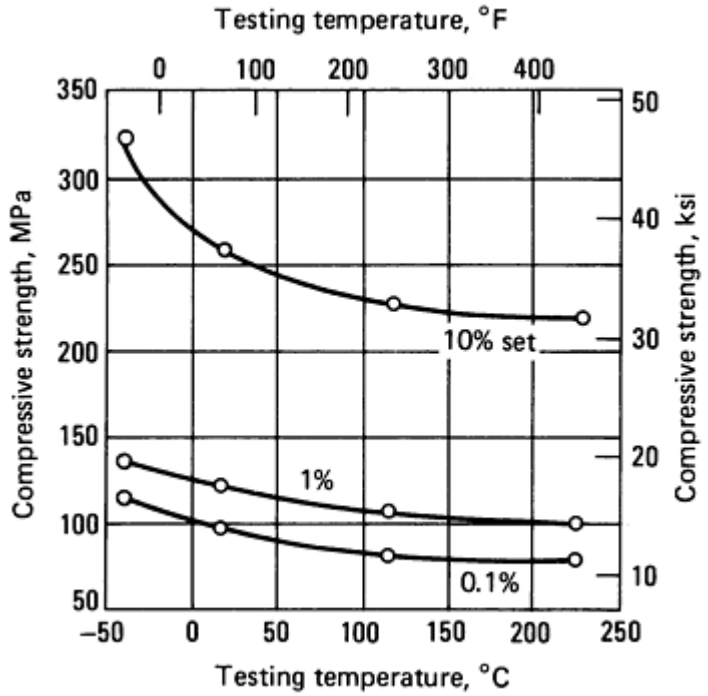

Fig. 11 Typical compressive strength for C83600

Hardness. 60 HB, typical

Elastic modulus. Tension, 83 GPa (12×10^6 psi) at 20 °C (68 °F). See also Fig. 12.

Solidus temperature. 925 °C (1700 °F)

Coefficient of linear thermal expansion. 20.2 μm/m · K (11.2 μin./in. · °F) at 20 to 100 °C (68 to 212 °F)

Specific heat. 380 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 88 W/m · K (51 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 19.6% IACS

Magnetic Properties

Magnetic permeability. 1.0

Fabrication Characteristics

Machinability. 80% of C36000 (free-cutting brass)

C85700, C85800
63Cu-1Sn-1Pb-35Zn

Commercial Names

Previous trade names. CA857, CA858

Common names. Leaded yellow brass; 63-1-1-35

Specifications

ASTM. B 30 (CA857, CA858), B 176 (CA858), B 271 (CA857), B 584 (CA857)

SAE. J462

Ingot identification number. 406

Government. QQ-C-390 (CA857), MIL-C-15345 (Alloy 3)

Chemical Composition

Composition limits. See Table 8. Addition of 0.20 to 0.30% Al improves castability.

Table 8 Composition limits of C85700 and C85800

Sand castings or centrifugal castings (C85700)	
Cu	58.0-64.0
Sn	0.50-1.50
Pb	0.80-1.50
Zn	32.0-40.0
Fe	0.7 max

Ni	1.0 max
Al	0.55 max
Si	0.05 max
Die castings (C85800)	
Cu	58.0 min
Sn	1.5 max
Pb	1.5 max
Zn	[a]
Fe	0.50 max
Al	[b]
Mn	0.25 max
Other	0.50 max[c]

(a) ASTM B 176, 31 to 41; SAE J462, 31.0 to 34.0.

(b) ASTM B 176, 0.25 max; SAE J462, 0.50 max.

(c) SAE J462 allows 0.05 Sb max, 0.50 Ni max, 0.05 As max, 0.05 S max, 0.01 P max, and 0.25 Si max before determination of total unnamed elements.

Applications

Typical uses. Bushings, hardware fittings ornamental castings, lock hardware

Mechanical Properties

Tensile properties. Typical data for separately cast test bars. Sand castings or centrifugal castings (C85700): tensile strength, 345 MPa (50 ksi); yield strength, 125 MPa (18 ksi) at 0.5% extension under load; elongation, 40% in 50 mm (2 in.). Die castings (C85800): tensile strength, 380 MPa (55 ksi); yield strength, 205 MPa (30 ksi) at 0.5% extension under load; elongation, 15% in 50 mm (2 in.)

Hardness. Sand castings or centrifugal castings (C85700), 75 HB; die castings (C85800), 102 HB

Elastic modulus. Tension: sand castings or centrifugal castings (C85700), 97 GPa (14×10^6 psi); die castings (C85800), 105 GPa (15×10^6 psi)

Mass Characteristics

Density. 8.41 g/cm^3 (0.304 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 16 mm/m ($\frac{3}{16}$ in./ft)

Thermal Properties

Liquidus temperature. 920 °C (1688 °F)

Solidus temperature. 903 °C (1657 °F)

Coefficient of linear thermal expansion. 22 μm/m · K (12 μin./in. · °F) at 20 to 260 °C (68 to 500 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 83.9 W/m · K (48.5 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 22% IACS

Magnetic Properties

Magnetic permeability. 1.0

Fabrication Characteristics

Machinability. 80% of C36000 (free-cutting brass)

C86100, C86200
64Cu-24Zn-3Fe-5Al-4Mn

Commercial Names

Common names. Manganese bronze (90,000 psi); High-strength yellow brass; CA861; CA862

Specifications

ASTM. C86100: none. C86200: Ingot, B 30; centrifugal castings, B 271; sand castings, B 584; continuous castings, B 505

SAE. J462. (Former alloy number: 430A)

Government. QQ-C-390, QQ-C-523. C86100: centrifugal castings, MIL-C-15345 (Alloy 5); investment castings, MIL-C-22087 (composition 7); sand castings, MIL-C-22229 (composition 10). C86200: investment castings, MIL-C-22087 (composition 9); precision castings, MIL-C-11866 (composition 20); sand castings, MIL-C-22229 (composition 9)

Ingot identification number. 423

Chemical Composition

Composition limits. C86100: 66.0 to 68 Cu, 4.5 to 5.5 Al, 2.0 to 4.0 Fe, 2.5 to 5.0 Mn, 1.0 Ni max, 0.2 Sn max, 0.2 Pb max, bal Zn. C86200: 60.0 to 68.0 Cu, 3.0 to 7.5 Al, 2.0 to 4.0 Fe, 2.5 to 5.0 Mn, 1.0 Ni max, 0.2 Sn max, 0.2 Pb max, bal Zn

Applications

Typical uses. Marine castings, gears, gun mounts, bushings, and bearings

Mechanical Properties

Tensile properties. Nominal. Tensile strength, 655 MPa (95 ksi); yield strength, 330 MPa (48 ksi); elongation, 20% in 50 mm (2 in.)

Compressive properties. Compressive strength, 345 MPa (50 ksi) at a permanent set of 0.1%

Hardness. 180 HB

Elastic modulus. Tension, 105 GPa (15×10^6 psi)

Impact strength. Izod, 16 J (12 ft · lbf)

Mass Characteristics

Density. 7.9 g/cm^3 (0.285 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. 2%

Thermal Properties

Liquidus temperature. 940 °C (1725 °F)

Solidus temperature. 900 °C (1650 °F)

Coefficient of linear thermal expansion. 22 μm/m · K (12 μin./in. · °F) at 20 to 260 °C (68 to 500 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 35 W/m · K (20 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 7.5% IACS at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.24 at field strength of 16 kA/m

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

Annealing temperature. 260 °C (500 °F)

C86300
64Cu-26Zn-3Fe-3Al-4Mn

Commercial Names

Common names. Manganese bronze (110,000 psi); High-strength yellow brass; CA863

Specifications

AMS. 4862

ASTM. Sand castings: B 22, B 584; centrifugal castings: B 271; continuous castings: B 505, ingot: B 30

SAE. J462

Government. QQ-C-390, QQ-C-523. Centrifugal castings, MIL-C-15345 (Alloy 6); investment castings, MIL-C-22087 (composition 9); precision castings, MIL-C-11866 (composition 21); sand castings, MIL-C-22229 (composition 8)

Ingot identification number. 424

Chemical Composition

Composition limits. 60.0 to 68.0 Cu, 2.5 to 5.0 Mn, 3.0 to 7.5 Al, 2.0 to 4.0 Fe, 0.2 Pb max, 0.2 Sn max, bal Zn

Consequence of exceeding impurity limits. Excessive Sn causes brittleness; excessive Pb or Ni decreases elongation.

Applications

Typical uses. Extra-heavy duty, high-strength alloy for gears, cams, bearings, screw-down nuts, bridge parts, hydraulic cylinder parts

Precautions in use. Not to be used in marine atmospheres, ammonia, or high-corrosive atmospheres

Mechanical Properties

Tensile properties. Nominal. Tensile strength, 820 MPa (119 ksi); yield strength, 460 MPa (67 ksi); elongation, 18% in 50 mm (2 in.)

Compressive properties. Compressive strength: 415 MPa (60 ksi) at permanent set of 0.1%; 670 MPa (97 ksi) at permanent set of 1%

Hardness. 225 HB

Elastic modulus. Tension, 105 GPa (15.5×10^6 psi)

Fatigue strength. Rotating beam, 170 MPa (25 ksi) at 100 million cycles

Impact strength. Izod, 20 J (15 ft · lbf). Charpy V-notch, 16 J (12 ft · lbf)

Creep-rupture characteristics. Stress for 0.17% creep in 10,000 h: 390 MPa (56.5 ksi) at 120 °C (250 °F); 225 MPa (32.5 ksi) at 150 °C (300 °F); 130 MPa (19 ksi) at 175 °C (350 °F); 3 MPa (0.5 ksi) at 230 °C (450 °F). See also Fig. 15 and 16.

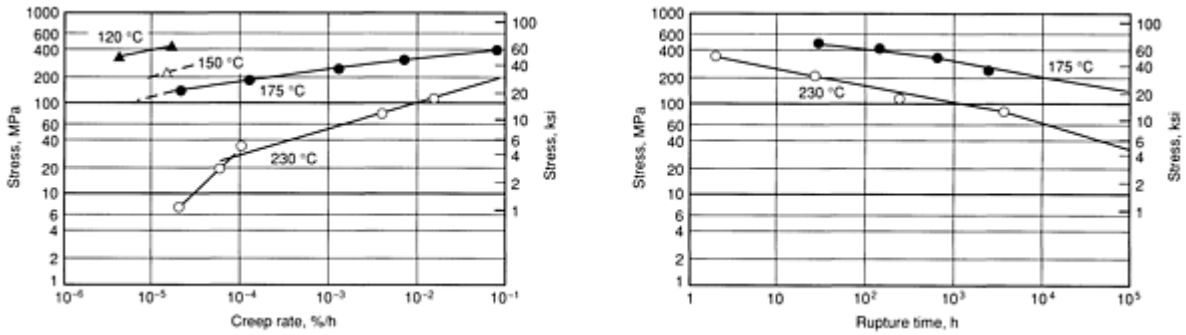

Fig. 15 Creep-rupture properties of C86300

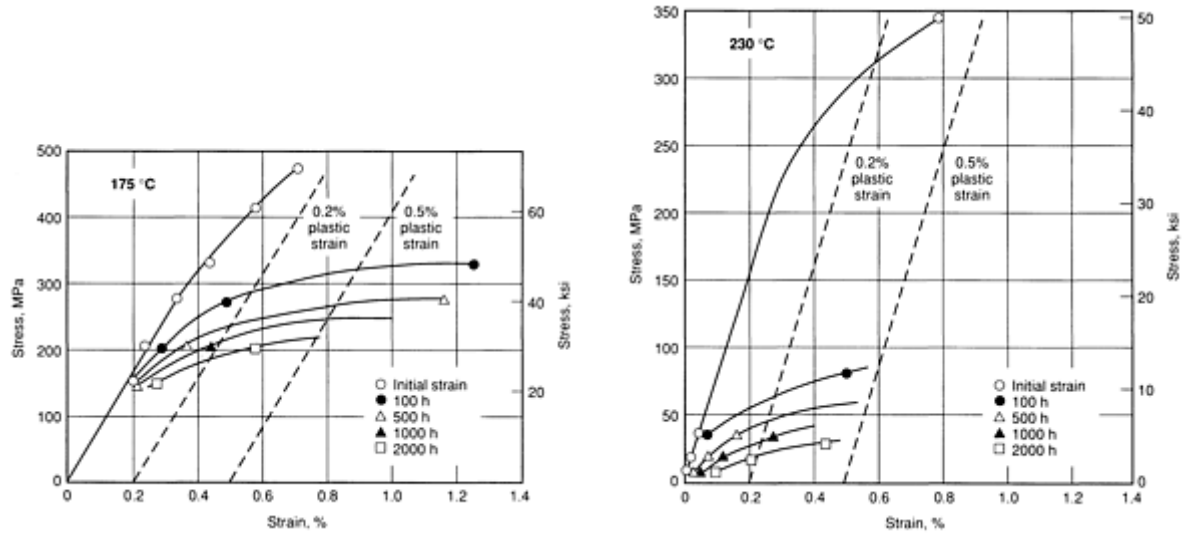

Fig. 16 Isochronous stress-strain curves for C86300

Mass Characteristics

Density. 7.7 g/cm^3 (0.278 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. 2%

Thermal Properties

Liquidus temperature. 923 °C (1693 °F)

Solidus temperature. 885 °C (1625 °F)

Coefficient of linear thermal expansion. 22 μm · K (12 μin./in. · °F) at 20 to 260 °C (68 to 500 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 36 W/m · K (21 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 9% IACS at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.09 at field strength of 16 kA/m

Fabrication Characteristics

Machinability. 8% of C36000 (free-cutting brass)

Annealing temperature. 260 °C (500 °F)

C86400
59Cu-0.75Sn-0.75Pb-37Zn-1.25Fe-0.75Al-0.5Mn

Commercial Names

Previous trade name. Leaded high-strength yellow brass; stem manganese bronze

Common name. Manganese bronze (60,000 psi)

Specifications

ASTM. Sand castings: B 584; centrifugal casting: B 271; ingot: B 30

Government. QQ-C-390, QQ-C-523

Ingot identification number. 420

Chemical Composition

Composition limits. 56.0 to 62.0 Cu, 1.5 Sn max, 0.5 to 1.5 Pb, 2.0 Fe max, 1.5 Al max, 1.5 Mn max, 1.0 Ni max, bal Zn

Applications

Typical uses. Free-machining manganese bronze for valve stems, marine castings and fittings, pump bodies

Mechanical Properties

Tensile properties. Typical tensile strength, 450 MPa (65 ksi); yield strength, 170 MPa (25 ksi); elongation, 20% in 50 mm (2 in.)

Compressive properties. Compressive strength: 150 MPa (22 ksi) at 0.1% permanent set; 600 MPa (87 ksi) at 10% permanent set

Hardness. 105 HB

Elastic modulus. Tension, 96 GPa (14×10^6 psi)

Impact strength. Izod, 40 J (30 ft · lbf). Charpy V-notch, 34 J (25 ft · lbf)

Mass Characteristics

Density. 8.32 g/cm^3 (0.301 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. 2%

Thermal Properties

Liquidus temperature. 880 °C (1615 °F)

Solidus temperature. 860 °C (1585 °F)

Coefficient of linear thermal expansion. 20 μm/m · K (11.4 μin./in. · °F) at 21 to 204 °C (70 to 400 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 88 W/m · K (51 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 22% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 60% of C36000 (free-cutting brass)

Casting temperature range. Light castings, 1040 to 1120 °C (1900 to 2050 °F); heavy castings, 955 to 1040 °C (1750 to 1900 °F)

Annealing temperature. 260 °C (500 °F)

C86500
58Cu-39Zn-1.3Fe-1Al-0.5Mn

Commercial Names

Previous trade name. High-strength yellow brass

Common name. Manganese bronze (65,000 psi)

Specifications

AMS. 4860A

ASTM. Sand castings: B 584; centrifugal castings: B 271, ingot: B 30

SAE. J 462

Government. QQ-C-390. Sand castings, MIL-C-22229 (composition 7); centrifugal castings, MIL-C-15345 (Alloy 4); investment castings, MIL-C-22087 (composition 5)

Ingot identification number. 421

Chemical Composition

Composition limits. 55.0 to 60.0 Cu, 0.4 to 2.0 Fe, 0.5 to 1.5 Al, 1.5 Mn max, 0.4 Pb max, 1.0 Sn max, 1.0 Ni max, bal Zn

Applications

Typical uses. Propeller hubs, blades, and other parts in contact with salt and fresh water, gears, liners

Mechanical Properties

Tensile properties. Typical. Tensile strength, 490 MPa (71 ksi); yield strength, 195 MPa (28 ksi); elongation, 30% in 50 mm (2 in.). See also Fig. 17.

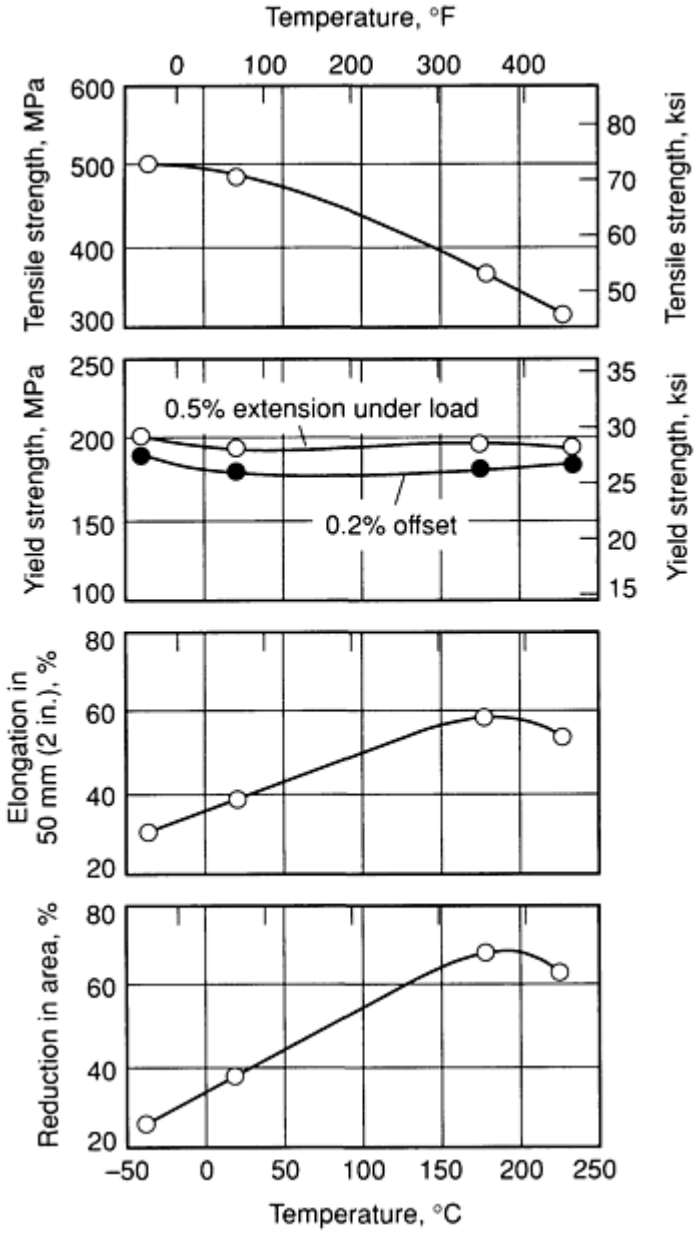

Fig. 17 Typical tensile properties of C86500

Compressive properties. Compressive strength: 165 MPa (24 ksi) at permanent set of 0.1%; 240 MPa (35 ksi) at permanent set of 1%; 545 MPa (79 ksi) at permanent set of 10%. See also Fig. 18.

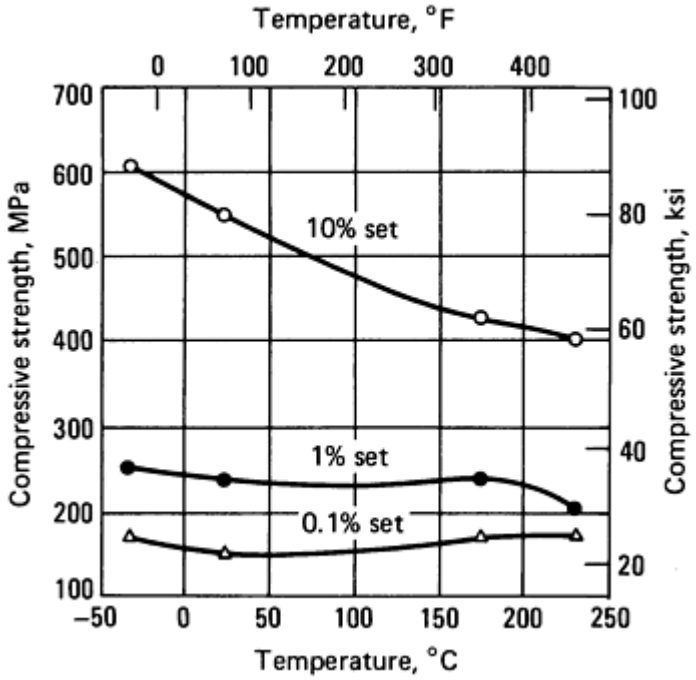

Fig. 18 Typical compressive strength of C86500

Hardness. 130 HB. See also Fig. 19.

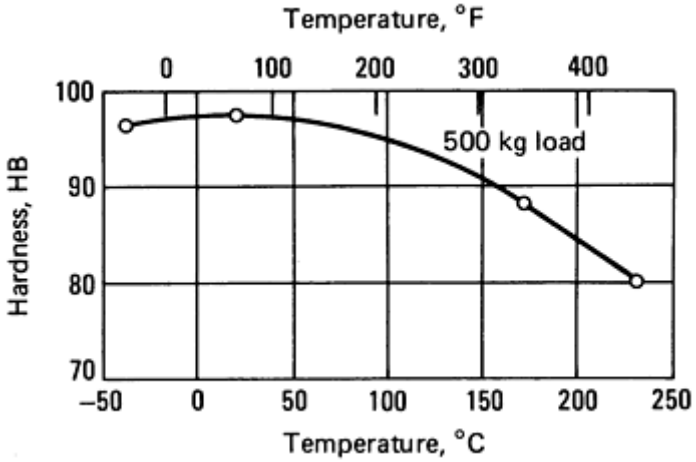

Fig. 19 Typical Brinell hardness of C86500

Elastic modulus. Tension, 105 GPa (15×10^6 psi). See also Fig. 20.

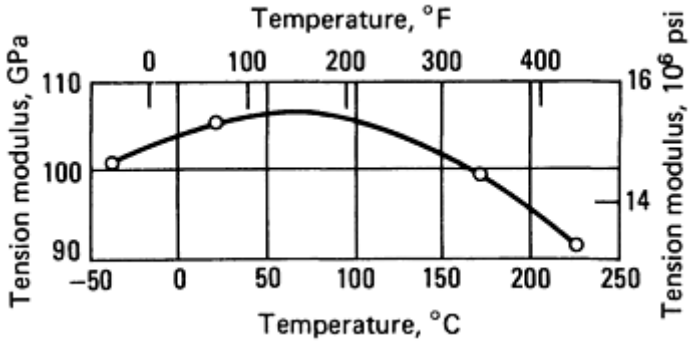

Fig. 20 Elastic modulus in tension for C86500

Fatigue strength. Reverse bending, 145 MPa (21 ksi) at 10^8 cycles. See also Fig. 21.

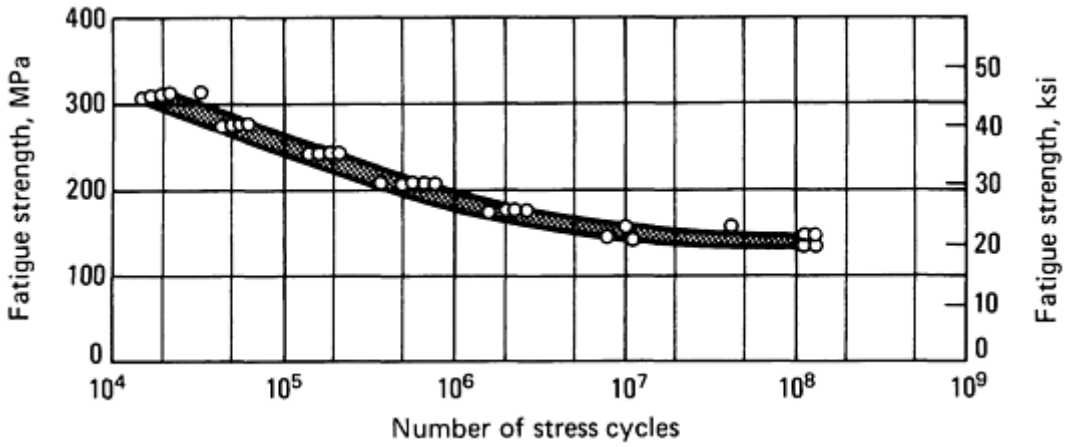

Fig. 21 Typical reverse bending fatigue curve at room temperature for C86500

Impact strength. Charpy, 42 J (31 ft · lbf). See also Fig. 22.

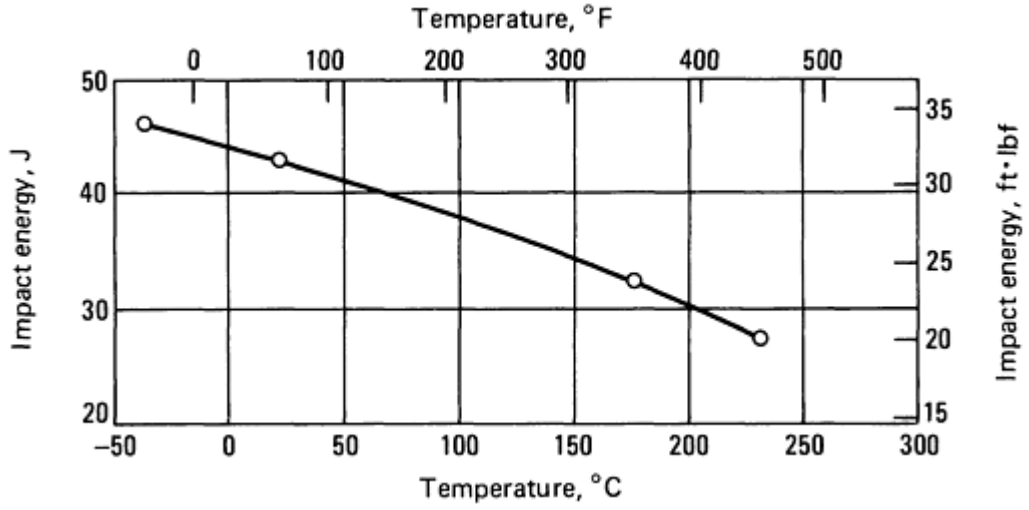

Fig. 22 Typical Charpy V-notch impact strength for C86500

Creep-rupture characteristics. Stress for 0.1% creep in 10,000 h: 190 MPa (28 ksi) at 120 °C (250 °F); 43 MPa (6.2 ksi) at 175 °C (350 °F); 12 MPa (1.7 ksi) at 230 °C (450 °F). See also Fig. 23 and 24.

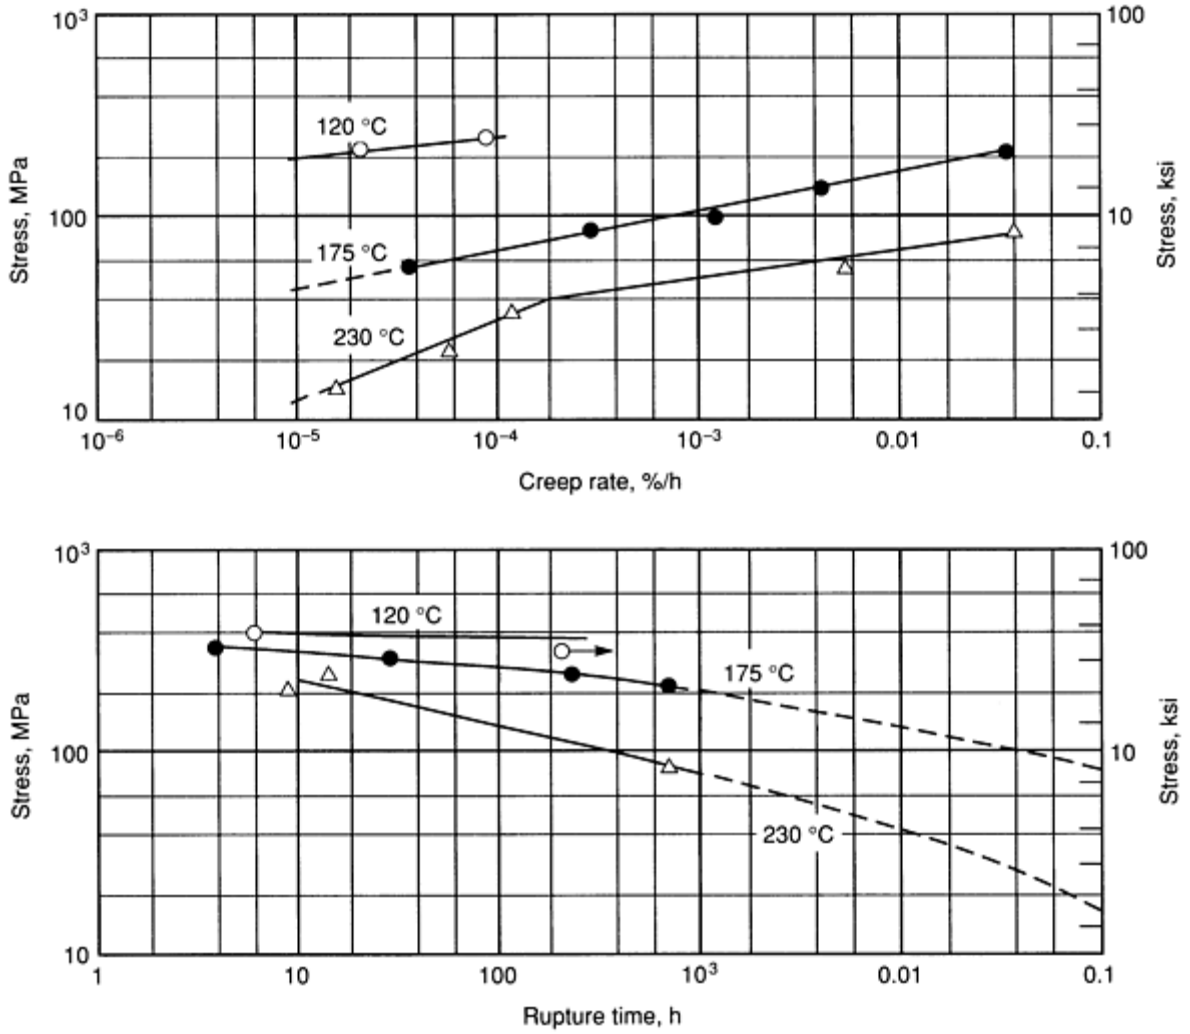

Fig. 23 Typical creep-rupture properties of C86500

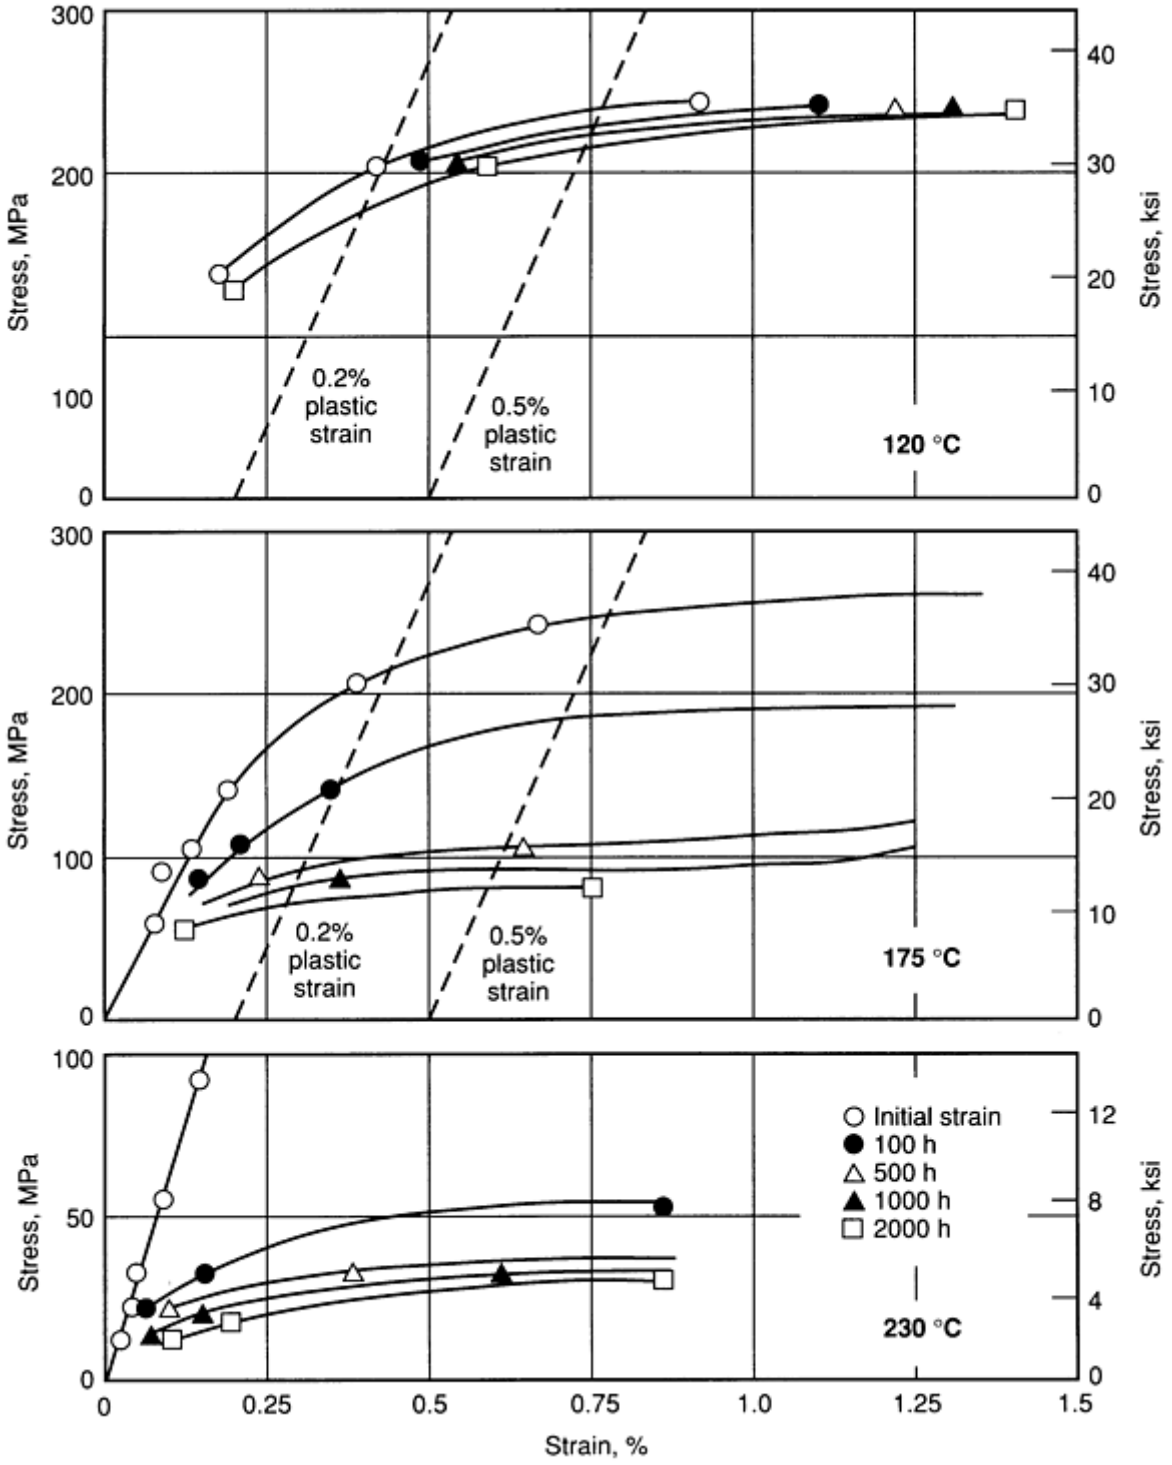

Fig. 24 Isochronous stress-strain curves for C86500

Mass Characteristics

Density. 8.3 g/cm^3 (0.299 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 1.65 to 2.15% for pouring temperature of 905 °C (1665 °F)

Thermal Properties

Liquidus temperature. 880 °C (1616 °F)

Solidus temperature. 862 °C (1583 °F)

Coefficient of linear thermal expansion. 20.3 μm/m · K (11.3 μin./in. · °F) at 21 to 93 °C (70 to 200 °F). See also Fig. 25.

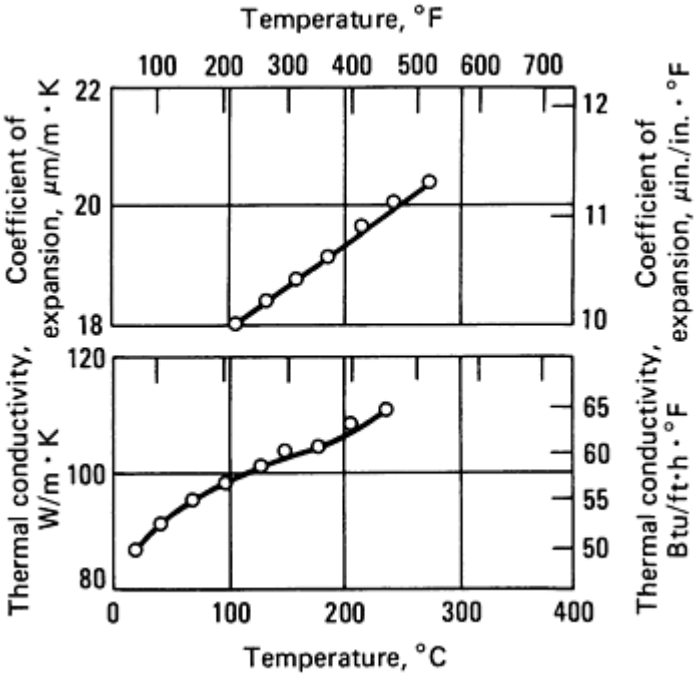

Fig. 25 Typical thermal properties of C86500

Specific heat. 373 J/kg · K (0.089 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 87 W/m · K (50.2 Btu/ft · h · °F) at 20 °C (68 °F). See also Fig. 25.

Electrical Properties

Electrical conductivity. Volumetric, 20.5% IACS at 20 °C (68 °F). See also Fig. 26.

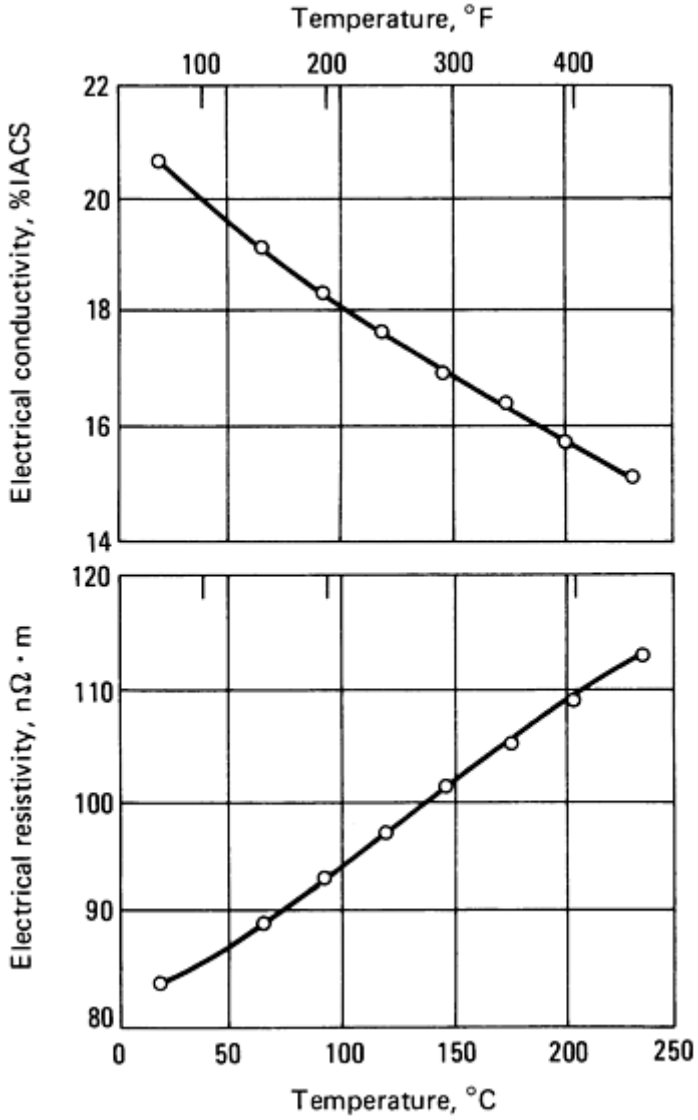

Fig. 26 Variation of electrical properties with temperature for C86500

Electrical resistivity. See Fig. 26.

Magnetic Properties

Magnetic permeability. 1.09 at field strength of 16 kA/m

Fabrication Characteristics

Machinability. 26% of C36000 (free-cutting brass)

Annealing temperature. 260 °C (500 °F)

C86700

Commercial Names

Previous trade name. CA867

Common names. Leaded high-strength yellow brass; 80,000 psi tensile manganese bronze

Specifications

ASTM. Centrifugal, B 271; ingot, B 30; sand, B 584, B 763

Chemical Composition

Composition limits. 55.0 to 60.0 Cu, 1.0 to 3.0 Al, 1.0 to 3.0 Fe, 0.5 to 1.5 Pb, 1.0 to 3.5 Mn, 1.0 Ni max, 1.5 Sn max, 30.0 to 38.0 Zn. Ingot for remelting specifications may vary from the ranges shown.

Copper and zinc specifications. In reporting chemical analyses by the use of instruments such as spectrograph, x-ray, and atomic absorption, copper may be indicated as balance. In reporting chemical analyses obtained by wet methods, zinc may be indicated as balance on those alloys with over 2% Zn.

Applications

Typical uses. High-strength free-machining manganese bronze valve stems

Mechanical Properties

Tensile properties. Typical data for as-sand-cast separately cast test bar (M01 temper): tensile strength, 585 MPa (85 ksi); yield strength, 290 MPa (42 ksi) at 0.5% extension under load; elongation, 20% in 50 mm (2 in.)

Hardness. Typically 80 HRB or 155 HB (3000 kg)

Elastic modulus. Tension: 105 GPa (15×10^6 psi) at 20 °C (68 °F)

Mass Characteristics

Density. 8.32 g/cm^3 (0.301 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 21 mm/m ($\frac{1}{4}$ in./ft)

Thermal Properties

Liquidus temperature. 880 °C (1616 °F)

Solidus temperature. 862 °C (1583 °F)

Coefficient of linear thermal expansion. 19 μm/m · K (11 μin./in. · °F) at 20 to 200 °C (68 to 392 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 32% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. M01 temper; 55% of C36000 (free-cutting brass)

Stress-relieving temperature. 260 °C (500 °F)

C86800

Commercial Names

Previous trade name. CA868

Common name. Nickel-manganese bronze

Specifications

ASTM. Die, B 176

Government. Sand, QQ-C-390; valves, WW-V-1967

Chemical Composition

Composition limits. 53.5 to 57.0 Cu, 2.0 Al max, 1.0 to 2.5 Fe, 0.20 Pb max, 2.5 to 4.0 Mn, 2.5 to 4.0 Ni, 1.0 Sn max, bal Zn. Ingot for remelting specifications may vary from the ranges shown.

Copper and zinc specifications. In reporting chemical analyses by the use of instruments such as spectrograph, x-ray, and atomic absorption, copper may be indicated as balance. In reporting chemical analyses obtained by wet methods, zinc may be indicated as balance on those alloys with over 2% Zn.

Applications

Marine fittings and propellers

Mechanical Properties

Tensile properties. Typical data for as-sand-cast separately cast test bars (M01 temper); tensile strength, 565 MPa (82 ksi); yield strength, 260 MPa (38 ksi) at 0.5% extension under load; elongation, 22% in 50 mm (2 in.)

Hardness. Typically 80 HB (3000 kg)

Elastic modulus. Tension, 105 GPa (15×10^6 psi) at 20 °C (68 °F)

Mass Characteristics

Density. 8.0 g/cm^3 (0.29 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. Patternmaker's shrinkage, 21 mm/m ($\frac{1}{4}$ in./ft)

Thermal Properties

Liquidus temperature. 900 °C (1652 °F)

Solidus temperature. 880 °C (1616 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 9.0% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. M01 temper, 30% of C36000 (free-cutting brass)

Stress-relieving temperature. 260 °C (500 °F)

C87300 (formerly C87200)

Commercial Names

Trade name. Everdur, Herculor, Navy Tombasil

Common name. Silicon bronze, 95-1-4, 92-4-4, 89-6-5

Specifications

ASTM. Centrifugal, B 271; ingot, B 30; sand, B 585, B 763

SAE. J461, J462

Government. QQ-C-390, WW-V-1967

Military. MIL-C-11866 (composition 19); MIL-C-22229

Other. Ingot code number 500A

Chemical Composition

Composition limits. 94.0 Cu min, 0.20 Pb max, 0.25 Zn max, 0.20 Fe max, 3.5 to 4.5 Si, 0.8 to 1.5 Mn

Cu + sum of named elements. 99.5 min

Applications

Typical uses. As a substitute for tin bronze where good physical and corrosion resistance are required. Bearings, bells, impellers, pump and valve components, marine fittings, statuary and art castings

Mechanical Properties

Tensile properties. Typical data for separately cast test bars: tensile strength, 380 MPa (55 ksi); yield strength, 170 MPa (25 ksi) at 0.5% extension under load; elongation, 30% in 50 mm (2 in.)

Compressive properties. Typical compressive strength, 125 MPa (18 ksi) at permanent set of 0.1%, 415 MPa (60 ksi) at permanent set of 10%

Hardness. 85 HB

Elastic modulus. Tension, 105 GPa (15×10^6 psi)

Impact strength. Izod, 45 J (33 ft · lbf)

Mass Characteristics

Density. 8.36 g/cm^3 (0.302 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 21 mm/m ($\frac{1}{4}$ in./ft)

Thermal Properties

Liquidus temperature. 916 °C (1680 °F)

Solidus temperature. 821 °C (1510 °F)

Coefficient of linear thermal expansion. Linear, 19.6 μm/m · K (10.9 μin./in. · °F) at 20 to 260 °C (68 to 500 °F)

Thermal conductivity. 28 W/m · K (16 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 6.7% IACS at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.0

Fabrication Characteristics

Machinability. 50% of C36000 (free-cutting brass)

Stress-relieving temperature. 260 °C (500 °F)

C87600

Commercial Names

Common names. Low-zinc silicon brass, CA876

Specifications

ASTM. Ingot, B 30; sand, B 584, B 763

Ingot code number. 500D

Chemical Composition

Composition limits. 88.0 Cu min, 0.50 Pb max, 4.0 to 7.0 Zn, 0.20 Fe max, 3.5 to 5.5 Si, 0.25 Mn max

Cu + sum of named elements. 99.5 min

Applications

Typical uses. Valve stems

Mechanical Properties

Tensile properties. Typical data for as-sand-cast separately cast test bars (M01 temper): tensile strength, 455 MPa (66 ksi); yield strength, 220 MPa (32 ksi) at 0.5% extension under load; elongation, 20% in 50 mm (2 in.)

Compressive strength. Typically, 415 MPa (60 ksi) at 0.1 mm/mm (0.1 in./in.) set

Elastic modulus. Tension, 115 GPa (17×10^6 psi) at 20 °C (68 °F)

Mass Characteristics

Density. 8.3 g/cm^3 (0.300 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 16 mm/m ($\frac{3}{16}$ in./ft)

Thermal Properties

Liquidus temperature. 971 °C (1780 °F)

Solidus temperature. 860 °C (1580 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 6.0% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. M01 temper; 40% of C36000 (free-cutting brass)

Stress-relieving temperature. 260 °C (500 °F)

C87610, Silicon Bronze

Specifications

ASTM. Ingot: B 30

Ingot code number. 500E

Chemical Composition

Composition limits. 90.0 Cu min, 0.20 Pb max, 3.0 to 5.0 Zn, 0.20 Fe max, 3.0 to 5.0 Si, 0.25 Mn max

Cu + sum of named elements. 99.5 min

Applications

Typical uses. Bearings, bells, impellers, pump and valve components, marine fittings, corrosion-resistant castings

Mechanical Properties

Tensile properties. Typical data for as-sand-cast separately cast test bars (M01 temper): tensile strength, 380 MPa (55 ksi); yield strength, 170 MPa (25 ksi) at 0.5% extension under load; elongation, 30% in 50 mm (2 in.)

Compressive strength. Typically 125 MPa (18 ksi) at 0.001 mm/mm (0.001 in./in.) set and 415 MPa (60 ksi) at 0.01 mm/mm (0.01 in./in.) set

Shear strength. Typically 193 MPa (28 ksi)

Hardness. Typically 85 HB (500 kg)

Impact strength. Izod: 45 J (33 ft · lbf)

Elastic modulus. Tension, 105 GPa (15×10^6 psi) at 20 °C (68 °F)

Mass Characteristics

Density. 8.4 g/cm^3 (0.302 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 21 mm/m ($\frac{1}{4}$ in./ft)

Thermal Properties

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 6.0% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. M01 temper; 40% of C36000 (free-cutting brass)

Stress-relieving temperature. 260 °C (500 °F)

C87500, C87800
82Cu-4Si-14Zn

Commercial Names

Trade name. Tombasil

Common name. Silicon brass, 82-4-14

Specifications

ASTM. C87500: ingots, B 30; centrifugal castings, B 271; sand castings, B 584. C87800: die castings, B 176

SAE. J462

Government. C 87500; sand castings, QQ-C-390; investment castings, MIL-C-22087 (composition 4). C87800: die castings, MIL-B-15894 (class 3)

Other. Ingot code 500T

Chemical Composition

Composition limits. C87500: 79.0 min Cu, 0.50 Pb max, 12.0 to 16.0 Zn, 0.50 Al max, 3.0 to 5.0 Si. C87800: 80.0 to 83.0 Cu, 0.25 Sn max, 0.15 Pb max, 0.15 Fe max, 0.15 Mn max, 0.15 Al max, 3.75 to 4.25 Si, 0.01 Mg max, 0.25 max others (total), bal Zn, but As, Sb, and S not to exceed 0.05 each, and P not to exceed 0.01

Applications

Typical uses. Bearings, gears, impellers, rocker arms, valve stems, brush holders, bearing races, small boat propellers

Mechanical Properties

Tensile properties. Typical data for separately cast test bars. Sand castings: tensile strength, 460 MPa (67 ksi); yield strength, 205 MPa (30 ksi) at 0.5% extension under load; elongation, 21% in 50 mm (2 in.). Die castings: tensile strength, 585 MPa (85 ksi); yield strength, 310 MPa (45 ksi) at 0.5% extension under load; elongation, 25% in 50 mm (2 in.)

Compressive properties. Compressive strength, 183 MPa (26.5 ksi) at a permanent set of 0.1%; 515 MPa (75 ksi) at a permanent set of 10%

Hardness. Sand cast, 134 HB; die cast, 163 HB

Elastic modulus. Tension: sand cast, 106 GPa (15.4×10^6 psi); die cast, 138 GPa (20.0×10^6 psi)

Impact strength. Charpy V-notch, 43 J (32 ft · lbf)

Fatigue strength. Rotating beam, 150 MPa (22 ksi) at 10^8 cycles. See also Fig. 27.

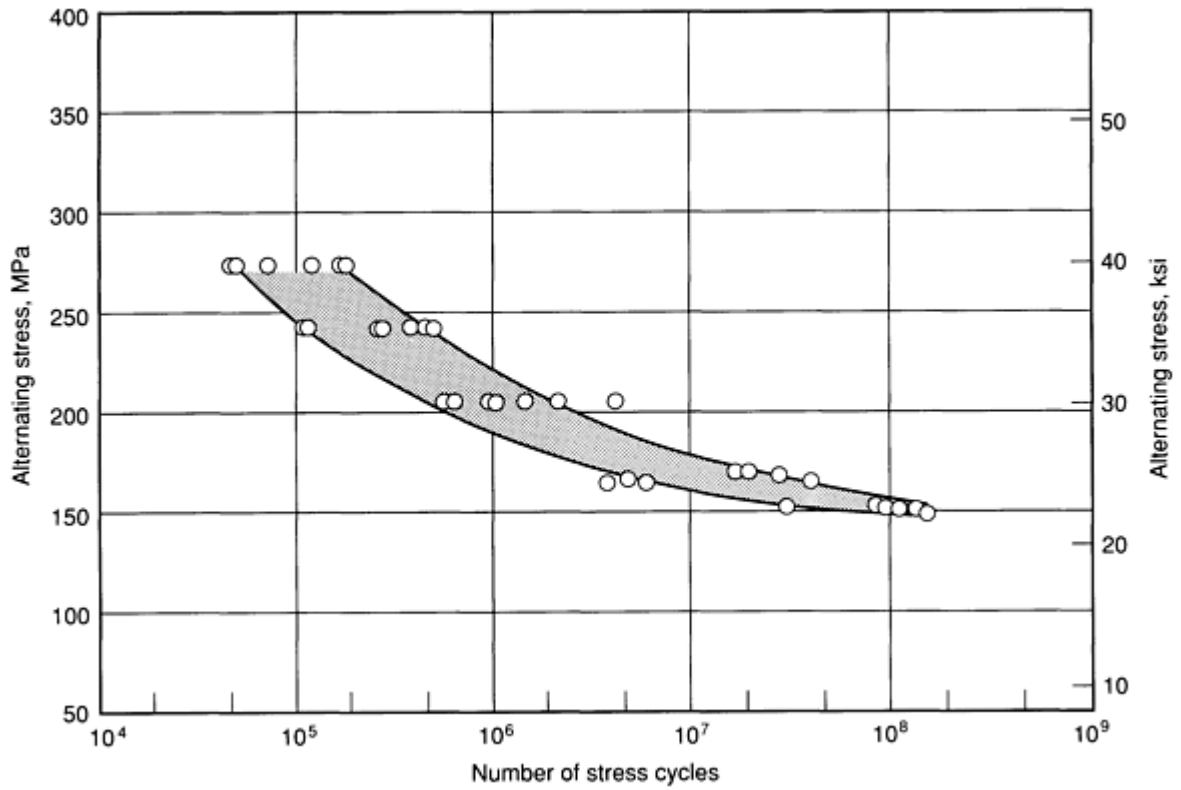

Fig. 27 Fatigue curve for C87500 and C87800

Creep-rupture characteristics. Limiting creep stress for 10^{-5}%/h: 195 MPa (28 ksi) at 175 °C (350 °F); 75 MPa (11 ksi) at 230 °C (450 °F); 9.5 MPa (1.4 ksi) at 290 °C (550 °F). Stress for rupture in 100,000 h: 125 MPa (18 ksi) at 230 °C (450 °F); 20 MPa (3 ksi)at 290 °C (550 °F)

Mass Characteristics

Density. 8.28 g/cm^3 (0.299 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 1.5 to 1.9%

Thermal Properties

Liquidus temperature. 917 °C (1683 °F)

Solidus temperature. 821 °C (1510 °F)

Coefficient of linear thermal expansion. 19.6 μm/m · K (10.9 μin./in. · °F) at 20 to 260 °C (68 to 500 °F). See also Fig. 28.

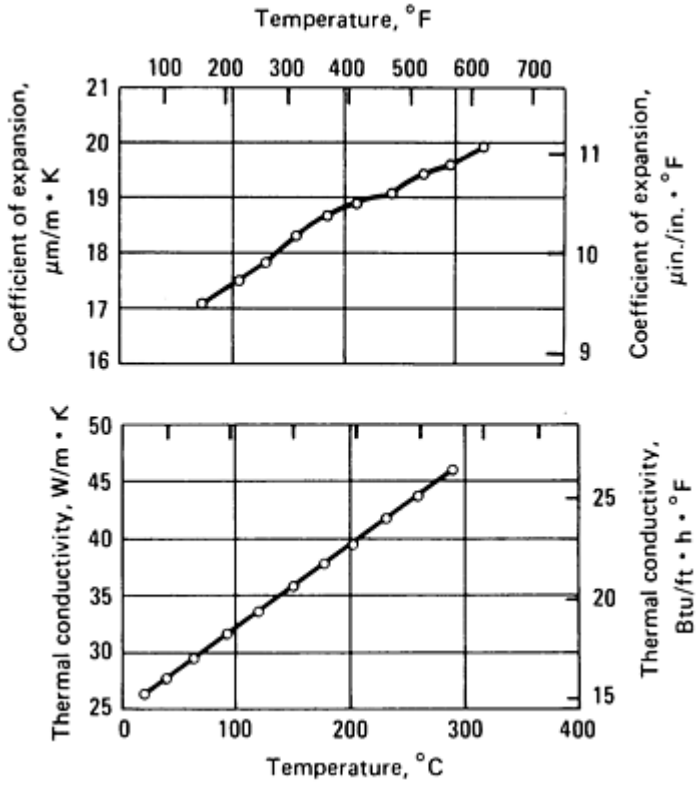

Fig. 28 Selected thermal properties of C87500 and C87800

Specific heat. 375 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 28 W/m · K (16 Btu/ft · h · °F) at 20 °C (68 °F). See also Fig. 28.

Electrical Properties

Electrical conductivity. Volumetric, 6.7% IACS at 20 °C (68 °F). See also Fig. 29.

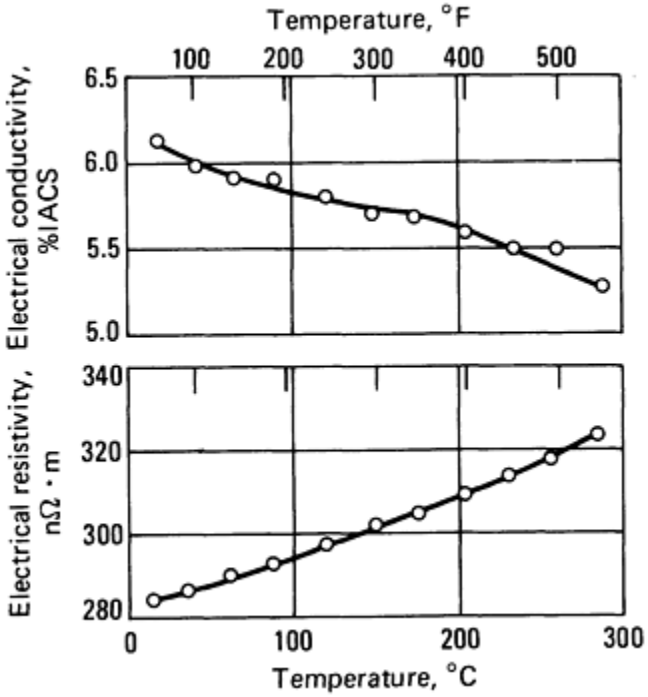

Fig. 29 Electrical conductivity and resistivity of C87500 and C87800

Electrical resistivity. 284 nΩ · m at 20 °C (68 °F). See also Fig. 29.

Magnetic Properties

Magnetic permeability. 1.0

Fabrication Characteristics

Machinability. C87500: 50% of C36000 (free-cutting brass). C87800: 40% of C36000

Casting temperature. 980 to 955 °C (1800 to 1750 °F)

Stress-relieving temperature. 260 °C (500 °F)

C87900

Commercial Names

Common names. Silicon yellow brass, CA879

Specifications

ASTM. Ingot: B 30; die: B 176

Government. MIL-B-15894

SAE. J461, J462

Ingot identification number. 500G

Chemical Composition

Composition limits. 63.0 Cu min, 0.25 Sn max, 0.25 Pb max, 30.0 to 36.0 Zn, 0.40 Fe max, 0.15 Al max, 0.8 to 1.2 Si, 0.15 Mn max, 0.50 Ni (including Co) max, 0.05 S max, 0.01 P max, 0.05 As max, 0.05 Sb max, Total named elements shall be 99.5% minimum.

Copper and zinc specifications. In reporting chemical analyses by the use of instruments such as spectrograph, x-ray, and atomic absorption, copper may be indicated as balance. In reporting chemical analyses obtained by wet methods, zinc may be indicated as balance on those alloys with over 2% zinc. In determining Cu min, copper may be calculated as Cu + Ni.

Applications

Typical uses. General-purpose die-casting alloy having moderate strength

Mechanical Properties

Tensile properties. Typical data for as-die-cast test bars (M04 temper): tensile strength, 485 MPa (70 ksi); yield strength, 240 MPa (35 ksi) at 0.2% offset; elongation, 25% in 50 mm (2 in.)

Hardness. Typically 70 HRB

Impact strength. Charpy unnotched: 68 J (50 ft · lbf)

Elastic modulus. Tension, 105 GPa (15×10^6 psi) at 20 °C (68 °F)

Mass Characteristics

Density. 8.5 g/cm^3 (0.308 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 15.6 mm/m ($\frac{3}{16}$ in./ft)

Thermal Properties

Liquidus temperature. 926 °C (1700 °F)

Solidus temperature. 900 °C (1650 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 15% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. M04 temper; 80% of C36000 (free-cutting brass)

Stress-relieving temperature. 260 °C (500 °F)

C90300
88Cu-8Sn-4Zn

Commercial Names

Common name. Tin bronze; 88-8-0-4; "G"-bronze

Specifications

ASTM. Sand castings: B 584; centrifugal castings: B 271; continuous castings: B 505; ingot: B 30

SAE. J462

Government. QQ-C-390, QQ-C-525. Sand castings: MIL-C-22229, composition 1; centrifugal castings: MIL-C-15345, alloy 8; investment castings: MIL-C-22087, composition 3; precision castings: MIL-C-11866, composition 26

Ingot identification number. 225

Chemical Composition

Composition limits. 86.0 to 89.0 Cu, 7.5 to 9.0 Sn, 3.0 to 5.0 Zn, 1.0 Ni max, 0.30 Pb max, 0.15 Fe max, 0.05 P max. (For continuous castings, 1.5 P max), 0.2 Sb max, 0.05 S max, 0.005 Si max, 0.005 Al max

Applications

Typical uses. Bearings, bushings, pump impellers, piston rings, valve components, seal rings, steam fittings, gears

Mechanical Properties

Tensile properties. Typical tensile strength, 310 MPa (45 ksi); yield strength, 145 MPa (21 ksi); elongation, 30% in 50 mm (2 in.)

Compressive properties. Compressive strength, 90 MPa (13 ksi)

Hardness. 70 HB

Elastic modulus. Tension, 97 GPa (14×10^6 psi)

Impact strength. Charpy V-notch, 19 J (14 ft · lbf)

Mass Characteristics

Density. 8.80 g/cm^3 (0.318 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. 1.6%

Thermal Properties

Liquidus temperature. 1000 °C (1830 °F)

Solidus temperature. 854 °C (1570 °F)

Coefficient of linear thermal expansion. 18 μm/m · K (10 μin./in. · °F) at 20 to 177 °C (68 to 340 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 74 W/m · K (43 Btu/ft · h · °F)

Electrical Properties

Electrical conductivity. Volumetric, 12% IACS at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.0

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

C90500
88Cu-10Sn-2Zn

C90700
89Cu-11Sn

Commercial Names

Common name. Tin bronze, 65; Phosphor gear bronze

Specifications

ASTM Continuous castings: B 505; ingot: B 30

Ingot identification number. 205

Chemical Composition

Composition limits. 88.0 to 90.0 Cu, 10.0 to 12.0 Sn, 0.15 Fe max, 0.1 to 0.3 P, 0.005 Al max, 0.30 Pb max, 0.50 Zn max, Pb + Zn + Ni, 1.0 max

Consequence of exceeding impurity limits. Ductility decreases rapidly with tin contents over 12%, with 13% a practical limit for gear applications.

Applications

Typical uses. Worm wheels and gears; bearings expected to carry heavy loads at relatively low speeds

Mechanical Properties

Tensile Properties. Typical. Sand castings: tensile strength, 305 MPa (44 ksi); yield strength, 150 MPa (22 ksi); elongation, 20% in 50 mm (2 in.). Permanent mold castings: tensile strength, 380 MPa (55 ksi); yield strength, 205 MPa (30 ksi); elongation, 16% in 50 mm or 2 in.

Hardness. Sand castings, 80 HB; permanent mold castings, 102 HB

Elastic modulus. Tension, 105 GPa (15×10^6 psi)

Fatigue strength. Rotating beam, 170 MPa (25 ksi) at 10^8 cycles

Mass Characteristics

Density. 8.77 g/cm^3 (0.317 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. 1.6%

Thermal Properties

C91700
86$\frac{1}{2}$Cu-12Sn-1$\frac{1}{2}$Ni

Commercial Names

Common name. Nickel gear bronze, 86$\frac{1}{2}$-12-0-0-1$\frac{1}{2}$

Specifications

ASTM. Ingot: B 30; sand castings: B 427

Other. Ingot code number 205

Chemical Composition

Composition limits. 85.0 to 87.5 Cu, 11.3 to 12.5 Sn, 0.25 Pb max, 1.3 to 2.0 Ni, 0.30 P max

Applications

Typical uses. Worm wheels and gears, bearings with heavy loads and relatively low speeds

Mechanical Properties

Tensile properties. Typical data for sand-cast test bars: tensile strength, 305 MPa (44 ksi); yield strength, 150 MPa (22 ksi) at 0.5% extension under load; elongation, 16% in 50 mm (2 in.). Typical data for centrifugal or permanent mold test bars: tensile strength, 415 MPa (60 ksi); yield strength, 220 MPa (32 ksi) at 0.5% extension under load; elongation, 16% in 50 mm (2 in.)

Hardness. Sand cast, 85 HB; centrifugal or permanent mold cast, 106 HB

Elastic modulus. Tension, 105 GPa (15×10^6 psi)

Mass Characteristics

Density. 8.75 g/cm^3 (0.316 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 16 mm/m ($\frac{3}{16}$ in./ft)

Thermal Properties

Liquidus temperature. 1015 °C (1860 °F)

Solidus temperature. 850 °C (1565 °F)

Coefficient of linear thermal expansion. 16.2 μm/m · K (9.0 μin./in. · °F) at 20 to 200 °C (68 to 392 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 71 W/m · K (41 Btu/ft · h · °F) at 20 °C (68 °F)

C92200

88Cu-6Sn-1$\frac{1}{2}$Pb-4$\frac{1}{2}$Zn

Commercial Names

Common name. Navy "M" bronze, steam bronze, 88-6-1$\frac{1}{2}$-4$\frac{1}{2}$

Specifications

ASTM. B 584, B 61, B 271, B 505, B 30

SAE. J462 (C92200)

Government. CA922, QQ-B-225 (Alloy number 1), MIL-B-16541, MIL-B-15345

Other. Ingot code number 245

Chemical Composition

Composition limits. 86.0 to 90.0 Cu, 5.5 to 6.5 Sn, 1.0 to 2.0 Pb, 3.0 to 5.0 Zn, 1.0 Ni max, 0.25 Fe max, 0.05 P max, (1.5 P max for continuous castings), 0.05 S max, 0.005 Si max, 0.25 Sb max

Applications

Typical uses. Component castings of valves, flanges and fittings, oil pumps, gear, bushings, bearings, backing for babbitt-lined bearings, pressure-containing parts at temperatures up to 290 °C (550 °F), and stresses up to 20 MPa (3 ksi)

Mechanical Properties

Tensile properties. Typical data for sand-cast test bars: tensile strength, 275 MPa (40 ksi); yield strength, 140 MPa (20 ksi) at 0.5% extension under load; elongation, 30% in 50 mm (2 in.). See also Fig. 30.

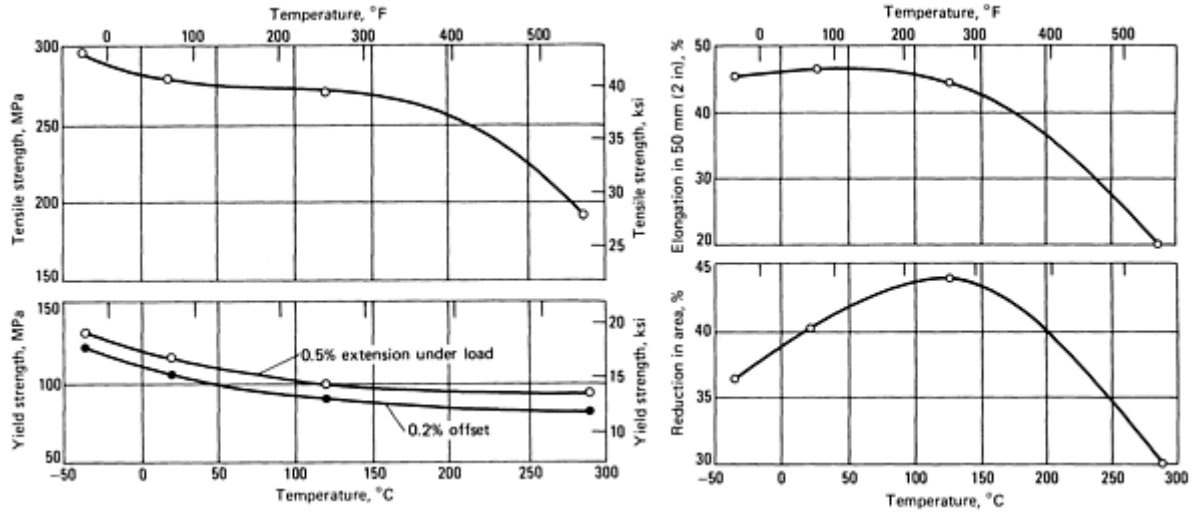

Fig. 30 Tensile properties of C92200

Compressive properties. Compressive strength, 105 MPa (15 ksi) at permanent set of 10%; 260 MPa (38 ksi) at permanent set of 0.1%. See also Fig. 31.

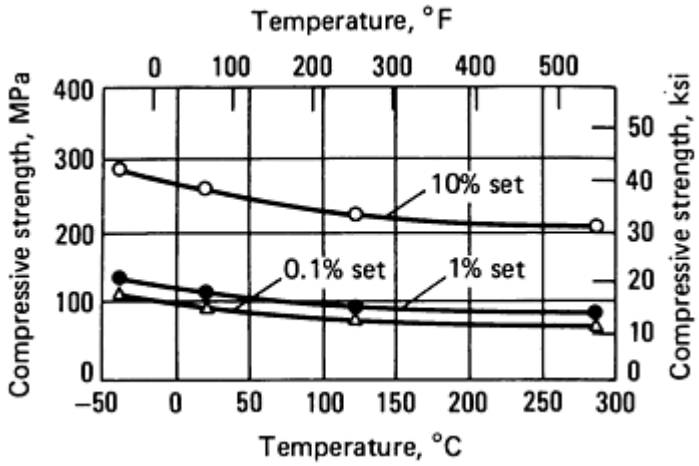

Fig. 31 Compressive strength of C92200

Hardness. 65 HB (500 kg load). See also Fig. 32.

Fatigue strength. Rotating beam, 76 MPa (11 ksi) at 10^8 cycles. See also Fig. 34.

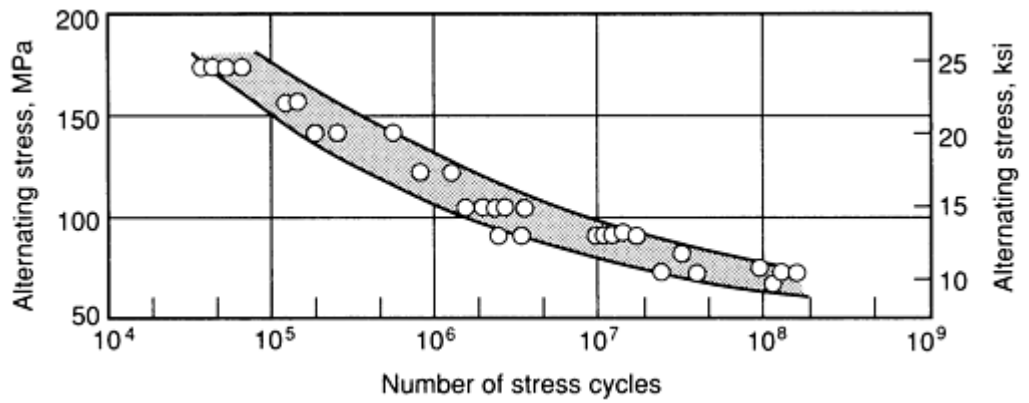

Fig. 34 Fatigue strength of C92200

Creep-rupture characteristics. Limiting creep stress for 10^{-5}%/h: 110 MPa (16.0 ksi) at 177 °C (350 °F); 77.2 MPa (11.2 ksi) at 232 °C (450 °F); 43 MPa (6.2 ksi) at 288 °C (550 °F). See also Fig. 35.

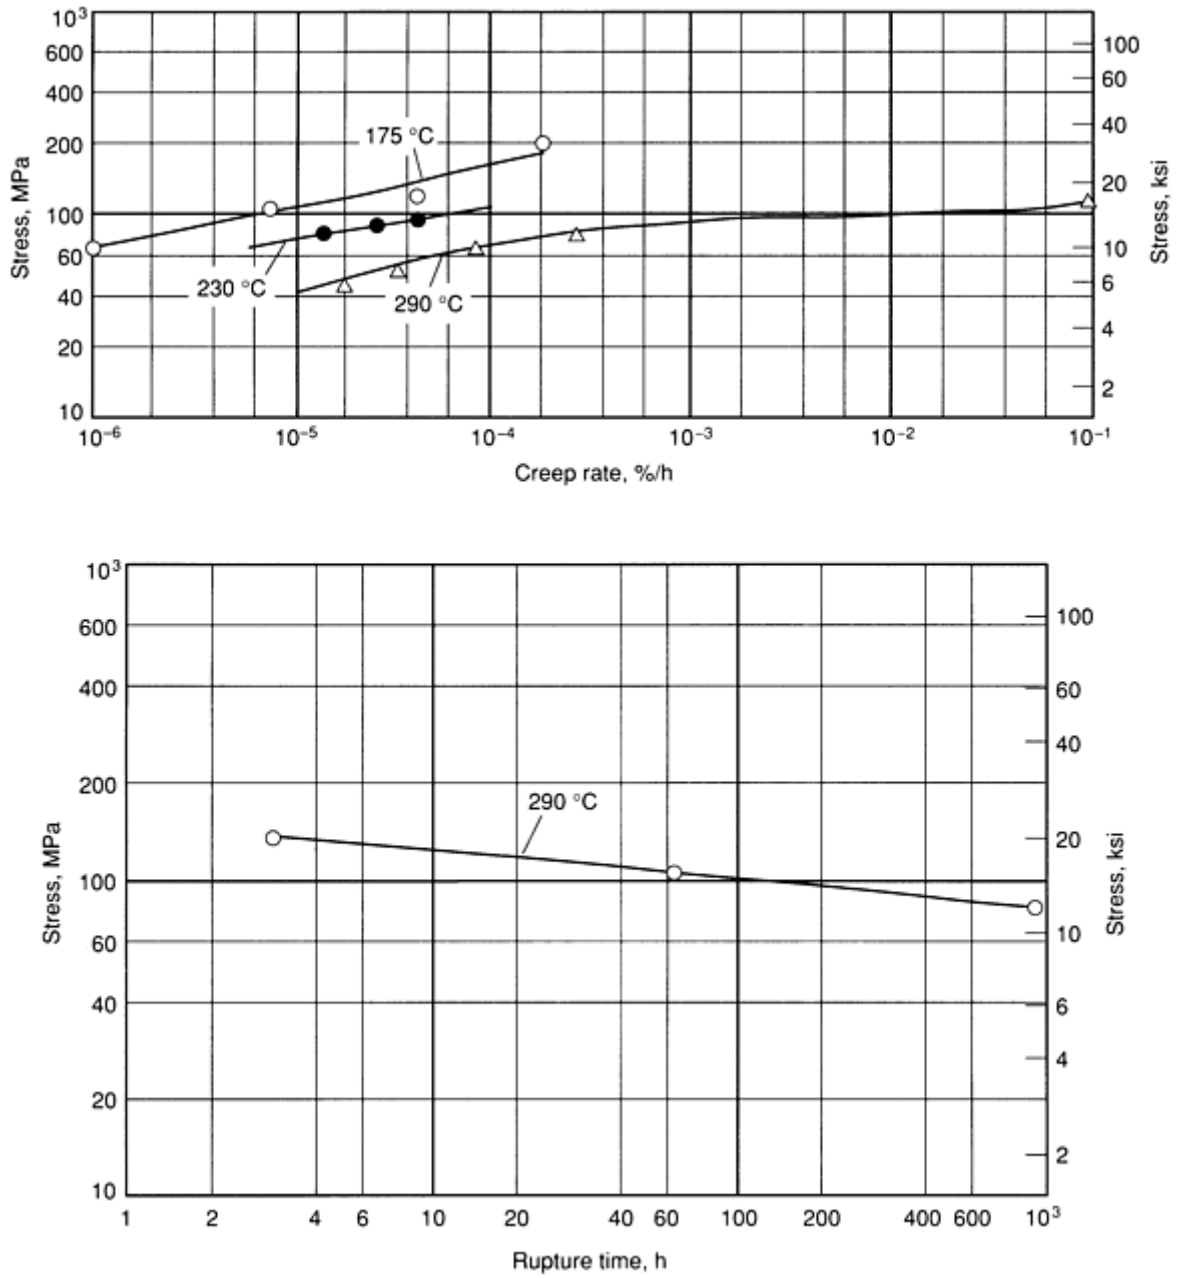

Fig. 35 Creep-rupture properties of C92200

Mass Characteristics

Density. 8.64 g/cm^3 (0.312 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 16 mm/m ($\frac{3}{16}$ in./ft)

Thermal Properties

Liquidus temperature. 990 °C (1810 °F)

Solidus temperature. 825 °C (1520 °F)

Incipient melting temperature. Pb, 315 °C (600 °F)

Coefficient of linear thermal expansion. See Fig. 36.

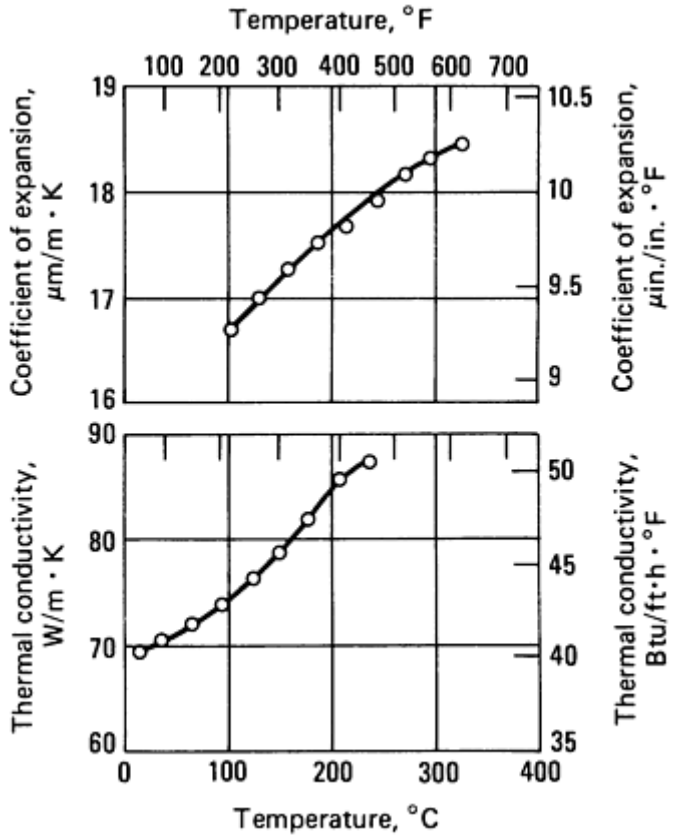

Fig. 36 Thermal properties of C92200

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 70 W/m · K (40 Btu/ft · h · °F) at 20 °C (68 °F). See also Fig. 36.

Electrical Properties

Electrical conductivity. Volumetric, 14.3% IACS at 20 °C (68 °F)

Electrical resistivity. 120 nΩ · at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.0

Fabrication Characteristics

Machinability. 42% of C36000 (free-cutting brass)

Weldability. Soldering: excellent. Brazing: excellent, but strain must be avoided during brazing and subsequent cooling because brazing is performed at temperatures within the hot short range. Oxyfuel gas welding and all forms of arc welding are not recommended.

Stress-relieving temperature. 260 °C (500 °F)

C92300
87Cu-8Sn-1Pb-4Zn

Commercial Names

Common names. Leaded tin bronze, leaded Navy "G"-bronze, 87-8-1-4

Specifications

ASTM. Sand castings: B 584; centrifugal castings: B 271; continuous castings: B 505; ingot: B 30

SAE: J462

Government. QQ-C-390. Centrifugal castings: MIL-C-15345 (Alloy 10)

Other. Ingot code number 230

Chemical Composition

Composition limits. 85.0 to 89.0 Cu, 7.0 to 9.0 Sn, 1.0 Pb max, 2.5 to 5.0 Zn, 1.0 Ni max, 0.25 Fe max, 0.05 P max (1.5 P max for continuous castings), 0.25 Sb max, 0.05 S max, 0.005 Si max, 0.005 Al max

Applications

Typical uses. Strong general-utility structural bronze for use under severe conditions; valves, expansion joints, special high-pressure pipe fittings, steam pressure castings

Mechanical Properties

Tensile properties. Typical data for sand-cast test bars: tensile strength, 275 MPa (40 ksi); yield strength, 140 MPa (20 ksi) at 0.5% extension under load; elongation, 25% in 50 mm (2 in.)

Compressive properties. Compressive strength, 69 MPa (10 ksi) at permanent set of 0.1%; 240 MPa (35 ksi) at permanent set of 10%

Hardness. 70 HB

Elastic modulus. Tension, 97 GPa (14×10^6 psi)

Impact strength. Izod, 18.3 J (13.5 ft · lbf)

Liquidus temperature. 1000 °C (1830 °F)

Solidus temperature. 855 °C (1570 °F)

Incipient melting temperature. Pb, 315 °C (600 °F)

Coefficient of linear thermal expansion. 18 μm/m · K (10 μin./in. · °F) at 20 to 177 °C (68 to 350 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 75 W/m · K (43 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 12% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 42% of C36000 (free-cutting brass)

Weldability. Soldering: excellent. Brazing: good, but strain must be avoided during brazing and subsequent cooling because brazing is performed at temperatures within the hot short range. Oxyfuel gas welding and all forms of arc welding are not recommended.

Stress-relieving temperature. 260 °C (500 °F)

C92500
87Cu-11Sn-1Pb-1Ni

Commercial Names

Common name. Leaded tin bronze, 640; 87-11-1-0-1

Specifications

ASTM. Continuous castings: B 505; ingot: B 30

SAE. J462

Other. Ingot code number 250

Chemical Composition

Composition limits. 85.0 to 88.0 Cu, 10.0 to 12.0 Sn, 1.0 to 1.5 Pb, 0.5 Zn max, 0.8 to 1.5 Ni, 0.15 Fe max, 0.20 to 0.30 P, 0.005 Al max

Applications

Typical uses. Gears, automotive synchronizer rings

Mechanical Properties

Tensile properties. Typical data for sand-cast test bars: tensile strength, 305 MPa (44 ksi); yield strength, 140 MPa (20 ksi) at 0.5% extension under load; elongation, 20% in 50 mm (2 in.)

Hardness. 80 HB

Elastic modulus. Tension, 110 GPa (16×10^6 psi)

Mass Characteristics

Patternmaker's shrinkage. 16 mm/m ($\frac{3}{16}$ in./ft)

Thermal Properties

Incipient melting temperature. Pb, 315 °C (600 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 30% of C36000 (free-cutting brass)

Weldability. Soldering: excellent. Brazing: good, but strain must be avoided during brazing and subsequent cooling because brazing is performed at temperatures within the hot short range. Oxyfuel gas welding and all forms of arc welding are not recommended.

Stress-relieving temperature. 260 °C (500 °F)

C92600
87Cu-10Sn-1Pb-2Zn

Commercial Names

Common name. Leaded tin bronze

Specifications

Ingot code number. 215

Chemical Composition

Composition limits. 86.0 to 88.5 Cu, 9.3 to 10.5 Sn, 0.8 to 1.2 Pb, 1.3 to 2.5 Zn, 0.75 Ni max, 0.15 Fe max, 0.25 Sb max, 0.05 S max, 0.005 Si max, 0.03 P max, 0.005 Al max

Applications

Typical uses. Commercial bronze for high-duty bearings where wear resistance is essential; strong general-utility structural bronze for use under severe conditions; bolts, nuts, gears; heavy-pressure bearings and bushings to use against hardened steel; valves, expansion joints, special high-pressure pipe fittings; pump pistons; elevator components; steam pressure castings

Mechanical Properties

Tensile properties. Typical data for sand-cast test bars: tensile strength, 304 MPa (44 ksi); yield strength, 140 MPa (20 ksi) at 0.5% extension under load; elongation, 30% in 50 mm (2 in.)

Compressive properties. Compressive strength, 85 MPa (12 ksi) at permanent set of 0.1%; 275 MPa (40 ksi) at permanent set of 10%

Hardness. 78 HRF, 72 HB

Elastic modulus. Tension, 105 GPa (15×10^6 psi)

Impact strength. Izod, 9 J (7 ft · lbf)

Mass Characteristics

Density. 8.70 g/cm^3 (0.315 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 16 mm/m ($\frac{3}{16}$ in./ft)

Thermal Properties

Liquidus temperature. 980 °C (1800 °F)

Solidus temperature. 845 °C (1150 °F)

Incipient melting temperature. Pb, 315 °C (600 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 9% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 40% of C36000 (free-cutting brass)

Weldability. Soldering: excellent. Brazing: good, but strain must be avoided during brazing and subsequent cooling because brazing is done at temperatures within the hot short range. Oxyfuel gas welding and all forms of arc welding are not recommended.

Stress-relieving temperature. 260 °C (500 °F)

C92700
88Cu-10Sn-2Pb

Commercial Names

Common name. Leaded tin bronze, 88-10-2-0

Specifications

ASTM. Continuous castings: B 505; ingot: B 30

SAE. J462

Other. Ingot code number 206

Chemical Composition

Composition limits. 86.0 to 89.0 Cu, 9.0 to 11.0 Sn, 1.0 to 2.5 Pb, 0.7 Zn max 1.0 Ni max, 0.15 Fe max, 0.25 P max, 0.005 Al max

Applications

Typical uses. Bearings, bushings, pump impellers, piston rings, valve components, steam fittings, gears

Mechanical Properties

Tensile properties. Typical data for sand-cast test bars: tensile strength, 290 MPa (42 ksi); yield strength, 145 MPa (21 ksi) at 0.5% extension under load; elongation, 20% in 50 mm (2 in.)

Hardness. 77 HB

Elastic modulus. Tension, 110 GPa (16×10^6 psi)

Mass Characteristics

Density. 8.8 g/cm^3 (0.317 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 16 mm/m ($\frac{3}{16}$ in./ft)

Thermal Properties

Liquidus temperature. 980 °C (1800 °F)

Solidus temperature. 845 °C (1550 °F)

Incipient melting temperature. Pb, 315 °C (600 °F)

Coefficient of linear thermal expansion. 18 μm/m · K (10 μin./in. · °F) at 20 to 177 °C (68 to 350 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 11% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 45% of C36000 (free-cutting brass)

Weldability. Soldering: excellent. Brazing: good, but parts must not be strained during brazing or subsequent cooling because brazing is done at temperatures within the hot short range. Oxyfuel gas welding and all forms of arc welding are not recommended.

Stress-relieving temperature. 260 °C (500 °F)

C92900
84Cu-10Sn-2$\frac{1}{2}$Pb-3$\frac{1}{2}$Ni

Commercial Names

Common name. Leaded nickel-tin bronze, 84-10-2$\frac{1}{2}$-0-3$\frac{1}{2}$

Specifications

ASTM. Sand and centrifugal castings: B 427; continuous castings: B 505; ingot: B 30

SAE. J462

Chemical Composition

Composition limits. 81.0 to 85.5 Cu, 9.0 to 11.0 Sn, 2.0 to 3.2 Pb, 2.8 to 4.0 Ni, 0.50 P max, 0.50 max other (total)

Applications

Typical uses. Gears, wear plates and guides, cams

Mechanical Properties

Tensile properties. Typical data for sand-cast test bars: tensile strength, 325 MPa (47 ksi); yield strength, 180 MPa (26 ksi) at 0.5% extension under load; elongation, 20% in 50 mm (2 in.)

Hardness. 80 HB

Elastic modulus. Tension, 97 GPa (14×10^6 psi)

Impact strength. Izod, 16 J (12 ft · lbf)

Mass Characteristics

Density. 8.79 g/cm^3 (0.318 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 16 mm/m ($\frac{3}{16}$ in./ft)

Thermal Properties

Liquidus temperature. 1030 °C (1887 °F)

Solidus temperature. 860 °C (1575 °F)

Incipient melting temperature. Pb, 315 °C (600 °F)

Coefficient of linear thermal expansion. 17 μm/m · K (9.5 μin./in. · °F) at 20 to 200 °C (68 to 392 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 58.2 W/m · K (33.6 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 9.2% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 40% of C36000 (free-cutting brass)

Weldability. Soldering: excellent. Brazing: good, but parts must not be strained during brazing or subsequent cooling because brazing is done at temperatures within the hot short range. Oxyfuel gas welding and all forms of arc welding are not recommended.

Stress-relieving temperature. 260 °C (500 °F)

C93200
83Cu-7Sn-7Pb-3Zn

Commercial Names

Common name. High-leaded tin bronze; bearing bronze 660; 83-7-7-3

Specifications

ASTM. Sand castings: B 584; centrifugal castings, B 271; continuous castings: B 505; ingot: B 30

SAE. J462

Government. QQ-C-390; QQ-C-525; QQ-L-225 (Alloy 12); MIL-C-15345 (Alloy 17); MIL-C-11553 (Alloy 12); MIL-B-16261 (Alloy VI)

Other. Ingot code number 315

Chemical Composition

Composition limits. 81.0 to 85.0 Cu, 6.3 to 7.5 Sn, 6.0 to 8.0 Pb, 2.0 to 4.0 Zn, 0.50 N max, 0.20 Fe max, 0.15 P max, 0.35 Sb max, 0.08 S max, 0.003 Si max. In determining Cu, minimum may be calculated as Cu + Ni.

Other phosphorus specifications. 1.5 P max for continuous castings; 0.50 P max for permanent mold castings

Applications

Typical uses. General-utility bearings and bushings, automobile fittings

Mechanical Properties

Tensile properties. Typical data for sand-cast test bars: tensile strength, 240 MPa (35 ksi); yield strength, 125 MPa (18 ksi) at 0.5% extension under load; elongation, 20% in 50 mm (2 in.)

Compressive properties. Compressive strength, 315 MPa (46 ksi) at permanent set of 10%

Hardness. 65 HB

Elastic modulus. Tension, 100 GPa (14.5×10^6 psi)

Impact strength. Izod, 8 J (6 ft · lbf)

Fatigue strength. Reverse bending, 110 MPa (16 ksi) at 10^8 cycles

Mass Characteristics

Density. 8.93 g/cm^3 (0.322 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 18 mm/m ($\frac{7}{32}$ in./ft)

Thermal Properties

Liquidus temperature. 975 °C (1790 °F)

Solidus temperature. 855 °C (1570 °F)

Incipient melting temperature. Pb, 315 °C (600 °F)

Coefficient of linear thermal expansion. 18 μm/m · K (10 μin./in. · °F) at 0 to 100 °C (32 to 212 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 59 W/m · K (34 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 12% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. 70% of C36000 (free-cutting brass)

Weldability. Soldering: excellent. Brazing: good, but parts must not be strained during brazing or subsequent cooling because brazing is done at temperatures within the hot short range. Oxyfuel gas welding and all forms of arc welding are not recommended.

Stress-relieving temperature. 260 °C (500 °F)

C93400

Commercial Names

Common name. High-leaded tin bronze, CA934, 84-8-8-0

Specifications

ASTM. Continuous, B 505; ingot, B 30

Government. QQ-C-390; MIL-C-22087; MIL-C-22229

Ingot identification number. 310

Chemical Composition

Composition limits. 82.0 to 85.0 Cu, 7.0 to 9.0 Sn, 7.0 to 9.0 Pb, 0.8 Zn max, 0.20 Fe max, 0.50 Sb max, Ni (including Co) 1.0 max, 0.08 S max, 0.50 P max (for continuous castings, phosphorus shall be 1.5% maximum), 0.005 Al max, 0.005 Si max. Ingot for remelting specifications vary from the ranges given.

Copper and zinc specifications. In reporting chemical analyses by the use of instruments such as spectrograph, x-ray, and atomic absorption, copper may be indicated as balance. In reporting chemical analyses obtained by wet methods, zinc may be indicated as balance on those alloys with over 2% zinc.

Applications

Typical uses. Bearings and bushings

Mechanical Properties

Tensile properties. Typical data for as-sand-cast separately cast test bars (M01 temper): tensile strength, 220 MPa (32 ksi); yield strength, 110 MPa (16 ksi) at 0.5% extension under load; elongation, 20% in 50 mm (2 in.)

Hardness. Typically 60 HB (500 kg)

Compressive strength. 330 MPa (48 ksi) at 0.1 mm/mm (0.1 in./in.) set

Impact strength. Izod, 6.8 J (5 ft · lbf)

Proportional limit. 55 MPa (8 ksi)

Fatigue strength. 100 MPa (15 ksi) at 10^8 cycles

Elastic modulus. Tension, 76 GPa (11×10^6 psi) at 20 °C (68 °F)

Mass Characteristics

Density. 8.87 g/cm^3 (0.320 lb/in.^{3} at 20 °C (68 °F)

Volume change on freezing. Patternmaker's shrinkage, 16 mm/m ($\frac{3}{16}$ in./ft)

Thermal Properties

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 12% IACS at 20 °C (68 °F)

Fabrication Characteristics

Machinability. M01 temper; 70% of C36000 (free-cutting brass)

Stress-relieving temperature. 260 °C (500 °F)

C93500
85Cu-5Sn-9Pb-1Zn

Commercial Names

Common name. High-leaded tin bronze, 85-5-9-1

Specifications

ASTM. Sand castings: B 584; centrifugal castings, B 271; continuous castings, B 505; ingot, B 30

SAE. J462

Government. QQ-C-390; QQ-L-225 (Alloy 14); MIL-B-11553B (Alloy 14)

Other. Ingot code number 326

Chemical Composition

Composition limits. 83.0 to 86.0 Cu, 4.5 to 6.0 Sn, 8.0 to 10.0 Pb, 2.0 Zn max, 0.50 Ni max, 0.20 Fe max, 0.02 P max (1.5 P max for continuous castings), 0.30 Sb max, 0.08 S max, 0.003 Si max. In determining Cu, minimum may be calculated as Cu + Ni.

Applications

Typical uses. Small bearings and bushings bronze backings for babbitt-lined automotive bearings

Mechanical Properties

Tensile properties. Typical data for sand-cast test bars: tensile strength, 220 MPa (32 ksi); yield strength, 110 MPa (16 ksi) at 0.5% extension under load; elongation, 20% in 50 mm (2 in.)

Compressive properties. Compressive strength, 90 MPa (13 ksi) at permanent set of 0.1%

Hardness. 60 HB

Elastic modulus. Tension, 100 GPa (14.5×10^6 psi)

Impact strength. Charpy V-notch or Izod, 11 J (8 ft · lbf)

Mass Characteristics

Density. 8.87 g/cm^3 (0.320 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 16 mm/m ($\frac{3}{16}$ in./ft)

Thermal Properties

Liquidus temperature. 1000 °C (1830 °F)

Solidus temperature. 855 °C (1570 °F)

Incipient melting temperature. Pb, 315 °C (600 °F)

Coefficient of linear thermal expansion. 18 μm/m · K (10 μin./in. · °F) at 20 to 200 °C (68 to 392 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 71 W/m · K (41 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 15% IACS at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.0

Fabrication Characteristics

Machinability. 70% of C36000 (free-cutting brass)

Weldability. Soldering: good. Brazing: good, but parts must not be strained during brazing or subsequent cooling because brazing is done at temperatures within the hot short range. Oxyfuel gas welding and all forms of arc welding are not recommended.

Stress-relieving temperature. 260 °C (500 °F)

C93700
80Cu-10Sn-10Pb

Commercial Names

CDA and UNS number. C93700

Common names. High-leaded tin bronze; bushing and bearing bronze; 80-10-10

Specifications

AMS. Sand and centrifugal castings: 4842

ASTM. Sand castings: B 22, B 584; centrifugal castings: B 271; continuous castings: B 505; ingot: B 30

SAE. J462

Government. QQ-C-390; MIL-B-13506 (Alloy A2)

Other. Ingot code number 305

Chemical Composition

Composition limits. 78.0 to 82.0 Cu, 9.0 to 11.0 Sn, 8.0 to 11.0 Pb, 0.70 Zn max, 0.70 Ni max, 0.15 Fe max, 0.05 P max, 0.50 Sb max, 0.08 S max, 0.003 Si max

Applications

Typical uses. Bearings for high speed and heavy pressure, pumps, impellers, applications requiring corrosion resistance, pressure-tight castings

Mechanical Properties

Tensile properties. Typical data for sand-cast test bars: tensile strength, 240 MPa (35 ksi); yield strength, 125 MPa (18 ksi) at 0.5% extension under load; elongation, 20% in 50 mm (2 in.). See also Fig. 37.

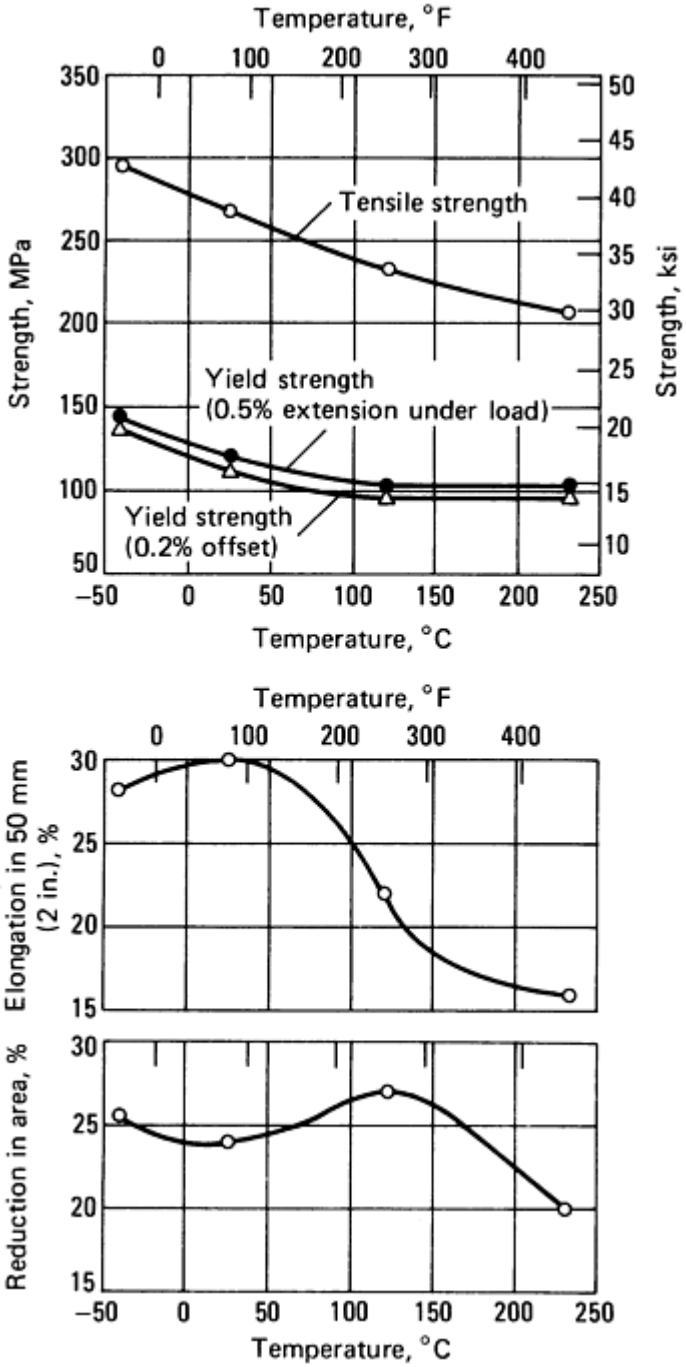

Fig. 37 Typical tensile properties of C93700 at various temperatures

Compressive properties. Compressive strength, 90 MPa (13 ksi) at permanent set of 0.1%; 325 MPa (47 ksi) at permanent set of 10%. See also Fig. 38.

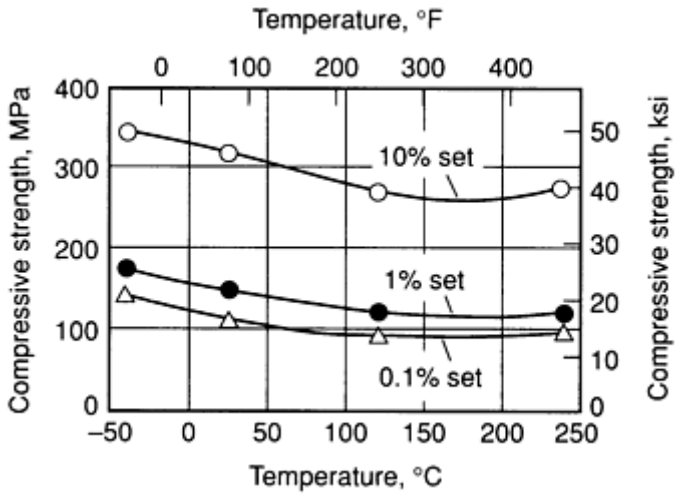

Fig. 38 Variation of compressive strength with temperature for C93700

Hardness. 60 HB

Elastic modulus. See Fig. 39.

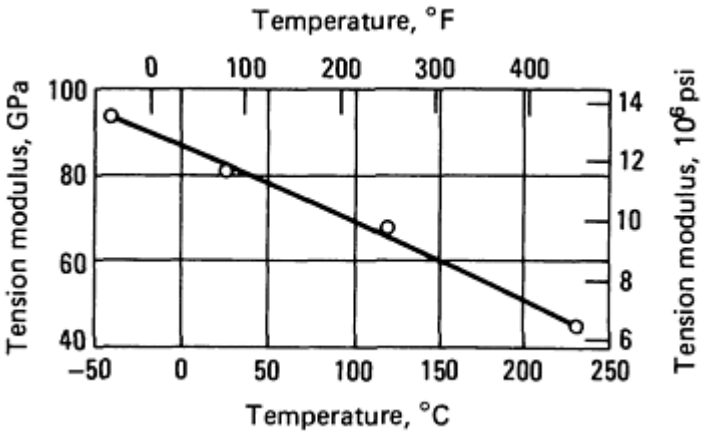

Fig. 39 Variation of elastic modulus with temperature for C93700

Impact strength. Izod, 7 J (5 ft · lbf); Charpy V-notch, 15 J (11 ft · lbf)

Fatigue strength. Reverse bending, 90 MPa (13 ksi) at 10^8 cycles. See also Fig. 40.

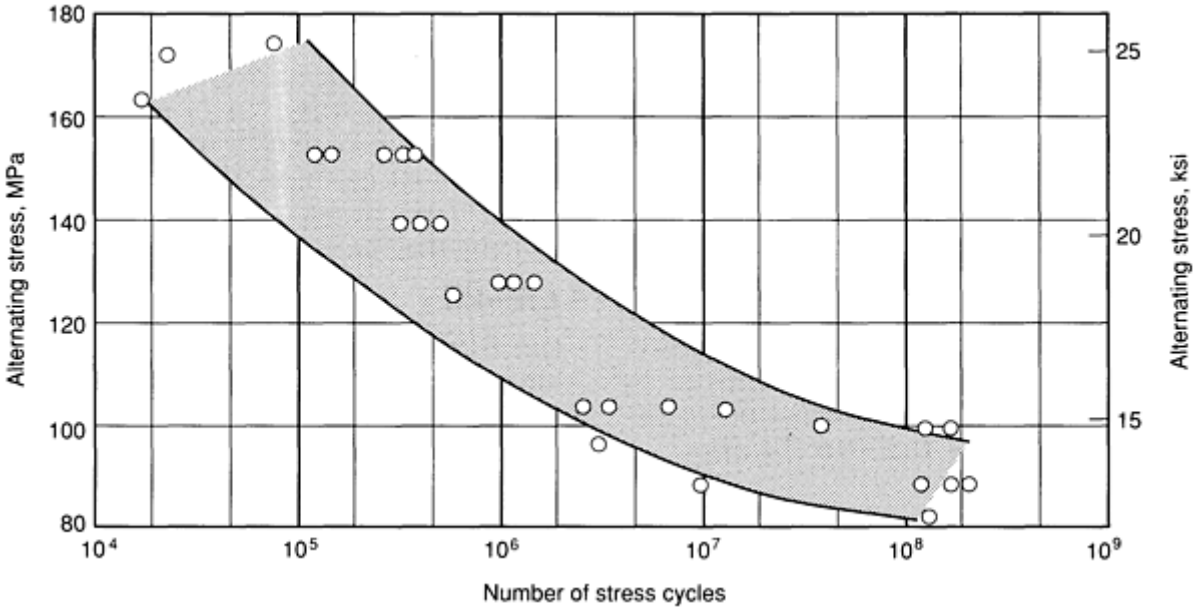

Fig. 40 Typical reverse bending fatigue curve for C93700

Creep-rupture characteristics. Limiting creep stress for 10^{-5}%/h: 71.7 MPa (10.4 ksi) at 177 °C (350 °F); 51 MPa (7.4 ksi) at 232 °C (450 °F); 12 MPa (1.8 ksi) at 288 °C (550 °F). See also Fig. 41.

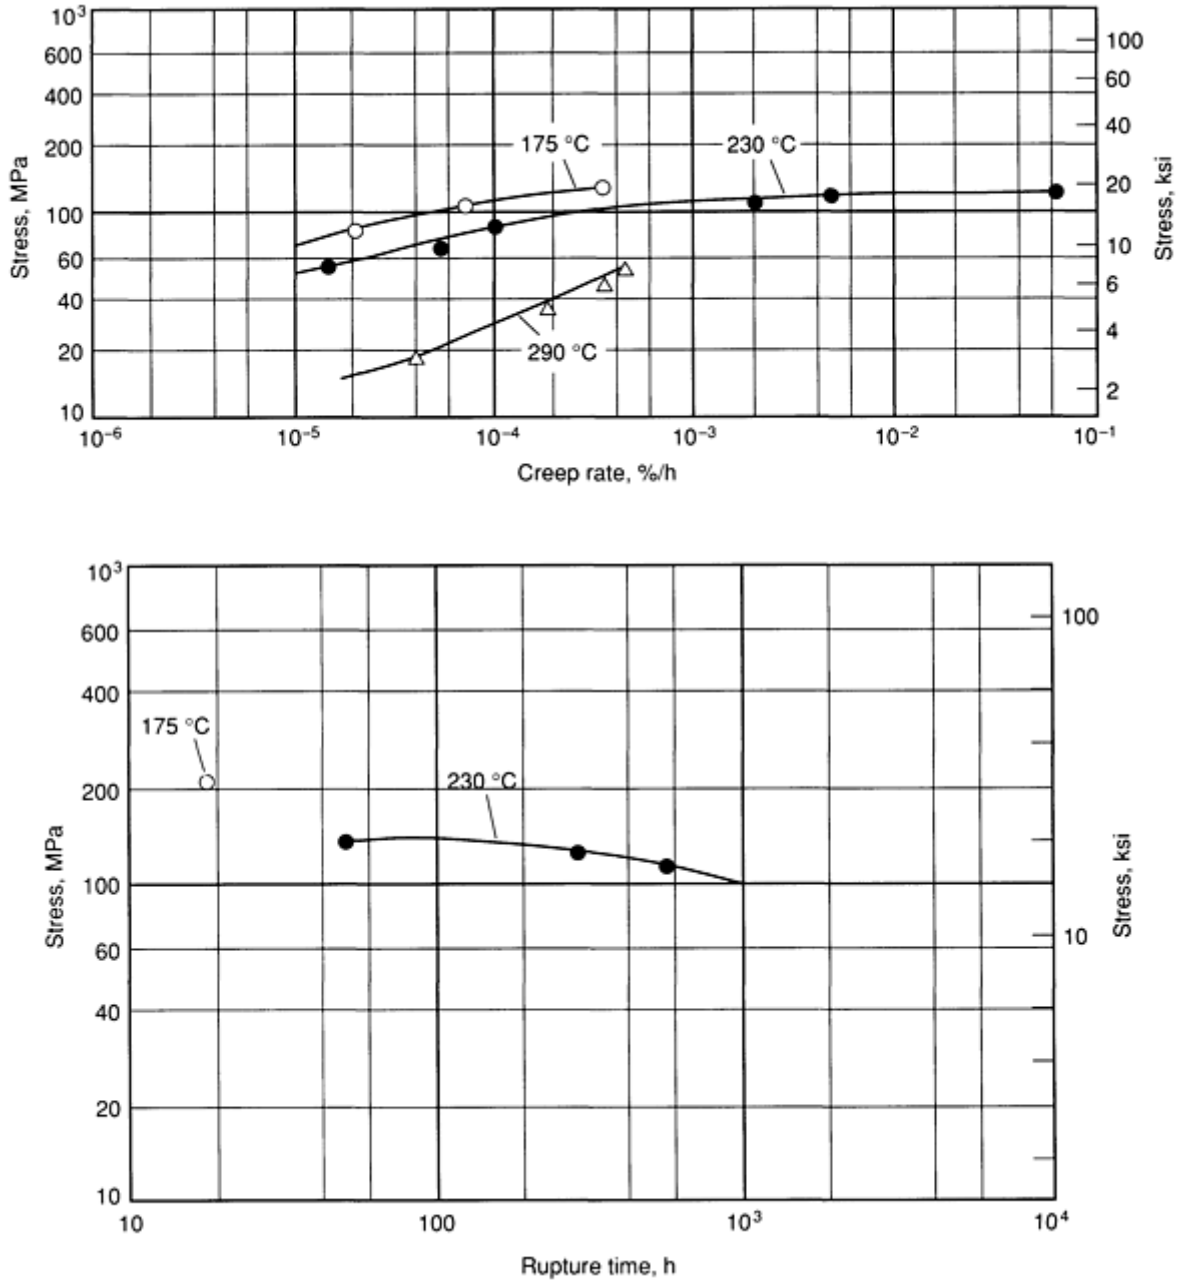

Fig. 41 Typical creep-rupture properties of C93700

Mass Characteristics

Density. 8.95 g/cm^3 (0.323 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. 7.3%

Patternmaker's shrinkage. 11 mm/m ($\frac{1}{8}$ in./ft)

Thermal Properties

Liquidus temperature. 930 °C (1705 °F)

Solidus temperature. 762 °C (1403 °F)

Incipient melting temperature. Pb, 315 °C (600 °F)

Coefficient of linear thermal expansion. 18.5 μm/m · K (10.3 μin./in. · °F) at 20 to 200 °C (68 to 392 °F). See also Fig. 42.

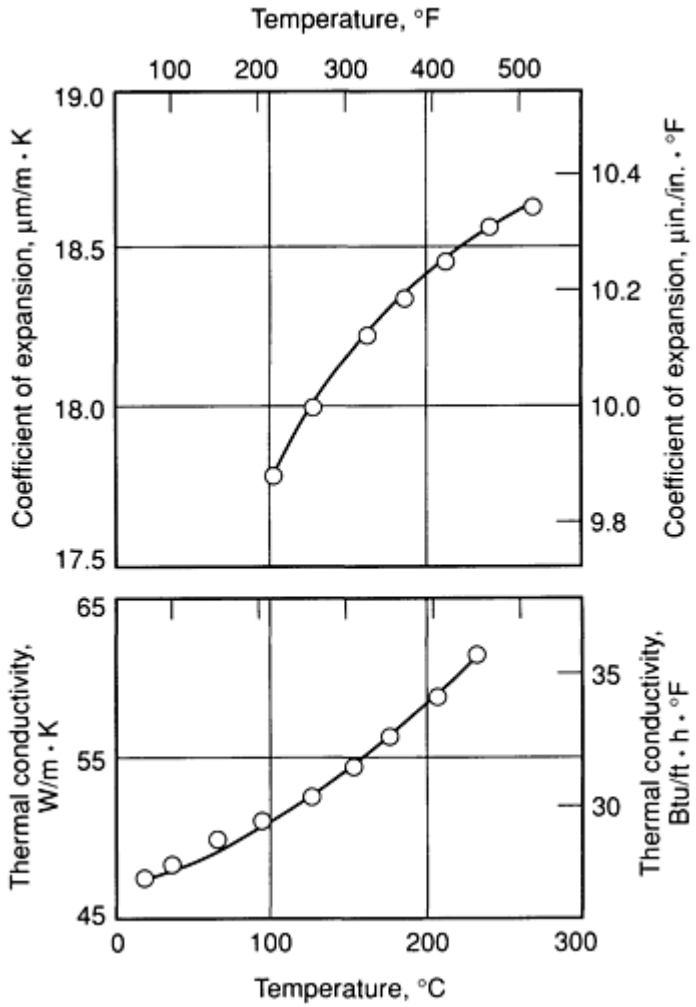

Fig. 42 Selected thermal properties of C93700

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 ° F)

Thermal conductivity. 46.9 W/m · K (27.1 Btu/ft · h · °F) at 20 °C (68 °F). See also Fig. 42.

Electrical Properties

Electrical conductivity. See Fig. 43.

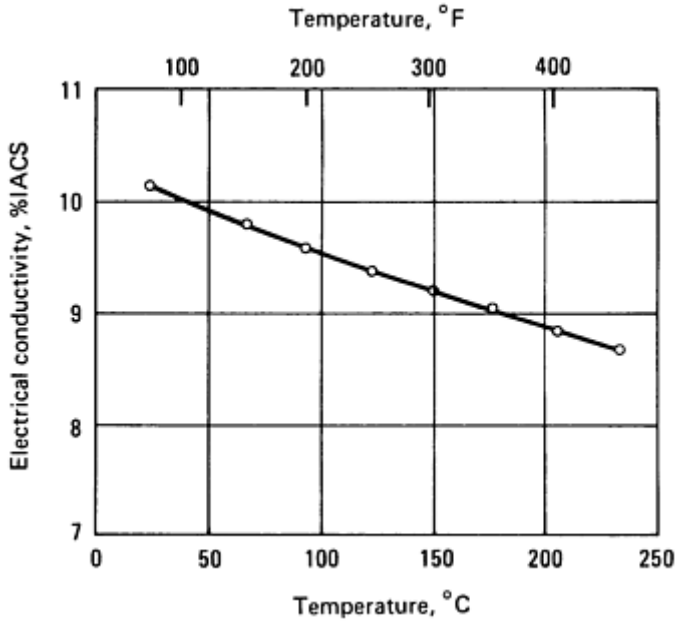

Fig. 43 Variation of electrical conductivity with temperature for C93700

Electrical resistivity. 170 nΩ · m at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.0

Fabrication Characteristics

Machinability. 80% of C36000 (free-cutting brass)

Weldability. Soldering: good. Brazing: good, but parts must not be strained during brazing or subsequent cooling because brazing is done at temperatures in the hot short range. Oxyfuel gas welding and all forms of arc welding are not recommended.

Stress-relieving temperature. 260 °C (500 °F)

C93800
78Cu-7Sn-15Pb

Commercial Names

Common names. High-leaded tin bronze, anti-acid metal, 78-7-15

Specifications

ASTM. Sand castings: B 66, B 584; centrifugal castings: B 271; continuous castings: B 505; ingot: B 30

SAE. J462

Government. QQ-C-390; QQ-C-525 (Alloy 7); QQ-L-225 (Alloys 19 and 7); MIL-B-16261 (Alloy IV)

Other. Ingot code number 319

Chemical Composition

Composition limits. 75.0 to 79.0 Cu, 6.3 to 7.5 Sn, 13.0 to 16.0 Pb, 0.70 Zn max, 0.70 Ni max, 0.15 Fe max, 0.05 P max, 0.70 Sb max, 0.08 S max, 0.003 Si max, 0.005 Al max. In determining Cu, minimum may be calculated as Cu + Ni.

Consequence of exceeding impurity limits. Aluminum or silicon causes lead sweating during solidification and may cause a substantial portion of castings to be unsound.

Applications

Typical uses. Locomotive engine castings and general-service bearings for moderate pressure; general-purpose wearing metal for rod bushings, shoes, and wedges; freight car bearings; backs for lined journal bearings for locomotive tenders and passenger cars; pumps impellers, and bodies for use in acid mine water.

Mechanical Properties

Tensile properties. Typical data for sand-cast test bars: tensile, 205 MPa (30 ksi); yield strength, 110 MPa

(16 ksi) at 0.5% extension under load; elongation, 18% in 50 mm (2 in.). Typical data for chilled centrifugally cast test bars; tensile strength, 230 MPa (33 ksi); yield strength, 140 MPa (20 ksi) at 0.5% extension under load; elongation, 12% in 50 mm (2 in.)

Shear strength. 105 MPa (15 ksi)

Compressive properties. Compressive strength: sand cast: 83 MPa (12 ksi) at permanent set of 0.1%, 260 MPa (38 ksi) at permanent set of 10%. Centrifugally cast: 130 MPa (19 ksi) at permanent set of 0.1%

Hardness. Sand-cast: 55 HB

Elastic modulus. Sand-cast test bars: tension, 72.4 GPa (10.5×10^6 psi)

Impact strength. Sand cast: Charpy V-notch or Izod, 7 J (5 ft · lbf)

Fatigue strength. Reverse bending, sand-cast test bars: 69 MPa (10 ksi) at 10^8 cycles

Mass Characteristics

Density. 9.25 g/cm^3 (0.334 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 11 mm/m ($\frac{1}{8}$ in./ft)

Thermal Properties

Liquidus temperature. 945 °C (1730 °F)

Solidus temperature. 855 °C (1570 °F)

Incipient melting temperature. Pb, 315 °C (600 °F)

Coefficient of linear thermal expansion. 18.5 μm/m · K (10.3 μin./in. · °F) at 20 to 205 °C (68 to 400 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 52 W/m · K (30 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 11.5% IACS at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.0

Fabrication Characteristics

Machinability. 80% of C36000 (free-cutting brass)

Weldability. Soldering: good. Brazing: poor. Oxyfuel gas welding and all forms of arc welding are not recommended.

Stress-relieving temperature. 260 °C (500 °F)

C93900
79Cu-6Sn-15Pb

Commercial Names

Common name. High-leaded tin bronze, 79-6-15

Specifications

ASTM. B 505, B 30

Chemical Composition

Composition limits. 76.5 to 79.5 Cu, 5.0 to 7.0 Sn, 14.0 to 18.0 Pb, 1.5 Zn max, 0.80 Ni max, 0.40 Fe max, 0.05 P max, 1.5 P max for continuous castings

Applications

Typical uses. Continuous castings only; common products include bearings for general service, pump bodies and impellers for mine use

Mechanical Properties

Tensile properties. Typical tensile strength, 220 MPa (32 ksi); yield strength, 150 MPa (22 ksi) at 0.5% extension under load; elongation, 7% in 50 mm (2 in.)

Hardness. 63 HB, typical

Elastic modulus. Tension, 76 GPa (11×10^6 psi)

Mass Characteristics

Density. 9.25 g/cm^3 (0.334 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 11 mm/m ($\frac{1}{8}$ in./ft)

Thermal Properties

Liquidus temperature. 943 °C (1730 °F)

Solidus temperature. 854 °C (1570 °F)

Incipient melting temperature. Pb, 315 °C (600 °F)

Coefficient of linear thermal expansion. 18.5 μm/m · K (10.3 μin./in. · °F) at 20 to 204 °C (68 to 400 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F)

Thermal conductivity. 52 W/m · K (30 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 11.5% IACS at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.0

Fabrication Characteristics

Machinability. 80% of C36000 (free-cutting brass)

C94300
70Cu-5Sn-25Pb

Commercial Names

Common name. High-leaded tin bronze, soft bronze, 70-5-25

Specifications

ASTM. B 584, B 66, B 271, B 505, B 30

SAE. J462 (CA943)

Government. QQ-L-225, Alloy 18; MIL-B-16261, Alloy V

Other. Ingot code number 322

Chemical Composition

Composition limits. 68.5 to 73.5 Cu, 4.5 to 6.0 Sn, 22.0 to 25.0 Pb, 0.50 Zn max, 0.70 Ni max, 0.15 Fe max, 0.70 Sb max, 0.05 P max, 0.08 S max

Supplementary composition limits. In determining Cu, minimum may be calculated as Cu + Ni 0.35 Fe max when used for steel-backed bearings. 1.5 P max for continuous castings

Applications

Typical uses. Bearings under light loads and high speed, driving boxes, railroad bearings

Mechanical Properties

Tensile properties. Typical data for sandcast test bars: tensile strength, 185 MPa (27 ksi); yield strength, 90 MPa (13 ksi) at 0.5% extension under load; elongation, 10% in 50 mm (2 in.); reduction in area, 8%

Compressive properties. Typical compressive strength: 76 MPa (11 ksi) at permanent set of 0.1%; 160 MPa (23 ksi) at permanent set of 10%

Hardness. 48 HB

Elastic modulus. Tension, 72.4 GPa (10.5×10^6 psi)

Impact strength. Izod, 7 J (5 ft · lbf)

Mass Characteristics

Density. 9.29 g/cm^3 (0.336 lb/in.^{3}) at 20 °C (68 °F)

Patternmaker's shrinkage. 11 mm/m ($\frac{1}{8}$ in./ft)

Thermal Properties

Solidus temperature. 900 °C (1650 °F)

Incipient melting temperature. Pb, 315 °C (600 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 62.7 W/m · K (36.2 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 9% IACS at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.0

Government. QQ-L-225, Alloy 15; MIL-B-16261, Alloy I

Chemical Composition

Composition limits. 6.0 to 8.0 Sn, 16 to 22 Pb, 1.2 Zn max, 1.0 Ni max, 0.8 Sb max, 0.005 Al max, 0.15 Fe max, 0.5 P max (1.5 P max for continuous castings), 0.08 S max, 0.005 Si max, bal Cu

Applications

Typical uses. Locomotive wearing parts, high-load low-speed bearings

Mechanical Properties

Tensile properties. Typical. Tensile strength, 170 MPa (25 ksi); yield strength, 83 MPa (12 ksi);elongation, 12% in 50 mm (2 in.)

Compressive properties. Compressive strength, 250 MPa (36 ksi)

Hardness. 50 HB

Elastic modulus. Tension, 72 GPa (10.5×10^6 psi); shear, 90 GPa (13×10^6 psi)

Fatigue strength. Rotating beam, 69 MPa (10 ksi) at 10^8 cycles

Impact strength. Izod, 5.4 J (4.0 ft · lbf)

Mass Characteristics

Density. 9.4 g/cm^3 (0.34 lb/in.^{3}) at 20 °C (68 °F)

Volume change on freezing. 1.1%

Thermal Properties

Liquidus temperature. 940 °C (1725 °F)

Solidus temperature. 800 °C (1475 °F)

Incipient melting temperature. 315 °C (600 °F)

Coefficient of linear thermal expansion. 18.5 μm/m · K (10.3 μin./in. · °F) at 20 to 200 °C (68 to 392 °F)

Specific heat. 376 J/kg · K (0.09 Btu/lb · °F) at 20 °C (68 °F)

Thermal conductivity. 52 W/m · K (30 Btu/ft · h · °F) at 20 °C (68 °F)

Electrical Properties

Electrical conductivity. Volumetric, 10% IACS at 20 °C (68 °F)

Magnetic Properties

Magnetic permeability. 1.0

Fabrication Characteristics

Machinability. 80% of C36000 (free-cutting brass)

C95200
88Cu-3Fe-9Al

Commercial Names

Previous trade name. Ampco Al

Common name. Aluminum bronze 9A; 88-3-9

Specifications

ASME. Sand castings: SB148; centrifugal castings: SB271

ASTM. Sand castings: B 148; centrifugal castings; B 271; continuous castings; B 505; ingot: B 30

SAE. J462

Government. Centrifugal, sand, and continuous castings; QQ-C-390; sand castings: MIL-C-22229

Other. Ingot code number 415

Chemical Composition

Composition limits. 86 Cu min, 8.5 to 9.5 Al, 2.5 to 4.0 Fe, 1.0 max other (total)

Consequence of exceeding impurity limits. Possible hot shortness and/or hot cracking, embrittlement, and reduced soundness of castings

Applications

Typical uses. Acid-resisting pumps, bearings, bushings, gears, valve seats, guides, plungers, pump rods, pickling hooks, nonsparking hardware
